Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Extended and Secondary study areas. It is possible that projects within the Secondary and Extended study areas that are included in the No Project/No Action Alternative would affect paleontological resources. However, any project considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for paleontological resource impacts. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The projects included in the No Project/No Action Alternative do not occur within the Primary Study Area, and the Project would not be constructed if this alternative is implemented. Therefore, **there would not be a substantial adverse effect** to paleontological resources, when compared to Existing Conditions.

16.3.6 Impacts Associated with Alternative A

16.3.6.1 Geology and Soils

Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Because there would be no direct Project-related construction or maintenance activities occurring in the Extended Study Area, there would be no increase in the risk of geologic or soils hazards to people or structures in the Extended Study Area, when compared to Existing Conditions or the No Project/No Action Alternative. Operation of the Project would result increased water level fluctuations at the San Luis Reservoir and increased reliability of water to agricultural, municipal and industrial water users, and an alternate supply to wildlife refuge users; these water delivery operations would not affect geology or soils. Alternative A would result in **no impact** to geology or soils or in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Extended Study Area. That discussion is also applicable to effects on soil erosion and loss of topsoil.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Extended Study Area. San Luis Reservoir currently experiences water level fluctuations; changing those would not affect the soils underlying the reservoir. Increased water reliability to agricultural, municipal and industrial water users, and an alternate supply to wildlife refuge users in the Extended Study Area would not affect underlying soils. Therefore, there would be **no impact** to geology or soils, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

The Project does not include a septic tank, alternative wastewater disposal system, or sewer system that would be constructed, operated, or maintained in the Extended Study Area; therefore, there would be **no impact** to geology or soils, when compared to Existing Conditions and the No Project/No Action Alternative.

Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant. Direct Project-related operational activities in the Secondary Study Area include the larger reservoirs having more stable water levels (i.e., would not fluctuate as widely) and altered discharge flows in downstream waterways. The only direct Project-related maintenance activity that would occur is the removal of sediment from the existing canal intakes. Because these Project-related activities in the Secondary Study Area are not expected to result in an increase in geologic or soils hazards to people or structures, when compared to Existing Conditions or the No Project/No Action Alternative, **no impact** to geology or soils is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Secondary Study Area. That discussion is also applicable to effects on soil erosion and loss of topsoil.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Secondary Study Area. The Red Bluff Pumping Plant is located on soils that have a low shrink/swell capacity. Therefore, **no impact** to geology or soils is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

The Project does not include a septic tank, alternative wastewater disposal system, or sewer system that would be constructed, operated, or maintained in the Secondary Study Area; therefore, there would be **no impact** to geology or soils, when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area (1.27 MAF)

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

The fundamental geology and soils in the Primary Study Area would remain unchanged with construction, operation, and maintenance of all of the Project facilities, when compared to Existing Conditions or the No Project/No Action Alternative; therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

During the construction phase, clearing and grubbing activities would occur. Demolition of existing structures and removal of asphalt and fencing would also occur. In addition, temporary access roads would be constructed within the reservoir footprint. These activities would result in an increase of soil erosion within the reservoir footprint. Construction phase soil erosion is expected to be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation, reservoir water surface elevations would fluctuate between a minimum of 340 feet and 480 feet. Shoreline erosion would occur along the zone of reservoir water elevation fluctuation. Sediment delivery into the reservoir resulting from shoreline erosion would be retained within the reservoir and not discharged. Shoreline soil erosion is expected to be **potentially significant**.

Maintenance activities, including garbage removal and maintenance of signs and buoys, would not be expected to result in increased soil erosion. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

No structures would be constructed within the proposed reservoir inundation area, except for the Sites Reservoir Inlet/Outlet Structure, which is addressed separately. Therefore, construction, operation, and maintenance of the reservoir would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No septic tanks or alternative wastewater disposal systems would be constructed within the Sites Reservoir Inundation Area. Therefore, construction, operation, and maintenance of the reservoir would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Reservoir Dams

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to Sites Reservoir Dams.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The construction of the dams would require the excavation, transport, stockpiling, grading, drilling, blasting, and use of a substantial quantity of bedrock, alluvium, and soil obtained from the borrow areas, and the installation of support structures. Equipment and vehicle staging areas would also be required. Construction activities with the potential for sediment delivery to Funks Creek and Stone Corral Creek include fill placement on the downstream face, and the fill stockpiles downstream of the dam. The soils disturbed by Project earthwork and construction activities, as well as stockpiled materials for use in the construction, would be susceptible to water-induced erosion and loss of topsoil. Construction phase soil erosion is anticipated to be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation and maintenance, no soils would erode because the soils would have been replaced with the dam structures. The dams would be faced with rip-rap protection on the reservoir side and vegetation on the landward side. Soil erosion is anticipated to be minimal, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Construction of the dams and saddle dams involves excavating all soils down to firm bedrock. Complete excavation of all soils would remove the expansion potential. Therefore, there would be **no impact** related to Project construction, operation, or maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No septic tanks or alternative wastewater disposal systems would be constructed within the damsites. Therefore, construction, operation, and maintenance of the dams would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Recreation Areas.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The construction of the Recreation Areas would require grading, including removal and/or stockpiling of surface soils and some bedrock. Construction phase soil erosion is anticipated to be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative. During operation, increased runoff from impervious surfaces developed at the recreation areas could increase erosion in local drainages, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. Maintenance activities, including road grading, vegetation control, and fuels management, could also increase erosion in local drainages, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Approximately 66 percent (802 acres) of the total area of the proposed Recreation Areas is classified by the NRCS as having a high shrink-swell potential. Impacts from constructing, operating, and maintaining Project facilities within the Recreation Areas on expansive soils are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

The Recreation Areas would have vault toilets, and waste would be transported and disposed of outside of the Primary Study Area. Vault toilets are not considered to be alternative wastewater disposal systems. Therefore, construction, operation, and maintenance would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Road Relocations and South Bridge.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Construction of the Road Relocations and South Bridge would require grading and cut/fill operations along the roads' footprints and 200-foot construction disturbance area. Slopes may be steepened, leading to increased erosion potential. Construction phase soil erosion is anticipated to be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation, increased runoff from impervious road surfaces could increase erosion in local drainages, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. This potential increase in runoff would require maintenance activities designed to reduce the impacts of the associated erosion.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

More than 50 percent (679 acres) of the total area of the Road Relocations and South Bridge are classified by the NRCS as having a high shrink-swell potential. An additional 125 acres are classified as having a low to high or moderate to high shrink-swell potential. Impacts from constructing, operating, and maintaining the roads and South Bridge on expansive soils are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No septic tanks or alternative wastewater disposal systems would be constructed, operated, or maintained within the road relocations. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from the Sites Pumping/Generating Plant to the Sites Reservoir Inlet/Outlet Structure, and Sites Reservoir Inlet/Outlet Structure

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from the Sites Pumping/Generating Plant to the Sites Reservoir Inlet/Outlet Structure, and Sites Reservoir Inlet/Outlet Structure.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Construction of these Project facilities would require the excavation, transport, stockpiling, grading, drilling, blasting. Tunnel construction would require stockpiling of rock spoil removed from the tunnel alignment. Slopes may be steepened leading to increased runoff potential. Construction phase soil erosion is anticipated to be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative. During Project operation and maintenance, areas would be covered with impervious material or vegetation; additional erosion is anticipated to be minimal, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Approximately 25 percent (24 acres) of the total area of these combined Project facilities is classified by the NRCS as having a high shrink-swell potential. Impacts from Project construction, operation, and maintenance are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No Project-related septic tanks or alternative wastewater disposal systems would be constructed, operated, or maintained at these facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Field Office Maintenance Yard

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Field Office Maintenance Yard.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The construction of the Field Office Maintenance Yard would require removal of topsoil and possibly some bedrock. Increased erosion may occur during construction, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. During Project operation and maintenance, areas would be covered with impervious material or vegetation; additional erosion is anticipated to be minimal, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Less than two percent (0.3 acre) of the total area of the Field Office Maintenance Yard is classified by the NRCS as having a high shrink-swell potential. Project construction, operation, and maintenance impacts are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

It is anticipated that a septic tank would be located in the vicinity of the Field Office Maintenance Yard. Soils in the vicinity of this Project feature are considered to have "limitations". Impacts are, therefore, considered **potentially significant** for construction, operation, and maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Holthouse Reservoir Complex and the Holthouse Reservoir Electrical Switchyard.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

During the dredging of Funks Reservoir, Funks Reservoir would be de-watered. Draining and maintenance of the reservoir could lead to increased erosion of exposed reservoir sediments, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would require the excavation, transport, stockpiling, grading, drilling, blasting, and use of a moderate quantity of bedrock, alluvium, and soil obtained from the borrow areas. Equipment and vehicle staging areas would also be required. Construction activities with the potential for sediment delivery to Funks Creek include fill placement on the downstream face and the fill stockpiles downstream of the dam. The soils disturbed by Project earthwork and construction activities, as well as stockpiled materials for use in the construction, would be susceptible to water induced erosion and loss of topsoil, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation, reservoir water surface elevations would fluctuate up to 14 feet. Shoreline erosion would occur along the zone of reservoir-elevation fluctuation. Sediment delivery into the reservoir resulting from shoreline erosion would be retained within the reservoir and not discharged. Shoreline soil erosion is anticipated to be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Periodic maintenance required for the existing Funks Reservoir includes road, vegetation, and fence maintenance, as well as debris removal, on an as-needed basis. The reservoir is currently also drained annually. These maintenance activities are expected to be the same for Holthouse Reservoir. These maintenance activities around the larger reservoir complex could increase erosion in local drainages, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

The existing Funks Reservoir is filled with water; no NRCS soil data is available. To be conservative, construction, operation, and maintenance impacts are considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Nearly 90 percent (324 acres) of the total area of the Holthouse Reservoir Complex, including the footprint of the Holthouse Reservoir Electrical Switchyard, is classified by the NRCS as having a high shrink-swell potential. Project construction, operation, and maintenance impacts are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No septic tanks or alternative wastewater disposal systems would be constructed, operated, or maintained within the Holthouse Reservoir Complex or at the Holthouse Reservoir Electrical Switchyard. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, and Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, and the GCID Canal Facilities Modifications.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The construction of the TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, as well as the proposed modifications to existing GCID Canal Facilities, would require the excavation, transport, stockpiling, grading, and use of a moderate quantity of bedrock, alluvium, and soil obtained from the borrow areas. Increased erosion may occur during Project construction, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. During Project operation and maintenance, areas would be covered with impervious material or vegetation; additional erosion is anticipated to be minimal, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

All soils at these facilities are classified by the NRCS as having a high shrink-swell potential. Project construction, operation, and maintenance impacts are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

The TRR Pumping/ Generating Plant would have portable toilets, and waste would be transported and disposed of outside of the Primary Study Area. Portable toilets are not considered to be alternative wastewater disposal systems. Therefore, construction, operation, and maintenance would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Delevan Transmission Line.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The construction of the Delevan Transmission Line would require the construction of a temporary access road along the alignment and soil excavation for tower footings. During Project construction, erosion is anticipated to occur, resulting in a **potentially significant impact.** Project operation would be an unmanned activity. Maintenance activities, including equipment inspections and vegetation maintenance, are expected to cause minimal soil erosion. Therefore, operation and maintenance would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

The Delevan Transmission Line alignment traverses soils that are classified by the NRCS as having a high shrink-swell potential. Project construction, operation, and maintenance impacts are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No Project-related septic tanks or alternative wastewater disposal systems would be constructed, operated, or maintained along the Delevan Transmission Line. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, and the Delevan Pipeline Electrical Switchyard.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Construction of the Delevan Pipeline and TRR Pipeline would require dewatering, as well as trenching of soils and alluvial material down to the design depth. The excess materials could be distributed on a 750-foot-wide strip on either side of the pipelines' alignment. Construction of the TRR Pipeline Road and Delevan Pipeline Electrical Switchyard would also result in ground disturbance. However, during the construction period additional erosion is anticipated to be minimal because the terrain is flat and generally surrounded by rice checks, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation, because the pipelines would be buried and operated remotely, no additional erosion impacts are anticipated, resulting in **no impact**, when compared to Existing Conditions or the No Project/No Action Alternative. Periodic maintenance inspections would not cause additional erosion impacts, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation and maintenance of the Delevan Pipeline Electrical Switchyard, areas would be covered with a gravel base; additional erosion is anticipated to be minimal, resulting in a *less-than-significant impact****, when compared to Existing Conditions or the No Project/No Action Alternative.***

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

More than 80 percent (176 acres) of the total area of these Project features is classified by the NRCS as having a high shrink-swell potential. Project construction, operation, and maintenance impacts of the Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard are, therefore, considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No Project-related septic tanks or alternative wastewater disposal systems would be constructed, operated, or maintained along the Delevan Pipeline, TRR Pipeline, or TRR Pipeline Road, or at the Delevan Pipeline Electrical Switchyard. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Delevan Pipeline Intake Facilities.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The construction of the Delevan Pipeline Intake Facilities would require dewatering; clearing and grading the construction workspace; excavating soils and alluvium from the forebay, afterbay, and pumping plant sites; and filling and re-grading where needed. During the construction period, additional erosion is anticipated, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. During Project operation and maintenance, areas would be covered with impervious material or vegetation; no additional erosion impacts are anticipated, resulting in **no impact**, when compared to Existing Conditions or the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

All soil at this Project feature location is classified by the NRCS as having a low shrink-swell potential. Construction, operation, and maintenance impacts are, therefore, considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

The Delevan Pipeline Intake Facilities would have portable toilets, and waste would be transported and disposed of outside of the Primary Study Area. Portable toilets are not considered to be alternative wastewater disposal systems. Therefore, construction, operation, and maintenance would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

Refer to the **Impact Geo/Soils-1** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Project Buffer.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

During Project construction, existing structures within the Project Buffer would be demolished and fences would be constructed, which may cause a temporary increase in soil erosion. Project construction, operation, and maintenance impacts are considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

The construction and operation of a fuelbreak around the entire perimeter of the Project Buffer, as well as maintenance of the fuelbreak, would cause increases in soil erosion, resulting in a **potentially significant impact**, when compared to Existing Conditions or the No Project/No Action Alternative.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

No structures would be constructed within the Project Buffer. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

No Project-related septic tanks or alternative wastewater disposal systems would be constructed within the Project Buffer. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

16.3.6.2 Minerals

Extended and Secondary Study Areas – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Min-1: Loss of Availability of a Known Mineral Resource that would be of Value to the Region and the Residents of the State

Aggregate minerals resources of the Stony Creek Fan (Glenn County) would be used for the NODOS Project. The Stony Creek Fan has an estimated material availability of 160 million cubic yards (DWR, 2002). Approximately 2,136,000 cubic yards of gravel would be imported from the Stony Creek Fan, located north of Willows (in the Secondary Study Area), to construct the Project (approximately 0.29 percent of the available resource). No mineral resources are required to operate and maintain the Project. Alternative A would, therefore, result in a **less-than-significant impact** on mineral resources in the Extended and Secondary study areas, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation (including operation of San Luis Reservoir) would not require mineral resources, resulting in **no impact** on mineral resources. In addition, the pump installation, operation, and maintenance at the Red Bluff Pumping Plant would not require mineral resources, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Min-2: Loss of Availability of a Locally Important Mineral Resource Recovery Site Delineated on a Local General Plan, Specific Plan, or Other Land Use Plan

Refer to the **Impact Min-1** discussion. That discussion is also applicable to locally important mineral resource recovery sites.

Impact Min-3: Expose People to Naturally Occurring Asbestos during Project Construction, Operation, or Maintenance

Ultramafic rocks containing naturally occurring asbestos would not be disturbed during Project construction, operation, or maintenance within the Extended and Secondary study areas. Therefore Alternative A would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Min-1: Loss of Availability of a Known Mineral Resource that would be of Value to the Region and the Residents of the State

Mineral resource areas are located outside of the Primary Study Area (Glenn County, 1997 and Colusa County, 1989). Approximately 2,136,000 cubic yards of gravel would be imported from the Stony Creek Fan, located north of Willows (in the Secondary Study Area), to construct the Project (approximately 0.29 percent of the available resource). No mineral resources are required to operate or maintain the Project. Therefore, construction, operation, and maintenance of Alternative A would not result in the loss of availability of any known mineral resource, or interfere with any existing commercial mining activity, resulting in **less-than-significant impact** on mineral resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Min-2: Loss of Availability of a Locally Important Mineral Resource Recovery Site Delineated on a Local General Plan, Specific Plan, or Other Land Use Plan

Refer to the **Impact Min-1** discussion. That discussion is also applicable to mineral resource recovery sites.

Impact Min-3: Expose People to Naturally Occurring Asbestos during Project Construction, Operation, or Maintenance

Rocks containing naturally occurring asbestos are not present in the Primary Study Area, nor are they present in the watershed draining into the Primary Study Area. Therefore, construction, operation, and maintenance activities associated with Alternative A would not expose people to naturally occurring asbestos, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

16.3.6.3 Paleontology

Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Because there would be no direct Project-related construction or maintenance occurring in the Extended Study Area, no paleontologically sensitive sediments would be disturbed. Therefore, there would be **no impact** to paleontological resources in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant. The only direct Project-related maintenance activity that would occur would be the removal of sediment from the existing canal intakes. Because neither of these Project-related activities in the Secondary Study Area is expected to affect paleontologically sensitive sediment, **no impact** to paleontological resources is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area (1.27 MAF)

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Inundation would not affect paleontological resources; however, excavations (borrow pits and other similar facilities) may occur within the reservoir inundation area. Thus, construction of the 1.27-MAF reservoir would affect rocks of the GVS, including the low sensitivity Boxer Formation and, to a lesser extent, the low to moderate sensitivity Cortina Formation, as well as low sensitivity Quaternary alluvium predominantly located within stream channels. Excavation within the potentially fossiliferous sediments of the GVS within the reservoir footprint would result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Reservoir Dams

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Construction of the footings and anchor walls for Golden Gate Dam and Sites Dam would involve deep excavation into potentially fossiliferous sediments of the GVS. The construction of Golden Gate and Sites dams would predominantly affect the moderate sensitivity Venado Sandstone of the Cortina Formation, and to a lesser extent the low sensitivity Boxer Formation. In addition, the seven saddle dams on the rim of the 1.27-MAF reservoir would affect the Boxer Formation and overlying low sensitivity basin fill. Because these saddle dam excavations would be shallower and of more limited extent than for Golden Gate and Sites dams, the impacts from construction of the saddle dams would be less than those associated with the larger Sites and Golden Gate dams. The deep excavation into potentially fossiliferous members of the GVS, as well as construction activities within other moderately sensitive rock units associated with dam construction, would result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The recreation areas would be constructed predominantly on the rim of the Sites Reservoir inundation area, and would affect the low sensitivity Boxer Formation, the low- to moderate-sensitivity Cortina Formation, and low sensitivity Quaternary alluvium. Construction of the Antelope Island Recreation Area, which would be located within the reservoir, would only impact the Boxer Formation and basin fill (for this analysis, it is considered the same as Quaternary alluvium). Recreation Area construction activities within the potentially fossiliferous member of the GVS would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Similar to the recreation areas, the road relocations would occur predominantly on the rim of and within the inundation area, and in the case of the South Bridge, within the inundation area. Construction associated with these features would affect the low sensitivity Boxer Formation, the low- to moderate-sensitivity Cortina Formation, and low sensitivity Quaternary alluvium. Road construction activities within the potentially fossiliferous member of the GVS would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant and Sites Electrical Switchyard

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The Sites Pumping/Generating Plant and its associated switchyard would be located on the eastern margin of the Sites Reservoir, immediately south of the Golden Gate Dam. Project construction would affect the low- to moderate-sensitivity Cortina Formation and a thin veneer of low sensitivity Quaternary alluvium. Construction activities within the potentially fossiliferous member of the GVS associated with construction of these facilities would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

This tunnel would extend through the low sensitivity Boxer Formation to the west and the low- to moderate-sensitivity Cortina Formation to the east. Low sensitivity Quaternary alluvium would be impacted at both ends of the tunnel. Construction activities within the potentially fossiliferous member of the GVS associated with construction of the tunnel would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Reservoir Inlet/Outlet Structure

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The Sites Reservoir Inlet/Outlet Structure would affect the low sensitivity Boxer Formation and low sensitivity Quaternary alluvium within the inundation area, and would affect the low- to moderate-sensitivity Cortina Formation and low sensitivity basin fill east of the inundation area. Construction activities within the potentially fossiliferous member of the GVS associated with construction of the Inlet/Outlet Structure would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Field Office Maintenance Yard

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The Field Office Maintenance Yard would affect the low- to moderate-sensitivity Cortina Formation and low sensitivity basin fill, resulting in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Funks Reservoir is located east of the Sites Reservoir, on low sensitivity basin deposits underlain by the moderate sensitivity Sites and Yolo members of the Cortina Formation. Dredging is not likely to affect these formations because most reservoirs build up a layer of sediment over time and dredging would be directed at removing that recent accumulation of sediment. Because it is recent, sediment dredging would have **no impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

The Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would be located adjacent to the existing Funks Reservoir, within the Sacramento Valley. Similar to that described for Sites Reservoir, the inundation of Holthouse Reservoir would not impact paleontological resources, but excavations within the inundation area and excavations associated with the dam construction and the electrical switchyard would impact paleontologically sensitive geologic units. Construction of these features would affect low sensitivity basin fill and, at depth, the moderate sensitivity Riverbank Formation. Excavation and other construction activities associated with the Holthouse Reservoir Complex within the moderate sensitivity Riverbank Formation would result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The majority of the construction associated with the existing GCID Canal consists of repairs or refurbishments, and would only affect previously disturbed sediment, which has a low paleontological sensitivity. Any excavations that extend beyond previously disturbed soil would affect the moderate sensitivity Modesto and Riverbank formations. Due to the possibility of disturbance to moderate sensitivity formations, construction activities associated with modifications to the GCID Canal would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Similar to the discussion for Sites and Holthouse reservoirs, the inundation of the TRR would not affect paleontological resources. However, excavation within the inundation area may occur, and excavations for dams and other structures around the rim of the inundation area would affect paleontologically sensitive units. The TRR would be located within the Sacramento Valley, and excavations associated with this reservoir would impact the moderate sensitivity Riverbank Formation and low sensitivity basin fill.

Construction associated with the connection to the GCID Canal would include the excavation of a canal energy dissipation bay with check structure, the inlet channel to the TRR, and the inlet control structure. These excavations would impact the moderate sensitivity Riverbank Formation and low sensitivity basin fill. Construction activities associated with these facilities within moderate sensitivity formations would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir Pumping/Generating Plant and Terminal Regulating Reservoir Electrical Switchyard

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Excavations associated with this pumping/generating plant and electrical switchyard, which would be located at the rim of the TRR, would impact the moderate sensitivity Riverbank Formation and low sensitivity basin fill. Construction activities associated with these facilities within a moderate sensitivity formation would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Construction of the TRR Pipeline, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard, which would be located between Holthouse Reservoir and the TRR, would affect the low- to moderate-sensitivity Cortina Formation and low-sensitivity basin fill. Construction activities within the potentially fossiliferous member of the GVS associated with construction of the TRR Pipeline, TRR Pipeline Road, and Delevan

Pipeline Electrical Switchyard would result in a **potentially significant impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The Delevan Transmission Line would affect the low- to moderate-sensitivity Cortina Formation and low sensitivity basin fill between the Sites Pumping/Generating Plant and the existing WAPA or PG&E transmission line, and low sensitivity Quaternary alluvium and basin deposits, the moderate sensitivity Modesto Formation, the moderate sensitivity Riverbank Formation, and the low- to moderate-sensitivity Cortina Formation between the existing WAPA or PG&E transmission line and the Sacramento River. Construction activities associated with placement of the transmission line tower footings within the potentially fossiliferous member of the GVS, or within moderate sensitivity formations, would result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The Delevan Pipeline would parallel the Delevan Transmission Line, and along its entire length would affect the same geologic units: low sensitivity Quaternary alluvium and basin deposits, the moderate sensitivity Modesto Formation, the moderate sensitivity Riverbank Formation, and the low- to moderate-sensitivity Cortina Formation. Construction activities associated with the Delevan Pipeline within the potentially fossiliferous member of the GVS, or within moderate sensitivity formations, would result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Geologic units that would be affected by construction of the Delevan Pipeline Intake Facilities consist of low sensitivity Quaternary alluvium deposited by the Sacramento River and the underlying moderate sensitivity Modesto Formation and high sensitivity Tehama Formation. Construction activities associated with the Delevan Pipeline Intake Facilities, within moderate and high sensitivity formations, would result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Excavations associated with the demolition of existing structures would be limited to previously disturbed sediments of no paleontological sensitivity, and the installation of fencing and creation of a fuelbreak would not involve excavations, and therefore, would not impact paleontological resources. Construction activities associated with the Project Buffer would, therefore, have **no impact** on paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

16.3.7 Impacts Associated with Alternative B

16.3.7.1 Geology and Soils

Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to geology and soils (**Impact Geo/Soils-1**), soil erosion and loss of topsoil (**Impact Geo/Soils-2**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to geology and soils:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on geology and soils (**Impact Geo/Soils-1**), soil erosion and loss of topsoil (**Impact Geo/Soils-2**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**), as described for Alternative A.

If Alternative B is implemented, the footprint or construction disturbance area of Sites Reservoir and Dams, the Road Relocations and South Bridge, and the Delevan Transmission Line would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility. Impacts due to geology and soils (**Impact Geo/Soils-1**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**) would be the same for Alternative B as was described for Alternative A. The effects of operation and maintenance activities associated with these facilities on soil erosion would be the same as described for Alternative A. The differences in the effects of construction activities between alternatives relative to soil erosion are described below.

Sites Reservoir Inundation Area (1.81 MAF)

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

During Project operation, reservoir surface elevations would fluctuate between a minimum of 340 feet and 520 feet. Shoreline erosion would occur along the zone of reservoir-elevation fluctuation and would have a greater impact than Alternative A because a greater surface area would be exposed to wave action and associated erosion. Sediment delivery into the reservoir resulting from shoreline erosion would be retained within the reservoir, similar to that described for Alternative A. Soil erosion impacts from Project construction, operation, and maintenance are considered **potentially significant**.

Sites Reservoir Dams

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Construction erosion impacts associated with Alternative B would be similar to those described for Alternative A. However, because of the total of nine saddle dams with Alternative B (compared to seven with Alternative A), and larger footprints for Sites and Golden Gate dams, overall construction erosion impacts associated with the Alternative B dams would increase. Increased soil erosion would result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Discharge Facilities

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

The footprint of the Delevan Pipeline Discharge Facility included in Alternative B would be less than half the size of the Delevan Pipeline Intake Facilities described for Alternative A; therefore, construction erosion impacts associated with this facility would be less than that described for Alternative A. However, the increased soil erosion associated with construction activities would still result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

16.3.7.2 Minerals

Extended, Secondary, and Primary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to known mineral resources of value (**Impact Min-1**), locally important resources (**Impact Min-2**), and naturally occurring asbestos (**Impact Min-3**), would be the same as described for Alternative A for the Extended, Secondary, and Primary study areas.

16.3.7.3 Paleontology

Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to paleontological resources (**Impact Paleo-1**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to paleontological resources:

- Recreation Areas
- Sites Electrical Switchyard
- Sites Pumping/Generating Plant
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on paleontological resources (**Impact Paleo-1**) as described for Alternative A.

The major differences between Alternatives B and A are related to the increased size of Sites Reservoir with Alternative B. The increase in reservoir size necessitates the addition of two saddle dams and the movement of various project components. In addition, Alternative B replaces the Delevan Pipeline Intake Facilities with the Delevan Pipeline Discharge Facility. The Alternative B facilities' construction impacts on paleontological resources that would differ from those described for Alternative A are discussed below.

Sites Reservoir Inundation Area (1.81 MAF)

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The reservoir included in Alternative B would be larger than for Alternative A, but would affect the same geologic units. These units consist of the low sensitivity Boxer Formation and the low- to moderate-sensitivity Cortina Formation, as well as low sensitivity basin fill. However, the larger reservoir may result in greater effects to paleontological resources than would occur with Alternative A. Construction of the 1.81-MAF Sites Reservoir would, therefore, result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Reservoir Dams

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The larger Sites Reservoir Inundation Area included in Alternative B necessitates slightly different locations for each dam and a larger excavation area for the footprints of Sites and Golden Gate dams, and therefore, may result in greater effects to paleontological resources than would occur with Alternative A. The effects on paleontological resources from construction of Alternative B's Sites and Golden Gate dams would, therefore, result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, Alternative B includes nine saddle dams, whereas Alternative A includes seven saddle dams, so more area would be disturbed with Alternative B than with Alternative A. The saddle dams would be located around the rim of Sites Reservoir, and therefore, would affect the low sensitivity Boxer Formation and low sensitivity basin fill, similar to that described for Alternative A. The effects on paleontological resources from construction of the Alternative B saddle dams would, therefore, result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

Excavations for Alternative B would be slightly less extensive than for Alternative A. The lengths of the saddle dam access roads would be reduced for Alternative B because the dams would be larger and are located closer to the main roads. This would, therefore, reduce the potential impacts to paleontological resources in those areas. However, an extension of an access road would be constructed for Alternative B to provide access from Saddle Dam 3 to Saddle Dams 1 and 2. This road extension would affect the Boxer Formation and overlying low sensitivity basin fill. Effects on paleontological resources from construction associated with road relocations and the South Bridge would be similar for Alternative B to the impacts described for Alternative A and would, therefore, result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The length of the proposed Delevan Transmission Line for Alternative B is greatly reduced from the length associated with Alternative A and would extend only from the Sites Electrical Switchyard to its connection with the existing WAPA or PG&E transmission line. Effects on paleontological resources from construction of the Alternative B transmission line would, therefore, be greatly reduced, when compared to the Alternative A transmission line. The Alternative B transmission line would extend through the westernmost margin of the Sacramento Valley, and would affect the low- to moderate-sensitivity Cortina Formation and low sensitivity basin fill, and would, therefore, result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Discharge Facility

Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources

The smaller size of the Delevan Pipeline Discharge Facility, when compared to the Delevan Pipeline Intake Facilities that are included in Alternative A, would lessen the effects to high and moderate paleontologically sensitive formations. Impacts to paleontological resources would be similar to those discussed for Alternative A and would, therefore, result in a **potentially significant impact** to paleontological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

16.3.8 Impacts Associated with Alternative C

16.3.8.1 Geology and Soils

Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to geology and soils (**Impact Geo/Soils-1**), soil erosion and loss of topsoil (**Impact Geo/Soils-2**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to geology and soils:

- Recreation Areas
- Sites Pumping/Generating Plant

- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on geology and soils (**Impact Geo/Soils-1**), soil erosion and loss of topsoil (**Impact Geo/Soils-2**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**) as described for Alternative A.

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts on geology and soils (**Impact Geo/Soils-1**), soil erosion and loss of topsoil (**Impact Geo/Soils-2**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**) as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Areas, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to geology and soils (**Impact Geo/Soils-1**), soil erosion and loss of topsoil (**Impact Geo/Soils-2**), the level of risk to life and property from activities on expansive soil (**Impact Geo/Soils-3**), and soils that are incapable of supporting septic tanks or alternative wastewater disposal systems (**Impact Geo/Soils-4**) as described for Alternative B.

16.3.8.2 Minerals

Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to known mineral resources of value (**Impact Min-1**), locally important resources (**Impact Min-2**), and naturally occurring asbestos (**Impact Min-3**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to minerals:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on known mineral resources of value (**Impact Min-1**), locally important resources (**Impact Min-2**), and naturally occurring asbestos (**Impact Min-3**) as described for Alternative A.

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to known mineral resources of value (**Impact Min-1**), locally important resources (**Impact Min-2**), and naturally occurring asbestos (**Impact Min-3**) as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Areas, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to known mineral resources of value (**Impact Min-1**), locally important resources (**Impact Min-2**), and naturally occurring asbestos (**Impact Min-3**) as described for Alternative B.

16.3.8.3 Paleontology

Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to paleontological resources (**Impact Paleo-1**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to paleontological resources:

- Recreation Areas
- Sites Electrical Switchyard
- Sites Pumping/Generating Plant
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on paleontological resources (**Impact Paleo-1**) as described for Alternative A.

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to paleontological resources (**Impact Paleo-1**) as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Areas, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to paleontological resources (**Impact Paleo-1**) as described for Alternative B.

16.4 Mitigation Measures

Mitigation measures are provided below and summarized in Tables 16-9 and 16-10 for the impacts that have been identified as significant or potentially significant.

16.4.1 Geology and Soils

Table 16-9
Summary of Mitigation Measures for
NODOS Project Impacts to/from Geology and Soils

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil	Sites Reservoir Inundation Area, Sites Reservoir Dams, Recreation Areas, Road Relocations and South Bridge, Sites Pumping/Generating Plant, Tunnel, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Facilities Modifications, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, Delevan Transmission Line, Delevan Pipeline Intake Facilities, Project Buffer	Potentially Significant	Mitigation Measure Geo/Soils-2: Prepare and Implement a Project Construction Erosion Control Plan and a Project Operation and Maintenance Erosion and Sediment Control Plan Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant

Table 16-9
Summary of Mitigation Measures for
NODOS Project Impacts to/from Geology and Soils

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil	Recreation Areas, Road Relocations and South Bridge, Sites Pumping/Generating Plant, Tunnel, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Facilities Modifications, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, Delevan Transmission Line, Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard	Potentially Significant	Mitigation Measure Geo/Soils-3: Perform a Geotechnical Investigation due to Expansive Soils at Project Facility Sites	Less than Significant
Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal	Field Office Maintenance Yard	Potentially Significant	Mitigation Measure Geo/Soils-4: Implement Measures for Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Geo/Soils-2: Prepare and Implement a Project Construction Erosion Control Plan and a Project Operation and Maintenance Erosion and Sediment Control Plan

To minimize soil erosion and loss of topsoil, DWR and Reclamation shall include in the construction contract the requirement for the preparation of an Erosion Control Plan prior to the start of Project construction and its implementation during Project construction. DWR and Reclamation shall also prepare an Erosion and Sediment Control Plan that shall be implemented during Project construction, operation, and maintenance. The Plans shall meet all local requirements and incorporate Best Management Practices (BMPs). BMPs may include, but would not be limited to:

- Preservation of existing vegetation
- The use of silt fences and/or straw bales and sheetpiles to separate project construction sites from waterways.

- Covering soil stockpiles with mulch or matting, as well as continuous maintenance of erosion control measures
- PennzSuppress® dust suppressant, or an equivalent product, to stabilize soil during and after construction
- Timely revegetation of disturbed sites to minimize post-construction erosion impacts. The use of native seeds and plants to assist in the conservation and enhancement of protected species shall be considered, as required by Section 7(a)(1) of the Endangered Species Act (ESA).

Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan

The Project is subject to construction-related stormwater permit requirements of the Clean Water Act National Pollutant Discharge Elimination System (NPDES) Permit Program. DWR and Reclamation shall obtain any required permits through the CVRWQCB before any ground-disturbing construction activities occur. DWR and Reclamation shall prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) that identifies BMPs to prevent or minimize the introduction of contaminants into surface waters. BMPs for the Project could include, but are not limited to, silt fencing, straw bale barriers, diversion ditches, fiber rolls, storm drain inlet protection, hydraulic mulch, and stabilized construction entrance. The SWPPP shall include development of site-specific structural and operational BMPs to prevent and control impacts on runoff quality, measures to be implemented before each storm event, inspection and maintenance of BMPs, and monitoring of runoff quality by visual and/or analytical means.

Mitigation Measure Geo/Soils-3: Perform a Geotechnical Investigation due to Expansive Soils at Project Facility Sites

A site-specific design-level geotechnical investigation, prepared by a licensed professional, shall be performed. The geotechnical investigation shall include measures to ensure potential damage related to expansive soils and non-uniformly compacted fill and engineered fill are minimized. Mitigation options may range from removal of the problem soils, and replacement, as needed, with properly conditioned and compacted fill, to design and construction of improvements to withstand the forces exerted during the expected shrink-swell cycles and settlements. All design criteria and specifications set forth in the geotechnical investigation shall be implemented to reduce impacts associated with problem soils.

Mitigation Measure Geo/Soils-4: Implement Avoidance Measures for Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

During Project design, Project engineers shall consider the soil types when designing the necessary septic tank facilities, and shall incorporate and implement measures to accommodate such facilities or their alternatives. Alternatives could include mound, lagoon, or constructed wetlands systems (University of Kentucky, 2001).

Implementation of **Mitigation** Measures **Geo/Soils-2, Geo/Soils-3, and Geo/Soils-4** would reduce the level of significance of Project impacts to geology and soils to **less than significant**.

16.4.2 Minerals

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

16.4.3 Paleontology

Table 16-10
Summary of Mitigation Measures for
NODOS Project Impacts to Paleontological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Paleo-1: Project Construction, Operation, and Maintenance Effects on Paleontological Resources	All Project Facilities, with the exception of the Project Buffer	Potentially Significant	Mitigation Measure Paleo-1a: Retain a Qualified Paleontological Resource Specialist Prior to the Start of Construction	Less than Significant
			Mitigation Measure Paleo-1b: Consultation with the Paleontological Resource Specialist Prior to and During Project Construction	
			Mitigation Measure Paleo-1c: Prepare and Implement a Paleontological Resources Monitoring and Mitigation Plan	
			Mitigation Paleo-1d: Conduct Paleontological Resources Awareness Training	
			Mitigation Measure Paleo-1e: Conduct Monitoring During Project Construction and Prepare Monthly Reports	
			Mitigation Measure Paleo-1f: Ensure Implementation of the Paleontological Resources Monitoring and Mitigation Plan	

Note:
LOS = Level of Significance

The significance of paleontological resources originates chiefly in their scientific value. Therefore, mitigation of impacts to paleontological resources can be achieved by the recovery of those values. This is accomplished through paleontological resources monitoring, and the scientific recovery of discovered fossils when they are encountered. Through the controlled excavation, study, and appropriate museum curation of fossil materials their scientific value is preserved, and potentially even enhanced through the new knowledge developed during their initial study. These mitigation measures are consistent with those recommended by the Society of Vertebrate Paleontology (SVP, No Date).

Mitigation Measure Paleo-1a: Retain a Qualified Paleontological Resource Specialist Prior to the Start of Construction

DWR and Reclamation shall retain a qualified Paleontological Resource Specialist at least 90 days prior to the start of construction. DWR and Reclamation shall keep resumes on file for the Paleontological Resource Specialist as well as qualified Paleontological Resource Monitors working on the Project. The Paleontological Resource Specialist shall meet the minimum or equivalent qualifications for a paleontological resources manager, as described in the Society of Vertebrate Paleontology guidelines of 1995. The experience of the Paleontological Resource Specialist shall include the following:

- Ability to recognize and collect fossils in the field
- Geological and biostratigraphic expertise
- Proficiency in identifying vertebrate and invertebrate fossils, and in assessing their scientific significance
- At least three years of paleontological resource mitigation and field experience in California and at least one year of experience leading paleontological resource mitigation and field activities

DWR and Reclamation shall ensure that the Paleontological Resource Specialist obtains qualified paleontological resource monitors to monitor Project construction activities, as the Paleontological Resource Specialist determines necessary on the Project. Paleontological Resource Monitors shall have the equivalent of the following qualifications:

- BS or BA degree in geology or paleontology and one year of experience monitoring in California
- AS or AA in geology, paleontology, or biology and four years' experience monitoring in California
- Enrollment in upper division classes pursuing a degree in the fields of geology or paleontology and two years of monitoring experience in California

Mitigation Measure Paleo-1b: Consultation with the Paleontological Resource Specialist Prior to and During Project Construction

At least 30 days prior to the start of Project construction, DWR and Reclamation shall provide maps or drawings to the Paleontological Resource Specialist that show the planned construction footprint. Maps shall identify all areas of the Project where ground disturbance is anticipated. (Site grading plan and plan and profile drawings for the utility lines are appropriate for this purpose). The plan drawings shall show the location, depth, and extent of all ground disturbances affecting paleontologically sensitive sediment. If Project construction proceeds in phases, maps and drawings may be submitted prior to the start of each phase. In addition, the proposed schedule of each Project phase shall be provided to the Paleontological Resource Specialist. Before work commences on affected phases, DWR and Reclamation shall notify the Paleontological Resource Specialist of any construction phase scheduling changes. If paleontological resources monitoring is ongoing, DWR and Reclamation shall ensure that the Paleontological Resource Specialist or Paleontological Resource Monitor consults weekly with the Project superintendent or construction field manager to confirm area(s) to be worked the following week and until ground disturbance is completed.

Mitigation Measure Paleo-1c: Prepare and Implement a Paleontological Resources Monitoring and Mitigation Plan

DWR and Reclamation shall ensure that the Paleontological Resource Specialist prepares a Paleontological Resources Monitoring and Mitigation Plan (PRMMP) to identify general and specific measures to minimize potential impacts to significant paleontological resources. Approval of the PRMMP by DWR and Reclamation shall occur prior to any ground disturbance. The PRMMP shall function as the formal guide for paleontological resources monitoring, collecting, and sampling activities, and may be modified by the Paleontological Resource Specialist to accommodate new data or Project changes.

This document shall be used as the basis of discussion when on-site decisions or changes are proposed. Copies of the PRMMP shall reside with the Paleontological Resource Specialist, each monitor, DWR's and Reclamation's on-site manager, and DWR and Reclamation.

The PRMMP shall be developed in accordance with professional guidelines, and be consistent with those issued by the Society of Vertebrate Paleontology (SVP, No Date), and shall include, but not be limited to, the following:

Procedures for the performance and sequence of resource-related tasks, such as any literature searches, pre-construction surveys, appropriate worker environmental training module, construction monitoring, mapping and data recovery, discovery situations, fossil preparation and collection, identification and inventory, preparation of final reports, transmittal of materials for curation, and final report shall be provided in the PRMMP, including:

- A discussion of the geologic units expected to be encountered, the location and depth of the units relative to the Project, when known, and the known paleontological sensitivity of those units
- A discussion of the locations of where the monitoring of Project construction activities is deemed necessary, and a proposed plan for monitoring and sampling
- An explanation of why, how, and how much sampling is expected to take place and in what units, including descriptions of different sampling procedures that may be used
- A discussion of procedures to be followed in the event of a significant fossil discovery, diverting construction away from a find, resuming construction, and how notifications will be performed
- A discussion of equipment and supplies necessary for collection of fossil materials and any specialized equipment needed to prepare, remove, load, transport, and analyze large-sized fossils or extensive fossil deposits
- Procedures for inventory, preparation, and delivery for curation into a retrievable storage collection in a public repository or museum, which meet the Society of Vertebrate Paleontology's standards and requirements for the curation of paleontological resources
- Identification of the institution(s) that will be approached to receive data and fossil materials collected, and requirements or specifications for materials delivered for curation

The PRMMP shall also provide guidance for preparation of a Paleontological Resources Report by the designated Paleontological Resource Specialist at the conclusion of ground-disturbing activities that may affect paleontological resources. The Paleontological Resources Report shall include an analysis of the collected fossil materials and related information, including a description and inventory of recovered fossil materials, a map showing the location of paleontological resources encountered, determinations of sensitivity and significance, and a statement by the Paleontological Resource Specialist that Project impacts to paleontological resources have been mitigated below the level of significance.

Mitigation Measure Paleo-1d: Conduct Paleontological Resources Awareness Training

Prior to ground disturbance and for the duration of Project construction activities involving ground disturbance, the Paleontological Resource Specialist shall prepare, and DWR and Reclamation shall conduct, weekly paleontological resources awareness training for the following workers: project managers, construction supervisors, forepersons, and general workers involved with or who operate ground-disturbing equipment or tools. Workers shall not excavate in paleontologically sensitive sediments prior to receiving paleontological resources awareness training. Worker training shall consist of a video or in-person presentation. The paleontological resources awareness training module may be combined with other training modules prepared for cultural and biological resources, hazardous materials, or other areas of interest or concern.

The paleontological resources awareness training shall address the possibility of encountering paleontological resources in the field, the sensitivity and importance of these resources, and legal obligations to preserve and protect those resources. The training shall include:

- A discussion of applicable laws and penalties under the law
- Good quality photographs or physical examples of vertebrate fossils
- Information that the Paleontological Resource Specialist or Paleontological Resource Monitor has the authority to halt or redirect construction in the vicinity of a fossil discovery or unanticipated impact to a paleontological resource
- Instruction that employees are to halt or redirect work in the vicinity of a find and to contact their supervisor and the Paleontological Resource Specialist or Paleontological Resource Monitor
- An informational brochure that identifies reporting procedures in the event of a discovery
- A certification of completion form signed by each worker indicating that he/she has received the training

Mitigation Measure Paleo-1e: Conduct Monitoring During Project Construction and Prepare Monthly Reports

DWR and Reclamation shall ensure that the Paleontological Resource Specialist and Paleontological Resource Monitor(s) monitor construction excavations consistent with the PRMMP in areas where potential fossil-bearing materials have been identified, both at reservoir sites and along any constructed linear facilities associated with the Project. In the event that the Paleontological Resource Specialist determines full-time monitoring is not necessary in locations that were identified as potentially fossil-bearing in the PRMMP, the Paleontological Resource Specialist shall notify DWR and Reclamation.

DWR and Reclamation shall ensure that the Paleontological Resource Specialist and Paleontological Resource Monitor(s) have the authority to halt or redirect construction if paleontological resources are encountered. DWR and Reclamation shall ensure that there is no interference with monitoring activities, as directed by the Paleontological Resource Specialist.

DWR and Reclamation shall ensure that the Paleontological Resource Specialist prepares and submits monthly summaries of monitoring and other paleontological resources management activities. The summary shall include the name(s) of the Paleontological Resource Specialist or Paleontological Resource Monitor(s) active during the month, general descriptions of training and monitored construction activities; and general locations of excavations, grading, and other activities. A section of the report shall include the geologic units or subunits encountered, descriptions of samplings, if any, and a list of identified fossils. A final section of the report shall address any issues or concerns about the Project relating to paleontological resources mitigation activities, including any incidents of non-compliance or any changes to the monitoring plan by the Paleontological Resource Specialist. If no monitoring took place during the month, the report shall include an explanation as to why monitoring was not conducted.

Mitigation Measure Paleo-1f: Ensure Implementation of the Paleontological Resources Monitoring and Mitigation Plan

DWR and Reclamation, through the designated Paleontological Resource Specialist, shall ensure that all components of the PRMMP are adequately performed during construction.

Implementation of **Mitigation Measures Paleo-1a, Paleo-1b, Paleo-1c, Paleo-1d, Paleo-1e**, and **Paleo-1f** would reduce the level of significance of Project impacts to paleontological resources to **less than significant**.

17. Faults and Seismicity

17.1 Introduction

This chapter describes the faults and seismicity setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for faults and seismicity is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

17.2 Environmental Setting/Affected Environment

17.2.1 Introduction

17.2.1.1 Fault Activity Classification

Faults are classified as active, potentially active, or inactive by the California Geological Survey (CGS), based on the age of most recent activity, as defined below:

- Historic faults have experienced surface rupture during historic time (approximately the last 200 years) and are associated with either a recorded earthquake with surface rupture, measurable surface displacement along a fault in the absence of notable earthquakes (aseismic creep), or displaced fault survey lines.
- Holocene age faults have had surface displacement within the past 11,000 years, as demonstrated by young geomorphic evidence, offset young deposits, or radiometrically dated material.
- Late Quaternary age faults show evidence of surface rupture within approximately the last 700,000 years, as demonstrated using the same geomorphic evidence as for Holocene faults.
- Quaternary age faults show evidence of surface rupture younger than approximately 1.6 million years ago, including faults that displace undifferentiated Plio-Pleistocene age deposits.
- Pre-Quaternary age faults show no evidence of movement within the Quaternary (approximately the past 1.6 million years) or lack evidence of displacement of younger deposits. Also included in this category are known faults for which detailed studies have not determined fault activity, and those faults identified only in preliminary mapping (Jennings, 1999).

The classification of “active” is applied to historic and Holocene age faults, “potentially active” is applied to Quaternary and late Quaternary age faults, and “inactive” is appied to pre-Quaternary age faults. These classifications were developed by the CGS and were adopted by the Alquist Priolo Act (1972) to help delineate Special Studies Zones where detailed geologic investigations are required prior to development. These classifications are not meant to imply that inactive fault traces will not rupture, only that they have not been shown to have ruptured for some time and the probability of fault rupture is low. The Alquist

Priolo Special Studies Zones do not address subsurface or “blind” faults, which can cause significant earthqauke damage without surface rupture.

The California Department of Water Resources, Division of Safety of Dams (DSOD) has published “Fault Activity Guidelines” (Fraser, 2001) that uses a more stringent criteria on fault activity classification than CGS. Its publication defines an active fault as having ruptured within the last 35,000 years. A conditionally active fault is defined as having ruptured in the Quaternary, but its displacement history during the last 35,000 years is unknown. Fault inactivity is demonstrated by a confidently located fault trace that is consistently overlain by unbroken geologic materials older than 35,000 years. Faults that have no indication of Quaternary activity are presumed to be inactive, except in regions of sparse Quaternary cover.

Table 17-1 compares the difference in fault activity classifications between CGS and DSOD. For this chapter, the more stringent fault activity classification set forth by DSOD is used.

Table 17-1
Comparison of Fault Activity Classification between the California Geological Survey and Division of Safety of Dams

Period	Epoch	Years Before Present	Fault Activity Classification	
			CGS	DSOD
Quaternary	Holocene	0 to 12,000 years	**Active** (Up to 11,00 years)	**Active** (Up to 35,000 years)
	Pleistocene	12,000 to 1.6 million years	**Potentially active** (Up to 1.6 million years)	**Conditionally active** (Up to 1.6 million years)
Pre-Quaternary			**Inactive** (Greater than 1.6 million years	**Inactive** (Greater than 1.6 million years

Notes:
CGS = California Geological Survey
DSOD = Division of Safety of Dams

17.2.1.2 Earthquake Magnitude and Intensity Measurement

Earthquake magnitude is a quantitative measure of the strength of an earthquake or the strain energy released by it, as determined by the seismographic or geologic observations. It does not vary with distance or the underlying earth material. This differs from earthquake intensity, which is a qualitative measure of the effects a given earthquake has on people, structures, loose objects, and the ground at a specific location. Intensity generally increases with increasing magnitude and in areas underlain by unconsolidated materials, and decreases with distance from the hypocenter (source of seismic energy) (CGS, 2002).

Several magnitude scales have been developed by seismologists. The original is the Richter magnitude, which measures the maximum trace amplitude registered on a seismogram. With appropriate distance corrections for the appropriate amplitude, the magnitude value is constant and is an effectice means of earthquake size classification.

The most commonly used scale is the moment magnitude scale. Moment magnitude is related to the physical size of fault rupture and the movement or displacement across the fault, and as such, is a more uniform measure of the strength of an earthquake. Another measure of earthquake size is seismic moment. The seismic moment determines the energy that can be radiated by an earthquake. The moment magnitude of an earthquake is defined relative to the seismic moment for that event.

An earthquake's magnitude is expressed in whole numbers and decimals (e.g., M6.8).

Earthquake intensity in a given location is typically measured using the Modified Mercalli intensity scale with values ranging from I to XII. The most commonly used adaptation covers the range of intensities from "I" (not felt except by very few, favorably situated), to "XII" (total damage, lines of sight disturbed, and objects thrown into the air).

Although an earthquake has only one magnitude, it can have many intensities that typically decrease with distance from the epicenter. Table 17-2 presents an approximate relationship between magnitude and maximuim expected intensity close to the epicenter.

Table 17-2
Comparison of Richter Magnitude and Modified Mercalli Intensity

Richter Magnitude	Expected Modified Mercalli Maximum Intensity (at epicenter)	
	Intensity	Observations and Effects
2	I – II	Usually detected only by instruments
3	III	Felt indoors
4	IV – V	Felt by most people; slight damage
5	VI – VII	Felt by all; many frightened and run outdoors; damage minor to moderate
6	VII – VIII	Everybody runs outdoors; damage moderate to major
7	IX – X	Major damage
8+	X – XII	Total and major damage

Source: Richter, 1958.

17.2.2 Extended Study Area

California straddles the juncture of two great crustal plates: the Pacific Plate and the North American Plate (CGS, 2003a). The cities of Monterey, Santa Barbara, Los Angeles, and San Diego are located on the Pacific Plate, which is constantly moving northwestward past the North American Plate. The North American Plate includes the remainder of California east of the San Andreas Fault[1]. The San Andreas Fault extends from the Gulf of California northwestward to Mendocino County and ends at the "Triple Junction" offshore of Cape Mendocino. The Triple Junction is where the American Plate, Pacific Plate, and the off-shore Gorda Plate meet. The relative rate of movement is approximately two inches (50 millimeters [mm]) per year. In California, approximately 40 mm per year of the slip occurs on the faults of the San Andreas system, and about 10 mm per year of slip occurs on faults in the Mojave Desert and Basin and Range area, east of the Sierra Nevada (a system known as the eastern California shear zone).

The constant motion of the crustal plates causes stress in the brittle upper crust of the earth. These tectonic stresses build up as the rocks are gradually deformed. This rock deformation, or strain, is stored in the rocks as elastic strain energy. When the strength of the rock is exceeded, rupture occurs along a

[1]Fractures in the earth's crust along which the rocks on one side have shifted relative to those on the other side are called faults. The total amount of displacement along a fault may be a few inches or many miles if it has accumulated over millions of years. Faults are more likely to have future earthquakes if they have had more recent earthquakes along them, have had greater total displacement, and are aligned so that movement can relieve the accumulating tectonic stresses.

fault. The rocks on opposite sides of the fault slide past each other as the rocks spring back to a relaxed position. The strain energy is released partly as heat and partly as seismic waves. These seismic waves produce the ground shaking of an earthquake.

There are thousands of recognized faults in California, hundreds of which have been given formal names, but only a very small number of these pose significant hazards. These faults are shown relative to the CVP and SWP service areas within the Extended Study Area (Figure 17-1). The motion between the Pacific and North American plates occurs primarily on the faults of the San Andreas Fault system and the eastern California shear zone. Other faults have much lower rates of movement, and correspondingly longer times between significant earthquakes.

Ground shaking from large earthquakes is responsible for most of the damage caused by earthquakes. Damage to structures is related to the type and quality of construction, and foundation materials. Building codes have been periodically revised to account for our current understanding of how earthquake shaking can damage buildings. Other earthquake hazards, including the surface rupture of a fault, and liquefaction and landslides that can be caused by the shaking, are significant hazards.

Earthquakes are detected every day in California by sensitive seismographs that record the very small vibrations of the earth. Each year, 100 to 150 earthquakes occur in the state that are big enough to be felt, but few of these cause damage. Earthquakes large enough to cause moderate damage to structures in the vicinity of the epicenter – those of M5 or larger – occur three or four times a year (CGS, 2003a).

On an average of once every two or three years, a moderate earthquake (M6 to 6.9) strikes somewhere in the state. An earthquake of this size, such as the Northridge (southern California) Earthquake of January 17, 1994 (M6.7) or the Coalinga (central California) Earthquake of May 2, 1983 (M6.5) is capable of causing major damage if the epicenter is near a densely populated area (CGS, 2003a).

Major earthquakes (M7 to 7.9) occur in California approximately every 10 years. Two recent major earthquakes, the Landers (San Bernardino County) Earthquake of June 28, 1992 (M7.3) and the Hector Mine (San Bernardino County) Earthquake of October 16, 1999 (M7.1) caused extensive surface fault rupture, but relatively little damage because they occurred in lightly populated areas of the Mojave Desert. Earthquakes of similar size, such as the M6.9 Loma Prieta (Santa Cruz County) Earthquake of October 17, 1989, cause extensive damage over large areas when they occur in densely populated regions. The two largest earthquakes in California, the Fort Tejon (Kern County) Earthquake of 1857 and the famous San Francisco Earthquake of 1906, were similar in magnitude (M7.9 and M7.8, respectively) and resulted from movement along the San Andreas Fault. Earthquakes of this size (M7.7 to 7.9) can cause more extensive damage over a larger area than the M7.1 to 7.4 earthquakes that have stricken California in recent decades (CGS, 2003a).

Great earthquakes (M greater than 8) have not occurred in California in historic time, but one earthquake in January 1700 may have been this large. Based on Native American oral histories, tree-ring studies, geological studies that show the uplift or subsidence of large areas of coastal land, and records of a tsunami that struck Japan and cannot be correlated with an earthquake anywhere else around the Pacific, a great (M9) earthquake occurred January 26, 1700 on the Cascadia Subduction Zone extending north from Cape Mendocino to British Columbia. An earthquake of this size is similar to the one that struck Alaska in 1964, and is capable of extensive damage over a very broad region (CGS, 2003a).

B.F. Sisk Dam, which impounds San Luis Reservoir, is near two seismic faults. It is 28 miles from the San Andreas Fault, and 23 miles from the Calaveras-Hayward Fault.

Reservoir-induced seismicity is a phenomenon where the weight of large deep reservoirs and the increased pore pressures trigger small localized earthquakes. Within the Extended Study Area, San Luis Reservoir has been suspected of creating reservoir-induced seismicity (William Lettis & Associates, Inc., 2002; Probe International, 2008).

During a period of rapid inflow in January and February 1969, a four-fold increase in seismic activity was recorded in the vicinity of San Luis Reservoir, followed by an additional 38 events during the remainder of the year. Subsequent to this, seismicity returned to background levels (Anderson et al., 1982). In 1974, 11 earthquakes occurred at the southern end of the reservoir during a period when there were minimal changes in water level. This subsequent series of events brought into question whether the 1969 activity was related to reservoir-induced seismicity (Wong and Strangberg, 1996).

17.2.3 Secondary Study Area

Faults and seismicity are a regional phenomenon. Movement on faults within the Secondary Study Area could have potential effects on Project features within the Primary Study Area. Although this discussion addresses faults and seismicity within the Secondary Study Area, their location relative to the Primary Study Area has been included.

Table 17-3 lists the locations of regionally active faults and potentially active faults significant to the Secondary Study Area due to proximity, activity status, date of most recent motion, and maximum moment magnitude (Mmax)[2]. Figure 17-2 shows the active and potentially active faults within the Secondary Study Area that could affect the operation of the proposed Project.

Table 17-3
Regional Active and Potentially Active Faults in the Secondary Study Area

Fault	Fault Type	Recency of Movement	Fault Classification	Maximum Moment Magnitude (Mmax)
San Andreas	Strike Slip	Holocene	Active	~8.0
Maacama Fault	Strike Slip	Holocene	Active	6.5
Bartlett Springs	Strike Slip	Holocene	Active	6.6
Coast Range	Normal	Late Pliocene	Not Active	Not characterized
Green Valley	Thrust	Pre-Late Quaternary	Not Active	Not characterized
Stony Creek	Thrust	Pre-Quaternary	Not Active	Not characterized
Great Valley	Blind Thrust	Holocene	Assumed to be Active	6.8
Corning	Blind Reverse	Late Pleistocene	Active	Not characterized
Cleveland Hills	Normal	Holocene	Active	5.7
Cascadia Subduction Zone	Megathrust	Holocene	Active	9

Source: William Lettis & Associates, Inc., 2002.

The right-lateral San Andreas Fault system forms the boundary between the North American and Pacific plates. The San Andreas Fault trends southeast from Cape Mendocino to the Gulf of California. Between Cape Mendocino and San Francisco, some portions of the fault lie off the coast of California. The San Andreas Fault has experienced significant activity during historic time, most recently during the 1989 Loma Prieta Earthquake (M6.9), which resulted in widespread damage throughout the Bay Area.

[2] The Mmax is the strongest earthquake that is likely to be generated along a fault. It is based on empirical relationships of surface rupture length, rupture area, and fault type, which are all related to the physical size of fault rupture and displacement across a fault.

Prior to that, the 1906 San Francisco Earthquake (estimated at M7.9) caused approximately 290 miles of surface fault rupture from Tomales Bay southward.

East of the San Andreas Fault, several strike-slip faults occur in northwest trending valleys, including the Maacama Fault and the Bartlett Springs Fault. Both faults have been active in Holocene time and are capable of producing seismic events up to M6.6. The CGS has published several Alquist-Priolo maps along both of these faults.

Further east, several inactive faults (Coast Range, Green Valley, and Stony Creek) occur at or near the contact between the Franciscan Formation and the Great Valley Sequence. Movement along these fault planes is generally attributed to eastward compression of the Coast Range and slippage along bedding planes. These three faults are considered not active.

The Great Valley Fault is a low-angle blind thrust fault located along the west side of the Sacramento and San Joaquin valleys. The fault plane is deepest to the west in rocks of the Coast Range Geomorphic Province and trends upward into sedimentary rocks of the Great Valley Geomorphic Province. It is a main component of the Coast Ranges-Sierran Block Boundary Zone, a broad compressional boundary between the Pacific Plate and the Sierra Nevada Microplate of North America (William Lettis & Associates, Inc., 2002). In its closest proximity to the Primary Study Area, it is approximately four to seven miles below the surface. Historically, seismic activity has occurred along the Great Valley Fault in the Sacramento Valley, notably the 1889 Antioch Earthquake (M6) and the 1892 Winters earthquakes (M6+). In addition, a swarm of small earthquakes (M3.6 to M4.0) occurred in the region of Maxwell and Williams in late 1943 that are believed to have originated along the Great Valley Fault. The segment of the Great Valley Fault nearest to Primary Study Area is assumed to be active.

The Corning Fault is a blind reverse fault located west of the Sacramento River and extending from Red Bluff southward into Glenn County. The fault trace is not visible on the surface. Based on evidence of uplifting and folding of the Modesto Formation (late Pleistocene) across the trace of the fault, the Corning fault is considered active.

The Cascadia Subduction Zone is the boundary between the subducting Pacific Plate and the North American Plate. Its closest occurrence to the Primary Study Area is approximately 150 miles west-northwest offshore of northern California, north of Cape Mendocino. The zone extends north offshore of Oregon, Washington, and southern Canada. Geological investigations (Atwater et al., 1995; Nelson et al., 1995), geophysical modeling (Fluck et al., 1997; Hyndman and Wang, 1995), and historical tsunami records from Japan (Satake et al., 1996) provide the basis for the current scientific consensus that the Cascadia Subduction Zone has the potential to generate mega-earthquakes that may rupture the entire 1,500-mile length of the plate boundary, with seismic events exceeding M9. The most recent great earthquake is estimated to have occurred approximately 300 years ago in 1700, based on tree ring evidence and Japanese tsunami records. Paleoseismic data indicate that earthquakes of this size may occur every 500 to 600 years. Historically, the 1992 Cape Mendocino earthquake (M7 to M7.2) is the most recent earthquake to occur on the Cascadia Subduction Zone.

The Cleveland Hills Fault is a normal fault located south of Lake Oroville. In 1975, several earthquakes occurred along the fault; the greatest event was M5.7. Surface rupturing along the fault line occurred for several miles. The fault is considered active. One Alquist-Priolo Act map was published mapping areas of surface rupture along the fault line.

Figure 17-3 shows the locations of seismic events within the Secondary Study Area. The majority of the historical seismic activity is associated with movement along the Bartlett Springs and Maacama faults west of the Primary Study Area. The concentration of seismic activity to the northwest is associated with the "Triple Junction". Earthquake hazards are greater there because that region is part of the Cascadia Subduction Zone, where plate collisions increase the potential for huge earthquakes. A cluster of minor to moderate seismic events in the Oroville area is associated with the Cleveland Hill Fault. Additional minor seismic activity occurs throughout the Secondary Study Area, and is generally attributed to compressional forces between the Coast Range Geomorphic Province and the Great Valley Geomorphic Province. These minor seismic events occur at moderate depth with no surface expression exhibited (William Lettis & Associates, Inc., 2002).

The CGS has produced an Earthquake Shaking Potential for California Map (CGS, 2008a). The map indicates that seismic shaking potential in the Secondary Study Area ranges from low to high, with the highest potentials existing along the San Andreas Fault and other faults in the Coast Range and southern California.

Liquefaction is the loss of soil strength due to seismic forces generating various types of ground failure. The potential for liquefaction must account for soil types and density, the groundwater table, and the duration and intensity of ground shaking. The USGS has produced numerous maps of areas within the Secondary Study Area showing liquefaction potential (USGS, 1996a). Many areas, such as artificial fill adjacent to the San Francisco Bay, have a high liquefaction potential.

The CGS has produced numerous maps showing landslide features and delineating potential slope-stability problem areas (CGS, 2011a). Many areas within the Secondary Study Area have high landslide susceptibility (CGS, 2011b).

Within the Secondary Study Area, Shasta Lake and Lake Oroville have been suspected of creating reservoir-induced seismicity (William Lettis & Associates, Inc., 2002; Probe International, 2008).

17.2.4 Primary Study Area

17.2.4.1 Methodology

William Lettis & Associates, Inc. completed a Phase II Fault and Seismic Hazards Investigation for the NODOS Integrated Storage Investigations in 2002. The report focused on the area around the proposed Sites Reservoir, particularly the proposed damsites, and is the primary source of information presented for the Primary Study Area in this chapter.

17.2.4.2 Fault Rupture Potential

No faults of Holocene age (i.e., active faults) are known to occur within the Primary Study Area. No Alquist-Priolo Act maps have been published for areas within the Primary Study Area.

The Phase II Fault and Seismic Hazards Investigation for the NODOS Integrated Storage Investigations (William Lettis & Associates, Inc., 2002) identified several inactive faults in proximity to the proposed Sites Reservoir and the Sites and Golden Gate damsites (Table 17-4). Two major sets of surface faults were recognized:

1. Northeast-striking high-angle faults that obliquely cut across the north-striking bedrock units, and consistently displace stratigraphic contacts in a right-lateral sense. Specific examples of these

structures include the informally named GG-1, GG-2, GG-3 and S-2 faults, all of which pass directly through the proposed Sites and Golden Gate damsites or are located near them (Figure 17-4).

2. North-striking faults that are generally parallel to bedding (Figure 17-4). The most laterally continuous example of these structures is the Salt Lake Thrust Fault, which is parallel to, and east of, the axis of the Sites anticline[3]. The Salt Lake Thrust Fault is approximately 0.9 mile west of the proposed Golden Gate damsite, and the southern end of the fault is approximately 1.7 miles northwest of the proposed Sites damsite. The trace of the fault passes through the site of proposed saddle dam SSD-2.

The northeast-striking GG-1, GG-2, GG-3, and S-2 faults are tear faults accommodating compression of the overlying formations above the plane of the Great Valley Thrust Fault. Movement along these faults probably occurred as a co-seismic event of moderate to large magnitude earthquakes on the underlying Great Valley Thrust Fault and probably do not act as independent seismic sources (William Lettis & Associates, Inc., 2002).

The Salt Lake Thrust Fault is an offshoot of the Great Valley Thrust Fault trending upward. Trench investigations across the trace of the Salt Lake Thrust Fault indicated that at least one, and probably three or more, surface ruptures have occurred in the past 30,000 to 70,000 years. If rupture events have a regular recurrence, then the trench evidence suggests that at least one surface rupturing event probably has occurred in the past 35,000 years (William Lettis & Associates, Inc., 2002).

The Phase II Fault and Seismic Hazards Investigation for the NODOS Integrated Storage Investigations (William Lettis & Associates, Inc., 2002) concluded that a three- to eight-inch fault slippage could occur along the northeast-striking GG-1, GG-2, GG-3, and S-2 faults that are located beneath the Project damsites or are in proximity to them. This slippage is assumed to be related to movement at depth along the Great Valley Thrust Fault.

Table 17-4
Faults in Proximity to the Proposed Sites Reservoir and Sites and Golden Gate Damsites

Fault	Fault Length	Sense of Displacement	Fault Separation (Horizontal)	Fault Separation (Vertical)	Fault Width	Nearest Distance to Golden Gate Damsite	Nearest Distance to Sites Damsite	Time of Last Movement*
GG-1	1.1 miles	Right-lateral	246 ± 82 feet	Unknown	2 feet	< 0.5 mile	3.1 miles	Holocene deposits unfaulted
GG-2	3.7 miles	Right-lateral	1,312 ±196/-98 feet	Unknown	2 feet	< 0.5 mile	1.7 miles	Holocene deposits unfaulted
GG-3	3.0 miles	Right-lateral	1,574 ± 65 feet	Unknown	2 feet	< 0.5 mile	0.4 mile	Early Holocene deposits unfaulted
S-2	2.4 miles	Right-lateral	558 ±164/-180 feet	None	3 feet	2.2 miles	< 0.5 mile	Early Holocene deposits unfaulted
S-3	Unknown	Thrust (east side up)	Unknown	Unknown	6 feet	600 feet	0.9 mile	Older than, and offset by, Faults S-2, GG-3
Salt Lake Thrust Fault	> 7 miles	Thrust (east side up)	Unknown	> 10 feet	2 feet	1.7 miles	0.9 mile	Pleistocene gravels offset

*Youngest faulted or oldest deposits that cross the fault are given.

Source: William Lettis & Associates, 2002.

[3] An anticline is a fold with strata sloping downward on both sides from a common crest.

17.2.4.3 Seismic Ground Shaking

On the basis of a probabilistic seismic hazard map that depicts the peak horizontal ground acceleration values exceeded at a 10 percent probability in 50 years (CGS, 2003b), the probabilistic peak horizontal ground acceleration values within the Primary Study Area range from 0.1g to 0.3g (where g equals the acceleration speed of gravity). These values indicate that the ground-shaking hazard in the Primary Study Area is moderately low.

Ground shaking intensity is largely a function of distance from the earthquake epicenter and underlying geology. The Primary Study Area is located on bedrock of the Great Valley Sequence (western portion) and recent alluvial deposits (eastern portion). Focal depths are generally deeper than 15 miles (William Lettis & Associates, 2002). Historically, the Primary Study Area has a low seismic activity rate. Data from the Northern California Seismic Network database indicate that no seismic event greater than M4.5 has occurred since 1970. Sparse data from the historical seismic record show nothing greater than a M4.5 (William Lettis & Associates, 2002).

17.2.4.4 Seismic-Related Ground Failure including Liquefaction

Liquefaction is the sudden temporary loss of shear strength in saturated loose to medium dense granular sediments subjected to ground shaking. Liquefaction generally occurs when seismically induced ground shaking causes pore water pressure to increase to a point equal to the weight of the overlying soil and rock above the water table. Liquefaction can cause foundation failure of buildings and other facilities due to the reduction of foundation bearing strength. The potential for liquefaction depends on the duration and intensity of earthquake shaking, particle size distribution of the soil, density of the soil, and elevation of the groundwater. Areas at risk due to the effects of liquefaction are typified by a high groundwater table and underlying loose to medium-dense granular sediments, particularly younger alluvium and artificial fill.

Liquefaction potential is low in the western portion of the Primary Study Area because the soils are well-drained (i.e., low groundwater table) and decreased depth to bedrock. Liquefaction potential in the eastern portion is moderate due to the higher groundwater table and greater soil depth. Project features located in this area include the Holthouse Reservoir Complex, the TRR and its associated facilities, the Delevan Pipeline, the Delevan Pipeline Intake/Discharge Facilities, and the Delevan Transmission Line

17.2.4.5 Landslides

Slope failures, commonly referred to as landslides, include many phenomena that involve the downslope displacement and movement of material, either triggered by static (i.e., gravity) or dynamic (i.e., earthquake) forces. Rock slopes exposed to either air or water can undergo rockfalls, rockslides, or rock avalanches; soil slopes experience shallow soil slides, rapid debris flows, and/or deep-seated rotational slides.

Landslide potential is low in the eastern portion of the Primary Study Area where the land profile is relatively flat. Landslide potential increases in the western upland portion where steeper slopes occur. Small to medium landslides have been observed on steep slopes within and adjacent to the proposed Sites Reservoir, particularly along the western side of Logan Ridge (eastern shoreline of proposed Sites Reservoir). These landslides occur in the Boxer Formation, which is composed primarily of mudstone. Small isolated rockslides have been observed within and adjacent to the proposed Sites and Golden Gate damsites. These rockslides occur in the Venado Sandstone member of the Cortina Formation.

17.2.4.6 Seiches and Tsunamis

The Primary Study Area is not located downslope of any large bodies of water, nor is it located within a coastal area. Therefore, existing hazards due to earthquake-induced seiches (wave oscillations in an enclosed or semi-enclosed body of water) or tsunamis (seismic sea waves) are negligible. The existing Funks Reservoir is considered too small to produce a significant seiche.

17.2.4.7 Reservoir-Induced Seismicity

The only existing reservoir within the Primary Study Area is Funks Reservoir. Depth of the water in the reservoir is the most important factor in reservoir-induced seismicity (Probe International, 2008). Funks Reservoir is too shallow to create reservoir-induced seismicity.

17.3 Environmental Impacts/Environmental Consequences

17.3.1 Regulatory Setting

Seismic hazards, as related to the building of structures, are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

17.3.1.1 Federal Plans, Policies, and Regulations

- National Earthquake Hazards Reduction Program Reauthorization Act of 2004

17.3.1.2 State Plans, Policies, and Regulations

- California Water Code, Division 3 Dams and Reservoirs
- Seismic Hazards Mapping Act of 1990
- Alquist-Priolo Earthquake Fault Zoning Act of 1972
- California Division of Mines and Geology Special Publication No. 42, Fault-Rupture Hazard Zones in California, 2007
- California Division of Mines and Geology Special Publication No. 117A, Guidelines for Evaluating and Mitigating Seismic Hazards in California, 2008
- California Code of Regulations, Title 23 Waters, Division 2 Department of Water Resources, Chapter 1 Dams and Reservoirs, Article 5

17.3.1.3 Regional and Local Plans, Policies, and Regulations

- Colusa County General Plan
- Glenn County General Plan

17.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for faults and seismicity:

Would the Project:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
  - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault?
  - Strong seismic ground shaking?
  - Seismic-related ground failure, including liquefaction?
  - Landslides?
- Inundation by seiche, tsunami, or mudflow?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Exposure of people or structures to fault rupture, seismic ground shaking, seismic-related ground failure, liquefaction, or landslides.
- Inundation by seiches or tsunamis.
- Reservoir-induced seismicity (increased seismicity due to the presence of a new reservoir or re-operation of existing reservoirs).

17.3.3 Impact Assessment Assumptions and Methodology

17.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to existing seismic hazards and impacts to the Project from those seismic hazards:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and

industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.
- Likely sources of major regional seismicity would be from earthquakes to the west of the Project area in the Coast Range or from a very rare Cascadia Subduction Zone event (occurrence every 500 to 600 years).
- No undiscovered major faults or seismic sources would have an impact.

17.3.3.2 Methodology

A combination of data, published reports, and professional experience with initial investigations for the proposed Project was used to evaluate the alternatives for potential impacts due to faults and seismicity.

The Extended and Secondary study area impact assessments primarily relied on data and publications (both printed and web-based) from the California Geological Survey and the United States Geological Survey. The Primary Study Area impact assessments primarily relied on the Phase II Fault and Seismic Hazards Investigation for the NODOS Integrated Storage Investigations (William Lettis & Associates, Inc., 2002). Professional experience with initial investigations included geological mapping within the Primary Study Area and core-drilling within the footprints of the proposed damsites.

17.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

17.3.5 Impacts Associated with the No Project/No Action Alternative

17.3.5.1 Extended and Secondary Study Areas – No Project/No Action Alternative

<u>Construction, Operation, and Maintenance Impacts</u>

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Sacramento River, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Seis-1: Exposure of People or Structures to Fault Rupture, Seismic Ground Shaking, Seismic-Related Ground Failure, Liquefaction, or Landslides

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to or from seismic hazards has been addressed in those environmental documents. In addition, the Project would not be constructed if this alternative is implemented. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Population growth will continue to occur throughout California throughout the period of Project analysis (i.e., 100 years), is included in the assumptions for the No Project/No Action Alternative, and as such, it may be expected to occur throughout the Extended and Secondary study areas. Growth within the counties is planned and guided in the various county General Plans, and structures that are constructed to accommodate such growth are expected to be constructed in suitable areas to applicable and appropriate seismic standards. In addition, the growth-inducing effects of the projects that are included in the No Project/No Action Alternative, as well as from planned growth in the counties that comprise the two study areas, are expected to have been addressed in the environmental documents that addressed those projects and County General Plans, pursuant to CEQA and/or NEPA. Therefore, growth would not affect these seismic hazards, and the seismic hazards are not expected to affect growth within the Extended or Secondary Study Area counties. Consequently, **there would not be a substantial adverse effect**, when compared to Existing Conditions. San Luis Reservoir, Shasta Lake, Lake Oroville, and Folsom Lake operations do not currently cause seismic hazards, and their continued operation is not expected to change that condition. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Seis-2: Inundation by Seiches or Tsunamis

The impacts of the projects that are included in the No Project/No Action Alternative have been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA. Their potential for impacts to or from seiches or tsunamis has been addressed in those environmental documents. In addition, the Project would not be constructed if this alternative is implemented. Population growth may be expected to occur throughout the Extended and Secondary study areas. The growth-inducing effects of the projects that are included in the No Project/No Action Alternative, as well as from planned growth in the counties that comprise the two study areas, are also expected to have been addressed in the environmental documents that addressed those projects and County General Plans, pursuant to CEQA and/or NEPA. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions. In addition, San Luis Reservoir, Shasta Lake, Lake Oroville, and Folsom Lake are not located on the coast, so they are not expected to cause or be affected by seiches or tsunamis. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Seis-3: Reservoir-Induced Seismicity

The impacts of the projects that are included in the No Project/No Action Alternative have been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA. Their potential for impacts to or from reservoir-induced seismicity has been addressed in those environmental documents. In addition, the Project would not be constructed if this alternative is implemented. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

The only examples of suspected reservoir-induced seismicity associated with existing State and federal reservoirs located within the Extended and Secondary study areas occurred over 35 years ago (San Luis Reservoir in 1969 and Lake Oroville in 1975). Major State and federal reservoirs within the Extended and Secondary study areas (Shasta, Folsom, San Luis, and Oroville) have been operated according to established engineering guidelines since their completion in 1945 (Shasta), 1956 (Folsom), 1967 (San Luis), and 1968 (Oroville) and will continue to operate according to these same guidelines in the future. The continued absence of reservoir-induced seismicity that has characterized the past 35 to 70 years of operation of these very large reservoirs should be anticipated in the future. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Modifications to operations of existing reservoirs would also have been evaluated pursuant to CEQA and/or NEPA, and any potentially significant or significant impact that was identified would have been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

17.3.5.2 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Seis-1: Exposure of People or Structures to Fault Rupture, Seismic Ground Shaking, Seismic-Related Ground Failure, Liquefaction, or Landslides

If the No Project/No Action Alternative is implemented, Sites Reservoir and its associated facilities would not be constructed. Therefore, Project-induced seismic impacts (including fault rupture, strong seismic ground shaking, and seismic-related ground failure) and liquefaction and landslides would be avoided in the Primary Study Area, and **would not have a substantial adverse effect**, when compared to Existing Conditions.

It is acknowledged that population growth may occur within Glenn and Colusa counties. Growth within the counties is planned and guided in the two counties' General Plans, and structures that are constructed to accommodate such growth are expected to be constructed in suitable areas to applicable and appropriate seismic standards. Therefore, growth would not affect these seismic phenomena, and the phenomena are not expected to affect growth within the counties. Consequently, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Seis-2: Inundation by Seiches or Tsunamis

If the No Project/No Action Alternative is implemented, the Project would not be completed. Therefore, there would be no increase in the risk of inundation by seiches or tsunamis to people or structures in the Primary Study Area from Project facilities. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions**.** Population growth may occur within Glenn and Colusa counties. Neither county is located on the coast; therefore, a seiche or tsunami would not occur there, **and would not have a substantial adverse effect** on additional people who may move into those counties in the future, when compared to Existing Conditions.

Impact Seis-3: Reservoir-Induced Seismicity

If the No Project/No Action Alternative is implemented, the Project would not be completed. Therefore, there would be no increase in the risk of reservoir-induced seismicity in the Primary Study Area. Projects and programs that are included in the No Project/No Action Alternative are not located within Glenn or Colusa counties, so they would not cause reservoir-induced seismicity in those counties. In addition, population growth and associated urban/suburban/rural development that may occur within the two counties in the future is expected to not affect reservoirs located within the counties. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions**.**

17.3.6 Impacts Associated with Alternative A

17.3.6.1 Extended and Secondary Study Areas – Alternative A

<u>Construction, Operation, and Maintenance Impacts</u>

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Pump Installation at the Red Bluff Pumping Plant, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Sacramento River, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Seis-1: Exposure of People or Structures to Fault Rupture, Seismic Ground Shaking, Seismic-Related Ground Failure, Liquefaction, or Landslides

With the exception of installing an additional pump at the RBPP, no Project facilities would be constructed, operated, or maintained in the Extended or Secondary study areas. When compared to Existing Conditions and the No Project/No Action Alternative, Project facilities would not expose people or structures to fault rupture, seismic ground shaking, seismic-related ground failure, liquefaction, or landslides. Similarly, those seismic events, if they occurred, would not affect Project facilities because most facilities would not be developed within those areas. The installation of a pump within the existing RBPP would not affect and is not expected to be affected by seismic events. There would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, the continued operation of San Luis Reservoir, Shasta Lake, Lake Oroville, and Folsom Lake would not cause these seismic events, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Seis-2: Inundation by Seiches or Tsunamis

Because no Project facilities would be constructed, operated, or maintained in the Extended or Secondary study areas (other than one pump to be installed at the existing RBPP), Project facilities would not be affected by seiches or tsunamis, if they were to occur there, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative. The installation of a pump within the existing RBPP would not affect and is not expected to be affected by a tsunami because the RBPP is not located in a coastal area, and it would not be affected by a seiche because it is not located on a waterbody. The continued operation of San Luis Reservoir would have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative, on tsunamis because the reservoir is not located in a coastal area. During the continued operation of San Luis Reservoir, Shasta Lake, Lake Oroville, and Folsom Lake, it is possible that a large earthquake-induced landslide could cause a seiche on these reservoirs. However, the seiche would be small to moderate, resulting in a **less-than-significant impact** when compared to Existing Conditions or the No Project/No Action Alternative**.**

Impact Seis-3: Reservoir-Induced Seismicity

The only examples of suspected reservoir-induced seismicity associated with existing State and federal reservoirs located within the Extended and Secondary Study Areas occurred over 35 years ago (San Luis Reservoir, 1969 and Lake Oroville, 1975). Major State and federal reservoirs within the Extended and Secondary study areas (Shasta, Folsom, San Luis and Oroville) have been operated according to established engineering guidelines since their completion in 1945 (Shasta), 1956 (Folsom), 1967 (San Luis) and 1968 (Oroville) and will continue to operate according to these same guidelines in the future. The continued absence of reservoir-induced seismicity that has characterized the past 35 to 70 years of operation of these very large reservoirs should be anticipated in the future resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, the addition of one pump to an existing bay at the RBPP would not cause or be affected by reservoir-induced seismicity because the RBPP is not located near or on a reservoir, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

17.3.6.2 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Seis-1: Exposure of People or Structures to Fault Rupture, Seismic Ground Shaking, Seismic-Related Ground Failure, Liquefaction, or Landslides

There are very few seismic hazard areas within the Primary Study Area. No active faults are known to be present within or immediately adjacent to the Primary Study Area, and there is low risk of fault failure (CGS, 2003a). Because there are few active faults in proximity to the Primary Study Area, the likelihood of fault rupture, strong seismic ground shaking and seismic-related liquefaction or landslides is also low. Detailed site-specific geologic and foundation investigations were used to develop design criteria to withstand reasonably probable seismic events.

The Phase II Fault and Seismic Hazards Investigation for the NODOS Integrated Storage Investigations (William Lettis & Associates, Inc., 2002) concluded that a three- to eight-inch fault slippage could occur along the northeast-striking GG-1, GG-2, GG-3, and S-2 faults that are located beneath the Project damsites or in proximity to them. DSOD would require that the design specifications be sufficient to mitigate an impact related to this slippage. Therefore, constructing, operating, and maintaining the Project facilities in this area would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project construction would involve creating high-angle temporary slopes at damsites, quarry areas, new roads, recreation areas, and temporary and permanent access roads. Project construction would also include trenching along the Delevan Pipeline. Localized slumping (i.e., landslides or trench wall failure) and liquefaction due to seismic shaking would pose a moderate threat, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation, increased soil moisture and reservoir surface level fluctuations along the shores of Sites Reservoir could exacerbate slope instability (particularly along the eastern shoreline west of Logan Ridge) and increase earthquake-induced landslide potential. Therefore, operation of the Project in this area would result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Seis-2: Inundation by Seiches or Tsunamis

The Primary Study Area is not located in a coastal area. Therefore, significant hazards due to earthquake-tsunamis (seismic sea waves) are negligible. It is possible that a large earthquake-induced landslide could cause a seiche on Sites Reservoir, but the seiche would be small to moderate and would result in a

less-than-significant impact, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Seis-3: Reservoir-Induced Seismicity

Alternative A proposes a 1.27-MAF Sites Reservoir, with a maximum depth of approximately 220 feet. Reservoirs are classified as deep (80 meters, 263 feet) to very deep (deeper than 150 meters, 492 feet). Sites Reservoir would be classified as a less than deep reservoir. Deep and very deep reservoirs account for the majority of reported examples of reservoir-induced seismicity (USGS, 1996b). Therefore, potential effects from reservoir-induced seismicity caused by Sites Reservoir would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

The smaller Holthouse Reservoir and TRR would be too shallow to create reservoir-induced seismicity, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

17.3.7 Impacts Associated with Alternative B

17.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to seismic conditions (**Impact Seis-1**), seiches or tsunamis (**Impact Seis-2**), and reservoir-induced seismicity (**Impact Seis-3**), would be the same as described for Alternative A for the Extended and Secondary study areas.

17.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to seismic conditions (**Impact Seis-1**) and seiches or tsunamis (**Impact Seis-2**), would be the same as described for Alternative A for all Primary Study Area Project facilities.

The impacts associated with Alternative B, as they relate to reservoir-induced seismicity (**Impact Seis-3**), would be the same as described for Alternative A for all Primary Study Area Project facilities, with the exception of Sites Reservoir. Alternative B includes a 1.81-MAF Sites Reservoir, compared to the 1.27-MAF Sites Reservoir evaluated for Alternative A. The potential impacts of the larger reservoir on reservoir-induced seismicity are discussed below.

Sites Reservoir Inundation Area

Impact Seis-3: Reservoir-Induced Seismicity

The Alternative B 1.81-MAF Sites Reservoir would have a maximum depth of approximately 260 feet, which is on the threshold of classifying it as a deep reservoir. However, the Alternative B Sites Reservoir would still be classified as a less than deep reservoir. Deep and very deep reservoirs account for the majority of reported examples of reservoir-induced seismicity (USGS, 1996b). Therefore, potential effects from reservoir-induced seismicity would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

17.3.8 Impacts Associated with Alternative C

17.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to seismic conditions (**Impact Seis-1**), seiches or tsunamis (**Impact Seis-2**), and reservoir-induced seismicity (**Impact Seis-3**), would be the same as described for Alternative A for the Extended and Secondary study areas.

17.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to seismic conditions (**Impact Seis-1**) and seiches or tsunamis (**Impact Seis-2**), would be the same as described for Alternative A for all Primary Study Area Project facilities.

The impacts associated with Alternative C, as they relate to reservoir-induced seismicity (**Impact Seis-3**), would be the same as described for Alternative A for all Primary Study Area Project facilities, with the exception of Sites Reservoir. Alternatives B and C include a 1.81-MAF Sites Reservoir. Therefore, the impacts associated with the Alternative C Sites Reservoir, as related to reservoir-induced seismicity (**Impact Seis-3**), would be the same as described for Alternative B for Sites Reservoir.

17.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 17-5 for the impacts that have been identified as significant or potentially significant.

Table 17-5
Summary of Mitigation Measures for
NODOS Project Impacts to/from Faults and Seismicity

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Seis-1: Exposure of People or Structures to Fault Rupture, Seismic Ground Shaking, Seismic-Related Ground Failure, Liquefaction, or Landslides	Road Relocations, Recreation Areas, Delevan Pipeline, Quarry Areas, All Project Damsites	Potentially Significant	Mitigation Measure Seis-1: Implement Slope Stabilization Methods; Design Facilities to Withstand Fault Rupture, Seismic Ground Shaking, and Ground Failure, and Liquefaction	Less than Significant

Note:
LOS = Level of Significance

To mitigate **Impact Seis-1**, implement **Mitigation Measure Seis-1**, as follows:

Mitigation Measure Seis-1: Implement Slope Stabilization Methods; Design Facilities to Withstand Fault Rupture, Seismic Ground Shaking, and Ground Failure, and Liquefaction

- The two main Project dams would be located on a fault. To minimize potential seismic-related Project impacts, the Project design includes features such as wide clay cores and additional filter material to reduce the risk of dam failure. In addition, temporary and permanent excavation cut slopes shall be designed to be stable. If slope instability is detected, excavation cut slopes shall be stabilized by flattening, installing engineered retaining structures, and/or providing appropriate drainage elements. Shoring shall be used to support vertical trench walls. Re-sloping or removal is the most common method of landslide or slope stabilization. Structural solutions are as listed. The proposed dams, dikes, and powerplants shall be designed to survive fault rupture, seismic ground shaking and ground failure, and liquefaction without loss of the reservoir or catastrophic damage. These hazards are of far less concern during construction when there is no potential for an uncontrolled reservoir release. Additionally, the probability of these hazards occurring during the relatively short Project construction period is remote, and steps to mitigate for them are not typically included in the design of a temporary structure. Construction mitigation would normally include excavating stable cutslopes and locating staging areas away from steep slopes or areas of suspected liquefiable soils or ground rupture. Dewatering may be required for temporary excavation cutslopes and shored or un-shored trenches (CGS, 2008b). During Project operation, landslide mitigation shall include adding earth or rock buttresses at the toes of potential slope failures following best management practices (BMPs) (USGS, 2000). Additionally, restraining walls, piles, caissons, rock anchors, or geotextiles shall be used to prevent or control slope movement.

Implementation of **Mitigation** Measure **Seis-1** would reduce the level of significance of Project impacts to/from faults and seismicity to **less than significant**.

18. Cultural Resources

18.1 Introduction

This chapter describes the cultural resources setting for the Extended, Secondary, and Primary study areas. Cultural resources are sites, buildings, structures, objects, and districts that may have traditional or cultural value. This broad range of resources includes archaeological sites that reflect the prehistoric and historic-era past; historic-era resources, such as buildings and structures; landscapes and districts; and traditional cultural properties (TCPs), i.e., those resources that are historically rooted in a community's beliefs, customs, and practices. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for cultural resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

18.2 Affected Environment

18.2.1 Extended Study Area

18.2.1.1 Prehistoric Context

Archaeologists study the physical evidence of past human behavior called "material culture[1];" they look for changes in material culture over time and across geographic regions to reconstruct the past. Change occurs in material culture because the culture of a single group of people has evolved in place due to environmental factors, population changes that include socioeconomic dynamics within the group, or influences from "outside" populations. There is evidence that neighboring populations shared ideas that are reflected by material culture traits. In some cases, a culture was replaced by a new group of people who arrived with artifacts that reflected their unique culture.

Archaeological evidence currently indicates that people arrived in California around 13,000 years ago. Engaged in the hunting of large game and gathering of plant foods, these early nomadic groups entered the region not only by land, but also by sea, following the coastline in boats (Moratto and Chartkoff, 2007). There is a minimal record of the earliest inhabitants, and their presence is demonstrated mainly by sparse remains of large stone spear points with a characteristic groove or "flute" sometimes associated with the fossilized remains of extinct animals (Negrini et al., 2006). Subsistence practices evolved over time from nomadic hunting and gathering to increased sedentism[2] with greater intensification of resource exploitation. This was paired with changes in technology, such as relinquishing the hunting spear for the

---

[1] Material culture refers to artifacts or other items that reflect a group's culture. Examples of material culture include, but are not limited to, items such as tools of flaked stone (e.g., arrowheads, scrapers), pottery, bone fish hooks, and shell beads.

[2] Sedentism refers to more permanent year-round settlement as opposed to a nomadic existence.

bow and arrow, and exchanging handstones and millingstones[3] for mortars and pestles. Although these changes generally occurred universally throughout the Extended Study Area, they did not all occur everywhere at the same time; thus the mortar and pestle are known in the San Francisco Bay Area by 6000 years before present (B.P.) (Milliken et al., 2007), but they don't appear in the Sierra Nevada until approximately 2500 B.P. (Hull, 2007).

The indigenous population grew as sedentism increased and resource availability stabilized, and as subsequent waves of migrants continued to arrive in the state; thereby leaving increased evidence (i.e., material culture) of human activity and changing human behavior. Gradual at first, growth among California's native populations became rapid in the period just prior to European incursion. As a result, evidence of past human activity, i.e., the "archaeological record," became progressively more complex. When systematic archaeological research began in California in the late 19th century, archaeologists began organizing the archaeological record into cultural stages to develop a chronological sequence, or "culture history," of California.

These cultural histories were developed regionally and archaeologists have produced a number of culture chronologies, using regionally specific nomenclature, across California. California has eight identified archaeological regions: the North Coast, Northeastern, Central Valley, Sierra Nevada, San Francisco Bay, Central Coast, Southern Coast, and Desert regions (Moratto, 1984). The regions, in turn, are divided into numerous subregions (Figure 18-1). The prehistoric context for the Extended Study Area includes portions of all of these regions. Within these regions, various chronologies attempt to account for changes in the archaeological record as a result of inferred changing human behavior. The archaeological record in California, therefore, reflects some shared broad-based patterns, but it also exhibits locally expressed culture traits. The numerous indigenous groups who arrived into the region now referred to as California were linguistically diverse, and they further distinguished themselves from their neighbors by developing cultural traits unique to their communities.

Fredrickson (cf. 1994) adapted Willey and Phillips' (1958) terminology for California and defined the following periods of culture development: the Paleo-Indian Period, followed by the Lower Archaic, Middle Archaic, Upper Archaic, Lower Emergent, and Upper Emergent periods. These concepts identify changes in resource procurement and social complexity over time and are often related to regionally broad patterns of culture that are reflected by the presence of similar artifact types. Other researchers also often identify these archaeological horizons according to the geological time scale and are, therefore, referred to as the Late Pleistocene, and early, middle, and late Holocene cultures.

As previously mentioned, although the various archaeological regions developed specific cultural traits, the prehistories of all of the regions reflect a similar progression of technological changes and social complexity over time. The broad periods defined by Fredrickson (cf. 1994) (the Paleo-Indian Period; the Lower, Middle, and Upper Archaic periods; and Lower and Upper Emergent periods) are applicable to all of the archaeological regions in the Extended Study Area; though to differing degrees. More detailed information about these stages is presented below in Section 18.2.1.3 under the Prehistoric Context for the Primary Study Area. Although the discussion focuses on the Primary Study Area, the general characteristics of the periods can be related to all of California prehistory.

[3] Handstones and millingstones are stone tools most often associated with the grinding of seeds. As the name implies, the handstone can be held in the hand. It has a generally flat surface that is rubbed across a similarly flat base, which is the millingstone.

18.2.1.2 Ethnographic Context

The indigenous peoples of California were extremely diverse and populous when Europeans first began to colonize the state. This diversity is reflected in the large number of mutually unintelligible languages that have been identified. At least 64, and possible as many as 80, languages were spoken (Shipley, 1978). These different languages essentially translate to individual tribes or tribelets. Although many ethnographic groups shared cultural traits based on geographic location and available resources, each also had unique expressions of culture.

The Extended Study Area overlaps portions of 32 identified Native American tribal groups in California (Figure 18-2) (Kroeber 1925: Plate 1). As with all California Indians, these groups subsisted by hunting and gathering. Coastal groups relied heavily on marine food resources, such as fish, shellfish, and marine mammals, as well as terrestrial resources, while interior groups relied primarily on terrestrial resources for shelter and subsistence. The Native populations were decimated by disease, loss of subsistence habitat, and genocide during the early years of colonization by Europeans and Euro-Americans. However, during the late 19th and early 20th centuries, ethnographers identified many viable Native communities surviving throughout California, including the Extended Study Area.

The territorial boundaries delineated by early ethnographers for Native California groups have varied over time and are often poorly defined. In addition, many tribal boundaries overlapped. The boundaries should not be considered fixed, but reflect general areas in which Native American groups resided. Most groups migrated within these general boundaries throughout the year. The Native California tribes affiliated with the Extended Study Area (and the Secondary Study Area and Primary Study Area, below) are depicted in Figure 18-2.

18.2.1.3 Historic-Era Context

The initiation of the historic era varied by region throughout California, but generally it began between the mid-1500s and mid-1800s. Historic-era cultural activities provide a record of Spanish, Mexican, and American rule, occupation, and land use. An abbreviated history is presented to provide a background of the presence, chronological significance, and historical relationship of cultural resources within the Extended Study Area.

The earliest explorations of California by Europeans were by sea. Portuguese captain Juan Rodriquez Cabrillo landed in the vicinity of San Diego in 1542. He also toured the Channel Islands before heading up the coast along the length of the State. He was followed by Sir Francis Drake in 1579 and Sebastian Viscano in 1602. None of these first explorers established settlements or had extensive interactions with Native Californians.

During the Spanish Period (1769 to 1822), the Spanish government established a series of presidios, missions, and towns along the Alta California (New Spain) coast, from San Diego to San Francisco. The Spanish colonized the local Native Americans along the way. Despite Spanish occupation, however, California remained largely unsettled throughout this period. The routes used to travel between the presidios and missions provided the outline for today’s U.S. 101 and I-5 (Kyle et al., 2002).

The Mexican people took New Spain back from the Spanish in 1822, and renamed it the Republic of Mexico, thus beginning the Mexican Period (1822 to 1848). During this time, the Catholic missions were secularized, and the Indians were left to fend for themselves. Large land grants, also known as ranchos, were given to loyal Californios[4]. Many governments ruled or vied for power over California during this time. This unrest lured outsiders who were seeking to take advantage of California's abundant resources. As more settlers arrived, relations between Mexico and the United States grew tense, ultimately resulting in war in 1846. California was formally annexed to the United States by the Treaty of Guadalupe Hidalgo in 1848, ending the Mexican-American War (Kyle et al., 2002).

The end of the Mexican-American War and the discovery of gold marked the beginning of the American Period (1848 to present). This discovery drew many people into California, caused a significant increase in the local non-native population and, in turn, decimated the indigenous population. Sacramento, San Francisco, Stockton, and many other cities grew from small settlements to "boom" towns, and roads, churches, schools, and other towns were built throughout the State. The American Civil War took place from 1861 to 1865, and although California's involvement was minimal, construction of the railroad may have been the most important immediate effect of the Civil War on California. Easy access to rail lines made citrus growing and other large-scale agricultural pursuits an important element in the State's economy. The creation of a government and a system of laws led to the admission of California as a free state in 1850 (Kyle et al., 2002).

18.2.1.4 Cultural Resources

Prehistoric Resources

Prehistoric resources are the material remains of human activities that predate contact with non-Native Americans. Prehistoric resources in the Extended Study Area may include habitation or village sites, temporary campsites, roasting pits/hearths, burials, bedrock milling features, lithic scatters, rock art, rock features (such as hunting blinds), and isolated artifacts.

Prehistoric resources have been found in many ecosystems and terrains, including river and stream drainages, and coastal strips, which are often prime locations for Native American village sites and processing camps. They are found in valleys, hills, mountains, deserts, grasslands, and forests, particularly adjacent water courses. Previous archaeological work indicates that areas within the Extended Study Area, such as Lake Almanor, San Luis Reservoir, New Melones Reservoir, and Castaic Lake, may be particularly sensitive for cultural resources, as opposed to areas, such as the plains of the Central Valley, where fewer resources have been recorded.

Ethnographic Resources

Ethnographic resources in the Extended Study Area may include known village sites, ceremonial sites, plant gathering locations, and hunting or fishing areas. Similar to prehistoric resources, ethnographic resources are likely to occur in the same types of areas, such as river and stream drainages and coastal strips, and within the same project components. The projects within the Extended Study Area where ethnographic resources may occur include, but are not limited to, Lake Almanor, New Melones Reservoir, and Castaic Lake.

Historic-Era Resources

Historic-era resources are physical sites, structures, or built features that coincide with the advent of written records. These resources include both historic-era archaeological sites and architectural structures.

[4] A term used to describe the Spanish-speaking people who moved into California and colonized the state during the Spanish and Mexican periods (1769 to 1848).

Historic-era resources within the Extended Study Area may include town sites, homesteads, ranches, privy pits, dumps, mining remains, transportation facilities, water conveyance systems, resource extraction facilities (such as quarries), and ranches and associated facilities. Architectural structures refer primarily to buildings and structures, such as bridges. Historic-era resources often occur in the same places as prehistoric sites, because these were the desirable locations for human settlement that provided food, shelter, and other necessary resources. Areas within the Extended Study Area that are particularly sensitive for historic-era resources include Lake Almanor, New Melones Reservoir, and more generally, the Sierra Nevada foothills.

Traditional Cultural Properties

TCPs within the Extended Study Area may include archaeological or ethnographic sites, geographical locations, or features that are associated with the cultural practices or beliefs of a living community that are rooted in that community's history, and are essential in maintaining the continuing cultural identity of the community. TCPs are most often associated with Native American practices and beliefs; however, other communities or cultural groups may acknowledge similar properties. TCPs can occur in any type of location, but tend to be located in proximity to prehistoric and ethnographic resources such as habitation sites. Similar to the archaeological and ethnographic resources listed above, TCPs would be expected in the vicinity of Lake Almanor, San Luis Reservoir, New Melones Reservoir, and Castaic Lake, although they could be situated anywhere within the Extended Study Area.

18.2.2 Secondary Study Area

18.2.2.1 Prehistoric Context

The prehistoric context for the Secondary Study Area contains six of the California archaeological regions (the North Coast, Northeastern, Central Valley, Sierra Nevada, San Francisco Bay, and Central Coast regions) and their subregions (Figure 18-1); all found in the northern portion of the State.

18.2.2.2 Ethnographic Context

The Secondary Study Area covers a large area that overlaps 13 of the identified Native American tribal groups in California (Figure 18-2). These ethnographic groups included the Yurok, Hupa, Chimariko, and Wintu in the extreme northern part of the Secondary Study Area; the Yana, Nomlaki, Konkow, Patwin, Nisenan, Plains Miwok and Bay Miwok tribal groups within the central portion of the Secondary Study Area; and the Coast Miwok, Bay Miwok Patwin, and Costanoan around the San Francisco Bay.

18.2.2.3 Historic-Era Context

The historic-era context for the Secondary Study Area is the same as that described for the Extended Study Area. Information on the historic-era context is presented in the Extended Study Area discussion.

18.2.2.4 Cultural Resources

Prehistoric Resources

The potential prehistoric resources in the Secondary Study Area are identical to those in the Extended Study Area: habitation or village sites, temporary campsites, roasting pits/hearths, burials, bedrock milling features, lithic scatters, rock art, rock features (such as hunting blinds), and isolated artifacts. Prehistoric resources within the Secondary Study Area are more likely to cluster around the watersheds of the Trinity, American, Sacramento, and Feather rivers, as well as the Bay/Delta region. Conversely, prehistoric resources within the plains of the central Sacramento Valley are likely to be less prevalent.

Ethnographic Resources

Ethnographic resources in the Secondary Study Area are the same as those in the Extended Study area, and may include known village sites, ceremonial sites, plant gathering locations, and hunting or fishing areas. Ethnographic resources are likely to cluster around the same locations as prehistoric resources, including the Trinity, American, Sacramento, and Feather rivers, Shasta Lake, Lake Oroville, and Folsom Lake, as well as the Bay/Delta region.

Historic-Era Resources

Similar to the Extended Study Area, historic-era resources within the Secondary Study Area may include town sites, structures, transportation facilities, water conveyance systems, resource extraction facilities (such as quarries), ranches and associated facilities, homesteads, privy pits, and dumps. Historic-era resources often occur in the same areas as prehistoric resources because these were the desirable locations for food, shelter, and resources. Areas particularly sensitive for historic-era resources include the watersheds of the Trinity, American, Sacramento, and Feather rivers, the San Francisco Bay/Delta region, as well as the plains of the central Sacramento Valley.

Traditional Cultural Properties

Similar to the Extended Study Area, TCPs within the Secondary Study Area may include sites, locations, or features that are associated with the cultural practices or beliefs of a living community that are rooted in that community's history, and are essential in maintaining the continuing cultural identity of the community. TCPs are most often associated with Native American beliefs and practices, such as areas where natural materials are gathered to enhance the continuity of cultural traditions like basket making supplies. However, other communities or cultural groups may acknowledge similar properties. TCPs may occur anywhere, but are likely to be located in proximity to prehistoric and ethnographic resources. TCPs are known to exist around Shasta Lake and the Lake Oroville area.

18.2.3 Primary Study Area

18.2.3.1 Prehistoric Context

The prehistoric context for the Primary Study Area lies at the boundary of the North Coast and Central Valley archaeological regions (Figure 18-1), but is almost entirely within the latter region. The known archaeological record for the regions around the Primary Study Area reflects the trajectory offered by Fredrickson (cf. 1994) that was provided earlier in this chapter. White et al. (2009), as presented below, outlined five periods to describe the cultural chronology for the regions that contain the Primary Study Area: the Paleo-Indian, Early (or Lower) Archaic, Middle Archaic, Late (or Upper) Archaic, and Emergent periods.

Paleo-Indian Period

Recent sampling at Borax Lake near Clear Lake provides tentative obsidian hydration dating evidence that indicates occasional obsidian quarrying activity was occurring in northern California as early as 16,000 years ago (White et al., 2009). However, the find remains unconfirmed, and no other archaeological traces of this age have been identified in the north state. The most reliable evidence indicates that northern California was first colonized at the end of the Pleistocene Era around 12,000 years ago. Sparse data indicate that these earliest peoples were small populations of culturally conservative hunters and foragers who moved between widespread resource patches and practiced technological traditions that were similar from region to region. Their co-occurrence with Pleistocene mega-fauna is suspected, but not demonstrated. The most ancient confirmed cultural traces in northern California are associated with the Western Clovis Tradition. The Western Clovis Tradition (Willig and Aikens, 1988), dating between approximately 13,500 to 10,500 B.P., is represented by one site and a few scattered artifacts in northern California, and is marked by use of the distinctive Clovis fluted projectile point; one of which was discovered along Thomes Creek in Tehama County north of the Primary Study Area. Diet and settlement specifics are unknown at this time and remain a matter of speculation (Fredrickson, 1984; Fredrickson and White, 1988).

Early (or Lower) Archaic Period

Early Archaic cultures are represented in the Primary Study Area by the Borax Lake Pattern, which is the northern California expression of the Western Stemmed Tradition dating between approximately 10,500 to 7000 B.P. (Willig and Aikens, 1988). The characteristic artifact types that reflect human activity during the Early Archaic include wide-stemmed projectile points, as well as handstones and millingstones. Deep flute-like basal thinning, large bladelet flakes, and well worked unifacial[5] tools are carryovers from Paleo-Indian technology. A few sites have produced plant and animal remains, indicating that the Borax Lake Pattern diet featured large nuts, and small and large game. Several sites attributed to this age have been identified within the foothills of Glenn and Colusa counties.

Middle Archaic Period

Middle Archaic cultures occurred from ca. 7500 to 2500 years B.P. It is widely documented in North America, and clearly established for northern California, that the geological period of the Middle Archaic, the Middle-Holocene, was a time of climatic instability (Adam and West, 1983; Benson et al., 2002). Although generally warmer and drier than the Early Holocene climate, the Middle Holocene was also marked by significant climatic fluctuations. Two consequences have been recognized in the regional archaeological record as a result of this instability. First, the development of upland and lowland soils was affected in such a way that the capacity of the landscape to store archaeological deposits was diminished; i.e., the more arid climate of the Middle Holocene diminished erosion and siltation mechanisms that cause soil build-up that normally traps and caps archaeological deposits. This was compounded by abrupt climatic events that would cause severe erosion of any archaeological remains that were developed. Second, the density and distribution of economically significant resources also appears to have been affected by climatic and landscape instability, leading to cultural responses such as local decreases in population, interregional population movements, and dietary change. Consequently, Middle Archaic archaeology is uncommon and the available record is problematic.

Several trends in prehistoric culture change first emerged during the Middle Archaic, including the development of settlements associated with ridgetops (Hildebrandt and Hayes, 1993), rivers/marshes (Heizer, 1949), and lakesides. Dietary specializations based on the acorn, deer, and freshwater and

[5] Unifacial tools demonstrate manufacturing methods (e.g., flaking) on one face or side; alternately bifacial tools are worked on two faces or sides.

anadromous fisheries also occurred. The archetypal[6] Middle Archaic culture is the Windmiller Pattern, which was present in the Sacramento and San Joaquin valleys, the Sacramento-San Joaquin Delta, and the Mt. Diablo region. Windmiller material culture featured artifacts made of varied stone materials, such as quartz crystals, chert, slate, obsidian, asbestos, and biotite, as well as red ochre, and worked clay. Worked shell included small beads, and red and black abalone square beads and various ornament styles Twined basketry is known from impressions left in baked clay. Other baked clay objects included cooking balls, perforated disks, and grooved net sinkers (Beardsley, 1954; Heizer, 1949; Moratto, 1984). Based on the rarity of ground stone tools, the abundance of projectile points, and the presence of remains from elk, pronghorn, deer, rabbit, coyote, beaver, lynx, bear, and waterfowl, it is assumed that hunting was the focus of Windmiller Pattern subsistence (Heizer, 1949; Moratto, 1984). The Mendocino Pattern and Berkeley Pattern were the distinct regional cultural traditions within the Primary Study Area that first emerged in northern California during the Middle Archaic Period.

Late (or Upper) Archaic Period

Regional climate stabilized around 3000 B.P., and by 2500 B.P., the widespread generalized technological traditions of the Middle Archaic Period were replaced by distinct regional specializations. Archaeologists have also found evidence of an increase over time in the scope and distance of intergroup trade patterns, a widespread change from less to more complex social forms, and an increase in population density. The archetypal Late Archaic culture is the Berkeley Pattern, which reflects the basic archaic adaptation of the rich alluvial basins of central California. There was also considerable cultural diversity within the Berkeley Pattern, and local cultures have been identified from the Delta north through the central Sacramento Valley and central North Coast Ranges (Bennyhoff, 1994; White, 2003). Certain traits, however, are common to all Berkeley Pattern variants, including a highly developed bone tool industry, atlatl[7] engaging hooks, and dart-sized non-stemmed points (Beardsley, 1954; Fredrickson, 1974; Lillard et al., 1939). Berkeley Pattern sites contain many features, especially fire-cracked rock heaps, shallow hearths, rock-lined ovens, house floors, cairns[8], and graves. Complete house floors suggest that large pole-framed houses between 12 and 18 feet in diameter were built. Clay with tule or bulrush impressions indicates that the houses were thatched and sod-packed. The Berkeley Pattern economy varied regionally, and generally focused on seasonally structured resources that could be harvested and processed in bulk, such as acorns, salmon, shellfish, and deer. The high frequency of mortars and pestles relative to chipped stone implies a heavy reliance on acorn processing (Fredrickson, 1974; Moratto, 1984).

Continuing a pattern of increasing cultural diversity in central California, Berkeley Pattern sites were established during the same time period as late Windmiller Pattern sites in the northern San Joaquin Valley (Fredrickson, 1974). In the North Coast Ranges, Berkeley Pattern sites were established during the same time period as the Mendocino Pattern sites, with the Berkeley Pattern prevalent in alluvial basins and the Mendocino Pattern common to adjoining foothill and mountain terrains, suggesting different ecological niches. The Primary Study Area, at the boundary of these niches (e.g., foothill habitat in the area of Sites Reservoir and valley habitat around the Terminal Regulating Reservoir), might be expected

---

[6] An archetype is the original model or type after which other similar things are patterned. The Windmiller was the original pattern identified within Central California that represented a Middle Archaic culture. Thus, analyses of other Middle Archaic cultures in Central California are compared to the Windmiller Pattern.

[7] An atlatl is a rod or stick-like device used to throw a spear; thereby giving the projectile greater velocity and force. An atlatl engaging hook, in this instance, is a carved stone hook attached to the atlatl; the spear is placed in the hook in preparation for throwing.

[8] Cairns are piles of stones, usually to mark graves.

to reveal archaeological remains that reflect elements of both the Berkeley and Mendocino patterns, with an emphasis on the latter.

Emergent Period

The relatively stable climate established at the outset of the Late Holocene continued through the modern period, although a "climatic anomaly" dating around 900 B.P. may have caused widespread disruption (comparable to the Middle Holocene) (Jones et al., 1999). In northern California, after 1100 B.P., many archaic technologies and cultural traditions disappeared in each region, and were replaced by the onset of cultural patterns and behaviors similar to those existing locally at the time of culture contact with Euro-Americans.

The archetypal Emergent Period culture is the Augustine Pattern. The Augustine Pattern is a widespread tradition that reflects the integration of long-distance trade spheres, and the introduction of the bow and arrow, which replaced the atlatl as the favored hunting implement. The Augustine Pattern has been divided into two phases common to most or all localities. Phase 1 markers include *Olivella* shell whole and lipped beads. Banjo-type abalone ornaments also first appear with Phase 1 of the Augustine Pattern, as well as elaborately incised bird bone whistles and tubes, and "flanged" soapstone pipes. Phase 2 artifacts include small corner-notched and triangular points, clam shell disk beads, bead drills, magnesite cylinders, bedrock mortars, and housepit sites often attributable to known ethnographic villages (Beardsley, 1954; Fredrickson, 1984; Moratto, 1984).

Other new traits that distinguished the Augustine Pattern include tightly flexed burials and cremation. Cremation was a form of burial apparently reserved for high status individuals during Phase 1, but was widespread during Phase 2 (Fredrickson, 1974; Moratto, 1984). Grave offerings, such as shell beads and ornaments, regularly occurred with utilitarian items, including mortars and pestles often broken before burial. In the Sacramento Valley area, fishing equipment is more common, elaborate, and diverse than in earlier phases, and includes several types of harpoons, bone fish hooks, and gorge hooks (Beardsley, 1954; Elsasser, 1978; Moratto. 1984). Basketry has been identified from charred remains found in graves, and a form of pottery is also known from sites in the Central Valley (Beardsley, 1954; Moratto, 1984). Baked clay balls, probably used for cooking, are a common constituent in Central Valley Archaeological Region sites where stone is absent (Beardsley, 1954; Moratto, 1984). The Augustine Pattern economy was regionally variable, although fishing and acorn gathering appear to have increased in importance over time. Shaped mortars and pestles predominate, with charred acorns frequently found in middens. Culture contact between Native Californians and immigrant populations from throughout the world occurred at various times in northern California. In the Sacramento Valley, contact generally occurred between 1750 and 1820.

18.2.3.2 Ethnographic Context

At the time of European contact with the Native Americans of California, the tribal groups known to have occupied the northern Sacramento Valley included the Wintu, Nomlaki, Yana, Konkow, Nisenan, and Patwin peoples. These populations settled primarily along streams and rivers and used a broad range of native plants and animals for subsistence, primarily focusing on acorns, fish, and deer. Population density in this region was one of the highest in the state.

The Primary Study Area is situated primarily within the ethnographic territory of the Hill and River Patwin and, to a lesser extent, in areas belonging to the Nomlaki, and the Konkow Maidu. Essentially all of the facilities in the Primary Study Area are located within ancestral Patwin lands. The exceptions are the northern portions of the T-C Canal and a section of the GCID Canal in Glenn County that are on lands affiliated with the Nomlaki, and a small portion of the GCID Canal south of the Glenn/Tehama County line that is in territory associated with Konkow occupation. The GCID Pumping Plant is on the border between the Nomlaki and Konkow Maidu.

Patwin

The Hill Patwin lived in the North Coast Range foothills, and the River Patwin inhabited approximately 80 miles along the Sacramento River. The Primary Study Area is at the northern limits of Patwin territory. The Patwin are linguistically classified as part of the Wintuan family of the Penutian language stock. Wintuan is separated linguistically and culturally into three major groups from north to south: the Wintu, Nomlaki, and Patwin. These three groups represent mutually-unintelligible languages. Each language was further subdivided into local dialects, differentiated into riverine and foothill zones (Shipley, 1978).

Throughout the middle and late Holocene up until European colonization, the indigenous people of northern California maintained hunting and gathering subsistence-based cultures. The absence of agriculture in the greater part of California may be linked with the efficiency of the collecting and hunting economy. Acorns were the staple food source of the Patwin, and were used in making gruel, soup, and bread. Other foods used by the Patwin include deer, fish (including salmon, perch, pike, and sucker), birds (such as geese, duck, and quail), blackberries, elderberries, grubs, worms, seeds, bulbs, and wild honey (Johnson, 1978).

Patwin architecture is very complex in terms of its permanence, size, and the amount of people required to organize and build community structures. Patwin dance houses are said to have been some of the largest in California (Kroeber, 1932; McKern, 1923). Patwin houses were constructed for both permanent and temporary functions, and have been designated into four types of permanent housing: the dwelling house, the menstrual hut, the sweat house, and the ceremonial dance house. Patwin dance houses were the largest community structures, and were larger than those of the Nomlaki and Wintu (Kroeber, 1925). Somewhat unique to the Patwin, although also practiced by the Pomo and Nomlaki, was the use of granaries, which were used to store acorns and other grains.

The Patwin traded shell beads for obsidian, along with cordage, headbands, and other commodities from neighbors such as the Pomo along the coast and the Maidu in the foothills of the Sierra Nevada (Kroeber, 1965). Patwin ceremonial and religious practices combined elements of social performance, lineage, social hierarchy, economy, and technology. The Kuksu Society, or “big-head” dance, practiced in varying forms throughout California, was a male secret society focusing on initiation through ritualistic raising of the dead (Kroeber, 1925, 1932).

Nomlaki

The Nomlaki occupied an area that is nearly entirely within the present-day boundaries of Glenn and Tehama counties. Within Glenn County, the Nomlaki lived in the western half of the county, occupying some portion of the western valley edge and the east-facing slopes of the North Coast Range. In Tehama County, they controlled both sides of the Sacramento River and lands westward to the county line (Goldschmidt, 1978).

The Nomlaki are linguistically closely related to the Patwin, and they also shared many cultural traits. For example, because they inhabited similar environments, Nomlaki subsistence practices and staple foods were virtually the same as those of their Patwin neighbors. Other common traits were the construction of semi-subterranean, earth-covered dance houses; the strong leadership of a community chief, which was an inherited position; and the existence of occupational specialization, in which specific families were considered specialists in a variety of positions, such as fishing, medicine, or basketry (Goldschmidt, 1978).

Trading was an occupational specialty, but non-specialist individual families might also conduct trade for necessities. Trade between Hill and River Nomlaki populations were common, whereby the River communities would supply fish, and the Hill families would provide seeds and animals. The Nomlaki also participated in the trading system that extended up the Sacramento Valley to the Oregon border; shells from the San Francisco Bay were traded for skins, yew wood, and obsidian that would be passed down from the north (Goldschmidt, 1978).

Konkow Maidu

The Konkow Maidu lived along the Sacramento River within the Primary Study Area, although most of their territory was in the west-facing slopes of the Sierra Nevada. Their territory included the watersheds of Big Chico and Honcut creeks, and the South Fork Feather River, significant portions of the North and Middle forks of the Feather River, and the Feather River proper downstream of Oroville to downstream of Honcut Creek. The Konkow Maidu language is distantly related to Patwin and Nomlaki because it, too, is of the Penutian language stock (Riddell, 1978).

Konkow winter villages consisted of multi-family semi-subterranean homes that were centered along the Sacramento River or adjacent to the lower reaches of the major drainages within their territory. During the other seasons, they moved throughout their lands to hunt and gather foods to sustain them through the winter months. The Konkow moved up into the higher mountain elevations to hunt deer in the summer, while the gathering of acorns, pine, and other nuts was an important activity in the fall. Berries, seeds, roots, bulbs, and greens were harvested when they were ripe. Other important animal resources included elk, rabbits, and salmon (Riddell, 1978).

Descendants of the ethnographic Patwin, Nomlaki, and Konkow Maidu continue to live in or near the Primary Study Area today. Many members of the Native American community continue to have strong ties to their ancestral lands

18.2.3.3 Historic-Era Context

Contact between Native Californians and immigrant populations from all over the world occurred at various times in northern California, dating to as early as 1579, when Sir Francis Drake visited the Coast Miwok in Tomales Bay. The Primary Study Area formed the northern frontier of Spanish and Mexican territory. Accordingly, the region's earliest known non-Native Californian visitors consisted of Spanish military expeditions on patrol. The history of early culture contact in the Sacramento Valley began with the Moraga expedition of 1808 and ended suddenly with a devastating smallpox epidemic in 1833.

Colusa County

Colusa County was established in 1851, with its modern boundaries defined in 1891. Although trappers were most likely the first Europeans to visit the area, the first written account of Colusa County comes from John Bidwell, who in 1843 passed through the area enroute from Oregon to Sacramento (then known as Captain Sutter's Fort *New Helvetia)*. The earliest noted use of the proposed Sites Reservoir area was by Granville P. Swift. Swift constructed a stone corral to hold wild horses that he traded, and was reputed to have built an adobe house near the corral between 1844 and 1846 (Hobart, 2001).

Cattle grazing activities brought permanent residents to the region. The first recorded pioneers arrived in 1853 and settled at the stone corral and nearby Antelope Valley (Shoopman, 1951). Farming began in the early 1850s and generally took place without irrigation, although abundant springs in the area provided additional water when needed. Crops grown in the Antelope Valley and vicinity included wheat, cling peaches, grapes, and nectarines that were shipped to market by steamships stopping in Colusa along the Sacramento River on their way to Sacramento (Colusa Sun, 1890).

Two key mining activities, including the excavation of sandstone and salt, took place in and around the Antelope Valley in the late 1800s and early 1900s. Alfred Knowles began the first sandstone quarry near the town of Sites in 1886, adding impetus to the construction of the Colusa & Lake Railroad, which delivered the rock to Colusa, and then to various locales such as San Francisco. To house the quarry workers who arrived from such diverse locations as Prussia, Ireland, Germany, Australia, Switzerland, the British Isles, Sweden, Portugal, and Italy, the settlement of Quarryville was established on a flat between two sandstone mines. The town contained 10 to 12 new houses, a hotel and a saloon, and large machinery sheds by 1897 (Colusa Daily Sun, 1897 in Wallace, 1970). When cement began to replace sandstone as the construction material of choice, the quarry business slumped, forcing the railroad to cease its service in 1915. The loss of railroad service caused further hardship on the quarries by limiting their ability to transport their stone to outside sources (Wagon Wheels, 1987). By the early 1920s, the Sites area had lost its two most valuable economic resources: sandstone mining and the railroad. Quarryville completely vanished by approximately 1917 (Colusa Daily Sun, 1916 in Wallace, 1970).

Although salt mining in Antelope Valley took place as early as 1860, more intensive mining activities began with the formation of the Antelope Crystal Salt Company in 1890. Salt mining in the proposed Sites Reservoir area, however, could not compete with larger firms from the Bay Area and southern California. The Antelope Crystal Salt Company was officially dissolved in 1900, thus ending the large-scale manufacturing of salt in Colusa County. In the spring of 1865, oil was discovered in Colusa County. Several test wells were drilled in the Antelope Valley area, but none proved profitable (Geis, 1923; Green, 1950).

The town of Sites was established in 1886 on land donated by John Sites, who arrived in the area in 1853 and owned over 5,000 acres where he farmed and raised cattle. The town was originally constructed to serve as the terminus for the Colusa & Lake Railroad, which was established primarily to provide transportation of local crops to market. By 1887, with the opening of the sandstone quarries and the influx of laborers, the town possessed a store, a post office and a school, soon followed by hotels, boarding houses, and a church (Green, 1950; Wagon Wheels, 1987). After the Colusa & Lake Railroad ceased its service and the quarries closed down, Sites was still a viable town serving farmers and ranchers in the area.

A series of economic and natural disasters dramatically affected the town. The closing of the quarries around 1910, coupled with the abandonment of the railroad, was detrimental to the economic health of the town during the early decades of the 20th Century. In 1965, a large wildfire measuring three to four miles wide swept through the town, destroying many of the houses, and sealing the fate of the once thriving community (Wagon Wheels, 1987). By 1987, the population of Sites had diminished to a total of 17. The school building, train depot, railroad warehouse, and churches have since vanished, and today only a handful of homes and abandoned structures dot the landscape that was once a bustling town. The remains of a water tank, a few partially buried railroad ties, and abandoned town streets are some of the few remaining relics of Sites.

Glenn County

Glenn County was created from the northern portion of Colusa County when that county was divided. It was incorporated on March 15, 1891. The county was named for Doctor Hugh J. Glenn, a dentist from Missouri, who came to California in 1849 and worked a mining claim at Murderer's Bar on the American River (Beck and Haase, 1974; Kyle et al., 2002). Dr. Glenn made several trips across the plains driving herds of cattle, horses, and mules from Missouri to California. In 1867, he purchased Rancho Jacinto in what is now Glenn County and began farming wheat (Gudde, 1998; Kyle et al., 2002). Dr. Glenn continued to purchase land until he had thousands of acres under wheat cultivation and 200 to 300 employees. The community of Jacinto, 27 miles north of the town of Colusa, served as the supply center for his operation because of its proximity to the Sacramento River. The town provided housing for his employees, a hotel, a large general store, several blacksmith shops, a butcher shop, a post office (1858-1910), several large grain warehouses, and the first school established in the region (Kyle et al., 2002). In 1879, the New Constitution and Democratic parties nominated Dr. Glenn for governor of California, but he was defeated by George C. Perkins. On February 17, 1883, Dr. Glenn was shot to death at his home by an employee. He did not live to see the county named after him. The land amassed by the man who would become known as the world's "Wheat King" has since been subdivided into smaller farms and is now all irrigated (Kyle et al., 2002). The town of Jacinto, where he established his empire, is gone.

The community of Willows was formed in 1876 when the Central Pacific Railroad pushed its lines northward to Oregon. The town was named from a clump of willow trees bordering a water hole fed by several springs that stood out on the otherwise treeless plain. In the early days, it was the only landmark between the settlements on the river to the west and the foothills to the east (Gudde, 1998; Kyle et al., 2002). By the time Willows was established, the water hole had been filled in. From 1880 until 1916, the post office was known as Willow until the *s* was added in 1917. Willows became a center for shipping in the late 19th century for many large wheat and barley ranches. When Glenn County was formed in 1891, Willows was named the County seat and continues as the County seat today (Kyle et al., 2002). The City of Willows also serves as the headquarters for the Mendocino National Forest, which covers the western section of the County (Beck and Haase, 1974).

Glenn County has retained its agricultural origins with over one thousand farms dominating the economy. Major commodities include rice, wheat, hay, almonds, walnuts, corn, oranges, prunes, milk products, and livestock (Glenn County Court, 2011).

18.2.3.4 Cultural Resources

Methodology

A records search for the Primary Study Area was conducted at the Northwest Information Center, California State University, Sonoma (NWIC) and the Northeast Information Center, California State University, Chico (NEIC), of the California Historical Resources Information System (CHRIS). Archival research of historical records at various repositories was conducted, and consultation with Native American Tribes and other knowledgeable individuals was initiated.

California State University, Chico's Archaeological Research Program (ARP) conducted an intensive pedestrian survey of the proposed Sites Reservoir, including the inundation area (except for lands that were inaccessible due to lack of landowner permission), the Sites and Golden Gate dam sites, the nine saddle dam locations, the Sites Reservoir Inlet/Outlet Structure, the Recreation Area locations, and the road relocations and South Bridge site. The inventory covered 35,774 acres, and 144 archaeological sites were recorded on California Department of Parks and Recreation forms (DPR 523); another 429 archaeological isolates were also recorded. A draft inventory report outlining the results of this study was prepared by White et al. (2009), which was updated in 2013 (Offermann, 2013).[9] Furthermore, the ARP conducted a partial archaeological inventory of the proposed Delevan Pipeline, Delevan Pipeline Intake Facilities, and Delevan Pipeline Discharge Facility (Westwood and White, 2005). Because the survey areas included a buffer around these facilities, virtually the entire area within the proposed Project Buffer has been surveyed; the exception being the area around and west of the Holthouse Reservoir Complex. Survey of the proposed Holthouse Reservoir Complex, however, has been initiated and approximately 348 acres of this facility have been studied by California Department of Water Resources (DWR) archaeologists. The remaining proposed Project facilities were not surveyed for archaeological resources due to lack of access or because the facilities were added too late to the Project description to allow for field work. Areas and facilities that remain to be surveyed for archaeological resources prior to Project construction include:

- 790 acres within the Sites Reservoir footprint
- Previously inaccessible portions of the Delevan Pipeline
- The remaining portions of the Holthouse Reservoir Complex (including the location of the Holthouse Reservoir Electrical Switchyard) and Project Buffer
- Sites Pumping/Generating Plant
- Tunnel from Sites Pumping/Generating Plant to the Sites Reservoir Inlet/Outlet Structure
- Sites Electrical Switchyard
- Field Office Maintenance Yard
- GCID Canal Facilities Modifications
- TRR
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline Electrical Switchyard
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- GCID Canal Connection to the TRR
- Delevan Transmission Line (only the portion that is not located within the Delevan Pipeline construction disturbance area).

An inventory of the built environment resources outside of the proposed Sites Reservoir Inundation Area was conducted in the fall of 2012 by URS Corporation (URS) (Jimenez, 2013). This inventory identified and recorded 15 resources on DPR 523 forms within the Primary Study Area. An evaluation of the resources determined that six appear eligible for listing in the National Register of Historic Places

[9] Archaeological data are considered confidential pursuant to California PRC 6254.10 and Section 304 of the National Historic Preservation Act; therefore, these reports are not appended to this document.

(NRHP) and the California Register of Historical Resources (CRHR), and nine do not appear eligible for the NRHP/CRHR. Two resources, Funks Dam and the Tehama-Colusa Canal, were found to be less than 45 years old and were not recorded. A listing of the recorded and evaluated resources is presented in Table 18-1. Descriptions of the resources are presented under "Historic-Era Resources" below.[10]

Table 18-1
Built Environment Resources Identified Outside of the Proposed Sites Reservoir Inundation Area in the Primary Study Area

Property Type	Site Name/Location	County	Owner	Description	Evaluation
Farmstead	Huffmaster Road Farmstead (1), Antelope Valley	Colusa	Private Ownership	Two circa 1964 and 1962 ranch-style houses, pre-1952 barns, non-historic period outbuildings	Evaluated-Ineligible
Farmstead	Huffmaster Road Farmstead (2), Antelope Valley	Colusa	Private Ownership	Circa 2006 single-family house, circa 1920 barn and 1970 shop	Evaluated-Ineligible
Farmstead	McDermott Road Farmstead (1), Maxwell	Colusa	Private Ownership	Two single-family houses, six silos, and two outbuildings.	Evaluated-Ineligible
Farmstead	McDermott Road Farmstead (2), Maxwell	Colusa	Private Ownership	A 1920 single-family house, circa 2000 barn, circa 1952 outbuilding, and single trailer	Evaluated-Ineligible
Farmstead	Funks Reservoir Farmstead	Colusa	Private Ownership	Circa 1933 single-family farmhouse, pole barn, lambing barn, workshop, livestock scale, water tank, pumphouse, and chicken coop	Evaluated-Ineligible
Farmstead	County Road 69 Farmstead, Antelope Valley	Glenn	Private Ownership	A 1938 single-family house, bunkhouse, and shed, all built in 1938; three 1967 pole barns and lambing barn, all built in 1967. Numerous non-historic buildings are also on the property	Evaluated-Ineligible
Quarry	Knowles Quarry, Maxwell	Colusa	Private Ownership	Circa 1886 Sites Sandstone quarry, also known as the Knowles Quarry. Two non-historic buildings, a mobile trailer, and pole barn, are on-site	Evaluated-Eligible
Canal	Glenn-Colusa Canal Headgate	Glenn	GCID	Circa 1941 eight-bay concrete constructed headgate/bridge; earthen bermed canal prism with stone riprap sides	Evaluated-Ineligible
Canal	Glenn-Colusa Canal	Colusa and Glenn	GCID	Circa 1887-1920 earthen canal	Evaluated-Eligible
Levee	Sacramento River Levee, near Stegeman	Colusa	USACE/Maxwell Irrigation District	Circa 1947-53 earthen berm levee/road	Evaluated-Eligible
Canal	Maxwell Irrigation District Canal, near Stegeman	Colusa	Maxwell Irrigation District	Maxwell Irrigation District, old pumping plant and drainage canal	Evaluated Ineligible/
Canal	Colusa Basin Drain	Colusa	Colusa Basin Drainage District	A 10-mile earthen bermed canal, built between 1903-1911; contributing features added in 1919-1920	Evaluated-Eligible
Railroad	Union Pacific Railroad Siphon, Willows	Glenn	GCID	Circa 1917 gravitational railroad siphon located on the GCID Canal and Union Pacific Railroad	Evaluated-Eligible

[10] Full descriptions and evaluations of the 15 evaluated built environment resources are presented in Jimenez (2013), including DPR 523 forms for each resource.

Table 18-1
Built Environment Resources Identified Outside of the Proposed Sites Reservoir Inundation Area in the Primary Study Area

Property Type	Site Name/Location	County	Owner	Description	Evaluation
Road	Colusa & Lake Railroad Historic District along Stone Corral Creek	Colusa	Colusa County	Two circa 1886 roads that include the historic C&LRR bed and a wagon road	Evaluated-Eligible
Utility Line	WAPA Transmission Line towers, near Funks Reservoir	Colusa	Private Ownership	Two circa 1958-60 transmission lines and towers that carry power for WAPA	Evaluated-Ineligible

Several other detailed cultural resources studies would be required to comply fully with federal and State cultural resources laws prior to construction of the Project (any alternative). These include the recordation of historic-era built environment resources within the reservoir footprint, and a detailed ethnographic study of the Primary Study Area to identify TCPs. Furthermore, in an effort to identify geographic areas sensitive for buried cultural resources, geoarchaeological studies would be conducted. Lastly, all cultural resources identified within the Primary Study Area would be evaluated for eligibility for inclusion in the NRHP and the CRHR. These activities would be carried out under the guidance of a programmatic agreement (PA), pursuant to the implementing guidelines of Section 106 of the National Historic Preservation Act (see Chapter 4 of this EIR/EIS) found at 36 CFR 800.4(b)(2), which allows for phased identification and evaluation of cultural resources in situations where the identification of historic properties cannot readily take place for a variety of reasons such as the consideration of alternatives that consist “of corridors or large land areas, or where access to properties is restricted…” A PA may also be used according to 36 CFR 800.14(b)(1)(ii), “[w]hen effects on historic properties cannot be fully determined prior to approval of an undertaking.” Given the large land base associated with the NODOS Project, the lack of access to all parcels within the Primary Study Area, and the large number of cultural resources that would ultimately require evaluation for NRHP/CRHR-eligibility, execution of a PA is the most efficient and effective manner to ensure that the lead federal agency would fulfill the requirements of the NHPA, including the identification of historic properties and the resolution of adverse effects to historic properties. Criterion 36 CFR 800.14(b)(1)(i), which refers to effects that are “similar or repetitive…in scope,” and which is appropriate to address reservoir fluctuations at the proposed Sites Reservoir, would also be included in the PA.

Potential impacts to historic properties in the Extended Study Area would similarly be discussed in the PA because individual projects or programs associated with the study area have not yet been determined, and may not be defined for many years in the future. The use of a PA to address future impacts to historic properties in the Extended Study Area is appropriate under several qualifying criteria found under 36 CFR 800.14(b)(1), including: 36 CFR 800.14(b)(1)(i), which refers to effects that “similar or repetitive or are multi-state or regional in scope” such as reservoir fluctuations, as previously mentioned; 36 CFR 800.14(b)(1)(ii), as noted above; 36 CFR 800.14(b)(1)(iii) for “[w]hen nonfederal parties are delegated major decision making responsibilities,” such as at the State or other local governments or water agencies; and 36 CFR 800.14(b)(1)(iv), when “routine management activities are undertaken at Federal installations, facilities, or other land management units” such as San Luis Reservoir.

The PA would involve the U.S. Bureau of Reclamation (Reclamation) as the lead federal agency, the Advisory Council on Historic Preservation, the California State Office of Historic Preservation, DWR, interested Native American tribes, and members of the public. Because DWR would be a participant in the PA, this agreement document would also ensure that the State would fulfill its obligations toward cultural resources pursuant to CEQA.

Prehistoric Resources

Human occupation in the Primary Study Area may extend back as far as 10,000 B.P. or more. Known prehistoric resources in the Primary Study Area include habitation or village sites, temporary campsites, bedrock milling features, lithic scatters, and isolated artifacts, such as projectile points, ground stone implements, cores or core tools, and flakes (White et al., 2009). Previous studies provide strong evidence that prehistoric resources are potentially present at all proposed Project feature locations.

Sites Reservoir Inundation Area, Golden Gate Dam, Sites Dam, Nine Saddle Dams, Recreation Areas, Road Relocations and South Bridge, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, and Field Office Maintenance Yard

The cultural resources inventory of the proposed Sites Reservoir Inundation Area and damsites identified 50 prehistoric sites, 14 of which are multi-component sites that include both prehistoric and historic elements. Site types include, but are not limited to, housepits, middens, bedrock mortar sites, and flaked stone and ground stone scatters. In addition, 100 prehistoric isolated artifacts were recorded, two of which are multi-component. These include flake stone tools, debitage (flaking residue from stone tool manufacture), handstones, millingstones, pestles, portable and bedrock mortars, battered cobbles, and anvil stones. Prehistoric archaeological resources may exist in portions of the Sites Reservoir Inundation Area and at some of the appurtenant facility locations that remain to be surveyed. These may include resources that are visible, as well as those that are completely buried and, therefore, invisible on the ground surface. Unmarked burials or cemeteries may be similarly present. As a result, areas that have not yet been studied would be surveyed according to the guidelines of the PA prior to Project construction. Furthermore, all prehistoric archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The footprint of the existing Funks Reservoir was inventoried and documented by Chartkoff (1969) and West, Levulett, and True (1976) prior to construction and inundation. Three prehistoric resources were identified and recorded during those efforts: CA-COL-233 (previously designated as Funks Creek 1 and Chartkoff-COL-28), CA-COL-242 (previously designated as Funks Creek 2 and Chartkoff-COL-37), and CA-COL-53 (previously designated as Funks Creek 3). Intensive artifact collection and limited trenching were conducted at all three sites, and limited excavation was conducted at CA-COL-242 and CA-COL-53. The studies revealed that the sites were recent prehistoric non-midden surface artifact scatters. Due to the nature of the sites and the low yield of subsurface artifacts obtained through excavation and trenching, it was further determined that the probability of discovering additional subsurface artifacts was very low. The report, therefore, concluded that the sites retained no opportunity to provide additional knowledge to the understanding of history or prehistory. As a result, they were determined not eligible for inclusion in the National Register.

A record search was conducted of the proposed Holthouse Reservoir Complex (i.e., Dam and Reservoir area) by the NWIC. The record search did not identify any previously recorded resources within the dam and reservoir footprint. The search also indicated that the Holthouse Dam and Reservoir, and consequently the Holthouse Reservoir Electrical Switchyard, are entirely within the limits of a survey conducted for the T-C Canal in 1965 (Treganza et al., 1965).

Approximately 348 acres of the Holthouse Reservoir Complex have been surveyed for the proposed Project. One prehistoric isolate, a chert flake, was recorded on the north shore of Funks Reservoir, but no archaeological sites have been found to date. However, archaeological resources may exist in portions of the reservoir that remain to be surveyed, including those that may be completely buried and are, therefore, invisible on the ground surface. Unmarked burials or cemeteries may be similarly present. Those portions of the Holthouse Reservoir Complex that have not yet been studied would be surveyed according to the guidelines of the PA prior to Project construction. Furthermore, prehistoric archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Glenn-Colusa Irrigation District Canal Facilities Modifications

A cultural resources record search of the GCID Canal and associated headworks facilities was conducted by White and Crawford (2003a) at the NWIC and the NEIC of the CHRIS. The records searches identified one previously recorded prehistoric resource, CA-GLE-106, in proximity to the GCID Canal alignment. CA-GLE-106 is a habitation site containing fractured stone and shell fragments. A pedestrian survey of the canal alignment at the locations where facility modifications would occur has not yet been undertaken; therefore archaeological resources may exist, including those may be completely buried and are, therefore, invisible on the ground surface. Unmarked burials or cemeteries may be similarly present. Archaeological survey would be conducted prior to Project construction according to the guidelines of the PA. Furthermore, prehistoric archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

White and Crawford (2003a) conducted a cultural resources records search at the NWIC and NEIC of the CHRIS that included the proposed TRR, the TRR Pumping/Generating Plant, and the GCID Canal Connection to the TRR. The records search consequently also included the locations of the proposed TRR Electrical Switchyard. No prehistoric resources within or near these project features were identified during the records search. As a result, archaeological resources may exist at the locations of these facilities, including those that may be completely buried and are, therefore, invisible on the ground surface. Unmarked burials or cemeteries may be similarly present. A pedestrian survey of all new facility footprints will occur prior to Project construction according to the guidelines of the PA. Furthermore, prehistoric archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line

A partial survey of the proposed Delevan Pipeline route east of Interstate 5 was conducted by California State University, Chico's ARP (Westwood and White, 2005). No prehistoric resources were identified as a result of the survey. However, archaeological resources may exist in areas that were not surveyed, including those that may be completely buried and are, therefore, invisible on the ground surface. Unmarked burials or cemeteries may be similarly present. Additional survey would be required to inspect the entire pipeline alignment, and for the TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line prior to Project construction according to the guidelines of the PA. Furthermore, prehistoric archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility

An inventory of the proposed Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility was conducted by California State University, Chico's ARP (Westwood and White, 2005). No prehistoric resources were documented as a result of this inventory. However, a previous cultural resource survey conducted by White (2003) along the Sacramento River resulted in the identification of prehistoric resources approximately 0.25 mile from the proposed intake. Resources observed by White (2003) included chipped stone tools, mortars, pestles, handstones, millingstones, earthenware, and middens. Although no archaeological resources have been identified at the locations of the Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility, it is possible that such resources may be completely buried and are, therefore, invisible on the ground surface. Unmarked burials or cemeteries may be similarly present. Should prehistoric remains be identified during Project construction, they would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Project Buffer

The archaeological inventory conducted within the Sites Reservoir Survey Area includes virtually all of the area within the proposed Project Buffer. Thirty-three prehistoric archaeological sites, of which nine are multi-component, and 21prehistoric archaeological isolates, were recorded within the Buffer beyond the footprint of the proposed Sites Reservoir and the appurtenant facilities. The area around the proposed Holthouse Reservoir Complex and acreage west to Sites Reservoir within the Project Buffer has not yet been inventoried for prehistoric resources. An inventory of this Project component would be conducted prior to Project construction according to the guidelines of the PA. Furthermore, prehistoric archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate. The inventories conducted for the Delevan Pipeline Intake/Discharge facilities include all of the area within the Project Buffer around those facilities.

Ethnographic Resources

Information regarding the ethnographic places in the Primary Study Area is provided from existing literature. A detailed inventory of the ethnographic resources in the Primary Study Area will be conducted prior to Project construction according to the guidelines of the PA. Furthermore, ethnographic resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate. These studies would be conducted for all elements of the Primary Study Area, as listed below.

The Primary Study Area is contained within the ethnographic territory of two Hill Patwin communities: the *Choo-hel'-mem-sel* and the *Ko'-roo* (Kroeber, 1932; White et al., 2009). The majority of ethnographic resources cluster around the northwest corner of the proposed Sites Reservoir. Ethnographic resources become scarcer in the eastern portions of the Primary Study Area that are in the Sacramento Valley. This is primarily because these lands were historically uninhabitable marshlands. Several ethnographic sites exist, however, near the Sacramento River, in and around the vicinity of the proposed Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility.

Sites Reservoir Inundation Area, Golden Gate Dam, Sites Dam, Nine Saddle Dams, Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, Recreation Areas, and Road Relocations and South Bridge

According to White et al. (2009), a majority of the proposed Sites Reservoir footprint, including the proposed inundation area, the Sites and Golden Gate damsites along with the nine saddle dam locations, the Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, the Recreation Areas, and associated Road Relocations and South Bridge site would be located within the ethnographic territory of the *Choo-hel'-mem-sel.* At least seven ethnographic place names are located in the vicinity of the Sites Reservoir footprint. A majority of the ethnographic sites identified are village or rancheria locations that tend to cluster around the proposed reservoir's northwest edge. One of these place names, *Choo'-dah-kut*, has been identified within Antelope Valley near the town of Sites (White et al., 2009).

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The existing Funks Reservoir and the proposed Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard are/would be located within the ethnographic territory of the *Choo-hel'-mem-sel* (Kroeber, 1932; White et al., 2009). No known ethnographic resources are located in the immediate vicinity of Funks Reservoir or the proposed Holthouse Reservoir.

GCID Canal Facilities Modifications

The existing GCID Canal and associated proposed headworks facilities are located within the ethnographic territory of the *Ko'-roo* (Kroeber, 1932; White et al., 2009). No known ethnographic resources are located in the immediate vicinity of the GCID Canal or associated headworks.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and the Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

The proposed TRR would be located within the ethnographic territory of the *Ko'-roo* (Kroeber, 1932; White et al., 2009). No known ethnographic resources are located in the immediate vicinity of the proposed TRR, the TRR Pumping/Generating Plant, TRR Electrical Switchyard, or the GCID Canal Connection to the TRR.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line

The proposed Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line would cross the ethnographic territories of both the *Choo-hel'-mem-sel* and the *Ko'-roo* (Kroeber, 1932; White et al., 2009). There are no known ethnographic resources within the immediate vicinity of the Delevan or TRR pipelines, the TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, or the Delevan Transmission Line.

Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility

The proposed Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility would be located within the ethnographic territory of the *Ko'-roo* (Kroeber, 1932; White et al., 2009). The intake structure and discharge facility are located adjacent to the ethnographic village of the *Ts'a*. There are several other ethnographic villages in proximity to those proposed structures, including the *K'etil* to the north and the *YYaitere* to the south.

Project Buffer

The proposed Project Buffer would surround all Project facilities, with the exception of the Delevan Pipeline, Delevan Transmission Line, TRR Pipeline and Road, Delevan Pipeline Electrical Switchyard, TRR to Funks Creek Pipeline, and portions of the other roads. The Project Buffer would, therefore, be located within the ethnographic territories described above for the facilities that it surrounds.

Historic-Era Resources

Historic-era resources occur throughout the Primary Study Area. Historic-era resources within the Primary Study Area may include both archaeological deposits and resources of the built environment. These resources are comprised of town sites, structures, transportation facilities, water conveyance systems, resource extraction facilities (such as quarries), ranches and associated facilities, homesteads, privy pits, and dumps.

Sites Reservoir Inundation Area, Golden Gate Dam, Sites Dam, Nine Saddle Dams, Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Recreation Areas, and Road Relocations and South Bridge

The cultural resources inventory identified 34 historic-era archaeological resources within the proposed Sites Reservoir footprint, the damsites, the recreation areas, and the location of the South Bridge; 14 of the sites are multi-component sites that include both prehistoric and historic elements (White et al., 2009). Site types are overwhelmingly related to farming and homesteading and include, but are not limited to, habitation features such as hearths, chimneys, flats, rock alignments, historical debris scatters, and farming equipment. In addition, 118 historic-era isolated artifacts or features were recorded, two of which are multi-component. Most historic-era isolated artifacts, such as fencing or plow blades, relate to ranching or farming activities. Historic-era archaeological resources may exist in portions of the Sites Reservoir inundation area and at some of the appurtenant facility locations that remain to be surveyed. These resources may be visible, or may be completely buried and, therefore, invisible on the ground surface. As a result, areas that have not yet been studied would be surveyed according to the guidelines of the PA prior to Project construction. Furthermore, all historic-era archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

The built environment study (Jimenez, 2013) identified two resources within these portions of the Primary Study Area, as described below:

- The Colusa & Lake Railroad Historic District is located along Stone Corral Creek and is, therefore, located within the footprint of the proposed Sites Dam. The entire length of the District is 1.5 miles, from west of the town of Sites to the east to 0.25 mile beyond the edge of the proposed Project Buffer, although the entire length of the railroad and road is eight miles. This historic district consists of visible remnants of the original wagon road that extended between Maxwell and Sites, and the footprint of the Colusa & Lake Railroad, which has since become Maxwell Sites Road. Both the railroad and the wagon road were constructed in 1886 to support the transfer of people and goods, particularly sandstone from the local quarries, from Sites to Maxwell and Colusa. The two transportation features are intimately linked as they criss-cross numerous times along Stone Corral Creek. The period of significance for the District is 1986 to 1915, from the time of construction until the tracks were removed from the railroad. The District appears eligible for the NRHP under Criterion A for its association with the Colusa & Lake Railroad and the development of the town of Sites. The District is eligible for the CRHR under Criterion 1.
- The Funks Reservoir Farmstead is located in the area of the proposed Sites Reservoir Inlet/Outlet Structure. This farm complex is contained on a 230-acre parcel and is comprised of a number of buildings that date to about 1933. The various structures include a single-family residence, an open-eaved barn, an enclosed pole barn, a shed-roof workshop, a chicken coop, a water tank, and a pumphouse. Although the land once belonged to an early Antelope Valley rancher, the buildings are not associated with him and are not architecturally significant. As a result, the Funks Reservoir Farmstead does not appear eligible for the NRHP or the CRHR.

In addition to the resources described above, other built environment historic-era resources within the reservoir footprint include 19 residential dwellings, 15 ranch compounds, and 27 miscellaneous outbuildings. None of these structures have been formally recorded or evaluated for eligibility to the NRHP or the CRHR for the Project. Recordation and NRHP/CRHR eligibility evaluation of these resources would be required prior to Project construction according to the guidelines of the PA. Furthermore, mitigation measures would be applied, as appropriate.

The proposed Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to the Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard have not yet been inventoried for historic-era archaeological resources. An inventory of these proposed Project components would be conducted prior to Project construction according to the guidelines of the PA. Furthermore, historic-era archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The footprint of the existing Funks Reservoir was inventoried and documented by Chartkoff (1969) and West et al. (1976) prior to its construction and inundation. One historic-era site, CA-COL-233 (previously designated as Funks Creek 1 and Chartkoff-COL-28), was recorded as a result of those studies. However, when Chartkoff (1969) recorded the site, only the prehistoric component was noted. It was not until

West et al. (1976) recorded the site that the historic-era component was added, although the trinomial still lacks the multicomponent designation. CA-COL-233 consists of a cabin and several associated historic-era items including a sewing machine, stove fragments, several tableware items, remnants of outbuildings, and other miscellaneous items. West et al. (1976) provided a date range of 1890 to 1916 for this site. CA-COL-233 was determined not eligible for inclusion in the National Register.

Approximately 348 acres of the proposed Holthouse Reservoir Complex have been surveyed for historic-era archaeological resources. No historic-era archaeological resources have been found to date, and a record search for the T-C Canal (White and Crawford 2003b) did not identify any previously recorded cultural resources in the vicinity of the existing Funks and proposed Holthouse reservoirs. However, resources may exist in portions of the reservoir complex that remain to be surveyed, including those that may be completely buried and invisible on the ground surface. The only known built environment resources within the Holthouse Reservoir Complex are the T-C Canal, Funks Dam, and the Western Area Power Administration (WAPA) Maxwell-Olinda 500-kV transmission lines. The T-C Canal and Funks Dam, which would be decommissioned within the reservoir footprint, were completed in 1980 and are, therefore, not of sufficient age to be considered for listing on the NRHP/CRHR. However, that portion of the T-C Canal in the Primary Study Area and Funks Dam would be recorded as cultural resources prior to Project construction.

The WAPA Transmission Line consists of two circuits with paralleling lattice steel towers that are aligned on a north-south axis 0.25 mile east of existing Funks Dam and through the proposed Holthouse Reservoir footprint. The towers are part of the 80-mile-long Maxwell-Olinda 500-kV transmission line that connects the Olinda Substation in Tehama County to the Maxwell Substation in Colusa County. The entire WAPA line contains 363 transmission towers. The segment within the Project area is approximately 0.5 mile in length where it crosses the footprint of the Holthouse Reservoir; towers within this section would be moved. The towers and transmission lines were built between 1958 and 1960 as part of a larger circuit. The substations at Olinda and Maxwell were both constructed in 1986 and this transmission line was re-circuited at that time. The WAPA Maxwell-Olinda 500-kV transmission lines have integrity, and even though the resource is part of a larger network of transmission lines and towers built between 1958 and 1960 throughout the western United States, the Olinda and Maxwell substations were not constructed until 1986. Therefore, the existing circuit is not yet over 45 years old, and is not eligible for the NRHP or the CRHR.

A cultural resources inventory of the Holthouse Reservoir Complex, including the location of the Holthouse Reservoir Electrical Switchyard, would be completed prior to Project construction according to the guidelines of the PA. Furthermore, historic-era resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Glenn-Colusa Irrigation District Canal Facilities Modifications

White and Crawford (2003a) conducted an archaeological records search for the GCID Canal at the NWIC and the NEIC of the CHRIS. Eight historic-era resources were identified along or adjacent the entire length of the Canal, including three historic-era town sites, a highway alignment, a California Historic Landmark, two railroad alignments, and the GCID Canal and associated features, itself. Of these eight resources, only the GCID Canal has been formally recorded and is identified by the State trinomial CA-GLE-605H. Only one other historic-era resource has been identified in the Project area in proximity to the GCID Canal Intake and headworks facilities. An additional six historic-era resources (a town site, a cemetery, a school building, a grange building, a river transportation feature, and a point of historical interest) were identified within one mile of the Canal. An archaeological survey for historic-era resources would be conducted prior to Project construction according to the guidelines of the PA. Furthermore, historic-era archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

The GCID Canal Railroad Siphon, and headworks and prism, were recorded as part of the NODOS built environment study (Jimenez, 2013). It is a circa 1917 engineered structure designed by the Central Irrigation District to convey water via gravitational forces under the railroad bed of the Southern Pacific Railroad. The siphon is constructed of board-formed concrete and is approximately 51 feet wide by 84 feet long with approximately four-foot-high walls. The concrete is buttressed slightly to the railroad bed and has horizontal structural cracks due to water pressure over time. The water level on the east side of the canal is slightly higher than the west side, as it gravitationally siphons water through tilting pipes under the railroad bed. According to GCID District Engineer Ben Pennock, the railroad siphon has not been altered, and is original to circa 1917. The Union Pacific Railroad siphon is significant for its association with the Central Irrigation District and GCID as part of an early irrigation district (Criteria A and 1). The siphon possesses a distinctive type of design and method of construction as an irrigation structure and expresses high artistic values represented in distinguishable characteristics as a feature of the original Central Irrigation Canal as it passes under the Southern Pacific Railroad. The railroad siphon is a unique engineered structure, designed to convey water by gravitational force under an existing railroad bed through pipes, like a straw, and is, therefore, eligible under Criteria C and 3. Thus, the GCID Canal Railroad Siphon appears individually eligible for the NRHP and the CRHR, and is a contributing element to the GCID Canal as a whole (see below).

The GCID Canal headgate structure was constructed around 1941, replacing an earlier headgate that was built as part of the Central Irrigation District in the late 19th century. The existing headgate is located 60 feet south of the original Central Irrigation District headgate. It operates as a narrow two-lane bridge across the canal from County Road 203 to County Road 205. The bridge deck is approximately 19 feet wide by 209 feet long, and is constructed of board-formed concrete; a simple pole railing interconnects with concrete posts. The canal prism was also modified in 1941 to accommodate the new headgate and was extended north to its present confluence with the Sacramento River at that time. Because the headgate is not directly associated with the original Central Irrigation District canal and features, it does not appear to be individually eligible for the NRHP or the CRHR. Also, because it does not date to the period of significance for the GCID Canal (see below), in general, it is not a contributing element to that resource.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

White and Crawford (2003a) conducted an archaeological records search at the NWIC and the NEIC of the CHRIS that included the proposed TRR, the TRR Pumping/Generating Plant, TRR Electrical Switchyard, and the GCID Canal Connection to the TRR. Except for the presence of the GCID Canal, recorded as site CA-GLE-605H, no other historic-era resources within or near these proposed Project features were identified during the records search. The built environment study, however, identified and evaluated three historic-era resources located within the vicinity of these Primary Study Area features (Jimenez, 2013). The resources (the GCID Canal and two farmsteads) are described below:

- The GCID Canal began construction as the Central Irrigation Canal in 1887, and assumed its current name in 1920. The ability of the canal to deliver water to farms along its length of 65 miles contributed significantly to the agricultural development of Glenn and Colusa counties. The GCID Canal was previously evaluated, and it appears to be eligible for listing to the NRHP and CRHR under Criteria A and 1, respectively, due to its association with the Central Irrigation District and the development of irrigation and farming in the Sacramento Valley. It also appears eligible for listing to the NRHP and the CRHR due to its association as an early 20th century engineered system that includes the main canal and associated ditches, which provided water to hundreds of farmsteads in the Sacramento Valley between 1887 to 1920 (Criteria C and 3). The period of significance for the GCID is between 1887 and 1920.
- The McDermott Road Farmstead (1) is located at the northeast corner of McDermott and Equipment roads, directly across the street from the planned TRR. The land was platted in 1912 by the Sacramento Valley Irrigation Company, who purchased the Central Irrigation District, and the property is bordered by lateral canals to the GCID Canal. However, there is no significant connection to the Central Irrigation District and the buildings present on the parcel are relatively modern. As a result, the McDermott Road Farmstead (1) does not appear eligible for either the NRHP or the CRHR.
- The McDermott Road Farmstead (2) is located directly across the street and west of McDermott Road Farmstead (1). This parcel will be directly adjacent to the east levee of the TRR. Like its eastern neighbor, the parcel was platted in 1912 by the Sacramento Valley Irrigation Company and it is bordered by a lateral canal of the GCID Canal. Structures on the farmstead include a 1920 single-family residence with a rear add-on porch and new double-pane vinyl windows, a circa 1952 outbuilding, and a circa 2000 large open hay barn. The residence lacks integrity and is not an exceptional example of an architectural type, and there is no significant connection to the Central Irrigation District; therefore, the McDermott Road Farmstead (2) does not appear NRHP/CRHR-eligible.

An archaeological survey for historic-era resources would be conducted within the Project area for the proposed TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and the GCID Canal Connection to the TRR prior to construction according to the guidelines of the PA. Furthermore, historic-era archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line

A partial archaeological survey of the proposed Delevan Pipeline route east of I-5 was conducted by California State University, Chico's ARP (Westwood and White, 2005). Three historic-era isolated features were identified as a result of the survey. These include a single palm tree stump, a pumping station in an abandoned canal, and an adjacent water control gate located in the abandoned canal. Limited access and poor surface visibility were issues for this proposed Project component, therefore, only a small portion of the Delevan Pipeline was examined. The proposed TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line have not been inventoried and additional surveys of these facility footprints would be completed prior to Project construction according to the guidelines of the PA. As a result, historic-era archaeological resources may exist in these Project areas that remain to be surveyed, including those resources that may be completely buried and invisible on the ground surface. Historic-era archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

The NODOS built environment study identified one historic resource within the footprint of the Delevan Pipeline (Jimenez, 2013). This resource, the Colusa Basin Drain (CBD) is a 10- to 20-foot-wide dirt canal. It was initially constructed in 1903 as the result of linear borrow trenches created while building levees in the area. The CBD was completed in 1911 and additions, such as culverts and headgates, were added in 1919 and 1920, probably in conjunction with the GCID and widespread irrigation development in the Sacramento Valley. The CBD, which is 33 miles long, flows through Glenn, Colusa, and Yolo counties; the Primary Study Area includes 1,500 feet of this length. Various portions of the CBD have been recorded in the past and it was evaluated for the NRHP/CRHR in 2007. The CBD appears eligible for listing to the NRHP and the CRHR due to its association with agricultural economy of the region (Criteria A and 1), and for its association for engineering involved in irrigating the Sacramento Valley (Criteria C and 3).

Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility

An archaeological inventory of the proposed locations for the proposed Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility were conducted by California State University, Chico's ARP (Westwood and White, 2005). No historic-era archaeological resources within the vicinity of the proposed facilities were documented as a result of this inventory. However, a cultural resource survey conducted by White (2003) along the Sacramento River resulted in the identification of historic-era resources nearby. Historic-era isolated artifacts or features recorded by White (2003) range from historic foundations to glass debris. It is possible that historic-era archaeological resources may be completely buried and invisible on the ground surface. Should buried historic-era remains be identified during Project construction, they would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

The Sacramento River levee and the Maxwell Irrigation District (MID) Canal, both located within the proposed footprint of the Delevan Pipeline Intake/Discharge Facilities, were recorded and evaluated as part of the built environment study (Jimenez, 2013). The levee is an earthen bermed structure that is approximately 15 feet high, approximately 15 feet wide across the top, and 75 feet wide at its base. The resource may date as early as 1936; however, it likely was constructed sometime between 1947 and 1953. The levee appears eligible for the NRHP/CRHR under Criterion A/1 due to its association with the Sacramento River Flood Protection Project, which stemmed from the Flood Control Act of 1917 and fostered agricultural development of the Sacramento Valley.

The MID Canal is located on the land side of the Sacramento River levee within the proposed footprints of the Delevan Pipeline Intake and Discharge facilities. It consists of a concrete-lined canal that parallels the toe of the levee and an abandoned pumphouse directly adjacent to the levee. As an involved irrigation system, the MID Canal was first formed in 1918. This portion of the canal was developed between 1947 and 1953, probably after the development of the Sacramento River levee. Although the MID Canal is over 45 years old, the portion of the canal and its associated features in the vicinity of the Delevan Pipeline Intake and Discharge facilities has limited history, and does not appear to be associated with an early part of the 1918 MID Canal. As a result, the MID Canal within the proposed footprint of the Delevan Pipeline Intake and Discharge Facilities does not appear eligible for the NRHP or the CRHR.

Project Buffer

The archaeological inventory within Sites Reservoir Survey Area includes virtually all of the area within the proposed Project Buffer. Seventeen historic-era archaeological sites (nine multi-component) were recorded within the Project Buffer beyond the footprint of the proposed Sites Reservoir and the appurtenant facilities, along with 20 historic-era archaeological isolates. The area around the proposed Holthouse Reservoir Complex, and acreage west to the Sites Reservoir within the Project Buffer, have not yet been inventoried for historic-era archaeological resources. An inventory of this Project component would be conducted prior to Project construction according to the guidelines of the PA. Furthermore, historic-era archaeological resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate. The inventories conducted for the proposed Delevan Pipeline Intake/Discharge Facilities include all of the area within the Project Buffer around those facilities.

The built environment inventory includes the Project Buffer around the proposed Sites Reservoir footprint. Four built environment resources that are not related to the other facility development have been identified, recorded, and evaluated for the NRHP/CRHP within the Buffer outside of the Sites Reservoir Inundation Area. These resources include three farmsteads and one quarry district, as presented below:

- Huffmaster Road Farmstead (1) contains two early 1960s ranch-style houses on a single parcel at the very south end of Antelope Valley within the Project Buffer. A number of outbuildings on the property appear to date to the mid-1900s, none of which are excellent examples of architecture. Huffmaster Road Farmstead (1) does not appear to meet any of the eligibility criteria for listing on the NRHP or the CRHR.
- Huffmaster Road Farmstead (2) is located in the southeast corner of Antelope Valley. Portions of the ranch that do not contain buildings would be inundated by the proposed Sites Reservoir. The property contains a residence from the early 2000s, a circa 1970 workshop, and a wooden barn from the 1920s. The parcel has been farmed since the 1860s, but there are no remaining extant structures that reflect the earliest days of the ranch, and the barn does not reflect an exceptional architectural style. As a result, Huffmaster Road Farmstead (2) does not appear eligible for listing on the NRHP or the CRHR.
- The County Road 69 Farmstead is situated at the north end of Antelope Valley in Glenn County. The property is a vernacular farmstead and an active cattle ranch that includes a single-family farmhouse, a bunkhouse, and two joining sheds that were all built around 1938. A nearby lambing barn and three separate pole barns were constructed in 1967. The farmstead has various features that are less than 45 years old, such as a 1973 double-wide mobilehome with carport, a metal shed/bathroom, and numerous auxiliary structures, such as silos, dog kennels, and corrals. Many of the 1938 buildings have been altered with the addition of aluminum sliding glass windows and T-111 plywood siding. Historically, the farmstead was a sheep farm that was converted to a cattle ranch after it was purchased by the current property owner sometime around 1982. Although many of the ranch buildings are over 45 years old, the County Road 69 Farmstead does not appear to meet any of the eligibility criteria for listing on the NRHP/CRHR.
- The Stone Corral Creek Quarries Historic District consists of two historic sandstone quarries located on the east-facing slope of Logan Ridge, and on both sides of Stone Corral Creek and Maxwell Sites Road. The Knowles Quarry, located north of Stone Corral Creek and Maxwell Sites Road, was the first quarry in the area. The quarry was developed by pioneer John Sites in 1887-1888 as the Sites

Sandstone Company. The McGilvray Quarry known, also as the Thompson Quarry, was first opened in 1897 and is located south of the Knowles Quarry, and south of Stone Corral Creek and Maxwell Sites Road; McGilvray purchased the property in 1900. Both quarries were major suppliers of stone for the rebuilding of San Francisco after the 1906 earthquake. They both also closed in 1914, and all equipment was liquidated in 1915. The McGilvray Quarry reopened for a time in 1925, and again in 1957. The Knowles Quarry has recently re-opened. Both quarries are defined by their geology and have steep sandstone cliffs that demonstrate past mining activities, such as visible markings of delaminated sandstone and drill holes.

- The McGilvray Quarry no longer contains any standing structures and has been recorded as an archaeological site (CA-COL-182) with at least five features that reflect past mining activities. The Knowles Quarry was recorded as part of the NODOS built environment study (Jimenez, 2013). This quarry contains several modular outbuildings that are not related to its historic past. However, both quarries are defined by their geology and have steep sandstone cliffs that demonstrate past mining activities, such as visible markings of delaminated sandstone and drill holes, and the general area has retained its integrity of location, setting, feeling and association in the rural setting along Stone Corral Creek. These characteristics lend to the delineation of the Stone Corral Creek Quarries Historic District. The quarries are also linked by having operated simultaneously for 17 years and shipped sandstone via the C&LRR. They provided sandstone for the construction of landmark buildings in San Francisco from before the 1906 earthquake (e.g., the Union Depot, the Ferry Building, the St. Francis Hotel, and the James Flood Building), and were significant in the rebuilding of the city post-1906 (e.g., the Gunst Building, three Home Telephone buildings, the W.F. Wood Building, and the Sherith Israel Synagogue). Furthermore, Knowles and McGilvray, both owners of Bay Area stone companies, worked closely with notable architects of the time and successfully marketed Colusa sandstone in San Francisco. McGilvray was also instrumental in the construction of San Francisco City Hall, became president of the San Francisco Builders Exchange, and was Commissioner of the Board of Public Works for the city. Knowles and McGilvray later partnered in granite quarrying in Madera County. Thus the Stone Corral Creek Quarries Historic District appears eligible for the NRHP/CRHR under Criteria A and 1for its contribution to early mining history in the Antelope Valley and to the pre- and post-1906 earthquake construction of significant structural landmarks in San Francisco, and under Criteria B and 2 for its association with Knowles and McGilvray. Although not yet demonstrated, the District may be eligible under Criteria D and 4 for the information regarding sandstone mining technology and mining life that might be contained in archaeological deposits at the quarry sites.

Traditional Cultural Properties

TCPs within the Primary Study Area may include sites, locations, or features that are associated with the cultural practices or beliefs of a living community that are rooted in that community's history, and are essential to maintaining the continuing cultural identity of the community. TCPs are most often associated with Native American practices and beliefs, however, other communities or cultural groups may acknowledge similar properties. TCPs include sites that are an integral aspect of cultural practices or beliefs, or areas where natural materials are gathered to enhance the continuity of cultural traditions, such as basket making supplies.

Currently, no TCPs have been identified within the Primary Study Area. A detailed report on the TCPs within the Primary Study Area will be completed prior to Project construction according to the guidelines of the PA. Furthermore, potential TCP resources that are identified would be evaluated for NRHP/CRHR eligibility pursuant to the PA protocols, and mitigation measures would be applied, as appropriate.

18.3 Environmental Impacts/Environmental Consequences

18.3.1 Regulatory Setting

Cultural resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable cultural resource regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

18.3.1.1 Federal Plans, Policies, and Regulations

- Antiquities Act of 1906
- Archaeological Resources Protection Act
- National Historic Preservation Act of 1966
- National Register of Historic Places
- Protection of Historic Properties (USC 36 CFR part 800)
- Native American Graves Protection and Repatriation Act

18.3.1.2 State Plans, Policies, and Regulations

- California Environmental Quality Act
- California Public Resources Code §5097.5
- California Register of Historical Resources
- California Native American Historic Resource Protection Act
- California Public Resources Code §5024.1
- California Public Resources Code §5097.9 to §5097.991
- California Health and Safety Code §7050.5: Disturbance of Human Remains
- Sections 8010–8011 of the California Health and Safety Code: California Native American Graves Protection and Repatriation Act

18.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

Cultural resources that are eligible for listing on the CRHR are collectively referred to as “historical resources,” while those eligible for the NRHP are identified as “historic properties.” Because the eligibility criteria are essentially the same and all resources eligible for the NRHP are also eligible for the CRHR, the term “historical resources” is used in this chapter to refer to cultural resources that have been determined eligible for the CRHP, the NRHP, or both.

18.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for cultural resources:

Would the Project:

- Cause a substantial adverse change in the significance of a historical resource as defined in §15064.5?
- Cause a substantial adverse change in the significance of an archaeological resource pursuant to §15064.5?
- Disturb any human remains, including those interred outside of formal cemeteries?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- A substantial adverse change in the significance of an archaeological resource pursuant to §15064.5.
- A substantial adverse change in the significance of a historical resource of the built environment as defined in §15064.5.
- Disturb a Traditional Cultural Property.
- Disturb any human remains, including those interred outside of formal cemeteries.

18.3.3 Impact Assessment Assumptions and Methodology

18.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to cultural resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational activities would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water to supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.
- Project construction, operation, and/or maintenance impacts can be direct, indirect, or cumulative. Direct impact examples include destruction of a NRHP/CRHR-eligible building or structure, or mechanical trenching through a significant archaeological site. An example of an indirect impact is providing increased access to an area that contains significant resources that may be subject to looting or vandalism.
- Construction of Project facilities has the potential to impact prehistoric and historic-era archaeological sites that are eligible for listing on the CRHR and the NRHP. This includes not-yet-identified archaeological sites that are buried and cannot be observed on the ground surface. Project construction activities that could disturb such resources would include, but not be limited to, ground-disturbing activities, such as clearing and grubbing, excavation, pipeline installation, backfilling, road and parking lot construction, well drilling, installation of amenities, inundation, and site revegetation.
- The built environment includes buildings and other structures, such as bridges and pumping facilities, and features like roads, canals, ditches, levees, and power lines. Any of these types of resources has the potential to meet the eligibility criteria for listing on the NRHP and the CRHR. Project construction activities could cause the demolition of eligible resources reflecting the built environment. Furthermore, construction or maintenance activities could modify elements that contribute to the eligibility of a particular resource.
- TCPs are tangible locations that are important to the cultural continuity of a community and have been important for more than 50 years, and also meet the criteria for eligibility for listing in the CRHR and the NRHP. TCPs can be archaeological or built environment resources, or they can be features of the natural landscape. Project construction activities that disturb the ground, such as clearing and grubbing, excavation, backfilling, road and parking lot construction, well drilling, installation of amenities, inundation, and site revegetation may impact TCPs. Similarly, demolition or modification of built environment resources may affect TCPs of that nature.
- Cemeteries are often marked by fencing or grave markers, or both. They may also be unmarked. Cemeteries are generally not considered eligible for listing on the CRHR or NRHP because it is often difficult to objectively apply the eligibility criteria without imbuing sentiment or "a sense of reverence" (Potter and Boland, 1992). However, some cemeteries can be considered for listing if one or more of the eligibility criteria, along with special criteria considerations, are met. Eligibility criteria considered for the listing of cemeteries are the same as those considered for any property. Project ground-disturbing activities, such as clearing and grubbing, excavation, backfilling, well drilling, road and parking lot construction, installation of pipelines and amenities, inundation, and site revegetation may impact cemeteries and burial places, both marked and unmarked, that meet the eligibility criteria for inclusion in the CRHR and the NRHP.

18.3.3.2 Methodology

The methodologies used to identify the range of cultural resources that could be potentially affected in the Primary Study Area are described in Section 18.2.1.3. Methods included a record search at the NWIC and the NEIC of the CHRIS, extensive archaeological survey of the Primary Study Area, and an inventory and evaluation of built environment resources located outside of the proposed Sites Reservoir Inundation Area.

The results of the cultural resources studies were compared with footprints of proposed Project facilities. This comparison identified the number of known archaeological sites and built environment resources that would be affected by the Project. Because their NRHP/CRHR eligibility has not yet been determined, the impact assessment for these resources assumes that at least some of the sites will be eligible. Built environment resource impact assessments were made for those resources that had been evaluated for the NRHP and the CRHR.

18.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

18.3.5 Impacts Associated with the No Project/No Action Alternative

18.3.5.1 Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

The No Project/No Action Alternative assumes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to historical resources has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on historical resources or historic properties that are archaeological sites, when compared to Existing Conditions.

Modeling results indicate that implementation of the No Project/No Action alternative would result in negligible or minor changes to water level fluctuations currently experienced in San Luis Reservoir, Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake; it is expected that Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, the Thermalito Complex, and Lake Natoma would continue to operate as regulating reservoirs, and therefore, continue to experience water level fluctuations. Modeling results indicate changes in the flow regimes of the rivers, creeks, and bypasses, and changes in inflow to the bays included in the Secondary Study Area ranging from negligible to noticeably increased or decreased. Regardless of the level of change, even minor water level fluctuations and flow regime changes have the potential to impact significant archaeological sites, and complete assessment of the effects of reservoir fluctuations and flow regime changes on cultural resources has never been conducted. However, because current operations were established prior to the passing of laws (e.g., NHPA) and their implementing regulations that protect cultural resources, **there would not be a substantial adverse effect** on NRHP/CRHR-eligible archaeological resources by the continued operation of these reservoirs and streams, when compared to Existing Conditions.

Population growth is expected to continue in California regardless of water availability. Development in local communities is addressed on a project-by-project basis at the local level. As a result, **there would not be a substantial adverse effect** on NRHP/CRHR-eligible to archaeological resources associated with population growth if the No Project/No Action Alternative is implemented, when compared to Existing Conditions.

Because ground-disturbing activities associated with the Project would not occur if the No Project/No Action Alternative is implemented, archaeological resources would not be directly affected, and **there would not be a substantial adverse effect** associated with the Project in the three study areas, when compared to Existing Conditions.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

Refer to the **Impact Cul-1** discussion. It would also apply to historical resources of the built environment.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. It would also apply to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. It would also apply to finds of human remains.

18.3.6 Impacts Associated with Alternative A

18.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, and Wildlife Refuge Water Use

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

No impact on archaeological resources would occur due to Project construction because no Project facilities would be constructed in the Extended Study Area. Water level fluctuations associated with changes in water deliveries to agricultural, municipal, industrial, and wildlife refuge users have the potential to impact significant archaeological sites, and because complete assessment of the effects of water level fluctuations on cultural resources has never been conducted, it is possible that there could be a **potentially significant impact** to archaeological resources that are historical resources or historic properties by the continued operation of those areas, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

Changes in system operation due to the Project, resulting in increased reliability to agricultural and municipal, and industrial water users, and an alternate supply to wildlife refuge users, would have no impact on built environmental features that currently exist. In addition, there are no built environment features located within the managed wetlands of the wildlife refuges. Therefore, **no impact** on historical resources or historic properties of the built environment would occur, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. It would also apply to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. It would also apply to finds of human remains.

San Luis Reservoir

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Fluctuating water elevations have been a part of annual operations at San Luis Reservoir since the facility began operating in the late 1960s. A complete assessment of the effects of reservoir fluctuations on cultural resources has never been conducted because the facility was constructed prior to development of the implementing regulations for Section 106 of the NHPA, and Reclamation is not required to conduct such an assessment pursuant to the existing reservoir operations standards. Both prehistoric and historic-era archaeological resources are known to exist within the reservoir footprint, but comprehensive studies have not been undertaken and the total number of resources present is unknown, nor have ethnographic studies occurred. Increased surface water level fluctuations and more severe drawdowns at the San Luis Reservoir have the potential to impact known and unknown archaeological resources. Furthermore, assuming the reoperation of the reservoirs constitute an undertaking pursuant to Section 3017 of the NHPA, compliance with Section 106 would be required. Therefore, Alternative A operations could result in a **potentially significant impact** to archaeological resources as defined in §15064.5, when compared to Existing Conditions and the No Project/No Action Alternative. Construction and maintenance activities would not occur as a result of this project component, and therefore, would have **no impact** on NRHP/CRHR-eligible archaeological sites, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

No built environment resources are known to remain within the reservoir footprint; therefore, there would be no impact to NRHP/CRHR-eligible, historic-era built environment resources as the result of increased surface water level fluctuations and more severe drawdowns at the San Luis Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, no Project construction or maintenance activities would occur within the reservoir; therefore, **no impact** on historic-era built environment structures would occur, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

No TCPs are currently known to exist around San Luis Reservoir. However, operations of Alternative A could have a **potentially significant impact** to TCPs, when compared to Existing Conditions and the No Project/No Action Alternative, if they are found at the reservoir. It is anticipated that there will be **no impact** to TCPs from construction and maintenance activities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion for San Luis Reservoir. Both prehistoric and historic-era archaeological resources are known to exist within the reservoir pool, but comprehensive studies have not been undertaken; as a result, it is not known if any cemeteries exist within the reservoir pool. Increased surface water level fluctuations and more severe drawdowns at the San Luis Reservoir have the potential to cause erosion and expose burial locations. Implementation of Alternative A may, therefore, result in a **potentially significant impact** to human remains at San Luis Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

18.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

The minimal Project construction identified for the Secondary Study Area would be limited to the installation of a pump into an existing feature of the built environment at the Red Bluff Pumping Plant, where no ground disturbance is expected to occur. Therefore, compared to Existing Conditions and the No Project/No Action Alternative, there would be **no impact** to significant archaeological resources that are historical resources or historic properties as the result of construction activities in the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative. There would also be **no impact** to NRHP/CRHR-eligible archaeological resources from changes in operations because no ground disturbance is expected to occur during that Project phase, when compared to Existing Conditions and the No Project/No Action Alternative.

Operational modifications would occur at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake within the Secondary Study Area to achieve the benefits associated with the Project, and would primarily include the retention of water in these reservoirs during drought years while water is released from Sites Reservoir. Overall, however, reservoir fluctuations would be reduced, and therefore, would not exceed those that occur during current operations. A comprehensive archaeological survey was conducted within the fluctuation zone at Lake Oroville, and over 400 archaeological resources were recorded (Walker and Delacorte, 2010). Similarly, an ethnographic study was conducted of the Lake Oroville area and nearly 60 resources important to the local Maidu community were identified within the footprint of the reservoir

(McCarthy, 2004); many of these resources appear eligible for the NRHP as contributors to two TCP complexes that include portions of the reservoir area (McCarthy, 2009).

Similar to San Luis Reservoir, a complete assessment of the effects of reservoir fluctuations on cultural resources has never been conducted at Trinity, Shasta, and Folsom lakes because the facilities were constructed prior to development of the implementing regulations for Section 106 of the NHPA, and Reclamation is not required to conduct such an assessment pursuant to the existing reservoir operations standards. Both prehistoric and historic-era archaeological resources are known to exist within the reservoir footprints, but comprehensive studies have not been undertaken and the total number of resources present is unknown, nor have ethnographic studies occurred. However, drawdowns are not anticipated to exceed those that currently take place, and reservoir fluctuations would be reduced.

In addition, it is expected that Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, the Thermalito Complex, and Lake Natoma would continue to operate as regulating reservoirs and would, therefore, continue to experience water level fluctuations. Modeling results indicate changes in the flow regimes of the rivers, creeks, and bypasses, and changes in inflow to the bays included in the Secondary Study Area ranging from negligible to noticeably increased or decreased. These minor water level fluctuations and flow regime changes would fall within the historic range of operations for these regulating reservoirs. Therefore, Alternative A operations would result in a **less-than-significant impact** to archaeological resources as defined in §15064.5 and TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities related to the Secondary Study Area would involve the removal of sediment from the existing two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant). Removed sediment would be placed in areas previously used for the deposit of fill materials. Maintenance activities would, therefore, have **no impact** to significant archaeological resources pursuant to §15064.5 for the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

Direct Project-related construction for the Secondary Study Area would be limited to the installation of an additional pump into an existing bay at the RBPP. The T-C Canal Intake at the pumping plant was constructed in the late 1960s and has been continually modified and maintained over the years. Although the intake does not meet the 50-year-old requirement necessary to be considered a historical resource, the intake would need to be recorded as a built environment feature. There would be **no impact** to built environment resources that are eligible to the CRHR or the NRHP as the result of construction, operation, and maintenance activities for the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. It would also apply to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. It would also apply to finds of human remains.

18.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area and Sites Reservoir Dams

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Construction of the proposed Sites Reservoir and dams would impact 57 known archaeological sites and 197 archaeological isolates, primarily through clearing and grubbing, and filling the reservoir. Portions of the reservoir footprint have not been surveyed due to lack of access, and those acres would require survey prior to construction; therefore, additional archaeological sites may be identified. There is also a possibility that archaeological resources that are not visible on the ground surface may be uncovered during Project construction. None of the recorded sites have yet been evaluated for eligibility to the CRHR or the NRHP. Until these studies are completed, it is expected that the construction, operation, and maintenance of the 1.27-MAF Sites Reservoir, the Golden Gate and Sites dams, and the seven saddle dams would result in a **potentially significant impact** on archaeological sites pursuant to §15064.5, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

Nineteen residential dwellings, 15 ranch compounds, and 27 miscellaneous outbuildings are located within the proposed footprint of the Sites Reservoir and dams. None of these structures have been formally recorded or evaluated for eligibility to the CRHR or the NRHP.

Maxwell Sites and Sites Lodoga roads have existed for well over 100 years, and Huffmaster and Peterson roads may be of similar age. All of these roads would be at least partially inundated by development of Sites Reservoir. The age of the roads qualifies them as cultural resources that require evaluation for eligibility to the NRHP and the CRHR; these evaluations have not yet occurred. If any of the buildings or roads within the 1.27-MAF Sites Reservoir and associated dams footprint are determined to be eligible for listing in the NRHP or the CRHR, inundation could have a **potentially significant impact** on built environment resources pursuant to §15064.5, when compared to Existing Conditions and the No Project/No Action Alternative. Because all structures would be removed from the Sites Reservoir footprint, **no impact** on NRHP/CRHR-eligible, built environment resources would occur during Project operation and maintenance activities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

No TCPs have been identified within the proposed Sites Reservoir and dam areas, to date; however, ethnographic studies have not yet been undertaken. The construction, operation, and maintenance of the 1.27-MAF Sites Reservoir and dams could result in a **potentially significant impact** to TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Two cemeteries are known to exist within the inundation area of the proposed Sites Reservoir. Evidence also indicates that there are likely unmarked cemeteries or burial places associated with Native American sites (prehistoric, ethnohistoric, and historic-era) within the reservoir area (White et al., 2009). As a result, the filling of Sites Reservoir and its operation and maintenance may have a **potentially significant**

impact on cemeteries that are historical resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Each of the five proposed recreation areas was included in the Sites Reservoir archaeological survey area (White et al., 2009), but two archaeological sites were identified at only the Peninsula Hills Recreation Area. However, buried archaeological remains may be present at any of the five recreation areas, when compared to Existing Conditions or the No Project/No Action Alternative. The known sites have not yet been evaluated for eligibility to the CRHR or the NRHP. The construction, operation, and maintenance of the recreation areas may result in a **potentially significant impact** to significant archaeological resources that are eligible for the CRHR or the NRHP, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as defined in §15064.5

No resources of the built environment are present at any of the five proposed recreation locations; therefore, Project construction, operation, and maintenance would have **no impact** to historical resources or historic properties of the built environment as defined in §15064.5, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

No TCPs are known to exist at any of the proposed recreation areas; however, ethnographic studies have not yet been undertaken. The construction, operation, and maintenance of the recreation areas could result in a **potentially significant impact** on TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Formal cemeteries are not present at any of the five proposed recreation areas. It is possible, however, that unmarked cemeteries or burial locations may be present. As a result, the construction, operation, and maintenance of the recreation areas may result in a **potentially significant impact** to human remains, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Construction of 46 miles of new public and private access roads (including associated detours and construction roads and all appurtenant features, such as culverts, fences, and guardrails) and the proposed South Bridge have the potential to impact nine known archaeological sites, none of which have been evaluated for eligibility to the CRHR or the NRHP. An additional four sites are located in proximity to the road footprints and have the potential for being impacted during construction activities. Unknown buried archaeological sites may also be present. Furthermore, the proposed asphalt batch plant location adjacent the proposed Field Office Maintenance Yard has not yet been surveyed; its construction may impact significant archaeological resources.

None of the known archaeological sites have been evaluated for eligibility to the CRHR or the NRHP; thus, when compared to Existing Conditions or the No Project/No Action Alternative, Project construction for proposed road relocations (including the asphalt batch plant) and South Bridge may have a **potentially significant impact** on archaeological resources as defined in §15064.5. Operation and maintenance of the new roads would have **no impact** to NRHP/CRHR-eligible archaeological sites, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

Built environment resources are not located within the footprint of the proposed road relocations; therefore, there would be **no impact** to historical resources or historic properties of the built environment, when compared to Existing Conditions and the No Project/No Action Alternative, due to road relocations or the construction, operation, or maintenance of South Bridge.

Impact Cul-3: Disturb a Traditional Cultural Property

Ethnographic studies have not been conducted for the proposed Project, so it is not known if TCPs are located along proposed routes for the road relocations or for South Bridge. Until those studies are complete, the construction, operation, and maintenance of the new roads may have a **potentially significant impact** on TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

No marked cemeteries are located within the footprints of the proposed road relocations or for South Bridge. It is possible, however, that currently undetected buried human remains are present along the routes; therefore, construction, operation, and maintenance of the new roads could have a **potentially significant impact** on human remains, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

The proposed Sites Pumping/Generating Plant and the Sites Reservoir Inlet/Outlet Structure locations, the Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, the Sites Electrical Switchyard, and the Field Office Maintenance Yard locations have not been surveyed and may contain archaeological sites. Buried archaeological deposits may be present at any of these locations. Therefore, a **potentially significant impact** to archaeological sites that are historical resources or historic properties may result during construction of these facilities, when compared to Existing Conditions or the No Project/No Action Alternative. Operation and maintenance of the Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir

Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard would have **no impact** on significant NRHP/CRHR-eligible archaeological resources, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

One resource of the built environment, the Funks Reservoir Farmstead, is located, in the vicinity of the proposed Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, the Sites Electrical Switchyard, and the Field Office Maintenance Yard. This resource was evaluated and does not appear to be eligible for listing on the NRHP/CRHR. As a result, construction of these facilities would have **no impact** to historical resources or historic properties of the built environment pursuant to §15064.5, when compared to Existing Conditions and the No Project/No Action Alternative. Because there are no NRHP/CRHR-eligible built environment resources in the vicinity, operation and maintenance of the Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard would have **no impact** on built environment resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

No TCPs have been identified within the proposed Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, the Sites Electrical Switchyard, and the Field Office Maintenance Yard to date; however, ethnographic studies have not yet been undertaken. The construction, operation, and maintenance of these facilities could result in a **potentially significant impact** to TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Formal cemeteries are not present within the footprints of the proposed Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard; however, the possible presence of unmarked burial locations cannot be discounted. The construction of these facilities could have a **potentially significant impact** on unmarked human remains, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance of the Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard would have **no impact** on human remains, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

A record search was recently conducted of the proposed Holthouse Reservoir Complex area, which includes the location of the Holthouse Reservoir Electrical Switchyard, by the NWIC of the CHRIS at Sonoma State University. The record search did not identify any previously recorded resources within the Holthouse Dam and Reservoir footprint, but it indicated that the Holthouse Reservoir Complex is entirely within the limits of a survey conducted for the T-C Canal in 1965 (Treganza et al., 1965).

The footprint of the existing Funks Reservoir was inventoried and documented by Chartkoff (1969) and West et al. (1976) prior to construction and filling of the reservoir. Three prehistoric and one historic-era archaeological sites were identified and recorded during those efforts: CA-COL-233 (previously designated as Funks Creek 1 and Chartkoff-COL-28), CA COL-242 (previously designated as Funks Creek 2 and Chartkoff-COL-37), CA COL 53 (previously designated as Funks Creek 3), and CA-COL-27H (previously designated 4-Col-27).

Intensive artifact collection and limited trenching were conducted at the three prehistoric sites at Funks Reservoir, and additional excavation was conducted at CA-COL-242 and CA-COL-53. The studies revealed that the sites were recent prehistoric non-midden surface artifact scatters. Due to the nature of the sites and the low yield of subsurface artifacts obtained through excavation and trenching, it was determined that the probability of discovering additional subsurface artifacts was very low. It was concluded that the sites retained no opportunity to provide additional knowledge to the understanding of history or prehistory, and, as a result, they were determined not eligible for inclusion in the NRHP. These sites are, therefore, similarly ineligible to the CRHR.

CA-COL-27H was a cabin with several historic-era items, including a sewing machine, stove fragments, tableware and other miscellaneous household items, and remnants of outbuildings. The site reflected occupation between 1890 and 1916. An evaluation by West et al. (1976) determined that the site was not eligible for inclusion in the NRHP. The cabin no longer exists.

Initial surveys of the Holthouse Reservoir Complex have failed to identify any archaeological resources. However, sites may exist in portions of the facility footprint that remain to be surveyed, or may be completely buried and invisible on the ground surface. As a result, construction and operation of the Holthouse Reservoir Complex and the Holthouse Reservoir Electrical Switchyard, when compared to Existing Conditions or the No Project/No Action Alternative, could have a **potentially significant impact** to archaeological sites pursuant to §15064.5.

Although known archaeological sites within the Funks Reservoir have been determined ineligible for the CRHR and the NRHP, there is the potential for uncovering buried archaeological remains during the dredging of Funks Reservoir to return it to design capacity. Thus, the dredging activities could have a **potentially significant impact** to NRHP/CRHR-eligible archaeological deposits, when compared to Existing Conditions and the No Project/No Action Alternative, because dredging could occur deeper than planned. Operation and maintenance activities at the Holthouse Reservoir Complex (including Funks Reservoir) could result in a **potentially significant impact** to archaeological resources that are eligible for the CRHR or the NRHP, when compared to Existing Conditions and the No Project/No Action Alternative, because dredging that may occur in the future could occur deeper than planned, exposing or damaging currently buried archaeological deposits.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

The built environment resources within the proposed Holthouse Reservoir Complex are the T-C Canal, Funks Dam, and the WAPA Maxwell-Olinda 500-kVoverhead transmission line, all of which would be decommissioned within the Holthouse Reservoir footprint. The T-C Canal and Funks Dam are not yet 50 years old (and, therefore, not old enough to be considered eligible for the NRHP), but they should be recorded as cultural resources because it will be important to have a record of their locations. Initial construction of the WAPA Transmission Line occurred over 50 years ago; however, the substations at either end of the circuit were not built until 1986. Therefore, the resource does not meet the age criterion for NRHP/CRHR eligibility. The construction, operation, and maintenance of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would, therefore, have **no impact** on built environment historical resources or historic properties, when compared to Existing Conditions and the No Project/No Action Alternative.

Built environment resources are not present within the Funks Reservoir footprint; therefore, the dredging of the reservoir, along with operation and maintenance activities, would have **no impact** on built environment historical resources or historic properties, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-3: Disturb a Traditional Cultural Property

Ethnographic studies have not been conducted for the proposed Project, so it is not known if TCPs are located within the proposed Holthouse Reservoir Complex (including Funks Reservoir). Until those studies are complete, the construction, operation, and maintenance of these new facilities may have a **potentially significant impact** on TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

There are no formal cemeteries within the footprint of the proposed Holthouse Reservoir Complex (including Funks Reservoir and the Holthouse Electrical Switchyard). It is possible, however, that unmarked burials are present. Therefore, construction, operation, and maintenance of the Holthouse Reservoir Complex, including dredging of the existing Funks Reservoir, could have a **potentially significant impact** on human remains, when compared to Existing Conditions and the No Project/No Action Alternative.

GCID Canal Facilities Modifications

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

White and Crawford (2003a) conducted a record search of the GCID Canal in 2003. The record search identified one prehistoric archaeological site located in proximity to the proposed GCID Canal Facilities Modifications, but no field investigation has been done to verify the site location and to determine whether the Project would impact the resource. It is also possible that buried archaeological sites could be adversely affected by Project activities in the area. Archaeological resources, as defined in §15064.5, could be subject to a **potentially significant impact** from Project construction, when compared to Existing Conditions or the No Project/No Action Alternative. **No impact** would likely occur to NRHP/CRHR-eligible archaeological sites as the result of operation and maintenance activities, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

Built environment resources associated with the proposed GCID Canal Facilities Modifications include the GCID Canal prism, along with the existing appurtenant features (refer to Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives). Most of these features would remain intact, but the California Northern Railroad Siphon structure at Mile 26.6 would be replaced, as would the 1941 headgate located near the GCID pumping station. The siphon and headgate and canal prism were evaluated for NRHP/CRHR eligibility. The siphon was built in 1917 as part of the original Central Irrigation Canal and is a unique structure designed to move canal water underneath the railroad bridge. The siphon, therefore, appears to be individually eligible for the NRHP/CRHR and is a contributing element to the GCID Canal as a whole. On the other hand, the headgate was constructed in 1941 and the adjacent canal prism was modified at the same time. These actions occurred outside of the period of significance for the GCID Canal, and because the headgate and canal prism are not significant engineering structures, the headgate and prism at this location are not considered eligible for the NRHP/CRHR either individually or as part of the GCID Canal proper. Because the California Northern Railroad Siphon appears eligible for inclusion to the NRHP and the CRHR, Project construction would have a **potentially significant impact** on historical resources or historic properties of the built environment, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance would have **no impact** on these same resources, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-3: Disturb a Traditional Cultural Property

Proposed Project construction would be concentrated within the GCID Canal, with an additional 50-foot buffer to each side. The Canal is not a TCP; therefore, there would be **no impact** to TCPs during construction, operation, and maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Formal cemeteries do not exist within the proposed GCID Canal Facilities Modifications footprint. However, it is remotely possible that unrecorded burials may be located within the 50-foot construction buffer, and that Project construction would have a **potentially significant impact** on human remains, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance activities would have **no impact** on human remains, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Delevan Transmission Line, Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Pipeline Intake Facilities

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

An archaeological study for the proposed Delevan Pipeline and Delevan Pipeline Intake Facilities involved a record search and a partial field inventory of the facility footprints east of I-5 (Westwood and White, 2005). Three isolated historic-era features were recorded: ISO-030-A (a palm tree stump); ISO-031-A (remnants of a pumping station in an abandoned canal); and immediately adjacent, ISO-032-A (a water outlet and control gate). The record search included the areas covered by the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, Delevan Transmission Line, Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Pipeline Intake Facilities. No previously recorded archaeological resources were identified in the facility footprints by the search. Along with all of the Delevan Pipeline west of I-5 (and some portions of the Delevan Pipeline east of the freeway), none of these latter facilities have been subject to archaeological survey. The lack of surveys, together with the potential for buried sites, indicates that Project construction could result in a **potentially significant impact** to archaeological resources pursuant to §15064.5, when compared to Existing Conditions or the No Project/No Action Alternative. Operation and maintenance of these facilities would have **no impact** on historical resources or historic properties that are archaeological sites, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5

In addition to the two historic-era isolates noted above (ISO-031-A and ISO-032-A), built environment resources within or adjacent to the footprints of the proposed TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, Delevan Transmission Line, Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Pipeline Intake Facilities include a portion of the GCID Canal, two McDermott Road farmsteads, the CBD, the Sacramento River levee, and the MID Canal. Isolates are generally not considered potentially eligible resources due to their limited ability to fulfill the NRHP/CRHR eligibility criteria. An evaluation of the GCID Canal and the CBD suggests that the resources are eligible for the NRHP and the CRHP under Criteria A and C, and 1 and 3, respectively. The Sacramento River levee similarly appears eligible for the NRHP/CRHR under criteria A/1. Conversely, neither of the McDermott Road farmsteads appears to meet the eligibility criteria because the buildings present either do not meet the age criteria for eligibility consideration, or they lack integrity and are not exceptional examples of an architectural type. The MID Canal also does not appear to be an eligible resource. The presence of the GCID Canal, the CBD, and the Sacramento River levee indicates that Project construction may have a **potentially significant impact** on a historical resource or historic property of the built environment, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance activities associated with these facilities would have **no impact** on NRHP/CRHR-eligible built environment resources, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-3: Disturb a Traditional Cultural Property

It has not yet been determined if TCPs are within the proposed TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, Delevan Transmission Line, Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Pipeline Intake Facilities areas. Therefore, it is possible that construction, activities could have a **potentially significant impact** to TCPs, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance tasks would have **no impact** to TCPs, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

There are no formal cemeteries within the footprints for these proposed facilities, but the presence of unrecorded burials is possible. As a result, construction of the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, Delevan Transmission Line, Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and Delevan Pipeline Intake Facilities could have a **potentially significant impact** on human remains, when compared to Existing Conditions and the No Project/No Action Alternative. There would be **no impact** to human remains due to operation and maintenance activities, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Project Buffer

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Most of the proposed Project Buffer was included in the Sites Reservoir archaeological survey area (White et al., 2009). Twenty-eight known archaeological sites and 33 archaeological isolates have been recorded within the Project Buffer and outside of the construction elements described above. Portions of the Project Buffer have not been surveyed due to late identification of this project feature. It is, therefore, possible that other archeological sites, in addition to buried archaeological remains, may be present within this area. Activities within the Project Buffer could include fence construction or creation of mitigation lands. The presence of known sites and lack of complete surveys, combined with the possibility of ground-disturbing construction, operation, or maintenance activities, indicates the possibility of a **potentially significant impact** to significant archaeological resources that are eligible for the CRHR or the NRHP, when compared to Existing Conditions or the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as defined in §15064.5

The built environment study identified four resources within the proposed Project Buffer: Huffmaster Road Farmstead (1), Huffmaster Road Farmstead (2), County Road 69 Farmstead, and the Stone Corral Creek Quarries Historic District. The Stone Corral Creek Quarries Historic District appears to be NRHP/CRHR-eligible for its contribution to the early mining history of Antelope Valley and the construction of significant landmark buildings in San Francisco, and for its association with prominent

Bay Area business men. None of the three farmsteads appears eligible for the NRHP or the CRHR because the buildings they contain are not old enough to be considered for NRHP/CRHR eligibility, or lack integrity and are not exceptional examples of an architectural style. The presence of the Stone Corral Creek Quarries Historic District suggests that the Project Buffer could have a **potentially significant impact** on built environment resources pursuant to §15064.5, when compared to Existing Conditions and the No Project/No Action Alternative. There would be **no impact** on the NRHP/CRHR-eligible built environment resources from operation and maintenance activities, when compared to Existing Conditions and the No Project/No Action Alternative, because any impacts to those resources would have been mitigated during construction.

Impact Cul-3: Disturb a Traditional Cultural Property

Ethnographic studies have not been conducted for this proposed Project feature, so it is not known if TCPs are located within the proposed Project Buffer. Until those studies are complete, any ground-disturbing construction, operation, or maintenance activities may have a **potentially significant impact** on TCPs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Formal cemeteries are not present within the proposed Project Buffer. It is possible, however, that unmarked cemeteries or burial locations may be present. As a result, any ground-disturbing construction, operation, or maintenance activities within the Proposed Take Line may result in a **potentially significant impact** to human remains, when compared to Existing Conditions and the No Project/No Action Alternative.

18.3.7 Impacts Associated with Alternative B

18.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to archaeological resources (**Impact Cul-1**), historic-era resources of the built environment (**Impact Cul-2**), TCPs (**Impact Cul-3**), and human remains (**Impact Cul-4**), would be the same as described for Alternative A for the Extended and Secondary study areas.

18.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to cultural resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard

- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on archaeological resources (**Impact Cul-1**), historic-era resources of the built environment (**Impact Cul-2**), TCPs (**Impact Cul-3**), and human remains (**Impact Cul-4**) as described for Alternative A.

The major differences between Alternatives B and A are related to the increased size of the Sites Reservoir with Alternative B. The increase in reservoir size necessitates the addition of two saddle dams and the movement of various project components. In addition, Alternative B replaces the Delevan Pipeline Intake Facilities with the Delevan Pipeline Discharge Facility, and shortens the Delevan Transmission Line. The Alternative B facilities' construction impacts on cultural resources that would differ from those described for Alternative A are discussed below.

Sites Reservoir Inundation Area (1.81 MAF) and Sites Reservoir Dams

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Construction of a 1.81-MAF Sites Reservoir, the Golden Gate and Sites dams, and nine saddle dams would have similar impacts on archaeological resources; the primary difference would be that 70 known archaeological sites have been recorded within the footprint of these larger facilities, rather than the 57 resources affected by Alternative A. Similarly, 230 archaeological isolates are within the footprint of the larger reservoir. As a result, Alternative B would have a **potentially significant impact** on NRHP/CRHR-eligible archaeological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as defined in §15064.5

Refer to the **Impact Cul-1** discussion. That discussion also applies to historic-era resources of the built environment.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. That discussion also applies to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. That discussion also applies to human remains.

Road Relocations and South Bridge

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Effects on archaeological resources from construction associated with road relocations and the South Bridge for Alternative B would be similar to the impacts described for Alternative A. However, excavations for this alternative would differ from Alternative A. The lengths of the saddle dam access roads would be reduced for Alternative B because the dams would be larger and would be located closer to the main roads. This would, therefore, reduce the potential impacts on archaeological resources in those areas. However, an extension of an access road would be constructed for Alternative B to provide access from Saddle Dam 3 to Saddle Dams 1 and 2, which has the potential to impact archaeological resources that would not be affected by Alternative A. Alternative B would have a **potentially significant impact** on NRHP/CRHR-eligible archaeological resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as defined in §15064.5

Refer to the **Impact Cul-1** discussion. That discussion also applies to historic-era resources of the built environment.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. That discussion also applies to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. That discussion also applies to human remains.

Delevan Transmission Line

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

The proposed Delevan Transmission Line from the Sites Electrical Switchyard to its connection with the existing WAPA or PG&E transmission lines would be shorter than the transmission line included in Alternative A. This reduced length would potentially result in impacts to fewer archaeological resources, historic-era resources of the built environment, TCPs, and human remains, but would still result in a **potentially significant impact** on NRHP/CRHR-eligible archaeological resources, historic-era resources of the built environment, TCPs, and human remains, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as defined in §15064.5

Refer to the **Impact Cul-1** discussion. That discussion also applies to historic-era resources of the built environment.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. That discussion also applies to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. That discussion also applies to human remains.

Delevan Pipeline Discharge Facility

Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5

Impacts to NRHP/CRHR-eligible archaeological resources, historic-era resources of the built environment, TCPs, and human remains would be similar to those discussed for Alternative A. However, the smaller size of this facility, when compared to the Delevan Pipeline Intake Facilities that are included in Alternative A, could potentially lessen the number of archaeological resources, historic-era resources of the built environment, TCPs, and human remains that would be affected. Despite the reduced potential effect, construction of this facility would still result in a **potentially significant impact** on historical resources and historic properties.

Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as defined in §15064.5

Refer to the **Impact Cul-1** discussion. That discussion also applies to historic-era resources of the built environment.

Impact Cul-3: Disturb a Traditional Cultural Property

Refer to the **Impact Cul-1** discussion. That discussion also applies to TCPs.

Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries

Refer to the **Impact Cul-1** discussion. That discussion also applies to human remains.

18.3.8 Impacts Associated with Alternative C

18.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to archaeological resources (**Impact Cul-1**), historic-era resources of the built environment (**Impact Cul-2**), TCPs (**Impact Cul-3**), and human remains (**Impact Cul-4**) would be the same as described for Alternative A for the Extended and Secondary study areas.

18.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to cultural resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The boundary of the Project Buffer would be the same for all three alternatives, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

The Alternative C design of the Delevan Pipeline Intake Facilities and Delevan Transmission Line is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to cultural resources as described for Alternative A.

The Alternative C design for the Sites Reservoir Inundation Area and Dams and Road Relocations and South Bridge would be the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to cultural resources as described for Alternative B.

18.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 18-2 for the impacts that have been identified as significant or potentially significant.

Table 18-2
Summary of Mitigation Measures for
NODOS Project Impacts to Cultural Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Cul-1: A Substantial Adverse Change in the Significance of an Archaeological Resource Pursuant to §15064.5	All Primary Study Area Project Facilities	Potentially Significant	Mitigation Measure Cul-1a: Avoid Impacts to Historical Resources/Historic Properties	No Impact
			Mitigation Measure Cul-1b: Conduct Archaeological Data Recovery	Less than Significant
			Mitigation Measure Cul-1c: Immediately Halt Construction if Cultural Resources are Discovered and Implement an Accidental Discovery Plan	Less than Significant
			Mitigation Measure Cul-1d: Protection of Archaeological Sites by Capping	Less than Significant
	Sites Reservoir, San Luis Reservoir, and Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use	Potentially Significant	Mitigation Measure Cul-1e: Develop Agreement Documents to Address Potential Future Operational Impacts to Cultural Resources	Less than Significant or Significant and Unavoidable
Impact Cul-2: A Substantial Adverse Change in the Significance of a Historical Resource of the Built Environment as Defined in §15064.5	Sites Reservoir Inundation Area, GCID Canal Facilities Modifications, TRR and associated TRR Facilities, Delevan Pipeline, Delevan Pipeline Intake/Discharge Facilities, and Project Buffer	Potentially Significant	Mitigation Measure Cul-1a: Avoid Impacts to Historical Resources	No Impact
			Mitigation Measure Cul-2a: Follow the Secretary of the Interior's Standards for the Treatment of Historical Resources/Historic Properties	Less than Significant
			Mitigation Measure Cul-2b: Record Built Environment Resources to Historic American Buildings Survey (HABS) and Historic American Engineering Record (HAER) Standards	Significant and Unavoidable if eligible for CRHR or NRHP listing

Table 18-2
Summary of Mitigation Measures for
NODOS Project Impacts to Cultural Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Cul-3: Disturb a Traditional Cultural Property	San Luis Reservoir and Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use	Potentially Significant	Mitigation Measure Cul-1e: Develop Agreement Documents to Address Potential Future Operational Impacts to Cultural Resources	Less than Significant or Significant and Unavoidable
	All Primary Study Area Project Facilities except for the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure Cul-1a: Avoid Impacts to Historical Resources	No Impact
			Mitigation Measure Cul-3: Consult with Native American Communities regarding How to Mitigate for Impacts to TCPs	Less than Significant; or Significant and Unavoidable for some categories of TCPs
Impact Cul-4: Disturb Human Remains, including those Interred Outside of Formal Cemeteries	San Luis Reservoir and Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use	Potentially Significant	Mitigation Measure Cul-1e: Develop Agreement Documents to Address Potential Future Operational Impacts to Cultural Resources	Less than Significant or Significant and Unavoidable
	All Primary Study Area Project Facilities	Potentially Significant	Mitigation Measure Cul-1a: Avoid Impacts to Historical Resources	No Impact
			Mitigation Measure Cul-4a: Relocation of Known Cemeteries	Less than Significant
			Mitigation Measure Cul-4b: Immediately Halt Construction if Human Remains are Discovered and Implement a Burial Treatment Plan	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Cul-1a: Avoid Impacts to Historical Resources/Historic Properties

If feasible, impacts to identified historical resources/historic properties, including prehistoric and historic-era archaeological sites, buildings and structures, TCPs, and human remains shall be avoided. Methods of avoidance may include, but are not limited to, Project re-design, or, when appropriate, deeding the site into a permanent conservation easement; incorporation of sites into parks, greenspace, or other open space; and protection measures, such as fencing.

Mitigation Measure Cul-1b: Conduct Archaeological Data Recovery

If it is infeasible to avoid impacts to archaeological sites that have been determined to be eligible for listing on the CRHR or the NRHP, additional research including, but not necessarily limited to, archaeological excavation shall be conducted. This work shall be directed by a qualified archaeologist who meets the U.S. Secretary of Interior's professional standards, and shall include preparation of a research design; additional archival and historical research to supplement the research design, when appropriate; archaeological excavation; analysis of artifacts, features, and other attributes of the resource; and preparation of a technical report documenting the methods and results of the investigation in accordance with the California Office of Historic Preservation Guidelines for Archaeological Research Design (1991). The purpose of this work is to recover a sufficient quantity of data to compensate for damage to or destruction of a resource that is eligible for the CRHR pursuant to criterion 4 of CCR 4852(b) or the NRHP pursuant to 36 CFR 60.4(d). The procedures to be used in this data recovery program shall be determined in consultation with responsible agencies and interested parties such as Native American tribes, as appropriate, within the parameters of the PA.

Mitigation Measure Cul-1c: Immediately Halt Construction if Cultural Resources are Discovered, and Implement an Accidental Discovery Plan

Not all cultural resources are visible on the ground surface. Protocols for addressing the accidental discovery of archaeological resources that are not visible on the ground surface during Project construction will be outlined in an Accidental Discovery Plan, as directed by the PA. If any cultural resources, such as structural features, unusual amounts of bone or shell, flaked or ground stone artifacts, historic-era artifacts, human remains, or architectural remains are encountered during any Project construction activities, work shall be suspended immediately at the location of the find and within an appropriate radius, with a minimum of 50 feet. A qualified archaeologist shall conduct a field investigation of the specific site and recommend mitigation deemed necessary for the protection or recovery of any cultural resource concluded by the archaeologist to represent a historical resource or unique archaeological resource. Mitigation measures shall be developed in consultation with responsible agencies and, as appropriate, interested parties such as Native American tribes. Implementation of the approved mitigation would be required before resuming construction activities at the archaeological site. All of the activities identified above shall be detailed in an Accidental Discovery Plan developed prior to construction so that all parties are aware of the actions required if buried archaeological resources are uncovered during Project construction. Discoveries of human remains shall be treated as described below for Mitigation Measure Cul-4b.

Mitigation Measure Cul-1d: Protection of Archaeological Sites by Capping

Capping archaeological sites that are considered historical resources with soil, gravels, rock, or specific kinds of vegetation can be a viable way to protect the deposits under some circumstances. For example, sites subject to inundation and water level fluctuations may be protected from erosion by applying a layer of gravel/rock (rip-rap), soil, cloth, or some combination of treatments. In such circumstances, regular monitoring would be required to evaluate the efficacy of the mitigation, and to identify if and when it is necessary to refresh the protection. A layer of soil, i.e., sterile fill, might also be placed over a site where construction of a building was planned, such that all construction disturbance would occur in the fill material. Planting vegetation, such as poison oak, wild rose, or blackberry brambles, over the top of a site is a useful deterrent for areas subject to looting.

Mitigation Measure Cul-1e: Develop Agreement Documents to Address Potential Future Operational Impacts to Cultural Resources

Protocols for addressing potential future operations impacts at Sites Reservoir and at existing facilities within the Extended Study Area shall be addressed in the PA. This may include preparation of Memoranda of Agreement for specific facilities and/or development of a Cultural Resources Management Plan, depending on the lead agency in charge of the facility. Management of historical resources/historic properties under such agreement documents might include standard measures for identification of historical resources/historic properties where needed, assessment of project impacts, and application of specific mitigation measures, as well as protocols for resource monitoring or stabilization techniques. Such agreement documents shall be developed in consultation with responsible agencies and interested parties, such as Native American tribes, as appropriate, within the parameters of the PA.

Mitigation Measure Cul-2a: Follow the Secretary of the Interior's Standards for the Treatment of Historical Resources/Historic Properties

Because construction of Project facilities has the potential to modify buildings or structures that are considered historical resources/historic properties, any alterations, including relocation, to historic buildings or structures shall conform to the Secretary of the Interior's Standards for the Treatment of Historic Properties and Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings (1995).

Mitigation Measure Cul-2b: Record Built Environment Resources to Historic American Buildings Survey (HABS) and Historic American Engineering Record (HAER) Standards

If avoidance or relocation of a building or structure that is considered eligible for the CRHR or NRHP is not feasible, and the resource must be demolished, a qualified architectural historian who meets the U.S. Secretary of Interior's professional standards shall be retained to document the impacted historical architectural resource to Historic American Buildings Survey (HABS) and Historic American Engineering Record (HAER) specifications. HABS and HAER documentation packages shall be entered into the Library of Congress as well as the NWIC or NEIC of the CHRIS.

Mitigation Measure Cul-3: Consult with Native American Communities regarding How to Mitigate for Impacts to TCPs

TCPs are often locations on the landscape that have sacred or other special meaning to Native American communities. Associated characteristics, such as an archaeological deposit, are not always present. Early and meaningful consultation with Native American communities shall occur to identify ways to mitigate impacts to TCPs. Interpretive programs, establishing or enhancing locations for traditional plants, or a visitor's center, are examples of ways to address these important issues. Consultation with Native American communities shall occur.

Mitigation Measure Cul-4a: Relocation of Known Cemeteries

Consultation shall occur with the entity (County, City, private) that has jurisdiction over the cemetery, and interested parties as appropriate, to identify a satisfactory place that is protected from future disturbance for the relocation of human remains. Similarly, if Native American burials are known to exist in an archaeological site, the Project proponent shall work with the appropriate tribe to identify a satisfactory location for re-interment of burials in a protected location.

Mitigation Measure Cul-4b: Immediately Halt Construction if Human Remains are Discovered, and Implement a Burial Treatment Plan

Project construction activities have the potential to have unanticipated significant impacts to buried human remains where there is no surface indication of their presence. In these circumstances, the requirements of California Health and Human Safety Code 7050.5 must be followed. In accordance with the California Health and Safety Code, if human remains are uncovered during ground-disturbing activities, the potentially damaging excavation must halt in the area of the remains and the local County Coroner must be notified. The Coroner is required to examine all discoveries of human remains within 48 hours of receiving notice of a discovery on private or state lands (Health and Safety Code Section 7050.5[b]). If the Coroner determines that the remains are those of a Native American, he or she must contact the Native American Heritage Commission (NAHC) by phone within 24 hours of making that determination (Health and Safety Code Section 7050[c]). Pursuant to the provisions of California Public Resources Code Section 5097.98, the NAHC shall identify a Most Likely Descendent (MLD). The MLD designated by the NAHC shall have at least 48 hours to inspect the site and propose treatment and disposition of the remains and any associated grave goods. All of the activities identified above shall be detailed in a Burial Treatment Plan, as directed by the PA, and developed in consultation with local Native American tribes prior to Project construction so that all parties are aware of the actions required if buried human remains are uncovered during Project construction.

Implementation of **Mitigation Measures Cul-1a, Cul-1b, Cul-1c, Cul-1d, Cul-1e, Cul-2a, Cul-2b, Cul-3, Cul-4a, and Cul-4b** would reduce the level of significance of Project impacts to **no impact** or **less than significant**, or some could remain **potentially significant and unavoidable**.

19. Indian Trust Assets

19.1 Introduction

This chapter discusses the Indian Trust Assets (ITAs) in the Extended, Secondary, and Primary study areas, and includes a discussion of the regulatory framework associated with ITAs. For this resource, the Extended Study Area is defined as the portions of the CVP and SWP service areas that could be affected by the North of the Delta Offstream Storage (NODOS) Project operations, located within 39 counties. The Secondary Study Area is defined as the CVP and SWP reservoirs, rivers, creeks, and associated floodplains that could be affected by Project operations, located in 22 counties.

The Primary Study Area (in Glenn and Colusa counties) is considered to be the footprint of the proposed Project facilities, the land immediately surrounding these facilities that could be affected by construction and/or maintenance activities (construction disturbance area), and the land parcels surrounding those areas that would be purchased (the Project Buffer). The NODOS Investigation focuses on offstream storage north of the Delta. Offstream storage located north of the Delta would require conveying water from the Sacramento River or one of its major tributaries to the new storage location. Offstream storage located north of the Delta would require conveying water from the Sacramento River or one of its major tributaries to the new storage location. An offstream storage conveyance system could either use existing diversions and canals and/or new diversions and conveyance. Water would be diverted during periods of relatively higher flow through the conveyance system, into the new offstream storage reservoir, and stored until it is needed to meet the planning objectives.

19.2 Regulatory Setting

Indian Trust Assets (ITAs) are legal interests in property held in trust by the U.S. for federally-recognized Indian tribes or individual Indians. An Indian trust has three components: (1) the trustee, (2) the beneficiary, and (3) the trust asset. ITAs can include land, minerals, federally-reserved hunting and fishing rights, federally-reserved water rights, and instream flows associated with trust land. Beneficiaries of the Indian trust relationship are federally-recognized Indian tribes with trust land; the U.S. is the trustee. By definition, ITAs cannot be sold, leased, or otherwise encumbered without approval of the U.S. The characterization and application of the U.S. trust relationship have been defined by case law that interprets Congressional acts, executive orders, and historic treaty provisions.

The federal government, through treaty, statute or regulation, may take on specific, enforceable fiduciary obligations that give rise to a trust responsibility to federally recognized tribes and individual Indians possessing trust assets. Courts have recognized an enforceable federal fiduciary duty with respect to federal supervision of Indian money or natural resources, held in trust by the federal government, where specific treaties, statutes or regulations create such a fiduciary duty.

Consistent with President William J. Clinton’s 1994 memorandum, “Government-to-Government Relations with Native American Tribal Governments,” the U.S. Bureau of Reclamation (Reclamation) assesses the effect of its programs on tribal trust resources and federally-recognized tribal governments. Reclamation is tasked to actively engage federally-recognized tribal governments and consult with such tribes on government-to-government level when its actions affect ITAS (Federal Register, 1994. The U.S. Department of the Interior (DOI) Departmental Manual Part 512.2 (1995) ascribes the responsibility for ensuring protection of ITAs to the heads of bureaus and offices. DOI is required to “protect and preserve Indian trust assets from loss, damage, unlawful alienation, waste, and depletion" (DOI Office of the Secretary, 2000). It is the general policy of the DOI to perform its activities and programs in such a way as to protect ITAs and avoid adverse effects whenever possible. Reclamation complies with procedures contained in Departmental Manual Part 512.2, guidelines, which protect ITAs. Reclamation carries out its activities in a manner that protects trust assets and avoids adverse impacts when possible. When Reclamation cannot avoid adverse impacts, it will provide appropriate mitigation or compensation. Reclamation is responsible for assessing whether the NODOS Investigation for surface storage to support restoration of ecological health and improvement of water management for beneficial uses in the Bay-Delta system has the potential to affect ITAs. Reclamation will comply with procedures contained in Departmental Manual Part 512.2, guidelines, which protect ITAs.

There are no potential impacts to ITAs in the vicinity of the Extended, Secondary, and Primary study areas.

19.3 Environmental Consequences

This section addresses the concern of whether any ITA, including Public Domain Allotments (PDAs), would be adversely affected or beneficially affected by any of the alternatives being considered. Types of actions that could affect ITAs and PDAs include interference with the exercise of a reserved water right, degradation of water quality where a water right exists, impacts to fish and wildlife where hunting and fishing rights exist, or noise near a land asset where it adversely impacts use of the reserved land.

19.3.1 Key Impact and Evaluation Criteria

To address environmental consequences related to ITAs, the following issues have been evaluated to determine potential impacts and their level of significance:

- Are ITAs present in or adjacent to the water development area?
- If an ITA was present, would any of the alternatives being considered impede, change, or potentially benefit current activities within the ITA?

19.3.2 Impact Assessment Assumptions and Methodology

19.3.2.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to ITAs:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant (RBPP).
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and RBPP).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.

- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.

19.3.2.2 Methodology

Reclamation maintains GIS coverage of Indian reservations and rancherias for the State of California. The impact assessment for ITAs was based on this GIS coverage and maps of ITAs for the three study areas.

19.3.3 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

19.3.4 Environmental Impacts

None of the water development areas, i.e., the Extended, Secondary or the Primary Study Area contain ITAs.

19.3.4.1 Impacts Associated with the No Project/No Action Alternative

Implementation of the No Action/No Project Alternative would entail no change from Existing Conditions.

Extended Study Area – No Project/No Action Alternative

There would be **no potential impacts** in the Extended Study Area because there are no ITAs within the vicinity of the Extended Study Area.

Secondary Study Area – No Project/No Action Alternative

There would be **no potential impacts** in the Secondary Study Area because there are no ITAs within the vicinity of the Secondary Study Area.

Primary Study Area – No Project/No Action Alternative

There would be **no potential impacts** to the Primary Study Area because there are no ITAs within the vicinity of the Primary Study Area.

19.3.4.2 Impacts Associated with Alternatives A, B and C

Alternative A: 1.27-MAF Sites Reservoir with Delevan Pipeline, Alternative B: 1.81-MAF Sites Reservoir with Release-only Delevan Pipeline, and Alternative C: 1.81-MAF Sites Reservoir with Delevan Pipeline

There would be **no potential impacts** associated with any of the three alternatives because there are no ITAs within the vicinity of the Extended, Secondary, or Primary study areas.

19.4 Mitigation Measures

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

20. Land Use

20.1 Introduction

This chapter describes the existing land uses for the Extended, Secondary, and Primary study areas. It also describes the planned land uses (according to the Tehama, Glenn, and Colusa County general plans) because Project facilities are proposed to be constructed in those counties. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for land use is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

20.2 Environmental Setting/Affected Environment

20.2.1 Extended Study Area

20.2.1.1 Methodology

Existing available documents were reviewed to characterize the existing land uses in the Extended Study Area.

20.2.1.2 Central Valley Project and State Water Project Service Areas

The Extended Study Area consists of the Central Valley Project (CVP) and the State Water Project (SWP) service areas located in northern and southern California. Land use in these areas varies considerably, depending on location, and includes agricultural, residential, commercial, industrial, and open space (which includes the wildlife refuges).

The CVP, operated by Reclamation, stores and delivers water within 29 of the State’s 58 counties, through the following facilities (considered industrial land uses): 21 reservoirs; 11 powerplants; 500 miles of major canals; and conduits, tunnels, and associated facilities (Reclamation, 2011). In the Central Valley, most municipal and industrial (M&I) service contract water use occurs near the cities of Redding and Sacramento and in some towns and cities in the San Joaquin Valley to meet the demand from those residential, commercial, and industrial land uses. Outside of the population centers of the San Francisco Bay Area and Sacramento and Stockton metropolitan areas, most of the CVP service area is rural, with irrigated agriculture representing the predominant land use (Reclamation, 2011).

SWP is a water storage and delivery system that is operated and maintained by DWR. The SWP stores and delivers water through the following facilities (considered industrial land uses): 34 storage facilities, reservoirs, and lakes; 20 pumping plants; four pumping-generating plants; five hydroelectric power plants; and approximately 701 miles of open canals and pipelines (DWR, 2013a). The SWP service area comprises almost 25 percent of California’s land area and more than 66 percent of its population. SWP water is used primarily for agricultural purposes (750,000 acres of irrigated farmland - mainly southern San Joaquin

Valley); the remaining water is used primarily on lands developed for residential, commercial, and industrial purposes.

20.2.1.3 San Luis Reservoir

San Luis Reservoir is located 12 miles west of the City of Los Banos in Merced County. It is a part of the San Luis Joint-Use Complex, which serves both the CVP and SWP (DWR, 2013b). The reservoir is located on all or portions of 28 parcels of land. Recreation and undeveloped open space comprise the land uses of the lands that surround the reservoir.

20.2.2 Secondary Study Area

20.2.2.1 Methodology

To characterize the land uses within the Secondary Study Area, a review of maps and aerial photography, existing available documents and websites of applicable agencies was conducted. Tehama County was contacted to obtain assessor's parcel number and Williamson Act contract information. General Plan land use designations were obtained by reviewing the County General Plan Land Use Map. The County designated land use describes the general type of land use that is allowed in a given area.

In addition, the California Department of Conservation, Office of Land Conservation's Farmland Mapping and Monitoring Program (FMMP) data were obtained and reviewed for the Red Bluff Pumping Plant site. The 2008 FMMP data set was used because this data was closest in date to the June 2009 baseline date. The FMMP Program inventories farmlands and classifies them according to their suitability for agricultural production as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, Farmland of Local Importance, Grazing Land, Urban and Built-up Land, Other Land, or Water. These classifications are described below:

- **Prime Farmland:** Farmland with the best combination of physical and chemical features able to sustain long term agricultural production. This land has the soil quality, growing season, and moisture supply needed to produce sustained high yields. Land must have been used for irrigated agricultural production at some time during the four years prior to the mapping date.
- **Farmland of Statewide Importance:** Farmland similar to Prime Farmland but with minor shortcomings, such as greater slopes or less ability to store soil moisture. Land must have been used for irrigated agricultural production at some time during the four years prior to the mapping date.
- **Unique Farmland:** Farmland of lesser quality soils used for the production of the State's leading agricultural crops. This land is usually irrigated, but may include nonirrigated orchards or vineyards as found in some climatic zones in California. Land must have been cropped at some time during the four years prior to the mapping date.
- **Farmland of Local Importance:** Land of importance to the local agricultural economy, as determined by each county's board of supervisors and a local advisory committee. The county-specific Board of Supervisors has the authority to adopt or recommend changes to this category of farmland.
- **Grazing Land:** Land on which the existing vegetation is suited to the grazing of livestock. This category was developed in Cooperation with the California Cattlemen's Association, University of California Cooperative Extension, and other groups interested in the extent of grazing activities.

- **Urban/Built-Up Land:** Land occupied by structures with a building density of at least one unit to 1.5 acres, or approximately six structures to a 10-acre parcel. This land is used for residential, industrial, commercial, construction, institutional, public administration, railroad and other transportation yards, cemeteries, airports, golf courses, sanitary landfills, sewage treatment, water control structures, and other developed purposes.
- **Other Land:** Land not included in any other mapping category. Common examples include low density rural developments; brush, timber, wetland, and riparian areas not suitable for livestock grazing; confined livestock, poultry or aquaculture facilities; strip mines, borrow pits; and waterbodies smaller than forty acres. Vacant and nonagricultural land surrounded on all sides by urban development and greater than 40 acres is mapped as Other Land.
- **Water:** Perennial water bodies with an extent of at least 40 acres.

20.2.2.2 Counties within the Secondary Study Area

Land use within the 22 counties of the Secondary Study Area varies greatly because of differences in population, economy, and environment; land uses include agricultural, residential, commercial, industrial, recreational, and undeveloped open space.

Urban development (i.e., residential, commercial, and industrial land uses) is concentrated around the State capitol of Sacramento, as well as in Sacramento County and in the counties of Solano, Contra Costa, Alameda, Santa Clara, San Mateo, San Francisco, Marin, and Sonoma, as well as in the Sacramento-San Joaquin Delta. Commercial and industrial land uses within Shasta, Tehama, Colusa, and Glenn counties are concentrated along transportation corridors. Land use in Del Norte, Humboldt, and Trinity counties is greatly influenced by the amount of public and Native American tribal lands, much of which is used for timber production and other natural resource-related uses (USFWS, et al., 1999).

The counties within the Secondary Study Area also have lands that are dedicated to operation of the CVP and SWP waterbodies, with recreation and open space land uses being the primary land uses surrounding the waterbodies.

Land uses surrounding Trinity Lake and Whiskeytown Lake are primarily open space with some recreation. Open space land use surrounds Lewiston Lake and Keswick Reservoir and is along the Klamath River downstream of the Trinity River, Spring Creek, and Clear Creek. Land uses along the Trinity River consist primarily of open space with some rural residential and recreation. Land uses surrounding Shasta Lake include open space, recreation, residential, commercial, and industrial.

Land uses along the Sacramento River consist primarily of agriculture from Shasta County to Sacramento, with some recreation and open space. Several wildlife refuges also exist along the Sacramento River corridor. The Tehama-Colusa (T-C) Canal is located downstream of the Red Bluff Pumping Plant (RBPP) on the west bank of the Sacramento River in Tehama County. The T-C Canal is owned by Reclamation and is operated by the Tehama-Colusa Canal Authority (TCCA). TCCA delivers water to agricultural land uses to approximately 150,000 acres of land within Tehama, Glenn, Colusa, and Yolo counties (TCCA, 2013). The T-C Canal facilities are an industrial land use.

The Glenn-Colusa Irrigation District (GCID) Canal is located approximately 80 miles north of the City of Sacramento in Tehama, Glenn, and Colusa counties. The GCID Canal is owned and operated by GCID, providing water to agricultural land uses within its district boundaries that include 175,000 acres in the Sacramento Valley (GCID, 2013). The GCID Canal facilities are an industrial land use.

The Feather River supplies water to the SWP via Lake Oroville, near the city of Oroville in Butte County. Land uses along the Feather River and at/near Lake Oroville include agricultural, residential, commercial, industrial, recreational, and open space. The Thermalito Complex (the Thermalito Diversion Dam, Diversion Dam Powerplant, Power Canal, Forebay, Pumping/Generating Plant, and Afterbay) is located downstream from Oroville Dam. The land use adjacent to these facilities is open space.

Land uses at and near the Sutter Bypass and Yolo Bypass channels include agriculture, open space, and wildlife refuges, including the Sutter National Wildlife Refuge and the Yolo Bypass Wildlife Area.

The American River supplies water to the CVP via Folsom Lake in Placer, El Dorado and Sacramento counties. Land uses along the American River and at/near Folsom Lake include residential, commercial, industrial, recreational, and open space. Lake Natoma (a regulating reservoir for releases from Folsom Lake) is located downstream of Folsom Lake. Land uses near Lake Natoma include primarily open space and recreation, with some residential and office uses.

The Sacramento-San Joaquin Delta (Delta) is located at the confluence of the Sacramento and San Joaquin rivers and consists of channels and sloughs that flow into Suisun Bay, San Pablo Bay, and then San Francisco Bay before entering the Pacific Ocean. The Delta and bays are undergoing rapid urbanization associated with substantial population growth in the Bay Area and Central Valley regions. Other land uses in these areas include agricultural, rural residential, open space, and recreational.

20.2.2.3 Red Bluff Pumping Plant

The RBPP, located on the Sacramento River approximately two miles southeast of the City of Red Bluff in unincorporated Tehama County, is owned and operated by Reclamation. It is located on one parcel of land that is designated General Industrial[1] in the Tehama County General Plan (Tehama County, 2013). The RBPP site is an industrial land use that is located on FMMP-designated Urban/Built-Up land.

20.2.3 Primary Study Area

20.2.3.1 Methodology

Data, including a list of the assessor's parcels required for each Project facility (including the Project Buffer), the required acreage of each Assessor's Parcel Number; the County zoning designations of the parcels; the FMMP land use designations of the parcels, and the Project facilities that would be located on parcels that have a Williamson Act contract and/or a Wetlands Reserve Program (WRP) easement (pursuant to the Natural Resources Conservation Service) were reviewed. Provided below is a summary of that data by Project facility grouping. The information provided below is for the Project facility groupings plus the areas around the facility groupings that would be needed for Project construction activities, except for the Project Buffer. The Project Buffer would not have a construction disturbance area, but is included in this discussion to characterize the Existing Setting in that area.

20.2.3.2 Glenn and Colusa Counties

The Primary Study Area is located within Colusa and Glenn counties. These two counties are primarily rural with low populations, when compared to the remainder of California. There are a few small

[1] The intent of the General Industrial land use classification is to provide for industrial land uses, including light and heavy manufacturing, industrial parks, support wholesale energy production, related office uses, and industrial uses of similar character. This designation allows for non-industrial firms that provide materials and services related to industrial uses. Additional non-industrial uses may be permitted on an interim basis with conditions that provide for reversion to industrial uses.

incorporated cities and several unincorporated areas in these counties. Surrounding the developed communities are farms, ranches, and orchards (i.e., rural residential and agricultural land uses).

Glenn County

Glenn County is located in the western portion of the Sacramento Valley, north of Colusa County. Glenn County is approximately 849,000 acres in size, with approximately 68 percent in agriculture, 31 percent considered "other land[2]", and less than 1 percent in urban (i.e., residential, commercial, and/or industrial) land uses in 2010 (DOC, 2013).

In 2010, Glenn County had 348,147 acres of Important Farmlands (including Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance) and an additional 226,837 acres of grazing land. Between 2008 and 2010, Important Farmlands decreased by 11 acres and grazing land decreased by 554 acres in Glenn County (DOC, 2013).

Colusa County

Colusa County is located in the western portion of the Sacramento Valley. The county is approximately 740,000 acres in size, with approximately 76 percent in agriculture, 23 percent considered "other land", and less than 1 percent in urban (i.e., residential commercial, and/or industrial land uses in 2010 (DOC, 2013).

In 2010, Colusa County had 554,695 acres of Important Farmlands (including Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance), and an additional 9,161 acres of grazing land. Between 2008 and 2010, Important Farmlands decreased by 1,023 acres and grazing land increased by 50 acres in Colusa County (DOC, 2013).

20.2.3.3 Primary Study Area Project Facility Locations

Data, including a list of the assessor's parcels required for each Project facility (including the Project Buffer), the required acreage of each Assessor's Parcel Number (APN); the County zoning designations of the APNs; the FMMP land use designations of the APNs, and the Project facilities that would be located on APNs that have a Williamson Act contract and/or a WRP easement were reviewed. Provided below is a summary of that data by Project facility grouping. The information provided below is for the Project facility groupings plus the areas around the facility groupings that would be needed for Project construction activities, except for the Project Buffer. The Project Buffer would not have a construction disturbance area, but is included in this discussion to characterize the Existing Setting in that area.

Sites Reservoir Inundation Area and Sites Reservoir Dams

The proposed Sites Reservoir (either the Alternative A 1.27-MAF Reservoir or the Alternatives B and C 1.81-MAF Reservoir), the sites of the dams that would be required for the three alternatives (nine dams for Alternative A and 11 dams for Alternatives B and C), and seven borrow areas for the Project would be located within Antelope Valley in unincorporated Glenn and Colusa counties. Construction activities for these facilities would occur within a 1,000-acre area located to the east of Sites Reservoir.

The Sites Reservoir Inundation Area for all three alternatives would inundate the town of Sites in unincorporated Colusa County. The town of Sites was established in the late 1800s; it is currently a rural

[2] Common examples include low density rural developments; brush, timber, wetland, and riparian areas not suitable for livestock grazing; confined livestock, poultry, or aquaculture facilities; strip mines or borrow pits; and waterbodies smaller than 40 acres. Includes vacant and nonagricultural land surrounded on all sides by urban development and greater than 40 acres.

and sparsely populated area, with an estimated population of 17 to 20 people (Colusa County, 2013). Sites are considered a Populated Place[3] by the U.S. Geological Survey (USGS GNIS, 2012).

Assessor's Parcels

The 1.27-MAF Sites Reservoir, associated dams (Alternative A), the borrow areas, plus the construction disturbance area to be located outside of Sites Reservoir would be located on all or portions of nine parcels of land in Glenn County, on all or portions of 128 parcels of land in Colusa County, and on all or portions of up to 12 additional parcels for which locations have not been determined.

The 1.81-MAF Sites Reservoir, associated dams (Alternatives B and C), the borrow areas, plus the construction disturbance area to be located outside of Sites Reservoir would be located on all or portions of eleven parcels of land in Glenn County, on all or portions of 136 parcels of land in Colusa County, and on all or portions of up to 12 additional parcels for which locations have not been determined.

Wetland Reserve Program Status

The proposed Sites Reservoir (both reservoir sizes), the dams required for the reservoir, the borrow areas, and the construction disturbance area to be located outside of Sites Reservoir would not be located on parcels of land that have WRP easements.

County Zoning Designations

Sites Reservoir and dams (Alternatives A, B, and C), the borrow areas, and the construction disturbance area to be located outside of Sites Reservoir would be located on lands that are zoned as Agricultural Preserve[4] (144-acre minimum) and Foothill Agricultural/Forestry[5] (144-acre minimum) in Glenn County, and Agriculture Preserve[6], Exclusive Agriculture[7], and Foothill Agricultural/Forestry (144-acre minimum) in Colusa County.

---

[3] A Populated Place is defined as a place or area with clustered or scattered buildings and a permanent human population (city, settlement, town, or village). A Populated Place is usually not incorporated and be definition has no legal boundaries. However, a Populated Place may have a corresponding "civil" record, the legal boundaries of which may or may not coincide with the perceived populated place.

[4] The Agricultural Preserve Zone is to be applied to lands which are covered by a California Land Conservation Act (Williamson Act) contract with the county for the following purposes:

- To preserve the maximum amount of the limited supply of agricultural land which is necessary in the conservation of the county's economic resources and vital for a healthy agricultural economy of the county
- To protect the general welfare of the agricultural community for encroachments of unrelated agricultural uses which, by their nature, would be injurious to the physical and economic well-being of the agricultural community

[5] The Foothill Agricultural/Forestry Zone classification is established for the following purposes:

- To provide areas for extensive agricultural activities
- To protect the timber and forest lands economically suitable for logging

[6] The Agriculture Preserve Zone is intended to be applied in areas where agriculture is the natural and desirable primary land use and where the protection of agriculture from the encroachment of incompatible uses is essential to the general welfare.

[7] The Exclusive Agriculture Zone is intended to be applied in agricultural lands with a General Plan land use designation of Agriculture-General. This Zone is to be applied to those areas where agricultural activities are the appropriate and desirable primary land use. This Zone is to be applied to those areas where the protection of agriculture from the encroachment of incompatible uses is essential to the general welfare of the county citizens. It is to help maintain, protect, enhance, and propagate the county's agricultural resources. It is to protect and maintain a viable agricultural economy in the county, and to protect agriculturalists from environmental impacts and pressures as they relate to groundwater, nonagriculture traffic, and encroachment from residential development resulting in common agriculture/residential conflicts related to noise, odors, spraying, vandalism, trespassing, and predation from wildlife habitating on nonmaintained adjacent ten-acre sized lots.

Farmland Mapping and Monitoring Program Designations

Sites Reservoir and dams (Alternatives A, B, and C), the borrow areas, and the construction disturbance area to be located outside of Sites Reservoir would be located on lands designated as Grazing Land, Local Potential Farmland, and Other Land in Glenn County, and on lands designated as Farmland of Local Importance and Other Land in Colusa County.

Williamson Act Contract Status

Sites Reservoir and dams (Alternative A), the borrow areas, and the construction disturbance area to be located outside of Sites Reservoir would be located on up to 86 parcels of land that have Williamson Act contracts. Of that total, eight contracts are with Glenn County, 66 contracts are with Colusa County, and up to 12 additional Williamson Act contracts are included for parcels for which locations have not been determined. Glenn County contracts renew on March 1 each year. Colusa County contracts renew on January 1 each year.

Sites Reservoir and dams (Alternatives B and C), the borrow areas, and the construction disturbance area to be located outside of Sites Reservoir would be located on up to 95 parcels of land that have Williamson Act contracts. Of that total, nine contracts are with Glenn County, 74 contracts are with Colusa County, and up to 12 additional Williamson Act contracts are included for parcels for which locations have not been determined.

Recreation Areas

Up to five locations were determined to be potentially feasible recreation areas at Sites Reservoir to provide recreation opportunities: Stone Corral Recreation Area (235 acres), Saddle Dam Recreation Area (329 acres), Peninsula Hills Recreation Area (373 acres), Antelope Island Recreation Area (49 acres), and Lurline Headwaters Recreation Area (219 acres) totaling 1,205 acres. All construction activities for the Recreation Areas would occur within the footprints of the individual recreation areas.

Assessor's Parcels

The Recreation Areas would be located on all or portions of four parcels of land in Glenn County and 11 parcels of land in Colusa County.

Wetland Reserve Program Status

The Recreation Areas would be located on no parcels of land that have WRP easements.

County Zoning Designations

The Recreation Areas would be located on lands that are zoned as Agricultural Preserve (144-acre minimum) in Glenn County, and Agriculture Preserve in Colusa County.

Farmland Mapping and Monitoring Program Designations

The Recreation Areas would be located on lands that are designated as Grazing Land and Local Potential Farmland in Glenn County and Farmland of Local Importance and Other Land in Colusa County.

Williamson Act Contract Status

The Recreation Areas would be located on 14 parcels of land that have Williamson Act contracts. Of that total, four contracts are with Glenn County, and 10 contracts are with Colusa County. Glenn County contracts renew on March 1 each year. Colusa County contracts renew on January 1 each year.

Road Relocations, South Bridge, and Terminal Regulating Reservoir Pipeline Road

Sites Reservoir would inundate several existing roads within Colusa County's jurisdiction; so as part of the Project (all alternatives), several roads would be rerouted to provide alternate access routes. In addition, new roads would be required to access various Project facilities. The "Road Relocations" discussed below include both the re-routed existing roads and the proposed Project roads. The South Bridge would be located within the footprint of the Sites Reservoir Inundation Area; therefore, the acreage in this discussion is limited to only the roads.

Assessor's Parcels

The Alternative A Road Relocations would be located on all or portions of 12 parcels of land in Glenn County and on all or portions of 45 parcels of land in Colusa County.

The Alternative B and C Road Relocations would be located on all or portions of 11 parcels of land in Glenn County and on all or portions of 42 parcels of land in Colusa County.

Wetland Reserve Program Status

The Road Relocations (all three alternatives) would be located on no parcels of land that have WRP easements.

County Zoning Designations

The Alternative A, B and C Road Relocations would be located on lands that are zoned as Agricultural Preserve (144-acre minimum) and Agricultural Preserve (72-acre minimum) in Glenn County, and Agriculture Preserve in Colusa County.

Farmland Mapping and Monitoring Program Designations

The Alternatives A, B and C Road Relocations would be located on lands that are designated as Farmland of Local Importance, Local Potential Farmland, Other Land, and Grazing Land.

Williamson Act Contract Status

The Alternative A Road Relocations would be located on 52 parcels of land that have Williamson Act contracts. Of that total, 11 contracts are with Glenn County, and 41 contracts are with Colusa County. Glenn County contracts renew on March 1 each year. Colusa County contracts renew on January 1 each year.

The Alternative B and C Road Relocations would be located on 48 parcels of land that have Williamson Act contracts. Of that total, 10 contracts are with Glenn County, and 38 contracts are with Colusa County.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and the Asphalt Batch Plant would be located to the west of the existing Funks Reservoir between it and the proposed Sites Reservoir on primarily open space lands.

Assessor's Parcels

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Asphalt Batch Plant, and associated construction disturbance area would be located on all or portions of seven parcels of land in Colusa County.

Wetland Reserve Program Status

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Asphalt Batch Plant, and associated construction disturbance area would be located on no parcels of land that have WRP easements.

County Zoning Designations

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Asphalt Batch Plant, and associated construction disturbance area would be located on lands that are zoned as Agriculture Preserve in Colusa County.

Farmland Mapping and Monitoring Program Designations

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Asphalt Batch Plant, and associated construction disturbance area would be located on lands that are designated as Farmland of Local Importance.

Williamson Act Contract Status

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Asphalt Batch Plant, and associated construction disturbance area would be located on six parcels of land that have Williamson Act contracts with Colusa County. Colusa County contracts renew on January 1 each year.

Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard

The Holthouse Reservoir Complex (which includes Holthouse Reservoir and Dam, breached Funks Dam, the dredging of Funks Reservoir, Holthouse Spillway and Stilling Basin, Holthouse Pumping Plant, T-C Canal Discharge Dissipater, the Funks Bypass Pipeline, and the Holthouse to T-C Canal Pipeline), the Holthouse Reservoir Electrical Switchyard, and the Delevan Pipeline Electrical Switchyard would be located on agricultural and open space lands, with the exception of Funks Reservoir and Funks Dam, which are existing facilities.

Assessor's Parcels

The Holthouse Reservoir Complex, the Holthouse Reservoir Electrical Switchyard, the Delevan Pipeline Electrical Switchyard, and associated construction disturbance area around these facilities would be located on all or portions of 14 parcels of land in Colusa County, as well as on up to 10 other parcels that are included within the Delevan Pipeline/TRR Pipeline construction disturbance area.

Wetland Reserve Program Status

The Holthouse Reservoir Complex, the Holthouse Reservoir Electrical Switchyard, the Delevan Pipeline Electrical Switchyard, and associated construction disturbance area around these facilities would be located on no parcels of land that have WRP easements.

County Zoning Designations

The Holthouse Reservoir Complex, the Holthouse Reservoir Electrical Switchyard, the Delevan Pipeline Electrical Switchyard, and associated construction disturbance area around these facilities would be located on lands that are zoned as Agriculture Preserve and Exclusive Agriculture in Colusa County.

Farmland Mapping and Monitoring Program Designations

The Holthouse Reservoir Complex, the Holthouse Reservoir Electrical Switchyard, the Delevan Pipeline Electrical Switchyard, and associated construction disturbance area around these facilities would be located on lands that are designated as Prime Farmland and Farmland of Local Importance.

Williamson Act Contract Status

The Holthouse Reservoir Complex, the Holthouse Reservoir Electrical Switchyard, the Delevan Pipeline Electrical Switchyard, and associated construction disturbance area around these facilities would be located on three parcels of land that have a Williamson Act contract with Colusa County, as well as on one other parcel that is included within the Delevan Pipeline/TRR Pipeline construction disturbance area. Colusa County contracts renew on January 1 each year.

Glenn-Colusa Irrigation District Canal Facilities Modifications

The GCID Canal is an existing irrigation canal that delivers water from the Sacramento River to irrigation districts along its route from its diversion point northwest of Hamilton City in Glenn County to southeast of Williams, in Colusa County. The proposed Project improvements include a new headgate structure, canal lining, and a railroad siphon replacement.

Assessor's Parcels

The modifications to the GCID Canal headgate structure and canal lining would be located on all or portions of one parcel of land in Glenn County.

The modifications to the GCID Canal railroad siphon would be located on all or portions of two parcels of land in Glenn County.

Wetland Reserve Program Status

The modifications to the GCID Canal headgate structure, canal lining, and railroad siphon would be located on no parcels of land that have WRP easements.

County Zoning Designations

The modifications to the GCID Canal headgate structure and canal lining would be located on lands that are identified as Canal on the Glenn County Zoning Map. The railroad siphon modifications would be located on the Canal, which does not have a zoning classification on the Zoning Map (Glenn County, 2006). The County's land use and zoning website (Glenn County, 2013) indicates that the lands encompassing the GCID Canal headgate structure, canal lining, and railroad siphon are zoned NL (meaning "no information available") and that the construction disturbance area for those facilities is zoned NL and Intensive Agriculture.

Farmland Mapping and Monitoring Program Designations

The modifications to the GCID Canal headgate structure and canal lining and associated construction disturbance area would be located on lands that are designated as primarily Other Land with a small amount of land designated as Farmland of Statewide Importance.

The modifications to the GCID Canal railroad siphon and associated construction disturbance area would be located on lands that are designated as primarily Urban/Built-Up Land, with a small amount of land designated as Prime Farmland, Farmland of Statewide Importance, and Farmland of Local Importance.

Williamson Act Contract Status

The modifications to GCID Canal headgate structure, canal lining, and railroad siphon would be located on no parcels of land that have Williamson Act contracts.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir to Funks Creek Pipeline, Terminal Regulating Reservoir to Funks Creek Outlet, and Terminal Regulating Reservoir Electrical Switchyard

Water conveyed down the GCID Canal would be directed into the proposed TRR. The TRR and its associated facilities would be located on agricultural lands.

Assessor's Parcels

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, TRR to Funks Creek Pipeline, TRR to Funks Creek Outlet, TRR Electrical Switchyard, and the construction disturbance area around these facilities would be located on all or portions of nine parcels of land in Colusa County.

Wetland Reserve Program Status

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, TRR to Funks Creek Pipeline, TRR to Funks Creek Outlet, TRR Electrical Switchyard, and the construction disturbance area would be located on no parcels of land that have WRP easements.

County Zoning Designations

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, TRR to Funks Creek Pipeline, TRR to Funks Creek Outlet, TRR Electrical Switchyard, and the construction disturbance area would be located on lands that are zoned as Exclusive Agriculture in Colusa County.

Farmland Mapping and Monitoring Program Designations

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, TRR to Funks Creek Pipeline, TRR to Funks Creek Outlet, TRR Electrical Switchyard, and the construction disturbance area would be located on lands that are designated as Prime Farmland, Farmland of Local Importance, and Other Land.

Williamson Act Contract Status

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, TRR to Funks Creek Pipeline, TRR to Funks Creek Outlet, TRR Electrical Switchyard, and the construction disturbance area would be located on no parcels of land that have Williamson Act contracts.

Delevan Pipeline and Terminal Regulating Reservoir Pipeline

The approximately 13.5-mile-long Delevan Pipeline would be routed from the Delevan Pipeline Intake/Discharge Facilities to Holthouse Reservoir for Alternatives A, B, and C. It would convey water from the Sacramento River to Holthouse Reservoir to fill Sites Reservoir, and also convey water from Holthouse Reservoir to release to the Sacramento River for Alternatives A and C. Although the Alternative B Delevan Pipeline would only convey water from Holthouse Reservoir to release to the Sacramento River, the Delevan Pipeline would have the same facility footprint for all three alternatives.

The 3.5-mile-long TRR Pipeline would convey water from the TRR to Holthouse Reservoir. The western 3.5-mile length of the Delevan Pipeline would parallel the TRR Pipeline.

Assessor's Parcels

The 10-mile-long eastern portion of the Delevan Pipeline, the TRR Pipeline, the 3.5-mile-long western portion of the Delevan Pipeline, and the construction disturbance area would be located on 64 parcels of land in Colusa County.

Wetland Reserve Program Status

The 10-mile-long eastern portion of the Delevan Pipeline and the construction disturbance area would be located on one parcel of land that has a WRP easement.

The 3.5-mile-long western portion of the Delevan Pipeline, the TRR Pipeline, and their construction disturbance area would not be located on parcels that have WRP easements.

County Zoning Designations

The 10-mile-long eastern portion of the Delevan Pipeline and the construction disturbance area would be located on lands designated as Exclusive Agriculture and Light or Heavy Industrial in Colusa County.

The 3.5-mile-long western portion of the Delevan Pipeline, the TRR Pipeline, and their construction disturbance area would be located on lands designated as Exclusive Agriculture in Colusa County.

Farmland Mapping and Monitoring Program Designation

The 10-mile-long eastern portion of the Delevan Pipeline and the construction disturbance area would be located on lands designated as Prime Farmland, Unique Farmland, and Other Land.

The 3.5-mile-long western portion of the Delevan Pipeline, the TRR Pipeline, and their construction disturbance area would be located on lands designated as Prime Farmland and Farmland of Local Importance.

Williamson Act Contract Status

The Delevan and TRR pipelines and their associated construction disturbance area would be located on 11 parcels of land that have Williamson contracts with Colusa County. Colusa County contracts renew on January 1 each year.

Delevan Transmission Line

A 230-kV Delevan Transmission Line would conduct electricity from an existing power source to provide all of the electricity needed by the Project's pumping plants.

The Delevan Transmission Line would differ between alternatives. In Alternatives A and C, it would parallel the Delevan Pipeline from the Delevan Pipeline Intake Facilities to the TRR. It would then be aligned from the TRR to the Sites Electrical Switchyard. The Alternative B Delevan Electrical Transmission Line would be aligned only from its connection with the existing PG&E 230-kV or WAPA 500-kV/230-kV transmission line to the Sites Pumping/Generating Plant. The transmission line towers (Alternatives A, B, and C) would be sited within a 150-foot-wide permanent transmission line easement.

Assessor's Parcels

The Alternatives A and C Delevan Transmission Line and associated construction disturbance area would be located on all or portions of 39 parcels of land in Colusa County.

The Alternative B Delevan Transmission Line and associated construction disturbance area would be located on all or portions of eight parcels of land in Colusa County.

Wetland Reserve Program Status

The Alternatives A and C Delevan Transmission Line and associated construction disturbance area would be located on one parcel of land that has a WRP easement.

The Alternative B Delevan Transmission Line and associated construction disturbance area would be located on no parcels of land that have a WRP easement.

County Zoning Designations

The Alternatives A and C Delevan Transmission Line and associated construction disturbance area would be located on lands designated as Agriculture Preserve and Exclusive Agriculture in Colusa County.

The Alternative B Delevan Transmission Line and associated construction disturbance area would be located on lands designated as Agriculture Preserve and Exclusive Agriculture in Colusa County.

Farmland Mapping and Monitoring Program Designation

The Alternatives A and C Delevan Transmission Line and associated construction disturbance area would be located on lands designated as Prime Farmland and Farmland of Local Importance.

The Alternative B Delevan Transmission Line and associated construction area would be located on lands designated as Farmland of Local Importance.

Williamson Act Contract Status

The Alternatives A and C Delevan Transmission Line and associated construction disturbance area would be located on 11 parcels of land that have Williamson Act contracts with Colusa County. Colusa County contracts renew on January 1 each year.

The Alternative B Delevan Transmission Line and associated construction disturbance area would be located on six parcels that have Williamson Act contracts with Colusa County.

Delevan Pipeline Intake Facilities

Alternatives A and C include a fish screen and pumping/generating facilities to divert water from the Sacramento River, and also includes a water release capability to the Sacramento River.

Assessor's Parcels

The Delevan Pipeline Intake Facilities and associated construction disturbance area would be located on all or portions of two parcels of land in Colusa County.

Wetland Reserve Program Status

The Delevan Pipeline Intake Facilities and associated construction disturbance area would be located on no parcels of land that have WRP easements.

County Zoning Designations

The Delevan Pipeline Intake Facilities and associated construction disturbance area would be located on lands designated as Exclusive Agriculture and Floodway in Colusa County.

Farmland Mapping and Monitoring Program Designation

The Delevan Pipeline Intake Facilities and associated construction disturbance area would be located on lands designated as Prime Farmland and Other Land.

Williamson Act Contract Status

The Delevan Pipeline Intake Facilities and associated construction disturbance area would be located on no parcels of land that have Williamson Act contracts.

Delevan Pipeline Discharge Facility

Alternative B includes the release-only Delevan Pipeline Discharge Facility. This alternative would provide no Sacramento River water diversion capability.

Assessor's Parcels

The Delevan Pipeline Discharge Facility and associated construction disturbance area would be located on all or portions of three parcels of land in Colusa County.

Wetland Reserve Program Status

The Delevan Pipeline Discharge Facility and associated construction disturbance area would be located on no parcels of land that have WRP easements.

County Zoning Designations

The Delevan Pipeline Discharge Facility and associated construction disturbance area would be located on lands designated as Exclusive Agriculture and Floodway in Colusa County.

Farmland Mapping and Monitoring Program Designation

The Delevan Pipeline Discharge Facility and associated construction disturbance area would be located on lands designated as Prime Farmland and Other Land.

Williamson Act Contract Status

The Delevan Pipeline Discharge Facility and associated construction disturbance area would be located on no parcels of land that have Williamson Act contracts.

Electrical Distribution Lines

The Electrical Distribution Lines would supply electricity to Golden Gate Dam, Sites Dam, South Bridge, and the Lurline Headwaters, Peninsula Hills, and Stone Corral recreation areas.

Assessor's Parcels

The Alternative A Electrical Distribution Lines and associated construction disturbance area would be located on all or portions of 16 parcels of land in Colusa County.

The Alternatives B and C Electrical Distribution Lines and associated construction disturbance area would be located on all or portions of 14 parcels of land in Colusa County.

Wetland Reserve Program Status

The Electrical Distribution Lines (Alternatives A, B, and C) and associated construction disturbance area would not be located on parcels of land that have WRP easements.

County Zoning Designations

The Electrical Distribution Lines (Alternatives A, B, and C) and associated construction disturbance area would be located on lands designated as Agriculture Preserve in Colusa County.

Farmland Mapping and Monitoring Program Designation

The Electrical Distribution Lines (Alternatives A, B, and C) and associated construction disturbance area would be located on lands designated as Farmland of Local Importance and Other Land.

Williamson Act Contract Status

The Alternative A Electrical Distribution Lines and associated construction disturbance area would be located on 16 parcels of land that have Williamson Act contracts with Colusa County. Colusa County contracts renew on January 1 each year.

The Alternatives B and C Electrical Distribution Lines and associated construction disturbance area would be located on 14 parcels of land that have Williamson Act contracts with Colusa County.

Project Buffer

The Project Buffer would consist of the land surrounding Project facility footprints, extending out to the nearest parcel boundary, to create a buffer around most Project facilities. The Delevan and TRR pipelines, Delevan Transmission Line, and Road Relocations and South Bridge would not have an associated Project Buffer, but portions of these facilities would be located within the buffer of other facilities due to their proximity to or connection with other facilities. In addition, the GCID Canal Facilities Modifications would not have an associated Project Buffer. The outer perimeter boundary of the Project Buffer would be the same for the three alternatives. Due to the differences in Project facilities between the three alternatives, the size and shape of the Project Buffer would differ between alternatives.

Assessor's Parcels

The Alternative A Project Buffer would be located on all or portions of 10 parcels of land in Glenn County and on all or portions of 102 parcels of land in Colusa County.

The Alternatives B and C Project Buffer would be located on all or portions of 10 parcels of land in Glenn County and on all or portions of 98 parcels of land in Colusa County.

Wetland Reserve Program Status

The Project Buffer (for Alternatives A, B, and C) would not be located on parcels of land that have WRP easements.

County Zoning Designation

The Alternative A, B and C Project Buffer would be located on lands that are zoned as Agricultural Preserve (144-acre minimum) and Foothill Agricultural/Forestry (144-acre minimum) in Glenn County, and as Agriculture Preserve, Exclusive Agriculture, Foothill Agricultural/Forestry (144-acre minimum), and Floodway in Colusa County.

Farmland Mapping and Monitoring Program Designation

The Alternative A, B and C Project Buffer would be located on lands designated as Grazing, Prime Farmland, Farmland of Local Importance, Local Potential Farmland, Unique Farmland, Water, and Other Land.

Williamson Act Contract Status

The Alternative A Project Buffer would be located on 81 parcels of land that have Williamson Act contracts. Of that total, eight contracts are with Glenn County, and 73 contracts are with Colusa County. Glenn County contracts renew on March 1 each year. Colusa County contracts renew on January 1 each year.

The Alternatives B and C Project Buffer would be located on 77 parcels of land that have Williamson Act contracts. Of that total, eight contracts are with Glenn County, and 69 contracts are with Colusa County.

20.3 Environmental Impacts/Environmental Consequences

20.3.1 Regulatory Setting

Land uses are inventoried at the State and local agency levels, and are regulated at the federal, State, and local agency levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

20.3.1.1 Federal Plans, Policies, and Regulations

- U.S Department of Agriculture, Natural Resources Conservation Service – Farmland Protection Policy Act of 1981
- U.S. Department of Agriculture, Natural Resources Conservation Service – Wetlands Reserve Program

20.3.1.2 State Plans, Policies, and Regulations

- California Department of Conservation, Office of Land Conservation – Important Farmland Inventory System and Farmland Mapping and Monitoring Program
- California Land Conservation Act of 1965 (Williamson Act)
- California State Planning and Zoning Laws

20.3.1.3 Regional and Local Plans, Policies, and Regulations

- Tehama County General Plan (2009)
- Tehama County Code (No Date)
- Glenn County General Plan (1993)
- Glenn County Code (No Date)
- Colusa County General Plan (2012)
- Colusa County Code (1991)

Several federal, State, and local land use planning and zoning, as well as agricultural conservation regulations, are in effect that are relevant to the action alternatives. The regulations are listed above and described in Chapter 4 Environmental Compliance and Permit Summary. They are also discussed briefly below to provide context for the information that is provided for the Project facilities environmental setting, as well as the impacts analysis, because several of the impact evaluation criteria in this chapter pertain to these issues.

- **U.S. Department of Agriculture, Natural Resources Conservation Service - Farmland Protection Policy Act of 1981:** This Act is a federal regulation that is intended to minimize the impact of federal programs with respect to the conversion of farmland to nonagricultural uses. It ensures that, to the extent possible, federal programs are administered to be compatible with State, local, and private programs and policies to protect farmland.
- **U.S. Department of Agriculture, Natural Resources Conservation Service – Wetlands Reserve Program:** The Wetlands Reserve Program (WRP) is a voluntary program that offers landowners the opportunity to protect, restore, and enhance wetlands on their property. The Program has several enrollment options. In exchange for the landowner precluding development on the lands and restoring the lands, the USDA NRCS pays certain costs to the landowner and provides technical assistance to the landowner to restore, protect, and enhance wetlands on eligible lands. Approximately 779 acres of land

in Glenn County have WRP easements; approximately 8,894 acres of land in Colusa County have WRP easements (NRCS, 2013).

- **Important Farmland Inventory System and Farmland Mapping and Monitoring Program:** The California Department of Conservation, Office of Land Conservation, maintains a statewide inventory of farmlands. These lands are mapped by the Division of Land Resource Protection as part of the Farmland Mapping and Monitoring Program (FMMP). Lands are classified according to their suitability for agricultural production as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, Farmland of Local Importance, Grazing Land, Urban and Built-up Land, Other Land, and Water.

- **California Land Conservation Act of 1965 (Williamson Act):** The Williamson Act enables local governments to enter into contracts with private landowners to promote the continued use of relevant land into agricultural or related open space use by establishing agricultural preserves. In return, landowners receive property tax assessments that are based on farming and open space uses instead of full market value. The Williamson Act was enhanced in 1998 with Farmland Security Zones (also known as Super Williamson Act lands).

- **California State Planning and Zoning Laws:** California Government Code Section 65300 et seq. establishes the obligation of cities and counties to adopt and implement General Plans. California Government Code Section 65800 et seq. establishes that zoning ordinances, which are laws that define allowable land uses in a specific district, are required to be consistent with the General Plan and any applicable Specific Plan. The individual General Plans and zoning ordinances that are applicable to the Project are listed in Section 20.3.1.3.

20.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for land use and planning and agriculture and forestry resources:

Would the Project:

- Physically divide an established community?

- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the FMMP of the California Resources Agency, to non-agricultural use?

- Conflict with existing zoning for agricultural use, or a Williamson Act contract?

- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code Section 12220(g)), timberland (as defined by Public Resources Code Section 4526), or timberland zoned Timberland Production (as defined by Government Code Section 51104(g))?

- Result in the loss of forest land or conversion of forest land to non-forest use?

- Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use or conversion of forest land to non-forest use?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Physical division of an established community.
- Conflict with an applicable land use plan, policy, or regulation of an agency with jurisdiction over the Project adopted for the purpose of avoiding or mitigating an environmental effect.
- Changes in land use as a result of implementing the alternatives that are considered to be incompatible with the existing land uses at and adjacent to the proposed Project facilities.
- Permanent conversion of Prime Farmland, as shown on the maps prepared pursuant to the FMMP of the California Resources Agency, to non-agricultural use. In contrast, temporary or non-permanent conversion (i.e., during Project construction) of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland would result in a less-than-significant impact. In addition, permanent conversion of Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland would result in a less-than-significant impact.
- Permanent conflict with existing zoning for agricultural use, and/or the permanent conversion of lands that have a Williamson Act contract. In contrast, temporary conflicts (i.e., during Project construction) with existing zoning for agricultural use, or the temporary conversion (i.e., during Project construction) of lands that have a Williamson Act contract would result in a less-than-significant impact if the lands are restored to agricultural land use and the temporary impact does not exceed three years.
- Permanent conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code Section 12220(g)), timberland (as defined by Public Resources Code Section 4526), or timberland zoned Timberland Production (as defined by Government Code Section 51104(g)). In contrast, temporary conflicts (i.e., during Project construction) with existing zoning for forest land or timberland would result in a less-than-significant impact.
- The permanent loss of forest land or permanent conversion of forest land to non-forest use. In contrast, the temporary loss or conversion (i.e., during Project construction) of forest land or timberland would result in a less-than-significant impact.
- Other changes in the existing environment which, due to their location or nature, could result in the permanent conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to non-agricultural use or permanent conversion of forest land to non-forest use. In contrast, temporary conversion (i.e., during Project construction) of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland, or the temporary conversion of forest land to non-forest use would result in a less-than-significant impact.

20.3.3 Impact Assessment Assumptions and Methodology

20.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to land use:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the RBPP.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and RBPP).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation, increased reliability of water supply to agricultural, municipal, and industrial water users, and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge facilities would be required.
- Temporary impacts to land use would occur during the Project construction period. Temporary impacts would occur within a "construction disturbance area". Because land use changes could occur anywhere within each Project facility footprint once Project construction starts, and to provide a worst-case scenario of land use impacts, the construction disturbance area for every Project facility (except for the Recreation Areas) was determined to consist of (1) the Project facility footprint, plus (2) an area outside of the Project facility footprint where Project construction activities could occur, in which the following activities could include, but are not limited to, facility construction/installation, facility assembly, materials laydown/storage, soil stockpiling, borrow areas, spoils disposal areas, and/or deliveries. Because some Project facilities would be located close to other Project facilities, some of the construction disturbance areas would be used for more than one Project facility. For the Recreation Areas, the construction disturbance area was determined to be the same as the permanent disturbance area.
- Permanent impacts to land use would occur at the facility footprint of every Project facility (i.e., the permanent disturbance area) and would last for the period of Project analysis (i.e., 100 years). Permanent impacts would begin when Project construction is complete. Permanent impacts would occur as a result of the presence of the Project facilities, from Project facility operations and

maintenance activities, and from the presence of the Project Buffer[8], which could preclude some existing land uses from occurring within that area.

- Defined construction disturbance areas were available for the Delevan and TRR pipelines, Delevan Transmission Line, Electrical Distribution Lines, and Roads Relocations. For all other Project facilities (in which the coordinate space was not defined for specific proposed Project facilities or construction disturbance areas for the facilities), the following assumptions were developed regarding size and potential location.
  - **Sites Reservoir Inundation Area and Sites Reservoir Dams and Borrow Areas:** In addition to the acreage for the footprints of the Sites Reservoir Inundation Area and Sites Reservoir Dams and Borrow Areas, a 1,000-acre construction disturbance area would be located to the east of Sites Reservoir. The precise location has not been defined; however, the parcels of land that are being considered for this area encompass the Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard facility footprints, as well as several proposed Project roads and other parcels located near those facilities. There are seven borrow areas defined within the Sites Reservoir Inundation Area, and they are accounted for within the inundation area calculations.
  - **Recreation Areas:** The construction disturbance area would be the same as the permanent disturbance area (i.e., it is the footprint of each Recreation Area). All Project facilities that would be located within the Recreation Areas (e.g., roads and distribution lines) are accounted for within the Recreation Areas facility grouping.
  - **Road Relocations, South Bridge, and TRR Pipeline Road:** The defined construction disturbance area along all Project roads would be 200 feet wide (100 feet on both sides of the roadways' centerline – except for the TRR Pipeline Road discussed below – its construction disturbance area would be less); the permanent disturbance area along the roads' alignments would average approximately 60 feet wide. Portions of the proposed roads would be located within the 1,000-acre construction disturbance area associated with Sites Reservoir Inundation Area and Sites Reservoir Dams (and the other facilities listed above that are included within the 1,000 acres). Because it is uncertain which land parcels would comprise the 1,000 acres, it was determined that the footprints of the proposed roads in those parcels should be accounted for with the roads and not as part of the Sites Reservoir and Dams category listed above. The 20-foot-wide gravel inspection road from the TRR to Holthouse Reservoir and Dam (known as the TRR Pipeline Road) would generate permanent ground disturbance, and it is accounted for in these calculations.
  - **Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard:** The construction disturbance area for these facilities would be approximately 99 acres (90 acres of facility footprints plus an assumed 10 percent extra [i.e., 9 acres] for construction activities). This 99 acres would be located within

[8] The Project Buffer lands would remain undeveloped; the existing vegetation would be maintained as wildlife habitat and protected from fuelwood harvest, grazing, and other forms of environmental degradation. Existing structures within the Project Buffer would be demolished and the remaining land would be managed as wildlife habitat. Existing agricultural lands would not be maintained as agriculture; they would be converted and managed as wildlife habitat.

the 1,000 acres mentioned above for the Sites Reservoir Inundation Area and Sites Reservoir Dams, and are accounted for in those calculations.

– **Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard:** The construction disturbance area for these facilities would be approximately 383 acres (348 acres of facility footprints plus an assumed 10 percent extra [i.e., 35 acres] for construction activities). The 383 acres would be located within the construction disturbance area for the Delevan and TRR pipelines, and are accounted for in those calculations. The Delevan Pipeline Electrical Switchyard would generate permanent ground disturbance and is accounted for in these calculations. The total facility footprints for this grouping would be 572 acres, including 224 acres of water surface associated with the existing Funks reservoir and additional facility footprints of 348 acres for the Project facility grouping.

– **Glenn-Colusa Irrigation District Canal Facilities Modifications:** The construction disturbance area for these facility modifications would be approximately 0.77 acre (0.7 acre for the canal lining and headgate structure plus an assumed 10 percent extra [i.e., 0.07 acre] for construction activities) plus approximately 0.22 acre (0.2 acre for the railroad siphon plus an assumed 10 percent extra [i.e., 0.02 acre] for construction activities). The total 0.99 acre would be located within the existing GCID Canal and the existing railroad siphon area.

– **Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir:** The construction disturbance area for these facilities would be approximately 214 acres (195 acres of facility footprints plus an assumed 10 percent extra [i.e., 19 acres] for construction activities). The 214 acres would be located within the construction disturbance area for the Delevan and TRR pipelines, and are accounted for in those calculations.

– **Delevan Pipeline and Terminal Regulating Reservoir Pipeline:** The construction disturbance area for these underground pipelines would be 1,500 feet wide and 13 miles long. The construction disturbance area attributed to the pipelines is approximately 2,058 acres for Alternatives A and C, and 2,265 acres for Alternative B, excluding acreage that is already accounted for under other Project facility groupings. There would be permanent disturbance associated with the two pipelines from regularly spaced aboveground facilities, such as blow-off structures, air valve structures, and an outlet and energy dissipater structure. The precise locations of these structures are not currently known, so their permanent disturbance is not accounted for in this land use analysis.

– **Delevan Transmission Line:** The construction disturbance area for the Delevan Transmission Line would be 150 feet wide and would be located within the 1,500-foot-wide construction disturbance area for the Delevan and TRR pipelines for nine miles of their approximate 13-mile length. The remaining four-mile-long portion of the Delevan Transmission Line that would not overlap with the Delevan and TRR pipeline construction disturbance area would result in approximately 71 acres of construction disturbance area. The permanent disturbance associated with the Delevan Transmission Line was calculated to be approximately 2.5 acres for Alternatives A and C and 0.5 acre for Alternative B, and was based on an assumed number of towers and an assumed disturbance needed for the footings of each tower (70 towers for Alternatives A and C and 15 towers for Alternative B). Because the precise locations of the towers is not known, it was assumed that land use impacts from the tower footings could occur anywhere along the 13-mile-long transmission line alignment. That assumption meant that the precise parcel of land, and its associated zoning, FMMP land use designation, and Williamson Act contract status could not be determined, resulting in presenting “potentially affected parcels” in the land use analysis, which would result in an overstatement regarding the number of parcels that would be affected, and a worst-case presentation of compatibility with existing zoning, FMMP land use designations, and Williamson Act contracts.

– **Electrical Distribution Lines:** Distribution lines to supply electricity to three of the Recreation Areas would be located within the Lurline Headwaters, Peninsula Hills, and Stone Corral recreation areas and have been accounted for within the Recreation Areas facility grouping. Other distribution lines that would be needed for the Project (e.g., for Golden Gate Dam, Sites Dam, and South Bridge) and connections to the Recreation Areas (but located outside of the Recreation Areas) are included in this Electrical Distribution Lines facility grouping.

– **Delevan Pipeline Intake Facilities (Alternatives A and C):** The permanent disturbance area (i.e., facility footprint) would be approximately 19.1 acres. The construction disturbance area for this facility would be smaller than the facility footprint (it would be approximately 17.1 acres) because approximately two acres of the facility footprint overlaps with the Delevan Pipeline construction disturbance area, and the two acres are accounted for in those calculations. In addition, the portion of the Delevan Pipeline construction disturbance area that is near to the Delevan Pipeline Intake Facilities is assumed to also be used for Delevan Pipeline Intake Facilities construction activities.

– **Delevan Pipeline Discharge Facility (Alternative B):** The permanent disturbance area (i.e., facility footprint) would be approximately 7.7 acres. The construction disturbance area for this facility would be smaller than the facility footprint (it would be approximately 6.3 acres) because approximately 1.4 acres of the facility footprint overlaps with the Delevan Pipeline construction disturbance area, and the 1.4 acres are accounted for in those calculations. In addition, the portion of the Delevan Pipeline construction disturbance area that is near to the Delevan Pipeline Discharge Facility is assumed to also be used for Delevan Pipeline Discharge Facility construction activities.

– **Project Buffer:** The Project Buffer would consist of the land that would be acquired for the Project beyond the facility footprints, out to the nearest existing parcel boundaries. The Project Buffer would surround Sites Reservoir, the Holthouse Reservoir Complex, and all facilities located between these two facilities; the Terminal Regulating Reservoir and associated facilities; and the Delevan Pipeline Intake/Discharge facilities[9]. Because the Project Buffer boundary would follow existing parcel boundaries, the width of the buffer around Project facilities would vary. The acreage for the temporary land use impacts of the Project Buffer would be zero; the changes in land use from creating this buffer (including fence construction, structure demolition, and fuelbreak creation) are considered a permanent land use impact.

[9] The Delevan Transmission Line and the Delevan Pipeline would not have an associated buffer. These two Project facilities do not require additional lands for long-term operation and maintenance.

20.3.3.2 Methodology

For the Extended Study Area, Project operational modeling results were reviewed to determine the expected changes in water deliveries and what those changes could mean relative to existing land uses.

For the Primary Study Area, the methodology used for assessing changes to land use, compatibility with Zoning and FMMP land use designations, and Williamson Act contract and WRP easement status of parcels that would be potentially affected by Project facilities (all three alternatives) was a multi-step process.

Project facilities that would be located near each other were grouped to prevent double-counting acreages. Acreages of the groups and associated construction disturbance areas around them were calculated using GIS. In instances where the coordinate space was not defined for specific proposed Project facility footprints or construction activity areas, assumptions were made regarding size and potential location.

The following Project facilities had spatially defined construction disturbance areas: Delevan and TRR pipelines, Delevan Transmission Line, Electrical Distribution Lines, and Road Relocations. For all other Project facilities (except for Sites Reservoir and the Project Buffer), the construction disturbance area associated with Alternatives A, B, and C was calculated as the Project facility footprint plus additional acreage that was added to the facility footprint (an assumed 10 percent of the facility footprint). Because the 10 percent additional acreage could be located in any area surrounding a Project facility, “potentially affected” parcels were identified and a list was created through a mapping review of the adjacent and overlapping parcel data.

To calculate permanent disturbance to land uses from the Project (Alternatives A, B, and C), the Project facility groupings were combined using a Union tool in GIS, which enabled all overlap between permanent facility footprints and the Project Buffer to be defined and eliminated prior to comparison with the agency datasets (i.e. Zoning, FMMP land use designations, Williamson Act contract status, and WRP easement status).

Subsequently, the consistency of Project facilities (including construction, operation, and maintenance activities) with the Zoning FMMP designated land uses and the counties’ General Plans’ policies was evaluated. In addition, the parcels where Project facilities would be constructed that have Williamson Act contracts and/or WRP easements were identified. Finally, the compatibility of Project facilities (including construction, operation, and maintenance activities) with existing land uses at and near those facility locations was evaluated.

It should be noted that the acreages presented in this chapter do not match acreages presented in other chapters in this EIR/EIS for every Project facility. This discrepancy is due to the necessary difference in methodology used to account for temporary and permanent impacts for the various environmental resources.

20.3.4 Topics Eliminated from Further Analytical Consideration

San Luis Reservoir is not discussed in the Extended Study Area for the No Project/No Action Alternative and Alternatives A, B, and C because changes to San Luis Reservoir storage conditions would have no effect on any of the land use issues being evaluated in this chapter.

Because no Project facilities would be constructed or maintained within the Extended Study Area for Alternatives A, B, and C, only operational impacts were discussed in the impacts analysis for the Extended Study Area (i.e., construction and maintenance impacts were not discussed).

The Secondary Study Area is not discussed for the No Project/No Action Alternative and Alternatives A, B, and C, as related to Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Sacramento River, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay because reservoir storage conditions and flow regime changes of those CVP/SWP reservoirs, rivers, creeks, and associated floodplains would have no effect on land use issues.

Land use changes and their compatibility with existing and General Plan designated land uses (**Impact Land-3)** are not relevant to the Primary Study Area for the No Project/No Action Alternative (and are, therefore, not discussed) because the projects and programs that are included in the No Project/No Action Alternative are not located within the Primary Study Area.

Established communities (**Impact Land-1)** are not discussed for the Primary Study Area for Alternatives A, B, and C except in the Sites Reservoir Inundation Area and Sites Reservoir Dams discussion; that criterion is not relevant to any other Project facility. The Town of Sites (which exists within the proposed footprint of the Sites Reservoir Inundation Area) is the only established community within the Primary Study Area.

20.3.5 Impacts Associated with the No Project/No Action Alternative

20.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, and Wildlife Refuge Water Use

Operational modeling of the No Project/No Action Alternative indicates that the change in CVP agricultural water supply deliveries between the No Project/No Action Alternative and Existing Conditions would range between -17 and 1 percent (indicating that the change could range from a decrease to a slight increase, when compared to Existing Conditions), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared. The change in SWP agricultural water supply deliveries between the No Project/No Action Alternative and Existing Conditions is predicted to range between -6 and 0 percent (indicating that the change could be a minor decrease ranging to no change, when compared to Existing Conditions), also depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared (refer to Chapter 6 Surface Water Resources for details).

Operational modeling of the No Project/No Action Alternative indicates that the change in CVP M&I water supply deliveries between the No Project/No Action Alternative and Existing Conditions would range between 0 and 149 percent (indicating that there could be no change and ranging to a substantial increase), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared. The change in SWP M&I water supply deliveries between the No Project/No Action Alternative and Existing Conditions is predicted to range between -11 and 4 percent (indicating that the change could be a decrease ranging to a slight increase, when compared to Existing Conditions), also depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared (refer to Chapter 6 Surface Water Resources for details).

Impact Land-1: Physical Division of an Established Community

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. With implementation of the No Project/No Action Alternative, CVP and SWP agricultural and M&I water supply deliveries within the Extended Study Area are predicted to change, when compared to Existing Conditions.

Operational modeling indicates that agricultural water deliveries (either CVP or SWP) in the Extended Study Area are predicted to decline or be approximately the same. These changes could result in a reduction in agricultural production, but not necessarily fewer acres of land in agricultural land use over the long-term, and not necessarily a change in land use from agriculture to another developed use. Reduced agricultural production could include, but may not be limited to, fewer acres of land cropped during Dry water years (i.e., periodic land fallowing), growing less water-intensive crops, or cropping land parcels fewer times per year.

CVP M&I water deliveries are expected to increase substantially in the Sacramento Valley and San Francisco Bay hydrologic regions; no change is expected in the San Joaquin River and Tulare Lake hydrologic regions. SWP M&I water deliveries are expected to decline or increase slightly throughout the hydrologic regions.

CVP Level 4 water deliveries to the wildlife refuges are expected to increase with implementation of the No Project/No Action Alternative, when compared to Existing Conditions. Changes in water deliveries to the wildlife refuges, whether they are increases or decreases, would not affect established communities because wildlife refuges do not have residential, commercial, and/or industrial development within their boundaries.

Regardless of the expected changes (increase or decrease) in water deliveries throughout the Extended Study Area as a result of implementing the No Project/No Action Alternative, the impacts of the projects included in the No Project/No Action Alternative have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to existing land uses has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on established communities, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. Urbanization that is planned according to County and City General Plans and zoning codes could be expected to cause the conversion of open space, agricultural, and rural residential land uses to M&I land uses (i.e., residential, commercial, industrial land uses). However, the General Plans and related construction activities would be subject to their own environmental reviews. Therefore, population growth associated with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on established communities, when compared to Existing Conditions.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with land use plans, policies, and regulations.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing Land Uses at and Adjacent to the Proposed Project Facilities

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential land use changes associated with the projects and programs included in the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to farmland conversions.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with agricultural use zoning and Williamson Act Contracts.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with forest land and timberland zoning.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to forest land conversions.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to farmland and forest land conversions.

20.3.5.2 Primary Study Area – No Project/No Action Alternative

Impact Land -1: Physical Division of an Established Community

If the No Project/No Action Alternative is implemented, the Project would not be constructed, and there would, therefore, be no construction, operation, or maintenance impacts within the Primary Study Area. Therefore, **there would not be a substantial adverse effect** on established communities, when compared to Existing Conditions.

Land uses that currently exist within the Primary Study Area, including, but not limited to, residential, agricultural, open space, and grazing, are expected to continue. Growth that may occur within the Primary Study Area, and its associated land uses, is expected to be in accordance with Glenn and Colusa counties' General Plans. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

In addition, projects included within the No Project/No Action Alternative would not be located within the Primary Study Area, and therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with land use plans, policies, and regulations.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to farmland conversions.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with agricultural use zoning and Williamson Act Contracts.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with forest land and timberland zoning.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to forest land conversions.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to farmland and forest land conversions.

20.3.6 Impacts Associated with Alternative A

20.3.6.1 Extended Study Area – Alternative A

<u>Operation Impacts</u>

With implementation of Alternative A, CVP and SWP agricultural water supply deliveries within the Extended Study Area are predicted to change, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operational modeling indicates that the change in CVP agricultural water supply deliveries between Alternative A and Existing Conditions would range between -8 and 3 percent (indicating that the change could be a minor decrease ranging to a slight increase, when compared to Existing Conditions), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared. The change in SWP agricultural water supply deliveries between Alternative A and Existing Conditions is predicted to range between -1 and 9 percent (indicating that the change could be a slight decrease to a slight increase), also depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared (refer to Chapter 6 Surface Water Resources for details).

Project operational modeling also indicates that the change in CVP agricultural water supply deliveries between Alternative A and the No Project/No Action Alternative would range between 2 and 11 percent (indicating that the change could be an increase up to a minor amount), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared. The change in SWP agricultural water supply deliveries between Alternative A and the No Project/No Action Alternative would range between 0 and 13 percent (indicating that there could be no change, ranging to a minor increase), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared (refer to Chapter 6 Surface Water Resources for details).

Agricultural Water Use

Impact Land -1: Physical Division of an Established Community

Alternative A's potential to increase agricultural water supply reliability and increase deliveries to agricultural land uses in the Extended Study Area is not likely to result in land use agencies within those jurisdictions planning to develop lands into agricultural land uses because much of the change in water deliveries is focused on the driest years (increasing water supply reliability thus decreasing the probability of developing additional acres of agricultural land uses). It is predicted that 19,000 fewer acres of agricultural land would result, when comparing Alternative A to Existing Conditions, and 2,000 additional acres of agricultural land are predicted to result when comparing Alternative A to the No Project/No Action Alternative (refer to Chapter 22 Socioeconomics for information regarding the 19,000-acre decrease and associated increase in crop production value, as well as the 2,000-acre increase and associated increase in crop production value).

The applicable land use agency would determine the plan for the land development in its community. Planned changes in land use, including those that would physically divide an established community if that was to occur, would undergo environmental review and approval, pursuant to CEQA and/or NEPA. This would, therefore, result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Land use changes that may occur within the Extended Study Area as a result of increased agricultural water supply reliability and increased water deliveries would be subject to applicable land use plans, policies, and regulations of the agency with jurisdiction over the lands where the land use changes could occur. Environmental analyses pursuant to CEQA and/or NEPA of such land use changes, if they were to occur, would include the review of relevant adopted zoning ordinances, General Plans, and maps for consistency with such regulations. Providing increased agricultural water supply reliability and deliveries within the CVP/SWP service areas of the Extended Study Area would not cause conflicts with these jurisdictional analyses. Therefore, **no impact** would occur, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Refer to the **Impact Land-2** discussion. That discussion is also applicable to the compatibility of land use changes expected as a result of Project implementation with existing and General Plan-designated land uses.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Providing increased agricultural water supply reliability and deliveries within the CVP/SWP service areas, as a result of implementation of Alternative A, is not expected to result in the conversion of FMMP-designated Farmland to a non-agricultural use. If that were to occur, environmental analyses pursuant to CEQA and/or NEPA of such land use changes would occur. There would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of lands that have a Williamson Act Contract

Providing increased agricultural water supply reliability and deliveries within the CVP/SWP service areas would not result in a conflict with the existing Agricultural zoning in the counties located within the Extended Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Providing increased agricultural water supply reliability and deliveries within the CVP/SWP service areas is not expected to affect forest land or forest land production because, as indicated in the **Impact Land-1** discussion, there would be little change expected to land uses (due to Alternative A's focus on providing water supply reliability) as a result of implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, Alternative A is not expected to result in a conflict with the existing zoning of forest land in the counties located within the Extended Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-6** discussion. That discussion is also applicable to forest land conversions.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide

Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-4**, **Impact Land-5**, and **Impact Land-6** discussions. That discussion is also applicable to farmland and forest land conversions.

Municipal and Industrial Water Use

With implementation of Alternative A, CVP and SWP M&I water supply deliveries within the Extended Study Area are predicted to change, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operational modeling indicates that the change in CVP M&I water supply deliveries between Alternative A and Existing Conditions would range between 0 and 151 percent[10] (indicating that there could be no change and ranging to a substantial increase), depending on hydrologic region and whether long-term averages or Dry and Critical[11] averages are compared. The change in SWP M&I water supply deliveries between Alternative A and Existing Conditions is predicted to range between 0 and 9 percent (indicating that the change could range from no change to a minor increase, when compared to Existing Conditions), also depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared (refer to Chapter 6 Surface Water Resources for details).

Project operational modeling also indicates that the change in CVP M&I water supply deliveries between Alternative A and the No Project/No Action Alternative would range between 0 and 1 percent (indicating that there could be no change or a slight change), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared. The change in SWP M&I water supply deliveries between Alternative A and the No Project/No Action Alternative would range between 5 and 16 percent (indicating that the change could be a slight to minor increase, when compared to Existing Conditions), depending on hydrologic region and whether long-term averages or Dry and Critical averages are compared (refer to Chapter 6 Surface Water Resources for details).

Impact Land -1: Physical Division of an Established Community

Alternative A's potential to increase M&I water supply reliability and increase deliveries to M&I land uses in the Extended Study Area could result in land use agencies within those jurisdictions planning to develop lands into M&I land uses, although much of the change in water deliveries would occur during the driest years (increasing water supply reliability and decreasing the probability of developing additional acres of M&I land uses). This is not expected to induce growth; it is instead expected to accommodate growth that is planned by local land use agencies. The applicable land use agency would determine the plan for the land development in its community. Planned changes in land use, including those that would physically divide an established community, would undergo environmental review and approval, pursuant to CEQA and/or NEPA. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

---

[10] It should be noted that the majority of this change would occur between Existing Conditions and the No Project/No Action Alternative, with a minor amount of change expected to occur between the No Project/No Action Alternative and Alternative A.

[11] It should be noted that much of the change would occur during the driest years (i.e., Project water would be provided during those years to provide reliability), so additional acreage may not be converted to M&I land uses.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

If land use agencies approve land use changes as a result of Alternative A's potential to increase water supply reliability and increase deliveries to M&I land uses in the Extended Study Area, those land use changes would be expected to comply with that agency's land use plans, policies, and regulations, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Refer to the **Impact Land-2** discussion. That discussion is also applicable to the compatibility of land use changes expected as a result of Project implementation with existing and General Plan-designated land uses.

Impact Land-4: Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

If land use agencies approve land use changes as a result of Alternative A's potential to increase water supply reliability and increase deliveries to M&I land uses in the Extended Study Area, and those land use changes result in the conversion of FMMP-designated Farmland to a non-agricultural use, those proposed land use changes would undergo environmental review and approval, pursuant to CEQA and/or NEPA. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, or the Permanent Conversion of Lands that have a Williamson Act Contract

If land use agencies approve land use changes as a result of Alternative A's potential to increase water supply reliability and increase deliveries to M&I land uses in the Extended Study Area, those land use changes would be expected to comply with that agency's existing zoning and applicable Williamson Act Contract provisions, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

If land use agencies approve land use changes as a result of Alternative A's potential to increase water supply reliability and increase deliveries to M&I land uses in the Extended Study Area, those land use changes would be expected to not conflict with zoning for forest land or timberland, or with timberland production. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-6** discussion. That discussion is also applicable to forest land conversions.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-4**, **Impact Land-5**, and **Impact Land-6** discussions. Those discussions are also applicable to farmland and forest land conversions.

Wildlife Refuge Water Use

Impact Land -1: Physical Division of an Established Community

The provision of an alternate Level 4 wildlife refuge water supply, associated with implementation of Alternative A, would have no effect on established communities within the Extended Study Area. This is because Alternative A would continue to provide this water (an alternative source to what is currently provided) only to lands within the wildlife refuges. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

No conflicts are expected with land use plans, policies, or regulations that are applicable to the Extended Study Area from the continued delivery of water to the wildlife refuges because only the water source would potentially change. The action (water delivery), location of water delivery, and amount of water to be delivered would not change. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Refer to the **Impact Land-1** discussion. That discussion is also applicable to the compatibility of land use changes expected as a result of Project implementation with existing and General Plan-designated land uses.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to farmland conversions.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with agricultural use zoning and Williamson Act Contracts.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Refer to the **Impact Land-1** discussion. That discussion is also applicable to potential conflicts with forest land and timberland zoning.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to forest land conversions.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-1** discussion. That discussion is also applicable to farmland and forest land conversions.

20.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Pump Installation at the Red Bluff Pumping Plant

Alternative A includes the installation of a pump into an existing concrete bay at the existing RBPP. The proposed additional pump would not increase the frequency of maintenance activities that are currently required at the pumping plant.

Impact Land -1: Physical Division of an Established Community

The RBPP is located within the land use footprint of an existing CVP facility owned and operated by Reclamation. No physical division of an established community would, therefore, occur as a result of the construction, operation, or maintenance of an additional pump or the maintenance dredging required for the Project. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

No conflicts with the Farmland Protection Policy Act, NRCS' WRP, and applicable Tehama County General Plan policies are expected (refer to Chapter 4 Environmental Compliance and Permit Summary for the list of applicable policies) from installing the Project pump into the existing RBPP. In addition, maintenance of the Project pump and dredging of the canal would occur when maintenance of the other RBPP facilities occurs, resulting in no conflicts. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Because the Project pump would be installed within the existing RBPP on land that is designated General Industrial by Tehama County, no changes in land use at the RBPP or adjacent parcels would occur as a result of the construction, operation, or maintenance of the pump, or maintenance dredging required for the Project. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

The existing RBPP (in which the pump is proposed to be installed) is not located on land that is FMMP-designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance; it is located on land that is designated as Urban/Built-Up. In addition, the Project's pump installation at the RBPP, as well as the pump's operation and maintenance and canal maintenance dredging required for the Project, would not require conversion of the existing FMMP-designated land use of the pumping plant site. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Because the Project pump would be installed within the existing RBPP site (land that is not zoned for agricultural use and does not have a Williamson Act contract), the pump's installation, operation, and maintenance, as well as canal maintenance dredging required for the Project, would not conflict with zoning for agricultural use or Williamson Act contract provisions. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Because the Project pump would be installed within the existing RBPP site (land that is not zoned for forest land, timberland, or timberland production), the pump's installation, operation, and maintenance, as well as canal maintenance dredging required for the Project, would not conflict with zoning for forest land or timberland, or with timberland production. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-6** discussion. That discussion is also applicable to forest land conversions.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-4**, **Impact Land-5**, and **Impact Land-6** discussions. Those discussions are also applicable to farmland and forest land conversions.

20.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge

As part of Project construction, 22 residences, four detached garages, one mobile home, 26 barns, and 37 other structures (a combination of sheds, silos, and a pump house) within the Sites Reservoir Inundation Area would be demolished. Existing septic tanks and other storage tanks would also be removed. In addition, two private cemeteries (Sites Cemetery and a Rancheria Cemetery) would be relocated, as well as many miles of fencing and asphalt would be removed. The roads that are currently routed through Antelope Valley would be re-routed, as necessary to provide alternate routes.

Table 20-1 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Sites Reservoir, Sites Reservoir Dams, and South Bridge.

Table 20-1
Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels		
Glenn County	9	9
Colusa County	128	128
Undetermined[c]	12	0
Total	**149**	**137**
Acreage of Potentially Affected Parcels		
Glenn County	1,795	1,795
Colusa County	10,669	10,669
Undetermined[c]	1,000	0
Total	**13,464**	**12,464**
Zoning Designation of Potentially Affected Parcels (Acres)		
Glenn County		
Agricultural Preserve (144-acre minimum)		1,592
Foothill Agriculture/Forestry (144-acre minimum)		182
Colusa County		
Agriculture Preserve		10,535
Exclusive Agriculture		33
Foothill Agriculture/Forestry (144-acre minimum)		7
N/A		115
Total	**13,464[d]**	**12,464**
FMMP Designation of Potentially Affected Parcels (Acres)		
Glenn County		
Local Potential Farmland		1,042
Grazing Land		727
Other Land		6
Colusa County		
Farmland of Local Importance		10,582
Other Land		107
Total	**13,464[d]**	**12,464**

Table 20-1
Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge – Alternative A Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels with Williamson Act Contracts		
Glenn County	8	8
Colusa County	66	66
Undetermined[c]	12	0
Total	**86**	**74**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Glenn County		1,606
Colusa County		9,286
Total	**11,892**[d]	**10,892**
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]Undetermined values represent construction disturbance areas for which locations have not been determined. Reported undetermined values are the maximum number of additional parcels or acreages that would be temporarily affected.

[d]The temporarily affected acreages by zoning and FMMP designations, and by Williamson Act contracts, cannot be determined because it is unknown which parcels would comprise the 1,000-acre construction disturbance area. Reported total temporarily affected acreages are the sum of the permanently affected acres and the 1,000-acre construction disturbance area.

Notes:

FMMP = Farmland Mapping and Monitoring Program
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
WRP = Wetland Reserve Program

Impact Land -1: Physical Division of an Established Community

Project construction includes the demolition of existing structures within Antelope Valley, the construction of dams to form Sites Reservoir, the construction of the South Bridge across the reservoir, and the filling of the reservoir. These activities would eliminate the town of Sites. Therefore, construction of Sites Reservoir (i.e., creating the inundation area), Sites Dams, and South Bridge would cause the physical division of an established community, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

No conflicts with the Farmland Protection Policy Act and NRCS' WRP are expected. The goals, objectives, and policies included in Glenn County's and Colusa County's General Plan land use elements have a strong focus on the preservation of agricultural land uses (refer to Chapter 4 Environmental Compliance and Permit Summary for the list of applicable policies). Colusa County's General Plan Land Use Element (Goal LU-4 and associated objectives and policies) also provide for the creation of Sites Reservoir, including action items to create a Sites Area Plan and the County's active participation in the Sites Joint Power Authority. Construction, operation, and maintenance of the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge would, therefore, result in a **significant impact,** as related to Glenn County's

General Plan, and a **less-than-significant impact**, as related to Colusa County's General Plan, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Construction, operation, and maintenance of the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge would result in changes in the existing agricultural, rural residential, and open space land uses, as well as to the General Plan-designated land uses from Glenn and Colusa County land use designations that promote agricultural land uses to recreational and public facility/industrial land uses. These expected changes in land use would be compatible with the existing surrounding land uses, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative. However, the expected changes would result in a **significant impact**, as related to the designated land uses, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

The Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge would not result in the conversion of FMMP designated Prime Farmland to nonagricultural uses because this land use type does not occur in this area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Construction, operation, and maintenance of Sites Reservoir, its associated dams, and South Bridge would conflict with the zoning of land in Glenn County that is currently zoned as Agricultural Preserve and Foothill Agriculture/Forestry, and Agriculture Preserve, Exclusive Agriculture, and Foothill Agriculture/Forestry (144-acre minimum) in Colusa County. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, up to 86 parcels of land that have Williamson Act contracts would be affected during Project construction (a **less-than-significant impact**), and 74 parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance. This permanent long-term impact would result in a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

In Glenn County, the applicable zoning designations are Foothill Agricultural/Forestry, Agricultural Preserve, or Recreational (Murrey, 2012). The zoning designations used in Colusa County for areas defined as Forest Land, Timberland, or Timberland zoned Timberland Production are Open Space, Upland Conservation, or Agriculture Preserve (Johanns, 2012).

Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge would impact 1,774 acres currently zoned as Agricultural Preserve and Foothill Agriculture/Forestry in Glenn County and 10,542 acres of land designated as Agriculture Preserve and Foothill Agriculture/Forestry (144-acre minimum) in Colusa County. This would result in a zoning conflict, and would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-6** discussion. Due to the land being zoned for forest land, and because it is currently unknown how many of the acres of forest land that are currently zoned Agricultural Preserve, Foothill Agriculture/Forestry, and Agriculture Preserve, this is considered a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge would change the existing environment of lands designated pursuant to the FMMP as Farmland of Local Importance and Local Potential Farmland. Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge would also change the existing environment of lands zoned as Foothill Agriculture/Forestry. These changes would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Table 20-2 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Recreation Areas.

Table 20-2
Recreation Areas – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels		
Glenn County	4	4
Colusa County	11	11
Total	**15**	**15**
Acreage of Potentially Affected Parcels		
Glenn County	293	293
Colusa County	877	877
Total	**1,170**	**1,170**
Zoning Designation of Potentially Affected Parcels (Acres)		
Glenn County		
Agricultural Preserve (144-acre minimum)	293	293
Colusa County		
Agriculture Preserve	877	877
Total	**1,170**	**1,170**

Table 20-2
Recreation Areas – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
FMMP Designation of Potentially Affected Parcels (Acres)		
Glenn County		
Local Potential Farmland	61	61
Grazing Land	232	232
Colusa County		
Farmland of Local Importance	811	811
Other Land	66	66
Total	**1,170**	**1,170**
Number of Potentially Affected Parcels with Williamson Act Contracts		
Glenn County	4	4
Colusa County	10	10
Total	**14**	**14**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Glenn County	293	293
Colusa County	828	828
Total	**1,121**	**1,121**
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

Notes:

FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. Construction, operation, and maintenance of the Saddle Dam Recreation Area, which would be located in Glenn County, would result in a **significant impact,** as related to Glenn County's General Plan, when compared to Existing Conditions and the No Project/No Action Alternative. Construction, operation, and maintenance of the remaining four recreation areas that would be located in Colusa County would result in a **less-than-significant impact**, as related to Colusa County's General Plan, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Refer to the **Impact Land-3** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Recreation Areas.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

No Prime Farmland would be affected by construction, operation, or maintenance of the Recreation Areas because no Prime Farmland is located at the Recreation Area sites. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Construction, operation, and maintenance of the Recreation Areas would conflict with the zoning of land in Glenn County that is currently zoned as Agricultural Preserve, and Agriculture Preserve in Colusa County. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, up to 14 parcels of land that have Williamson Act contracts would be affected during Project construction (a **less-than-significant impact**), and during Project operation and maintenance. This permanent long-term impact would result in a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Refer to the **Impact Land-6** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Recreation Areas (acreages applicable to Recreation Areas are provided in Table 20-2).

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-7** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Recreation Areas (acreages applicable to Recreation Areas are provided in Table 20-2).

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-8** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Recreation Areas.

Road Relocations and Terminal Regulating Reservoir Pipeline Road

Table 20-3 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing and operating/maintaining the Alternative A Road Relocations and TRR Pipeline Road.

Table 20-3
Road Relocations and Terminal Regulating Reservoir Pipeline Road – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels

Table 20-3
Road Relocations and Terminal Regulating Reservoir Pipeline Road – Alternative A Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]There is less than one acre in these categories, but more than zero.

[d]Differences between temporary and long-term acreages for these categories are due to the TRR Pipeline Road being located within the Delevan and TRR Pipeline disturbance area, thus having no construction disturbance area of its own. This also applies to the differences in the number of parcels affected.

Notes:
FMMP = Farmland Mapping and Monitoring Program
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. The Colusa County discussion is also applicable to portions of the Road Relocations and the entire length of the TRR Pipeline Road. The portions of the Road Relocations that would be constructed, operated, and maintained in Glenn County would result in a **significant impact**, as related to Glenn County's General Plan, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

Refer to the **Impact Land-3** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Road Relocations and TRR Pipeline Road.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

No Prime Farmland would be affected by construction, operation, or maintenance of the Road Relocations and TRR Pipeline Road because no Prime Farmland is located along those alignments. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Operation and maintenance of the Road Relocations and TRR Pipeline Road would conflict with the zoning of land in Glenn County that is currently zoned as Agricultural Preserve, and Agriculture Preserve in Colusa County. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, up to 52 parcels of land that have Williamson Act contracts would be affected during Project construction (a **less-than-significant impact**), and 48 parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance. This permanent long-term impact would result in a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Refer to the **Impact Land-6** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Road Relocations and TRR Pipeline Road (acreages applicable to Road Relocations and TRR Pipeline Road are provided in Table 20-3).

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Site visits to the area did not reveal forest land that would be affected by the Project. Therefore, there would be no permanent loss of forest, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Road Relocations and TRR Pipeline Road would change the existing environment of lands designated pursuant to the FMMP as Farmland of Local Importance, and Local Potential Farmland (acreages are presented in Table 20-3). This would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant

Table 20-4 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing and operating/maintaining the Alternative A Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant.

Table 20-4
Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
FMMP Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Farmland of Local Importance	0[c]	89
Total	**0**[c]	89
Number of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	0[c]	6
Total	**0**[c]	**6**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	0[c]	79
Total	**0**[c]	79
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]All construction disturbance area numbers for this Project facility grouping are zero because the construction disturbance area for this grouping would be within the Sites Reservoir construction disturbance area. It is noted that the actual construction disturbance area for this grouping would be 99 acres within the 1,000-acre construction disturbance area (90 acres plus 10 percent).

Notes:
FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant, as that discussion pertains to Colusa County.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The construction and operation/maintenance of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant would result in changes in the existing agricultural and open space land uses, as well as to the General Plan-designated land uses from Colusa County land use designations that promote agricultural land uses to public facility/industrial land uses. These expected changes in land use would be compatible with the existing surrounding land uses, resulting in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No

Action Alternative. The expected changes would result in a **significant impact**, as related to the designated land uses, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

No Prime Farmland in Colusa County would be affected by construction, operation, or maintenance of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant because these Project facilities would not be located on Prime Farmland. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Construction, operation, and maintenance of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant would conflict with the zoning of land in Colusa County that is currently zoned as Agriculture Preserve. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, no parcels of land that have Williamson Act contracts would be affected during Project construction (due to these facilities being constructed within the construction disturbance area of the Sites Reservoir Inundation Area and Sites Reservoir Dams), which would result in a **less-than-significant impact.** Six parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance. This permanent long-term impact would result in a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant would impact 89 acres designated Agriculture Preserve in Colusa County. This would result in a zoning conflict, and would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Site visits to the area did not reveal forest land. Therefore, there would be no permanent loss of forest, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, and Asphalt Batch Plant would change the existing environment of lands designated pursuant to the FMMP as Farmland of Local Importance (acreages are presented in Table 20-4). This would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard

Table 20-5 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard.

Table 20-5
Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]

Table 20-5
Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]All construction disturbance area numbers for this Project facility grouping are zero because the construction disturbance area for this grouping would be within the Delevan Pipeline/TRR Pipeline construction disturbance area. It is noted that the actual construction disturbance area for this grouping would be 383 acres within the pipeline construction disturbance area (348 acres plus 10 percent).

Notes:
FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard, as that discussion pertains to Colusa County.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The construction, operation, and maintenance of the Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard would result in changes in the existing agricultural and open space land uses (but not to the water land use of Funks Reservoir), as well as to the General Plan-designated land uses from Colusa County land use designations that promote agricultural land uses to public facility/industrial land uses. These expected changes in land use would be compatible with the existing surrounding land uses, resulting in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative. The expected changes would result in a **significant impact**, as related to the designated land uses, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Approximately 115 acres of Prime Farmland in Colusa County would be affected by operation and maintenance of the Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Construction, operation, and maintenance of the Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard would conflict with the zoning of land in

Colusa County that is currently zoned as Agriculture Preserve and Exclusive Agriculture. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, no parcels of land that have Williamson Act contracts would be affected during Project construction (due to these facilities being constructed within the construction disturbance area of the Delevan and TRR pipelines), which would result in a **less-than-significant impact.** Three parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance. This permanent long-term impact would result in a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard would impact 92 acres of land designated Agriculture Preserve and 256 acres of land designated Exclusive Agriculture in Colusa County. This would result in a zoning conflict, and would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Site visits to the area did not reveal forest land. Therefore, there would be no permanent loss of forest, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard would change the existing environment of lands designated pursuant to the FMMP as Prime Farmland and Farmland of Local Importance (acreages are presented in Table 20-5). This would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Table 20-6 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of construction, operation, and maintenance activities associated with modifications to the Alternative A GCID Canal Facilities.

Table 20-6
Glenn-Colusa Irrigation District Canal Facilities Modifications[c] – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels		
Glenn County	0[c]	3
Acreage of Potentially Affected Parcels		
Glenn County	0[c]	1
Zoning Designation of Potentially Affected Parcels (Acres)		
Glenn County

Total	**0**	**0**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Glenn County		
Total	**0**	**0**
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]Includes the canal headgate, canal lining, and railroad siphon.

[d]There is less than one acre in these categories, but more than zero.

Notes:
FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

The proposed modifications would occur at the existing GCID Canal (which is zoned as Canal or is unzoned). Such modifications would not conflict with Glenn County's focus on agricultural production, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The modifications to the existing GCID Canal Facilities (headgate structure, canal lining, and railroad siphon) would not result in changes in the existing public facility/industrial land use of the Canal Facilities. The existing Canal Facilities are located in an undesignated area that is surrounded by the Intensive Agriculture land use designation by Glenn County, so proposed modifications to those facilities (which would occur only within the Canal) would be compatible with the General Plan-designated land use. Therefore, the proposed GCID Canal Facilities Modifications would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Land in the southeast corner of the railroad siphon footprint is designated Prime Farmland in Glenn County. Because this is a proposed replacement of an existing railroad siphon and would be within the Canal, no conversion of lands would occur, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

The modifications to the existing GCID Canal Facilities (headgate structure, canal lining, and railroad siphon) would not result in changes in the existing public facility/industrial land use of the Canal Facilities. The existing Canal Facilities are located in an unzoned area that is surrounded by land currently zoned as Exclusive Agriculture by Glenn County, so proposed modifications to those facilities (which would occur only within the Canal) would be compatible with the County zoning. Therefore, the proposed GCID Canal Facilities Modifications would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

No parcels of land that have Williamson Act contracts would be affected during Project construction, which would result in **no impact.** In addition, no parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance; therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

Because the Canal is not zoned, the GCID Canal Facilities Modifications would result in no conflict with existing zoning. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

The GCID Canal is not considered forest land. Therefore, there would be no loss of forest land from the GCID Canal Facilities Modifications, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The railroad siphon footprint is FMMP-designated primarily Urban/Built-Up Land, with slivers of land designated Prime Farmland, Farmland of Statewide Importance, and Farmland of Local Importance. The Canal lining and headgate structure footprint is FMMP-designated Other Land. Because these modifications are to existing facilities and would be within the Canal, no conversion of lands would occur, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, and Terminal Regulating Reservoir Electrical Switchyard

Table 20-7 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing and operating/maintaining the Alternative A TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard.

Table 20-7
Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir to Funks Creek Pipeline, Terminal Regulating Reservoir to Funks Creek Outlet, and Terminal Regulating Reservoir Electrical Switchyard – Alternative A Land Use Summary

Table 20-7
Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir to Funks Creek Pipeline, Terminal Regulating Reservoir to Funks Creek Outlet, and Terminal Regulating Reservoir Electrical Switchyard – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	0[c]	0
Total	**0[c]**	**0**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	0[c]	0
Total	**0[c]**	**0**
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]All construction disturbance area numbers for this Project facility grouping are zero because the construction disturbance area for this grouping would be within the Delevan Pipeline/TRR Pipeline and TRR construction disturbance areas. It is noted that the actual construction disturbance area for this grouping would be 214 acres (195 acres plus 10 percent).

[d]There is less than one acre in this category, but more than zero.

Notes:

FMMP = Farmland Mapping and Monitoring Program
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard, as that discussion pertains to Colusa County.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The construction, operation, and maintenance of the TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard would result in changes in the existing agricultural and open space land uses, as well as to the General Plan-designated land uses from Colusa County land use designations that promote agricultural land uses to public facility/industrial land uses. These expected changes in land use would be compatible with the existing surrounding land uses, resulting in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative. The expected changes would result in a **significant impact**, as related to the designated land uses, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Approximately 194 acres of Prime Farmland in Colusa County would be affected by operation/maintenance of the TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Construction, operation, and maintenance of the TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard would conflict with the zoning of land in Colusa County that is currently zoned as Exclusive Agriculture. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

No parcels of land that have Williamson Act contracts would be affected during Project construction, which would result in **no impact.** In addition, no parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance; therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard would impact 194 acres designated as Exclusive Agriculture in Colusa County, which is not considered to be forest land. This would, therefore, result in no conflict, and would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

The lands that TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard would be located on do not have forest land, so no conversion of forest land to non-forest use would occur, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The TRR, TRR Pumping/Generating Plant, GCID Canal Connection to the TRR, and TRR Electrical Switchyard would change the existing environment of lands designated pursuant to the FMMP as Prime Farmland and Farmland of Local Importance (acreages are presented in Table 20-7). This would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline and Terminal Regulating Reservoir Pipeline

Table 20-8 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Delevan Pipeline and the TRR Pipeline.

Table 20-8
Delevan Pipeline and Terminal Regulating Reservoir Pipeline – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b, c]
Number of Potentially Affected Parcels		
Colusa County	64	0
Acreage of Potentially Affected Parcels		
Colusa County	2,058	0
Zoning Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Exclusive Agriculture	2,015	0
Light or Heavy Industrial	19	0
N/A	24	0
Total	**2,058**	**0**
FMMP Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Prime Farmland	957	0
Unique Farmland	1,001	0
Farmland of Local Importance	46	0
Other Land	54	0
Total	**2,058**	**0**
Number of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	11	0
Total	**11**	**0**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	425	0
Total	**425**	**0**
Number of Potentially Affected Parcels with WRP Easements	**1**	**0**
Number of Potentially Affected Acres with WRP Easements	**5**[d]	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]All permanent impact numbers for this Project facility grouping are zero because these are underground facilities.

[d]The actual WRP easement that would be affected during Project construction is 4.6 acres.

Notes:
FMMP = Farmland Mapping and Monitoring Program
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Delevan Pipeline and TRR Pipeline, as that discussion pertains to the Farmland Protection Policy Act and Colusa County's General Plan. The Delevan Pipeline and TRR Pipeline would not be located within Glenn County, so that County's General Plan is not applicable to this Project facility.

The Delevan Pipeline would cross one parcel that has a WRP easement. During the Project construction period, 4.6 acres of WRP easement land would be affected, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance of the Delevan Pipeline would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative because the periodically spaced blowoff valves and similar valves along the pipeline would be installed to avoid on-site wetlands.

Construction, operation, and maintenance of the TRR Pipeline would not affect any parcels that have a WRP easement, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The Delevan Pipeline and TRR Pipeline would result in changes in the existing agricultural and open space land uses during only the Project construction period, resulting in a **significant impact** during that time, when compared to Existing Conditions and the No Project/No Action Alternative. Other than providing access to periodically spaced blowoff valves and similar valves along the pipelines, the pipelines would be underground facilities that would not result in permanent impacts to the existing land uses (i.e., the pipelines would be compatible with existing land uses) during the Project operation and maintenance period, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, construction of the pipelines would be incompatible with the Colusa County General Plan-designated land uses, resulting in a **significant impact** during the Project construction period, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance of the pipelines would be compatible with the General Plan-designated land uses, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Prime Farmland exists along the proposed pipeline alignments. However, no Prime Farmland would be permanently affected by operation or maintenance of the pipelines because they would be installed underground, thus allowing existing land uses to continue after Project construction is complete. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

There would be no permanent conflicts with existing agricultural zoning or Williamson Act contracts from pipeline operation and maintenance because they would be installed underground. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

There would be no permanent conflicts with existing forest land zoning from pipeline operation and maintenance because they would be installed underground. In addition, the land that the pipelines would cross is not zoned for forest land. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

There would be no permanent loss of forest land from the pipelines' operation and maintenance because they would be installed underground. In addition, the land that the pipelines would cross is not zoned for forest land, indicating that forest land does not exist along the pipelines' alignment. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Delevan Pipeline and TRR Pipeline would only temporarily change the existing environment of lands designated pursuant to the FMMP as Prime Farmland, Unique Farmland, and Farmland of Local Importance (acreages are presented in Table 20-8) during Project construction. Because the pipelines would be installed underground, no permanent conversion of farmland or forest land is expected, except where periodically spaced blowoff valves and similar valves would be installed, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

The Alternative A Delevan Transmission Line would parallel, and be completely within the construction disturbance area of, the proposed Delevan Pipeline, with the exception of the westernmost 3.5 miles. Because the impacts of the eastern approximately nine miles of the proposed transmission line route construction disturbance area are already accounted for in the impact assessment for the Delevan Pipeline, only the remaining 3.5 miles of the transmission line are evaluated here. Table 20-9 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Delevan Transmission Line.

Table 20-9
Delevan Transmission Line – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels		
Colusa County	12	39[c]
Acreage of Potentially Affected Parcels		
Colusa County	71	3[c]
Zoning Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Agriculture Preserve	31	
Exclusive Agriculture	40	
Total	**71**	**3[c]**
FMMP Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Prime Farmland	2	
Farmland of Local Importance	70	
Total	**71**	**3[c]**
Number of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	7	11[c]
Total	**7**	**11[c]**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	54	3[c]
Total	**54**	**3[c]**
Number of Potentially Affected Parcels with WRP Easements	**1**	**0**
Number of Potentially Affected Acres with WRP Easements	**2[d]**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]Because the placement of the transmission line towers is currently not known, each parcel along the alignment would be potentially affected, resulting in 2.5 acres actual permanent disturbance.

[d]The actual WRP easement that would be affected during Project construction is 2.3 acres.

Notes:

FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Delevan Transmission Line, as that discussion pertains to the Farmland Protection Policy Act and Colusa County's General Plan. The transmission line would not be located within Glenn County, so that County's General Plan is not applicable to this Project facility.

The Delevan Transmission Line would cross one parcel that has a WRP easement. During the Project construction period, 2.3 acres of WRP easement land would be affected, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance of the Delevan Transmission Line would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative because the transmission line towers would be installed so they span the parcel, and access to the towers for maintenance would be infrequent and would be routed to avoid on-site wetlands.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The Delevan Transmission Line would result in changes in the existing agricultural and open space land uses during only the Project construction period, resulting in a **significant impact** during that time, when compared to Existing Conditions and the No Project/No Action Alternative. Other than providing access to periodically spaced transmission line towers along the alignment, the transmission line would not result in permanent impacts to the existing land uses (i.e., it would be compatible with existing land uses) during the Project operation and maintenance period, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, construction of the transmission line would be incompatible with the Colusa County General Plan-designated land uses, resulting in a **significant impact** during the Project construction period, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance of the transmission line would be compatible with the General Plan-designated land uses, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Prime Farmland exists along the proposed transmission line alignment. However, due to the few acres of Prime Farmland (i.e., less than two acres) that would be affected by Project construction, and the fact that the transmission line tower footings would impact a total of 2.5 acres of land along the entire transmission line alignment, it may be possible to construct the transmission line tower footings on land that is not designated as Prime Farmland. After Project construction is complete, existing land uses could continue. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Minimal permanent conflicts are expected with existing agricultural zoning (resulting in a **less-than-significant impact** relative to zoning) or Williamson Act contracts from transmission line operation and maintenance because the transmission line tower footings would permanently impact a total of 2.5 acres of land along the entire transmission line alignment, and could permanently affect 11 parcels of land that have Williamson Act contracts. Due to the potential conflicts, this is considered a **significant impact** relative to Williamson Act contracts, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The Delevan Transmission Line would impact 31 acres of land designated Agriculture Preserve in Colusa County. This would result in a zoning conflict, and would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-6** discussion. The land is, therefore, zoned for forest land. However, site visits to the area did not reveal forest land. Therefore, there would be no permanent loss of forest, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Delevan Transmission Line would temporarily change the existing environment of lands designated pursuant to the FMMP as Prime Farmland, Unique Farmland, and Farmland of Local Importance (acreages are presented in Table 20-9). This would occur during the Project construction period, and would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Table 20-10 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Delevan Pipeline Intake Facilities.

Table 20-10
Delevan Pipeline Intake Facilities – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels		
Colusa County	0[c]	2
Acreage of Potentially Affected Parcels		
Colusa County	0[c]	19
Zoning Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Exclusive Agriculture	0[c]	15
Floodway	0[c]	4
Total	**0[c]**	**19**
FMMP Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Prime Farmland	0[c]	13
Other Land	0[c]	6
Total	**0[c]**	**19**

Table 20-10
Delevan Pipeline Intake Facilities – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	0	0
Total	**0**	**0**
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	0	0
Total	**0**	**0**
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]All construction disturbance area numbers for this Project facility grouping are zero because the construction disturbance area for this grouping would be within the adjacent Delevan Pipeline construction disturbance area. It is noted that the actual construction disturbance area for this grouping would be 17.1 acres within the pipeline construction disturbance area (it would be smaller than the permanent facility footprint because of an overlap between the Delevan Pipeline construction disturbance area and Delevan Pipeline Intake Facilities permanent facility footprint).

Notes:
FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Delevan Pipeline Intake Facilities, as that discussion pertains to Colusa County.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The Delevan Pipeline Intake Facilities would result in changes in the existing agricultural and floodway land uses during Project construction, operation, and maintenance periods, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, the current design, construction activities, and location of the proposed Delevan Pipeline Intake Facilities would potentially conflict with the operation of the existing Maxwell Irrigation District facilities located adjacent on the upstream side of the proposed facilities. This would result in a **potentially significant impact** on that land use, when compared to Existing Conditions and the No Project/No Action Alternative.

The Delevan Pipeline Intake Facilities would be incompatible with the Colusa County General Plan-designated land uses, resulting in a **significant impact** during the Project construction, operation, and maintenance periods, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Approximately 13 acres of Prime Farmland in Colusa County would be affected by operation and maintenance of the Delevan Pipeline Intake Facilities, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would conflict with the zoning of land in Colusa County that is currently zoned as Exclusive Agriculture. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

No parcels of land that have Williamson Act contracts would be affected during Project construction, which would result in **no impact.** In addition, no parcels of land that have Williamson Act contracts would be affected during Project operation and maintenance; therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The Delevan Pipeline Intake Facilities would impact 15 acres designated Exclusive Agriculture in Colusa County (which is not considered to be forest land). This would, therefore, result in no conflict, and would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

The lands that the Delevan Pipeline Intake Facilities would be located on do not have forest land, so no conversion of forest land to non-forest use would occur, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Delevan Pipeline Intake Facilities would permanently change the existing environment of approximately 13 acres of land designated pursuant to the FMMP as Prime Farmland. This would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Electrical Distribution Lines

Table 20-11 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative A Electrical Distribution Lines.

Table 20-11
Electrical Distribution Lines – Alternative A
Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels		
Colusa County	16	16[d]
Acreage of Potentially Affected Parcels		
Colusa County	27	0[c]
Zoning Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Agriculture Preserve	27	
Total	**27**	**0**[c]
FMMP Designation of Potentially Affected Parcels (Acres)		
Colusa County		
Farmland of Local Importance	26	
Other Land	0[c]	
Total	**27**	**0**[c]
Number of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	16	16[d]
Total	**16**	**16**[d]
Acreage of Potentially Affected Parcels with Williamson Act Contracts		
Colusa County	27	0[c]
Total	**27**	**0**[c]
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]There is less than one acre in this category, but more than zero.

[d]Because the placement of the electrical distribution lines is currently not known, each parcel along the alignment would be potentially affected.

Notes:

FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Electrical Distribution Lines, as that discussion pertains to Colusa County.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The Electrical Distribution Lines would result in changes in the existing agricultural and open space land uses during only the Project construction period, resulting in a **significant impact** during that time, when compared to Existing Conditions and the No Project/No Action Alternative. Other than providing access to the distribution line poles along the alignments, the distribution lines would not result in permanent impacts to the existing land uses (i.e., it would be compatible with existing land uses) during the Project operation and maintenance period, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, construction of the distribution lines would be incompatible with the Colusa County General Plan-designated land uses, resulting in a **significant impact** during the Project construction period, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance of the distribution lines would be compatible with the General Plan-designated land uses, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

Prime Farmland does not exist along the proposed distribution line alignments. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

Minimal permanent conflicts are expected with existing agricultural zoning (resulting in a **less-than-significant impact relative to zoning**) or Williamson Act contracts from distribution line operation and maintenance because the distribution line poles would require a very small amount of land along the entire distribution line alignments, permanently affecting up to 16 parcels of land that have Williamson Act contracts. Due to the potential conflicts, this is considered a **significant impact relative to Williamson Act contracts**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The Electrical Distribution Lines would have no permanent impact on land designated Agriculture Preserve in Colusa County, except at the individual pole locations, which would comprise a very small amount of land. This would result in minimal zoning conflict, and would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

The alignments of the Electrical Distribution Lines do not have forest land, so no conversion of forest land to non-forest use would occur, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Electrical Distribution Lines would not permanently change the existing environment of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local

Potential Farmland to another land use, except at the individual pole locations, which would comprise a very small amount of land. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Table 20-12 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing and maintaining the Alternative A Project Buffer.

Table 20-12
Project Buffer – Alternative A
Land Use Summary

Descriptor	Temporary Impacts	Permanent Impacts*

Table 20-12
Project Buffer – Alternative A
Land Use Summary

Descriptor	Temporary Impacts	Permanent Impacts*
Number of Potentially Affected Parcels with WRP Easements	0	0
Number of Potentially Affected Acres with WRP Easements	0	0

*All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

Notes:
FMMP = Farmland Mapping and Monitoring Program
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
WRP = Wetland Reserve Program

Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect

Refer to the **Impact Land-2** discussion for the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge. That discussion is also applicable to the Project Buffer because the Project Buffer would be located in both Glenn and Colusa counties.

Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and General Plan Designated Land Uses at and Adjacent to the Proposed Project Facilities

The Project Buffer would serve to buffer the Project facilities and activities from adjacent and surrounding land uses. The boundary of the Project Buffer would be fenced, using fencing materials that are similar to what is currently used in Glenn and Colusa counties for ranches. The lands within the Project Buffer would be managed as open space, which would be compatible with the existing and General Plan land uses that are adjacent to the Project facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Resources Agency, to Non-Agricultural Use

The Project Buffer would include 284 acres of Prime Farmland and 7 acres of Unique Farmland. It would be managed as open space. The land is zoned for agricultural purposes, but may be used for grazing or open space, in addition to being actively cropped. The change from an actively cropped agricultural land use to grazing or open space would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the Permanent Conversion of Lands that have a Williamson Act Contract

The Project Buffer would conflict with the zoning of land in Glenn County that is currently zoned as Agricultural Preserve and Foothill Agriculture/Forestry; and Agriculture Preserve, Exclusive Agriculture, Foothill Agriculture/Forestry, and Floodway in Colusa County. The permanent conflict from Project operation and maintenance would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, 81 parcels of land that have Williamson Act contracts would be permanently affected by the Project Buffer, which would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land (as Defined in Public Resources Code Section 12220(g)), Timberland (as Defined by Public Resources Code Section 4526), or Timberland Zoned Timberland Production (as Defined by Government Code Section 51104(g))

The Project Buffer encompasses lands in both Glenn and Colusa counties that are zoned for forest land and/or timberland; specifically, lands zoned as Foothill Agricultural/Forestry and Agricultural Preserve in Glenn County, and Foothill Agricultural/Forestry and Agriculture Preserve in Colusa County. This would result in a zoning conflict, and would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use

Refer to the **Impact Land-6** discussion. Due to the land being zoned for forest land and/or timberland, this is considered a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Land-8: Other Changes in the Existing Environment Which, due to Their Location or Nature, Could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or Permanent Conversion of Forest Land to Non-Forest Use

The Project Buffer Line would permanently change the existing environment of lands designated pursuant to the FMMP as Prime Farmland, Unique Farmland, Farmland of Local Importance, and Local Potential Farmland (acreages are presented in Table 20-12). The Project Buffer would also change the existing environment of lands zoned as Foothill Agriculture/Forestry. These changes would result in a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

20.3.6.4 Summary of Alternative A Land Use Impacts

Table 20-13 provides a summary of the number of potentially affected parcels, the acreage of those parcels, the zoning designations, the number of parcels and acreage of parcels with Williamson Act contracts, and the number of parcels and acreage of parcels with WRP easements for Alternative A.

Table 20-13
Summary of Land Use Impacts – Alternative A

Table 20-13
Summary of Land Use Impacts – Alternative A

	No. of Potentially Affected Parcels		Acreage of Potentially Affected Parcels		Zoning Designation of Potentially Affected Acreages			No. of Potentially Affected Parcels with Williamson Act Contracts		No. of Potentially Affected Acres with Williamson Act Contracts		No. of Potentially Affected Parcels with WRP Easements		No. of Potentially Affected Acres with WRP Easements	
Project Facility	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Desig.	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]There is one parcel total with a WRP easement that would be affected.

[d]The subtotals by designations of acreages of temporary impacts cannot be determined because it is unknown which parcels would comprise the complete construction disturbance area.

[e]The numbers for parcels and acreages of temporary impacts for this Project facility grouping are zero because they are within and already accounted for under the numbers for parcels and acreages of temporary impacts for another Project facility grouping.

[f]The parcel totals are the count of distinct parcels across all Project facility groupings considered in the analysis (i.e. the total count does not represent the sum of column, as one parcel could be affected by several facilities). Therefore, these totals assume the worst case impact.

Notes:

Desig. = Designation
Perm. = Permanent
Temp. = Temporary
WRP = Wetland Reserve Program

Zoning Designations:

AP1 = Agricultural Preserve (Glenn County)
AP2 = Agriculture Preserve (Colusa County)
DU = Designation Undetermined
EA = Exclusive Agriculture
F = Floodway
FA-F = Foothill Agricultural/Forestry
IA = Intensive Agriculture
LHI = Light or Heavy Industrial
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
NL = No Information Available

Table 20-14 provides a summary of impacts to FMMP-designated land for Alternative A.

Table 20-14

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed in this table or Table 20-13.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed in this table or Table 20-13.

[c]For the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge Project facilities grouping, a total of 13,464 acres would be temporarily affected during Project construction. The acreage cannot be assigned to a specific FMMP category because the 1,000 acres of construction disturbance area that would be located outside of the Sites Reservoir footprint have not been defined.

[d]There is less than one acre in these categories, but more than zero.

[e]The numbers for parcels and acreages of temporary impacts for this Project facility grouping are zero because they are within and already accounted for under the numbers for parcels and acreages of temporary impacts for another Project facility grouping.

[f]A total of 2.5 acres would be permanently disturbed from transmission line poles, but due to pole locations being currently unknown, the affected FMMP category cannot currently be determined. Therefore, 2.5 acres of land more than the total listed in Long-Term Impacts would be permanently affected.

Notes:
FMMP = Farmland Mapping and Monitoring Program

FMMP Designations:

D = Urban and Built-up Land
DU = Designation Undetermined
G = Grazing Land
L = Farmland of Local Importance
LP = Local Potential Farmland
P = Prime Farmland
S = Farmland of Statewide Importance
U = Unique Farmland
W = Water
X = Other Land

20.3.7 Impacts Associated with Alternative B

20.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to established communities (**Impact Land-1**); potential conflicts with land use plans, policies or regulations (**Impact Land-2**); compatibility with existing land uses adjacent to proposed Project facilities (**Impact Land-3**); effects on FMMP designated land uses (**Impact Land-4**); consistency with existing zoning, or effects on parcels that have Williamson Act contracts (**Impact Land-5**); consistency with forest land zoning (**Impact Land-6**) or effects on forest land (**Impact Land-7**); and other changes in the environment that could convert farmland or forest land to other uses (**Impact Land-8**); would be the same as described for Alternative A for the Extended Study Area.

20.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to established communities (**Impact Land-1**); potential conflicts with land use plans, policies or regulations (**Impact Land-2**); compatibility with existing land uses adjacent to proposed Project facilities (**Impact Land-3**); effects on FMMP designated land uses (**Impact Land-4**); consistency with existing zoning, or effects on parcels that have Williamson Act contracts (**Impact Land-5**); consistency with forest land zoning (**Impact Land-6**) or effects on forest land (**Impact Land-7**); and other changes in the environment that could convert farmland or forest land to other uses (**Impact Land-8**); would be the same as described for Alternative A for the Secondary Study Area.

20.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to land use:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road

- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprint or construction disturbance area of Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge; the Road Relocations and TRR Pipeline Road; the Delevan Transmission Line; and the Electrical Distribution Lines would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility. The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities would differ between the alternatives, the acreage of land within the Project Buffer would also differ. The acreage summaries of the potential temporary and permanent land use changes associated with Alternative B are presented in Tables 20-15 through 20-20.

These differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on established communities (**Impact Land-1**); its potential conflicts with land use plans, policies or regulations (**Impact Land-2**); its compatibility with existing land uses adjacent to proposed Project facilities (**Impact Land-3**); its effects on FMMP designated land uses (**Impact Land-4**); its consistency with existing zoning, or effects on parcels that have Williamson Act contracts (**Impact Land-5);** its consistency with forest land zoning (**Impact Land-6**) or effects on forest land (**Impact Land-7**); and other changes in the environment that could convert farmland or forest land to other uses (**Impact Land-8**) as described for Alternative A.

Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge

Table 20-15 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing and maintaining the Alternative B Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge.

Table 20-15

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]Undetermined values represent construction disturbance areas for which locations have not been determined. Reported undetermined values are the maximum number of additional parcels or acreages that would be temporarily affected.

[d]The temporarily affected acreages by zoning and FMMP designations and Williamson Act contracts cannot be determined because it is unknown which parcels would comprise the 1,000-acre construction disturbance area.

Notes:
FMMP = Farmland Mapping and Monitoring Program
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)
WRP = Wetland Reserve Program

Road Relocations and Terminal Regulating Reservoir Pipeline Road

Table 20-16 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative B Road Relocations and TRR Pipeline Road.

Table 20-16
Road Relocations and Terminal Regulating Reservoir Pipeline Road – Alternative B
Land Use Summary

Descriptor	Temporary Impacts[a,c]	Permanent Impacts[b]

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]There is less than one acre in these categories, but more than zero.

[d]Differences between temporary and long-term acreages for these categories are due to the TRR Pipeline Road being located within the Delevan and TRR Pipeline disturbance area, thus having no construction disturbance area of its own. This also applies to the differences in the number of parcels affected.

Notes:
FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Delevan Transmission Line

Table 20-17 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of constructing, operating, and maintaining the Alternative B Delevan Transmission Line.

Table 20-17

Land Use Summary

Descriptor	Temporary Impacts[a]	Permanent Impacts[b]
Number of Potentially Affected Parcels with WRP Easements	**0**	**0**
Number of Potentially Affected Acres with WRP Easements	**0**	**0**

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]All construction disturbance area numbers for this Project facility grouping are zero because the construction disturbance area for this grouping would be within the adjacent Delevan Pipeline construction disturbance area. It is noted that the actual construction disturbance area for this grouping would be 6.3 acres within the pipeline construction disturbance area (it would be smaller than the permanent facility footprint because of an overlap between the Delevan Pipeline construction disturbance area and Delevan Pipeline Intake Facilities permanent facility footprint).

Notes:

FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

Electrical Distribution Lines

Table 20-21
Summary of Land Use Impacts – Alternative B

Project Facility	No. of Potentially Affected Parcels		Acreage of Potentially Affected Parcels		Zoning Designation of Potentially Affected Acreages			No. of Potentially Affected Parcels with Williamson Act Contracts		No. of Potentially Affected Acres with Williamson Act Contracts		No. of Potentially Affected Parcels with WRP Easements		No. of Potentially Affected Acres with WRP Easements	
	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Desig.	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]	Temp.[a]	Perm.[b]

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed.

[c]There is one parcel total with a WRP easement that would be affected.

[d]The subtotals by designations of acreages of temporary impacts cannot be determined because it is unknown which parcels would comprise the complete construction disturbance area.

[e]The numbers for parcels and acreages of temporary impacts for this Project facility grouping are zero because they are within and already accounted for under the numbers for parcels and acreages of temporary impacts for another Project facility grouping.

[f]The parcel totals are the count of distinct parcels across all Project facility groupings considered in the analysis (i.e. the total count does not represent the sum of column, as one parcel could be affected by several facilities). Therefore, these totals assume the worst case impact.

[g]The Delevan Pipeline and TRR Pipeline facility grouping is the same for all three alternatives. The acreages of temporary impacts are slightly different due differences in the boundaries associated with other Project facility groupings and the method applied to reduce the double counting of acreages.

Notes:

Desig. = Designation
Perm. = Permanent
Temp. = Temporary
WRP = Wetland Reserve Program

Zoning Designations:

AP1 = Agricultural Preserve (Glenn County)
AP2 = Agriculture Preserve (Colusa County)
DU = Designation Undetermined
EA = Exclusive Agriculture
F = Floodway
FA-F = Foothill Agricultural/Forestry
IA = Intensive Agriculture
LHI = Light or Heavy Industrial
NL = No Information Available
N/A = There is no County zoning designation (e.g., the area is located in a roadway corridor that is not officially zoned by the County)

Table 20-22 provides a summary of impacts to FMMP-designated land for Alternative B.

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed in this table or Table 20-21.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed in this table or Table 20-21.

[c]For the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge Project facilities grouping, a total of 15,414 acres would be temporarily affected during Project construction. The acreage cannot be assigned to a specific FMMP category because the 1,000 acres of construction disturbance area that would be located outside of the Sites Reservoir footprint have not been defined.

[d]There is less than one acre in these categories, but more than zero.

[e]The numbers for parcels and acreages of temporary impacts for this Project facility grouping are zero because they are within and already accounted for under the numbers for parcels and acreages of temporary impacts for another Project facility grouping.

[f]A total of 0.5 acre would be permanently disturbed from transmission line poles, but due to pole locations being currently unknown, the affected FMMP category cannot currently be determined. Therefore, 0.5 acre of land more than the total listed in Long-Term Impacts would be permanently affected.

Notes:
FMMP = Farmland Mapping and Monitoring Program

FMMP Designations:

D = Urban and Built-up Land
DU = Designation Undetermined
G = Grazing Land
L = Farmland of Local Importance
LP = Local Potential Farmland
P = Prime Farmland
S = Farmland of Statewide Importance
U = Unique Farmland
W = Water
X = Other Land

Table 20-23 provides a summary comparison of land use impacts for Alternative B and Alternative A.

Table 20-23
Land Use Summary: Alternative B Compared to Alternative A[a]

Descriptor	Alternative B		Alternative A	
	Temporary Impacts	Permanent Impacts	Temporary Impacts	Permanent Impacts

Water	0	3	0	3
Other Land	124	286	124	287
Designation Undetermined	15,414	1[b]	13,464	3[b]
Total	**19,637**	**26,424**	**17,680**	**26,425**
Number of Potentially Affected Parcels with Williamson Act Contracts	135	113	133	113
Acreage of Potentially Affected Parcels with Williamson Act Contracts	16,126	22,687	14,362	22,688
Number of Potentially Affected Parcels with WRP Easements	1	0	1	0
Number of Potentially Affected Acres with WRP Easements	5	0	7	0

[a]Totals may not match due to the rounding of individual acreages that comprise the totals.

[b]A total of 2.5 acres under Alternative A and 0.5 acres under Alternative B would be permanently disturbed from transmission line poles, but due to pole locations being currently unknown, the affected FMMP category cannot currently be determined. Therefore, 2.5 acres under Alternative A and 0.5 acres under Alternative B of land more than the total listed in Long-Term Impacts would be permanently affected.

[C]There is less than one acre in these categories, but more than zero.

Notes:

FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

20.3.8 Impacts Associated with Alternative C

20.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to established communities (**Impact Land-1**); potential conflicts with land use plans, policies or regulations (**Impact Land-2**); compatibility with existing land uses adjacent to proposed Project facilities (**Impact Land-3**); effects on FMMP designated land uses (**Impact Land-4**); consistency with existing zoning, or effects on parcels that have Williamson Act contracts (**Impact Land 5);** consistency with forest land zoning (**Impact Land-6**) or effects on forest land (**Impact Land-7**); and other changes in the environment that could convert farmland or forest land to other uses (**Impact Land-8**); would be the same as described for Alternative A for the Extended Study Area.

20.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to established communities (**Impact Land-1**); potential conflicts with land use plans, policies or regulations (**Impact Land-2**); compatibility with existing land uses adjacent to proposed Project facilities (**Impact Land-3**); effects on FMMP designated land uses (**Impact Land-4**); consistency with existing zoning, or effects on parcels that have Williamson Act contracts (**Impact Land-5**); consistency with forest land zoning (**Impact Land-6**) or effects on forest land (**Impact Land-7**); and other changes in the environment that could convert farmland or forest land to other uses (**Impact Land-8**); would be the same as described for Alternative A for the Secondary Study Area.

20.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to land use:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road

- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to land use as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge; the Road Relocations and TRR Pipeline Road; and the Electrical Distribution Lines is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to land use as described for Alternative B.

Provided below in Table 20-24 is a summary of the potential temporary and permanent land use changes that are expected to occur as a result of the Project Buffer. The boundary of the Project Buffer would be the same for all alternatives, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on established communities (**Impact Land-1**); potential conflicts with land use plans, policies or regulations (**Impact Land-2**); compatibility with existing land uses adjacent to proposed Project facilities (**Impact Land-3**); effects on FMMP designated land uses (**Impact Land-4**); consistency with existing zoning, or effects on parcels that have Williamson Act contracts (**Impact Land-5);** consistency with forest land zoning (**Impact Land-6**) or effects on forest land (**Impact Land-7**); and other changes in the environment that could convert farmland or forest land to other uses (**Impact Land-8**) as described for Alternative A.

Project Buffer

Table 20-24 provides a summary of the potential temporary and permanent land use changes that are expected to occur as a result of the Alternative C Project Buffer.

Table 20-24

Table 20-26
Summary of Impacts to FMMP-Designated Land – Alternative C

Project Facility	Acreage																		
	Temporary Impact to FMMP-Designated Land[a]									Permanent Impact to FMMP-Designated Land[b]									
	D	G	L	LP	P	S	U	X	DU	D	G	L	LP	P	S	U	W	X	DU

[a]Acreage of temporary impacts consist of the Project facility footprints plus the associated construction disturbance area. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed in this table or Table 20-25.

[b]Acreage of permanent impacts consist of the Project facility footprints. All numbers have been rounded to the acre. Due to rounding of all acreages listed in this table, individual acreages may not add up to the total acreages listed in this table or Table 20-25.

[c]For the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge Project facilities grouping, a total of 15,414 acres would be temporarily affected during Project construction. The acreage cannot be assigned to a specific FMMP category because the 1,000 acres of construction disturbance area that would be located outside of the Sites Reservoir footprint have not been defined.

[d]There is less than one acre in these categories, but more than zero.

[e]The numbers for parcels and acreages of temporary impacts for this Project facility grouping are zero because they are within and already accounted for under the numbers for parcels and acreages of temporary impacts for another Project facility grouping.

[f]A total of 2.5 acre would be permanently disturbed from transmission line poles, but due to pole locations being currently unknown, the affected FMMP category cannot currently be determined. Therefore, 2.5 acre of land more than the total listed in Long-Term Impacts would be permanently affected.

Notes:
FMMP = Farmland Mapping and Monitoring Program

FMMP Designations:
D = Urban and Built-up Land
G = Grazing Land
L = Farmland of Local Importance
LP = Local Potential Farmland
P = Prime Farmland
S = Farmland of Statewide Importance
U = Unique Farmland
W = Water
X = Other Land
DU = Designation Undetermined

Table 20-27 provides a summary comparison of land use impacts for Alternative C and Alternative A.

Table 20-27
Land Use Summary: Alternative C Compared to Alternative A[a]

Descriptor	Alternative C		Alternative A	
	Temporary Impacts	Permanent Impacts	Temporary Impacts	Permanent Impacts
Number of Potentially Affected Parcels	278	209	274	209
Acreage of Potentially Affected Parcels	19,636	26,425	17,680	26,425
Zoning Designation of Potentially Affected Parcels (Acres)				
Agricultural Preserve	2,100	24,753	2,095	24,752
Exclusive Agriculture	2,055	1,030	2,055	1,030
Foothill Agriculture/Forestry	0	450	0	450
Floodway	0	14	0	14
Intensive Agriculture	0	0	0	0
Light or Heavy Industrial	19	0	19	0
N/A	43	174	42	175
No Information Available	0	1	0	1
Designation Undetermined	15,419	3	13,469	3
Total	**19,636**	**26,425**	**17,680**	**26,425**
FMMP Designation of Potentially Affected Parcels (Acres)				
Urban and Built-up Land	1	0[c]	1	0
Grazing Land	369	2,601	360	2,594
Farmland of Local Importance	1,624	21,514[b]	1,622	21,515[b]
Local Potential Farmland	144	1,414	148	1,410
Prime Farmland	960	606[b]	960	606[b]
Farmland of Statewide Importance	0[c]	0[c]	0[c]	0[c]
Unique Farmland	1,001	7	1,001	7
Water	0	3	0	3
Other Land	123	287	124	287
Designation Undetermined	15,414	3[b]	13,464	3[b]
Total	**19,636**	**26,425**	**17,680**	**26,425**
Number of Potentially Affected Parcels with Williamson Act Contracts	136	113	133	113
Acreage of Potentially Affected Parcels with Williamson Act Contracts	16,126	22,689	14,362	22,688
Number of Potentially Affected Parcels with WRP Easements	1	0	1	0
Number of Potentially Affected Acres with WRP Easements	7	0	7	0

[a]Totals may not match due to the rounding of individual acreages that comprise the totals.

[b]A total of 2.5 acres would under Alternative A and C would be permanently disturbed from transmission line poles, but due to pole locations being currently unknown, the affected FMMP category cannot currently be determined. Therefore, 2.5 acres under Alternative A and C of land more than the total listed in Long-Term Impacts would be permanently affected.

[C]There is less than one acre in these categories, but more than zero.

Notes:

FMMP = Farmland Mapping and Monitoring Program
WRP = Wetland Reserve Program

20.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 20-28 for the impacts that have been identified as significant or potentially significant.

Table 20-28
Summary of Mitigation Measures for NODOS Project Impacts to Land Use

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Land-1: Physical Division of an Established Community	Sites Reservoir Inundation Area and Sites Reservoir Dams (construction, operation, and maintenance effects on the Town of Sites)	Significant	No feasible mitigation	Significant and Unavoidable
Impact Land-2: Conflict with an Applicable Land Use Plan, Policy, or Regulation of an Agency with Jurisdiction over the Project Adopted for the Purpose of Avoiding or Mitigating an Environmental Effect	Sites Reservoir Inundation Area and Sites Reservoir Dams, Saddle Dam Recreation Area, Road Relocations, Project Buffer (construction, operation, and maintenance)	Significant in Glenn County	Mitigation Measure Land-2a: To the Extent Possible, Work with Glenn County to Encourage the County to Modify or Amend the Glenn County General Plan to Bring it into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable
	Delevan Transmission Line, Delevan Pipeline (construction, operation, and maintenance)	Significant	Mitigation Measure Land-2b: Execute an Agreement with NRCS to Amend WRP Easement Contract and Conduct Post-Construction Wetland Restoration	Less than Significant
Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the **<u>Existing</u>** and General Plan Designated **<u>Land Uses</u>** at and Adjacent to Proposed Project Facilities	Delevan Pipeline, TRR Pipeline, Delevan Transmission Line, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility, Electrical Distribution Lines (construction)	Significant	Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant
	Sites Reservoir Inundation Area and Sites Reservoir Dams (construction effects on Sites Cemetery and the Rancheria Cemetery)	Significant	Mitigation Measure Cul-4a: Relocation of Known Cemeteries	Less than Significant
	Sites Reservoir Inundation Area (construction, operation, and maintenance effects on the Town of Sites)	Significant	Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable

Table 20-28
Summary of Mitigation Measures for NODOS Project Impacts to Land Use

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
	Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure Land-3b: Execute an Agreement with Maxwell Irrigation District to Minimize and Avoid Short-Term and Long-Term Impacts to Existing Facilities and Operations	Less than Significant
Impact Land-3: Changes in Land Use as a Result of Implementing the Alternatives that are Considered to be Incompatible with the Existing and **General Plan Designated Land Uses** at and Adjacent to Proposed Project Facilities	Sites Reservoir Inundation Area and Sites Reservoir Dams; Recreation Areas; Road Relocations; South Bridge, and TRR Pipeline Road; Sites Pumping/Generating Plant; Sites Electrical Switchyard; Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure; Sites Reservoir Inlet/Outlet Structure; Field Office Maintenance Yard; Asphalt Batch Plant; Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard; Delevan Pipeline Electrical Switchyard; TRR; TRR Pumping/Generating Plant; GCID Canal Connection to the TRR; TRR Electrical Switchyard; Delevan Pipeline Intake Facilities; Delevan Pipeline Discharge Facility (construction, operation, and maintenance)	Significant	Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable
	Delevan Pipeline and TRR Pipeline, Delevan Transmission Line, Electrical Distribution Lines (construction)	Significant	Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with Proposed Project Land Uses	Less than Significant or Significant and Unavoidable
Impact Land-4: Permanent Conversion of Prime Farmland, as Shown on the Maps Prepared Pursuant to the FMMP of the California Natural Resources Agency, Department of Conservation, to Non-Agricultural Use	Road Relocations, South Bridge, and TRR Pipeline Road (Colusa County); Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard; Delevan Pipeline Electrical Switchyard; TRR; TRR Pumping/Generating Plant; GCID Canal Connection to the TRR; TRR Electrical Switchyard; Delevan Pipeline Intake Facilities; Delevan Pipeline Discharge Facility (operation and maintenance)	Significant	Mitigation Measure Land-4a: Enter into Agricultural Conservation Easements with Glenn and Colusa Counties	Less than Significant

Table 20-28
Summary of Mitigation Measures for NODOS Project Impacts to Land Use

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Land-5: **Permanent Conflict with Existing Zoning for Agricultural Use**, and/or the Permanent Conversion of Lands that have a Williamson Act Contract	Sites Reservoir Inundation Area and Sites Reservoir Dams; Recreation Areas; Road Relocations, South Bridge, and TRR Pipeline Road; Sites Pumping/Generating Plant; Sites Electrical Switchyard; Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure; Sites Reservoir Inlet/Outlet Structure; Field Office Maintenance Yard; Asphalt Batch Plant; Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard; Delevan Pipeline Electrical Switchyard; TRR; TRR Pumping/Generating Plant; GCID Canal Connection to the TRR; TRR Electrical Switchyard; Delevan Pipeline Intake Facilities; Delevan Pipeline Discharge Facility; Project Buffer (operation and maintenance)	Significant	Mitigation Measure Land-5a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Zoning Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable
Impact Land-5: Permanent Conflict with Existing Zoning for Agricultural Use, and/or the **Permanent Conversion of Lands that have a Williamson Act Contract**	Sites Reservoir Inundation Area and Sites Reservoir Dams; Recreation Areas; Road Relocations, South Bridge, and TRR Pipeline Road; Sites Pumping/Generating Plant; Sites Electrical Switchyard; Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure; Sites Reservoir Inlet/Outlet Structure; Field Office Maintenance Yard; Asphalt Batch Plant; Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard; Delevan Pipeline Electrical Switchyard; Delevan Transmission Line; Delevan Pipeline Intake Facilities; Delevan Pipeline Discharge Facility; Electrical Distribution Lines; Project Buffer (operation and maintenance)	Significant	Mitigation Measure Land-5b: Acquire Lands Through Eminent Domain Mitigation Measure Land-5c: For Land Permanently Acquired other than by Eminent Domain, Seek County Approvals to Rescind Williamson Act Contracts and Enter in Open Space Contracts or Open Space Easements	Less than Significant Less than Significant or Significant and Unavoidable

Table 20-28
Summary of Mitigation Measures for NODOS Project Impacts to Land Use

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Land-6: Permanent Conflict with Existing Zoning for, or Cause Rezoning of, Forest Land, Timberland, or Timberland Zoned Timberland Production	Sites Reservoir Inundation Area and Sites Reservoir Dams; Recreation Areas; Road Relocations, South Bridge, and TRR Pipeline Road; Sites Pumping/Generating Plant; Sites Electrical Switchyard; Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure; Sites Reservoir Inlet/Outlet Structure; Field Office Maintenance Yard; Asphalt Batch Plant; Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard; Delevan Pipeline Electrical Switchyard; Delevan Transmission Line; Project Buffer (operation and maintenance)	Significant	Mitigation Measure Land-5a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Zoning Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable
Impact Land-7: The Permanent Loss of Forest Land or Permanent Conversion of Forest Land to Non-Forest Use	Sites Reservoir Inundation Area and Sites Reservoir Dams, Recreation Areas, Project Buffer (operation and maintenance)	Significant	Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable
Impact Land-8: Other Changes in the Environment which, due to their Location or Nature, could Result in the **Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use** or Permanent Conversion of Forest Land to Non-Forest Use	Sites Reservoir Inundation Area and Sites Reservoir Dams; Recreation Areas; Road Relocations, South Bridge, and TRR Pipeline Road; Sites Pumping/Generating Plant; Sites Electrical Switchyard; Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure; Sites Reservoir Inlet/Outlet Structure; Field Office Maintenance Yard; Asphalt Batch Plant; Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard; Delevan Pipeline Electrical Switchyard; TRR; TRR Pumping/Generating Plant; GCID Canal Connection to the TRR; TRR Electrical Switchyard; Delevan Pipeline and TRR Pipeline; Delevan Transmission Line; Delevan Pipeline Intake Facilities; Delevan Pipeline Discharge Facility; Project Buffer (operation and maintenance)	Significant	Mitigation Measure Land-4a: Enter into Agricultural Conservation Easements with Glenn and Colusa Counties	Less than Significant

Table 20-28
Summary of Mitigation Measures for NODOS Project Impacts to Land Use

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Land-8: Other Changes in the Environment which, due to their Location or Nature, could Result in the Permanent Conversion of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, Farmland of Local Importance, and Local Potential Farmland to Non-Agricultural Use or **Permanent Conversion of Forest Land to Non-Forest Use**	Sites Reservoir Inundation Area, Sites Reservoir Dams, Project Buffer (operation and maintenance)		Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with the Proposed Project Land Uses	Less than Significant or Significant and Unavoidable

"Temporary" impacts, as discussed in this chapter, are the "construction" impacts listed in this table. "Permanent" impacts, as discussed in this chapter, are the "operation and/or maintenance" impacts listed in this table.

Note:
LOS = Level of Significance

Mitigation Measure Land-2a: To the Extent Possible, Work with Glenn County to Encourage the County to Modify or Amend the Glenn County General Plan to Bring it into Consistency with the Proposed Project Land Uses

Prior to the start of Project construction, DWR and Reclamation shall, to the extent possible, work with Glenn County to modify or amend its General Plan for consistency with proposed Project land uses, or to implement other appropriate measures to minimize conflicts between the Project and County policies.

Mitigation Measure Land-2b: Execute an Agreement with NRCS to Amend WRP Easement Contract and Conduct Post-Construction Wetland Restoration

Prior to the start of Project construction, DWR and Reclamation shall execute an agreement with NRCS to amend the existing WRP easement contract to allow the construction and operation of the Delevan Transmission Line and Delevan Pipeline. Project Engineers shall design the transmission line and the construction contractor shall install the transmission line tower footings to span the parcel of land that has the WRP easement (a distance of approximately 680 feet). Project Engineers shall design the pipeline and the construction contractor shall install the pipeline to avoid the wetlands in the subject parcel of land, to the extent feasible. The pipeline length across the subject parcel is approximately 650 feet. Upon completion of pipeline installation, the area that was disturbed by Project construction shall be restored to a functional wetland condition.

Mitigation Measure Cul-4a: Relocation of Known Cemeteries

Consultation shall occur with the entity (County, City, private) that has jurisdiction over the cemetery, and interested parties as appropriate, to identify a satisfactory place that is protected from future disturbance for the relocation of human remains. Similarly, if Native American burials are known to exist in an archaeological site, the Project proponent shall work with the appropriate tribe to identify a satisfactory location for re-interment of burials in a protected location.

Mitigation Measure Land-3a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Land Use Designations to Bring them into Consistency with the Proposed Project Land Uses

Prior to the start of Project construction, DWR and Reclamation shall, to the extent possible, work with Glenn and Colusa counties to modify or amend the counties' General Plan land use designations, or to implement other appropriate measures to eliminate the Project's conflicts with those designations.

Mitigation Measure Land-3b: Execute an Agreement with Maxwell Irrigation District to Minimize and Avoid Short-term and Long-Term Impacts to Existing Facilities and Operations

Prior to the start of Project construction, DWR and Reclamation shall execute an agreement with the Maxwell Irrigation District to ensure that Project construction and operation of the Delevan Pipeline Intake Facilities or the Delevan Pipeline Discharge Facility will not adversely affect the operation of the existing adjacent Maxwell Irrigation District facility.

Mitigation Measure Land-4a: Enter into Agricultural Conservation Easements with Glenn and Colusa Counties

DWR and Reclamation shall enter into agricultural conservation easement**s** with Glenn and Colusa counties **for** lands used for agricultural production to ensure agriculture remains viable in perpetuity and to prevent incompatible development on the selected parcels.

Mitigation Measure Land-5a: To the Extent Possible, Work with Glenn and Colusa Counties to Encourage the Counties to Modify or Amend the Glenn County and Colusa County General Plans' Zoning Designations to Bring them into Consistency with the Proposed Project Land Uses

Prior to the start of Project construction, DWR and Reclamation shall, to the extent possible, work with Glenn and Colusa counties to modify or amend the counties' zoning designations, or to implement other appropriate measures to eliminate the Project's conflicts with those designations.

Mitigation Measure Land-5b: Acquire Lands through Eminent Domain

During the Project land acquisition process, DWR and Reclamation shall acquire parcels through eminent domain.

Mitigation Measure Land-5c: For Land Permanently Acquired other than by Eminent Domain, Seek County Approvals to Rescind Williamson Act Contracts and Enter into Open Space Contracts or Open Space Easements

Prior to permanently acquiring lands other than by eminent domain during the land acquisition process, DWR and Reclamation shall seek County approvals to rescind Williamson Act Contracts and enter into Open Space Use Agreements or Open Space Easements with the counties.

There is no feasible mitigation for **Impact Land-1** as it relates to the Town of Sites, so it is considered significant and unavoidable.

Implementation of **Mitigation Measures Land-2b, 3a** (for some Project facilities), **3b, 4a, 5b,** and **Cul-4a,** would reduce the level of significance of Project impacts to **less than significant**.

Implementation of **Mitigation Measures Land-2a, 3a** (for some Project facilities), **5a,** and **5c** would reduce the level of significance of Project impacts to less than significant if DWR and Reclamation are successful in working with the counties regarding consistency with the General Plans, General Plan land use designations, General Plan zoning designations, and/or regarding Williamson Act contracts. If working with the counties does not result in the Project being consistent with the counties' General Plans, General Plan land use designations, General Plan zoning designations, and/or regarding Williamson Act contracts, these impacts are considered **significant and unavoidable**.

21. Recreation Resources

21.1 Introduction

This chapter provides a description of the recreation resources setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Recreation is one of several benefits typically provided by public and private water supply projects. The amount of visitation at regional lakes and reservoirs can reasonably be expected to increase as the population of California increases. Projections indicate that the population of California, which was nearly 37 million in 2005, is expected to exceed 49 million in 2030 (DOF, 2007).

Popular recreation activities in California fall into two categories: (1) water-dependent activities, such as boating, waterskiing, swimming, and fishing; and (2) water-enhanced activities, such as wildlife viewing, camping, hiking, and hunting. The quality of the recreation experience at lakes, reservoirs, and streams depends on water levels, natural conditions, and the level of facility development.

The regulatory setting for recreation resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively, except when quantitative estimates were possible. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

21.2 Affected Environment

21.2.1 Extended, Secondary, and Primary Study Areas

21.2.1.1 Methodology

<u>Recreation Resources, Use, and Capacity</u>

There are approximately 1,400 reservoirs in California. Their function is to store and distribute water to supplement the needs of agriculture and urban water users. Some provide hydropower and flood control benefits. Recreation is also a beneficial use of many of these facilities. The level of detail for existing recreation resources varies, based on whether the resource would be affected by the Project. This analysis is based upon the recreation areas as they existed as of June 2009.

The following key sources of information were used in the preparation of this chapter:

- Recreation studies completed for the SWP Oroville Facilities Federal Energy Regulatory Commission (FERC) relicensing (2003 to 2004) (DWR, 2007a)
- CALFED Final Programmatic EIS/EIR (CALFED, 2000)
- North-of-the-Delta Offstream Storage Investigation Report, Appendix J – Recreation (Rischbieter and Elkins, 2000)
- Comparative Inventory of Recreation Facilities at California's Largest Reservoirs (Rischbieter, 2001)

- Sacramento River Public Recreation Access Study (EDAW, 2003)
- South Delta Improvements Program Draft EIR/EIS (Reclamation, 2005)
- Recreation Facilities of the State Water Project: An Inventory (Thrapp, 1989)
- Recreation Lakes of California (14th Edition) (Dirksen and Dirksen, 2003)
- Regional recreation guides
- Internet websites (Refer to Section 21.5 References)

Some of the recreation areas were visited to verify facility information. Detailed recreation use data were collected for Black Butte Lake and East Park Reservoir in 2000.

Recreation use is measured in recreation days (or recreation visitor days), with one recreation day representing one person spending a day or a portion of a day in one or more types of recreation activities[1]. For the purposes of this analysis, the peak recreation season is defined as Memorial Day weekend through Labor Day weekend (approximately 100 days), and the primary recreation season is considered to be from May 1 through September 30. At some areas, recreation occurs much earlier or later in the year depending on elevation and weather (i.e., an extended recreation season). In general, the primary recreation season is defined as those months when visitation equals or exceeds the monthly average for the year.

Recreation resource capacity can be measured by looking at availability of space, number and condition of facilities, visitor perceptions, or the ecological carrying capacity of the affected sites. Capacity is the number of visitors that a site is capable of handling with no apparent or undue environmental degradation (California State Parks, 2004). For the tables presented in this chapter that specify recreation use and capacity at reservoirs in the Extended and Secondary study areas (in Sections 21.2.2.1 and 21.2.3.1), the recreation capacity was based on the number of campsites, picnic areas, boat launches, and other facilities at each reservoir, and an estimate of optimum carrying capacity in persons for each recreation resource over a typical recreation seasonal period. This number was compared to the reported recreation use to derive a capacity percentage.

21.2.2 Extended Study Area

21.2.2.1 Recreation Resources, Use, and Capacity

This section includes descriptions of CVP, SWP, local water-dependent or water-enhanced recreation resources, and the wildlife refuges in the Extended Study Area. Table 21-1 shows the recreation use and capacity at the reservoirs within the Extended Study Area, and Figure 21-1 depicts the existing lakes and reservoirs.

[1]This is one standard definition of a recreation visitor day, but should not to be confused with the 12-hour recreation visitor day definition used by some federal agencies.

Table 21-1
Recreation Use and Capacity at Reservoirs in the Extended Study Area[a]

Name	Storage Capacity (Acre-Feet)	Surface Area (Acres)	Shoreline (Miles)	Approximate Recreation Capacity[b]	Approximate Recreation Use[b]	Capacity (Percent)	Operator[c]	County
Tri-Dam Reservoirs[d]	932,000	14,000	146	1,090,000	900,000	83	USACE, EBMUD	Calaveras, San Joaquin, Amador
New Melones Reservoir[e]	2,400,000	12,500	100	700,000	500,000	71	Reclamation	Calaveras, Tuolumne
Don Pedro Reservoir[d]	2,030,000	12,960	160	660,000	450,000	68	TID	Tuolumne
Lake McClure[d]	1,032,000	7,147	80	956,000	600,000	63	MIDPD	Mariposa
San Luis Reservoir SRA[f]	2,095,000	15,400	77	1,036,000	492,000	47	DWR/State Parks	Merced
Pyramid Lake SRA[f]	180,000	1,360	21	285,000	126,000	44	DWR	Los Angeles
Castaic Lake SRA[f]	323,700	2,235	29	1,300,000	614,000	47	DWR/State Parks	Los Angeles
Silverwood Lake SRA[f]	78,000	990	13	690,000	330,000	48	DWR/State Parks	San Bernardino
Lake Perris SRA[f]	131,450	2,340	10	1,144,000	872,000	76	DWR/State Parks	Riverside
Totals and Percent Capacity	**9,202,150**	**68,932**	**636**	**7,861,000**	**4,884,000**	**62**		

[a]It is difficult to obtain recent reported recreation information because many agencies no longer collect and report this information. The recreation use reported is approximate and represents an average of the three most recent years of available data, or a single year when only one year was available. Although the data indicate that recreation use does not currently meet or exceed the capacity of the recreational facilities at these reservoirs, some of them may be at or near capacity on a few summer weekends and especially on holiday weekends, such as Memorial Day and July 4th weekends.

[b]The units for Recreation Capacity and Recreation Use are recreation visitor days (RVDs), defined as a visit by one person for part or all of one day.

[c]USACE= U.S. Army Corps of Engineers; EBMUD = East Bay Municipal Utility District; Reclamation = U.S. Bureau of Reclamation; TID = Turlock Irrigation District; MIDPD = Merced Irrigation District Parks Department; DWR = California Department of Water Resources; State Parks = California Department of Parks and Recreation;

[d]Local Agency water project.

[e]Central Valley Project

[f]State Water Project

Note:

SRA = State Recreation Area

Tri-Dam Reservoir Complex

The Tri-Dam Reservoir Complex includes New Hogan, Comanche, and Pardee reservoirs. Recreation opportunities include camping, fishing, and boating. New Hogan Reservoir facilities include three campgrounds, day-use and picnic areas, two launch ramps and a marina. Comanche Reservoir provides six campgrounds and two day-use areas, plus two boat ramps at concessionaire-operated marinas. Water skiing and swimming is allowed. Pardee Reservoir facilities include two campgrounds and several day-use areas, with one boat ramp and a large marina. Shoreline access is restricted at these two reservoirs and there is virtually no opportunity for recreation outside the developed areas. Swimming is prohibited at Pardee Reservoir (Rischbieter, 2001).

New Melones Reservoir

New Melones Reservoir is the fourth-largest reservoir in California. It was constructed by the U.S. Army Corps of Engineers (USACE) for water, power, and flood control, as well as recreation. The facilities and recreation opportunities are currently administered by the U.S. Bureau of Reclamation (Reclamation).

Despite its very large size, New Melones has only two public recreation areas with camping facilities: the Glory Hole Recreation Area and the Tuttletown Recreation Area. However, there are five campgrounds with more than 300 campsites, four boat ramps, and a large marina, as well as several developed and primitive areas for day-use shoreline access (Rischbieter, 2001).

Don Pedro Reservoir

Don Pedro is the fifth largest reservoir in California. It is located in the Sierra Nevada foothills east of the cities of Modesto and Stockton. Built in a deep canyon of the Tuolumne River, Don Pedro Reservoir provides water, power, and flood control benefits for Turlock Irrigation District. The recreational facilities are maintained and operated by the Don Pedro Recreation Agency. The facilities include three recreation areas and two full-service marinas. The recreation areas include launch ramps, picnic facilities, and a total of 550 campsites. Boat-in camping is allowed, but there is little opportunity for roadside access (Rischbieter, 2001).

Lake McClure

Located in the Mother Lode Country of the Sierra foothills, Lake McClure is the closest reservoir to the City of Modesto. Lake McClure has four developed recreation areas and a fifth at Lake McSwain (the small re-regulation reservoir located downstream), all operated by Merced Irrigation District Parks Department. The campgrounds are equipped with bathrooms, showers, laundry facilities, and marina facilities. Day use areas include sandy beaches and swim lagoons, often in grassy park-like settings, that include group facilities and play equipment (Rischbieter, 2001).

San Luis Reservoir

San Luis Reservoir, a joint CVP/SWP facility, is the largest reservoir in the San Joaquin Valley. O'Neill Forebay and San Luis Reservoir are part of the San Luis Reservoir State Recreation Area (SRA), which also includes the Los Banos Detention Reservoir. The forebay has relatively stable water levels and provides popular swimming, boating, fishing, and camping opportunities.

In contrast, San Luis Reservoir has a very large annual water level fluctuation and frequent strong afternoon winds, so its primary activities are fishing, boating, wind surfing, and picnicking. San Luis Reservoir and O'Neill Forebay have two developed campgrounds and one primitive campground. There are four boat ramps at the two lakes, plus extensive day use areas with lawns and beaches at O'Neill Forebay. All facilities are operated by the California Department of Parks and Recreation (Rischbieter, 2001).

San Luis Reservoir has two major boat ramps: the Basalt boat ramp near Basalt Campground, and the Dinosaur Point boat ramp at the west end of San Luis Reservoir. Table 21-2 details the size and operating range of these ramps.

Table 21-2
San Luis Reservoir State Recreation Area Boat Ramp Bottom Elevations

	Elevation (Feet)	Feet Below MNWS	Number of Boat Ramp Lanes
Dinosaur Point Boat Ramp	378	166	4
Basalt Boat Ramp	340	204	2

Note:
Maximum Normal Water Surface (MNWS) elevation occurs at 544 feet.

Source: Martin, pers. comm., 2011.

The Basalt Campground receives its water supply from the reservoir at the Basalt Water Intake. The water intake is located at elevation 345.

Pyramid Lake State Recreation Area

Pyramid Lake has 21 miles of shoreline and a surface area of 1,297 acres. Recreation opportunities include boating, swimming, picnicking, camping, and fishing. The shoreline is rugged and accessible only by boat. The nearby Los Alamos campground has 93 campsites and two group campgrounds. Boat-in picnic sites and restrooms are scattered around the lake at several locations. The recreation program at the lake is administered by a concessionaire operating pursuant to an agreement with the U.S. Forest Service (USFS) (Thrapp, 1989).

Castaic Lake State Recreation Area

Castaic Lake and Lagoon has 29 miles of shoreline, and its afterbay Lagoon has three miles of shoreline. Together, they provide many opportunities for recreation, including a 60-unit campground and a group campground. There are two boat launches for water sports, including sailing, fishing, and power boating. The lagoon has one ramp and is limited to non-power boats. Visitors may sail, canoe, or fish (Dirksen and Dirksen, 2003). A grassy area is available for outdoor events. The recreational facilities at this SWP reservoir are operated by Los Angeles County. Castaic Lake State Recreation Area is operated by the California Department of Parks and Recreation.

Silverwood Lake State Recreation Area

Silverwood Lake SRA occupies 2,400 acres. The lake has 13 miles of shoreline and a surface area of approximately 1,000 acres. The lake is open to all types of boating, although several brushy areas were not cleared and provide natural fish habitat for anglers. There are two campgrounds, a group camp, a visitor information building, and three boat-in picnic areas. Recreational activities include swimming, boating, waterskiing, fishing, hiking, camping, picnicking, and bicycling. Silverwood Lake SRA is operated by California State Parks (Dirksen and Dirksen, 2003).

Lake Perris State Recreation Area

Lake Perris, operated by California Department of Parks and Recreation, is the southernmost reservoir of the SWP. There are 421 RV and tent campsites and six group campgrounds, a full service marina and boat ramp, and swimming and ski beaches. Recreation activities include swimming, horseback riding, sailing, power boating, camping, water skiing, fishing, hiking, bicycling, hunting, and rock climbing (Dirksen and Dirksen, 2003). As of 2013, Lake Perris is operating at reduced water and visitor capacity until remediation of seismic concerns at Perris Dam is completed.

Wildlife Refuges and Wildlife Areas

There are several wildlife refuges in the Extended Study Area from San Luis Reservoir to Kern County that receive Level 4 refuge water (Figure 1-7 in Chapter 1 Introduction): the West Bear Creek Unit of the San Luis National Wildlife Refuge (NWR) Complex; the Los Banos, Volta, and Mendota Wildlife Areas (WAs); the Merced Unit of the Merced NWR; the China Island and Salt Slough units of the North Grasslands WA; private wetlands in the Grassland Resource Conservation District; and Kern and Pixley NWRs. Recreation activities within these refuges include hunting, fishing, wildlife observation, photography, and environmental education programs (Reclamation, 2011).

21.2.3 Secondary Study Area

21.2.3.1 Recreation Resources, Use, and Capacity

This section includes descriptions of CVP, SWP, and local water-dependent or water-enhanced recreation resources in the Secondary Study Area. The existing lakes and reservoirs are listed in Table 21-3, and are depicted on Figure 21-2.

Table 21-3
Recreation Use and Capacity at Reservoirs in the Secondary Study Area[a]

Name	Storage Capacity (Acre-Feet)	Surface Area (Acres)	Shoreline (Miles)	Approximate Recreation Capacity[b]	Approximate Recreation Use[b]	Capacity (Percent)	Operator[c]	County

S. Army Corps of Engineers; YCFCWCD = Yolo County Flood Control & Water Conservation District; Concession = Concessionaires for Reclamation.

[d]Local Agency Water Project

[e]Central Valley Project

[f]State Water Project

Sources: Rischbieter, 2001; DWR, 2007b, 2008, and 2012; Guthrie et. al., 1995; Dirksen and Dirksen, 2003; Stienstra, 2004; Dean's AnglerNet.com, 2011; FishersNet.com, 2011; Fishsniffer.com, 2011; USFS, 2011.

Klamath River

Recreation activities on the Klamath River (upper and lower) include kayaking, boating, fishing, and hunting. The Klamath River is also popular for whitewater rafting and recreational gold mining. The river is 263 miles long, and flows through the Klamath and Six Rivers national forests in California. Several wildlife refuges near the Oregon border offer hunting, wildlife viewing, and other recreation resources. The Klamath Wildlife area in southern Oregon is adjacent to the river (Mt. Shasta Region Travel Center, 2011). A total of 250.8 miles of the Klamath River, from 100 yards downstream of the Iron Gate Dam to the river mouth at the Pacific Ocean, is designated as "recreational[2]" in the State and federal Wild and Scenic River acts. The federal act also designates 11.7 miles of the Klamath River as "wild[3]", and 23.5 miles as "scenic[4]" (NWSRS, 2013; CPRC, 2013).

Trinity River

The Trinity River ranges from stretches of calm water to rapids and cascades. SR 299 is adjacent to the river for many miles, allowing access for recreation activities that include fishing, hiking, swimming, rafting, kayaking, recreational gold mining, and wildlife viewing. The Trinity River is widely known for its fishing opportunities (Trinity County Visitors Guide, 2011). Most of the Trinity River from 100 yards downstream of Lewiston Dam to its confluence with Klamath River at Weitchpec is designated as either "recreational" (120 miles), "scenic" (39 miles), or "wild" (44 miles) in the State and federal Wild and Scenic Rivers acts (NWSRS, 2013; CPRC, 2013).

Whiskeytown-Shasta-Trinity National Recreation Area

The Whiskeytown-Shasta-Trinity National Recreation Area (NRA) includes Trinity Lake, Lewiston Lake, Shasta Lake, Keswick Reservoir, and Whiskeytown Lake. The lakes are components of the CVP. Of the five lakes, Shasta is the largest and receives most of the recreation use. Water levels at Shasta and Trinity lakes fluctuate, based on water supply and demand, but levels at Whiskeytown, Lewiston, and Keswick do not change much during the recreation season (Reclamation, 2005.)

Trinity Lake is the third largest reservoir in California, with more than 147 miles of shoreline. Recreation opportunities and much of the lands surrounding this component of the NRA are managed by USFS. Anglers fish along the shore for various fish species. Private resorts and Forest Service campgrounds offer facilities ranging from housekeeping cabins to rustic campgrounds. Four marinas offer houseboat, skiboat, fishing boat, canoe, and jetski rentals. The maximum storage capacity of Trinity Lake is 2,447,000 acre-feet at elevation 2,370 feet. However, the lake is rarely allowed to store water at full capacity because of its flood control requirements. The only month when the lake is allowed to fill completely is June; the lake is, therefore, rarely full during the remaining months of the primary recreation season.

Trinity Lake has seven ramps at elevations from 2,170 feet to the maximum water surface elevation of 2,370 feet (Table 21-4). Four of the ramps (Stuart Fork, Bowerman, Clark Springs, and Fairview) are relatively short and are out of the water when Trinity Lake is drawn down 60 feet (to elevation 2,310 feet).

---

[2] Wild = those rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted.

[3] Scenic = those rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible in places by roads.

[4] Recreational = those rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shoreline, and that may have undergone some impoundment or diversion in the past.

Table 21-4
Trinity Lake Boat Ramp Bottom Elevations

	Elevation (Feet)	Feet Below MNWS	Boat Ramp Lanes
Stuart Fork	2,338	32	2
Clark Springs	2,324	46	2
Bowerman	2,323	47	2
Fairview	2,313	57	3
Trinity Center	2,300	70	3
Cedar Stock	2,230	140	3
Minersville	2,170	200	2

Note:
Maximum Normal Water Surface (MNWS) elevation occurs at 2,370 feet.
Source: Reclamation, 2005; USFS, 2011.

When Trinity Lake reaches elevation 2,300 feet, which often occurs in July, August, or September, only the Minersville and Cedar Stock boat ramps are available. Minersville becomes usable when the lake drops to elevation 2,305. It is the only ramp extending below elevation 2,230, so in late summer during Critical years, it is the only available boat ramp on Trinity Lake.

Lewiston Lake is best known for its quality fly fishing and is also popular with trollers and bank anglers. A 10-mile-per-hour speed limit makes the lake popular with float tubers and canoeists. The area also offers excellent wildlife viewing and recreation on the lands surrounding the reservoir, which are managed by USFS.

Shasta Lake is the largest reservoir in California and the primary water storage facility of the CVP. It has 29,740 surface acres and more than 370 miles of shoreline. Recreation on and around this portion of the NRA is also managed by USFS. Much of the outdoor recreation and tourism in Shasta County is related to Shasta Lake. There are several marinas, campgrounds, boat-in campgrounds, boat ramps, and related facilities around Shasta Lake (USFS, 2011). Shasta Lake is very popular for houseboating and other water sports, as well as a major fishing destination. There are more than 16 species of fish available. Bass fishing tournaments are frequently held at the lake. Of the seven public boat ramps at Shasta Lake (Table 21-5), only the Centimudi and Jones Valley boat ramps extend more than 160 feet down in elevation. Commercial ramps at Bridge Bay Resort, Digger Bay Marina, and Silverthorn Marina also may be available to the public.

Keswick Reservoir is the afterbay for Shasta Lake and regulates the hydropower releases. It is approximately five miles long with a surface area of 630 acres. Most of its shoreline is steep and brushy, providing limited access for shore anglers. There is a small paved boat ramp and vault toilets at the day-use area. Fed by cold water released from the penstocks at Shasta Dam, Keswick is used little except for a few anglers who fish when the power plants at Shasta Dam are operating. BLM manages much of the recreation opportunities surrounding the reservoir. An extensive off-highway vehicle, mountain bike, and national recreation trail comprises a majority of the recreation use around the reservoir.

Recreation around Whiskeytown Lake is operated by the National Park Service and offers 3,220 surface acres and 36 miles of shoreline. There are two major campgrounds and two day-use areas with swimming beaches plus complete marina facilities at two of the three boat ramps. Houseboats or overnight stays on boats are not allowed. Fishing occurs from boats and from the shore (Dirksen and Dirksen, 2003; Stienstra, 2004).

Table 21-5
Shasta Lake Boat Ramp Bottom Elevations

	Elevation (Feet)	Feet Below MNWS	Boat Ramp Lanes
Bailey Cove	1,017	50	2
Antlers	992	75	4
Hirz Bay	972	95	2 to 3
Packers Bay	952	115	2 to 4
Silverthorn Marina[a]	942	125	1 to 2
Digger Bay Marina[b]	937	130	2
Sugarloaf[c]	907	160	2
Bridge Bay Resort	882	185	2
Centimudi	857	210	2 to 4
Jones Valley	857	210	1 to 4

[a]Silverthorn ramp is not paved from elevation 1,023 feet to elevation 942 feet.
[b]Digger Bay ramp is usable to elevation 930 feet on an unpaved ramp.
[c]Sugarloaf ramp is a low water ramp that is not available until elevation 992 feet.

Note:
Maximum Normal Water Surface (MNWS) elevation occurs at 1,067 feet.

Source: USFS, 2011.

Clear Creek

Lower Clear Creek begins downstream of Whiskeytown Lake on National Park Service lands; the upstream portion of lower Clear Creek is part of the Whiskeytown-Shasta-Trinity NRA. Downstream of the NRA, the majority of the land surrounding the creek is owned by the U.S. Bureau of Land Management (BLM). BLM lands within the lower Clear Creek corridor receive substantial public recreational use. Recreational opportunities include swimming, beach use, hiking, fishing, limited hunting, kayaking, gold panning, and bird watching. Salmon spawning viewing is also an important recreation activity during the fall. A recreation survey conducted in 1980 concluded that there were 15,000 recreation user days along lower Clear Creek during the summer months, but this survey was conducted prior to the increase in BLM-managed lands along lower Clear Creek, when most lands were in private holdings (BLM, 2008).

Spring Creek

Spring Creek flows are regulated by Spring Creek Dam and diluted by flows from Whiskeytown Lake via the Clear Creek Tunnel. Spring Creek flows are contaminated with acid mine drainage from the Iron Mountain Mine, which is located on upstream tributaries of the creek and is designated as a Superfund site. Consequently, no recreation occurs along this reach of Spring Creek.

Sacramento River – Shasta Dam (Keswick) to Colusa (Sacramento River Conservation Area)

The main river recreation resources and public access sites within the Secondary Study Area are located along the Sacramento River from the Shasta Dam to the City of Colusa. These resources include day use sites, boat launches, trail accesses, fishing accesses, recreational vehicle parks, wildlife areas, and undeveloped open space areas.

Between Keswick Dam (downstream of Shasta Dam) and the City of Red Bluff, much of the Sacramento River is confined by geology and narrow bands of riparian forest, but from Red Bluff to the City of Chico, the river meanders over a broad floodplain. From Chico to Colusa, sloughs and broad basins extend for miles on either side of the river. There is also an extensive system of levees and weirs for flood control purposes. These conditions create many opportunities for water-based recreation. Fly fishing and conventional fishing in and along the Sacramento River occur year-round. Various fish species are abundant at different times during the year. Fishing is popular downstream of the Red Bluff Diversion Dam (RBDD). In addition, rafting, canoeing, camping, and swimming are popular activities. Power boat use and whitewater rafting require a minimum river flow of at least 5,000 cfs. Tables 21-6A and 21-6B list existing public recreation sites between Red Bluff and Colusa on the Sacramento River (EDAW, 2003). Recreation use along the Sacramento River is generally less than the capacity of the recreation sites, with the exception of occasional special events, such as those that occur on major holiday weekends or during periods of exceptional salmon fishing.

Recreational use of the Sacramento River and its tributaries probably has paralleled increased population growth in the region. It is expected that demand for recreation activities, such as bird watching, wildlife viewing, nature observation, and hiking, will increase over the next 40 years, and the demand for traditional Sacramento River recreation uses, such as hunting, fishing, and boating, will continue (EDAW, 2003). However, salmon fishing recently declined due to closed fall-run Chinook salmon seasons in 2008 and 2009, and a restricted fall-run Chinook salmon season in 2010 (Lyons, pers. comm., 2012).

Lake Almanor

Lake Almanor has the second largest surface area among California's reservoirs. Recreation opportunities are provided by 22 resorts with five full-service marinas with rental boats, and moorage for private boats. Much of the lakeshore is private property, but there are stretches of National Forest lands open to the public and an extensive paved bicycle path on the west side of the lake. The Forest Service and PG&E also provide a few public facilities (Rischbieter, 2001; PG&E, 2002).

Lake Red Bluff Recreation Area

The Lake Red Bluff Recreation Area is administratively managed and operated by the Mendocino National Forest. However, the federal lands in this area are owned by Reclamation and are adjacent to the RBDD within the city limits of Red Bluff. Approximately 65,000 people recreated in and along the Sacramento River near the RBDD in 1995 (Guthrie, et al., 1995). Most of them used one of three locations: City Park, Ide Adobe State Historical Park, and the boat launch ramp area at the Lake Red Bluff Recreation Area. The majority of this use occurred in the summer months during the "gates in" period of the RBDD (Reclamation, 2002). However, Lake Red Bluff no longer exists because the gates that formed it were permanently raised in 2012.

Black Butte Reservoir

Black Butte Reservoir is located on Stony Creek, approximately eight miles west of the town of Orland in northern Glenn and southern Tehama counties, in a transition zone between the Sacramento Valley and the foothills of the Coast Range at an elevation of 470 feet. There are six recreation areas, a dam overlook, and several nature trails. Each recreation area includes restrooms and fishing access with other facilities, including campgrounds, a marina, boat ramps, an outdoor amphitheater, fish cleaning stations, and an off-highway vehicle park. Recreation lands surrounding the reservoir total approximately 4,000 acres (Rischbieter and Elkins, 2000).

Lake Oroville State Recreation Area

Lake Oroville SRA includes Lake Oroville, the second largest storage reservoir in California, and much of the Thermalito Complex, which are owned and operated by DWR as part of the SWP. Recreation resources at Lake Oroville SRA include boating, fishing, fully developed and primitive camping, picnicking, swimming, horseback riding, mountain biking, wildlife watching, and hunting. Lake Oroville has two full-service marinas, numerous boat ramps, 10 floating campsites, 84 boat-in campsites, and seven two-stall floating toilets (DWR, 2004). The Oroville WA contains the surface of the Thermalito Afterbay and surrounding lands, and some lands adjacent to the Feather River. Recreation activities include boating, waterskiing, hunting, fishing, wildlife viewing, camping, and picnicking.

Lake Oroville has five public boat ramps with two lanes or more, a DWR service ramp, and five one-lane cartop boat ramps (Table 21-7). Four of the cartop ramps are shallow, reaching only to elevations between 825 and 866 feet. Foreman Creek Ramp is much deeper, extending to 730 feet, as does the DWR Service Ramp. The five major public boat ramps (Loafer Creek, Enterprise, Lime Saddle, Spillway, and Bidwell Canyon) launch most of the recreational boats on Lake Oroville. A day-use area and Aquatic Center are popular at Thermalito Forebay. These Lake Oroville SRA recreational facilities are managed by California Department of Parks and Recreation, which has entered into a contract with the Feather River Recreation and Park District for Aquatic Center operation. No motorized boating is allowed at the North Forebay area, but personal watercraft use is popular at South Forebay.

Table 21-7
Lake Oroville Boat Ramp Bottom Elevations

	Elevation (Feet)	Feet Below MNWS	Boat Ramp Lanes
Stringtown Cartop	866	34	1
Dark Canyon Cartop	851	49	1
Vinton Gulch Cartop	848	52	1
Nelson Bar Cartop	825	75	1
Loafer Creek	775	125	2 to 8
Enterprise	750	150	2
Foreman Creek Cartop	730	170	1
DWR Service Ramp	730	170	2
Lime Saddle	702	198	2 to 4
Spillway	695	205	2 to 12
Bidwell Canyon	675	227	2 to 7

Note:
Maximum Normal Water Surface (MNWS) elevation occurs at 900 feet.
Source: DWR, 2004; Dossey, pers. comm., 2012; Rischbieter, pers. comm., 2011.

Stony Gorge Reservoir

Stony Gorge Reservoir is located approximately 23 miles west of Willows and upstream of Black Butte Lake on Stony Creek. Its primary purpose is to provide irrigation water, but there is one recreation area on the north end of the reservoir. Use declines in the latter half of summer and fall as the water level declines. There are primitive campsites for tents and recreational vehicles, and one reservable pay-for-use group campsite. No hunting or off-road vehicle use is permitted. Some permanent restrooms are available. There is one single-lane concrete boat ramp at Stony Gorge that is available year-round (Dirksen and Dirksen, 2003).

Feather River

Downstream of Lake Oroville, the Feather River passes through the Oroville WA and several towns before joining the Sacramento River at Verona. The most popular recreation area is Riverfront Park near Marysville. Facilities include picnic areas, restrooms, nearby campgrounds and lodging, and a boat ramp. Verona Marina, located at the mouth of the Feather River, has a boat ramp which is used primarily by boat anglers. Recreation activities on the Feather River downstream of Lake Oroville include boating, fishing, camping, picnicking, swimming, wildlife viewing, and hunting. Several miles of the river near the City of Oroville are popular for bank fishing, and boat anglers frequent the lower river. Recreational facilities include public and private launch ramps, camp and day-use facilities, and trails (Stienstra, 2004).

New Bullard's Bar Reservoir

New Bullard's Bar Reservoir is located on the Yuba River in the Tahoe and Plumas national forests in Yuba County. Popular recreation activities include waterskiing, wakeboarding, houseboating, wildlife viewing, power boating, non-motorized boating, fishing, hiking, mountain biking, and camping. The Yuba County Water Agency and the USFS maintain 30 boat access camps and lakeside camping. Emerald Cove Marina is a full-service facility offering rental houseboats and fishing boats along with moorings for private houseboats (YCWA, 2010).

East Park Reservoir

East Park Reservoir is located approximately 20 miles west of Maxwell in the Stony Creek watershed. The reservoir is located between the towns of Lodoga and Stonyford and 10 miles south of Stony Gorge Reservoir. There are areas on the west and east shores of the reservoir that are developed for recreation. Although there are no concrete boat ramps, there are two designated and six informal boat launch sites on the lake (Hinton and Campbell, 2003). There are no formally defined campsites or user fees at East Park except for three reservable fee group campsites: Chisholm Cove Group Camp, Hole in the Wall, and Coyote Cove. Camping areas are user defined and are located near the water's edge. There are approximately 44 acres of camping area available to the public at East Park (Tetra Tech, 2004).

Englebright Reservoir

Englebright Reservoir is located in the Sierra Nevada foothills approximately 21 miles east of Marysville. Recreation opportunities include boat-in camping, fishing, a marina, a store, and a café. Boats can be launched near the dam or at Joe Miller Recreation Area. A variety of rental boats are available at Skippers Cove (Dean's AnglerNet.com, 2011).

Indian Valley Reservoir

Indian Valley Reservoir, including the Cache Creek Recreation Area, is located on the North Fork of Cache Creek in Lake County, and is operated by the Yolo County Flood Control & Water Conservation District. It is located in a secluded area of the Coast Range and is surrounded by public land managed by the BLM. There are four designated recreation areas, which include a marina and unimproved and primitive campsites. Boating speed is limited to 10 mph, and waterskiing and jetskis are prohibited (Rischbieter and Elkins, 2000; FishersNet.com, 2011).

Clear Lake

Clear Lake provides many year-round recreation resources including fishing, boating, sailing, swimming, and waterskiing. There are eight county parks, two State parks, and three city parks located on the lake's perimeter, with 11 no-fee public boat ramps. There are also many private resorts and marinas. Clear Lake hosts many bass fishing tournaments. Because of Clear Lake's elevated mercury levels, a health advisory is in effect for consumption of fish caught in the lake (Stienstra, 2004; Dirksen and Dirksen, 2003).

Folsom Lake State Recreation Area and Lake Natoma

Folsom Lake and Lake Natoma are owned by Reclamation, and recreation is managed through an agreement with the California Department of Parks and Recreation. Folsom Lake is located east of the City of Sacramento and extends to the north and south forks of the American River. Recreation resources include boating, camping, fishing, picnicking, and an extensive trail system. The trail system connects to the American River Parkway, a 6,000-acre open corridor that connects trails and parks throughout the City of Sacramento. Facilities at Folsom Lake include two major campgrounds and multi-stage boat ramps to provide continuous boating under fluctuating water level conditions (Rischbieter, 2001).

Folsom Lake has eight major boat ramps with two or more lanes and two one-lane ramps more suitable for cartop boats (Table 21-8). Both one-lane ramps are relatively shallow ramps, and Bigger's Cove ramp is out of the water by the end of September every year. Some of the ramps are not available until the lake elevation is 18 to 58 feet below the normal maximum water surface elevation.

Table 21-8
Folsom Lake Boat Ramp Bottom Elevations

	Elevation (Feet)	Feet Below MNWS	Boat Ramp Lanes
Bigger's Cove (Peninsula North)	434	34	1
New Stage Four (Granite Bay)	425	43	4
Rattlesnake Bar	425	43	2
Peninsula South	410	58	1
5 percent Ramp (Granite Bay)	408	60	4
Folsom Point (Old Dyke 8)	406	62	4
Old Stage One to Four[a] (Granite Bay)	395	73	2-10
Folsom Lake Marina (Brown's Ravine)	395	73	4
Hobie Cove[b] (Brown's Ravine)	375	93	4
Low Water Ramp[c] (Granite Bay)	370	98	2

[a]Stage Three boat ramp (10 lanes) starts at elevation 450 feet, Stage two (10 lanes) starts at elevation 435 feet, and Stage One (2 lanes) starts at elevation 420 feet.
[b]Hobie Cove boat ramp starts at elevation 426 feet.
[c]Low Water ramp starts at elevation 410 feet.

Note:
Maximum Normal Water Surface (MNWS) elevation occurs at 468 feet.

Source: Moses, pers. comm., 2011.

Lake Natoma is the regulating reservoir for Folsom Lake. The water is very cold and lake levels can fluctuate three or four feet per day. This narrow lake has approximately 500 surface acres, with 13 miles of shoreline. The lake covers old dredge tailings, which create good fish habitat, but can be a boating hazard. Waterskiing is prohibited and a five-mile-per-hour speed limit is enforced. Boats with small motors, canoes, kayaks, inflatables, sail boats, and sail-boards are permitted. There are three group camps and a boat ramp at Negro Bar. The California State University Sacramento Aquatic Center near Nimbus Dam has a boat ramp and offers rentals and lessons for aquatic sports (Stienstra, 2004).

American River

The lower American River flows for 23 miles downstream of Lake Natoma and Folsom Dam through the greater Sacramento urban area. Recreation activities include recreational boating, rafting, kayaking, fishing, swimming, and wading. The river passes through the American River Parkway. This heavily used parkway is a paved bike, walking, running, hiking, and equestrian trail that extends from Lake Natoma to Discovery Park. The American River Parkway provides a greenbelt for several communities and experiences over one million visitors annually. There are more than a dozen public access points or parks along the trail. This is a Class 1 rafting river (with three Class II rapids) and is used heavily from Memorial Day weekend to Labor Day. Fishing is also popular in this reach (Stienstra, 2004). The 23 miles of the lower American River from Nimbus Dam to the confluence with the Sacramento River is designated "recreational" in the State and federal Wild and Scenic Rivers System (NWSRS, 2013).

Lake Berryessa

Lake Berryessa, which is directly managed by Reclamation, is the largest reservoir in the eastern foothills of the Coast Range. Its primary purposes are water supply, hydroelectric power, and recreation. Located near major metropolitan areas (Sacramento and the San Francisco Bay Area) and known for excellent year-round fishing, it is one of northern California's more popular lakes. There are several public access areas along the western shoreline for day use, one boat ramp, and several recreation areas operated by concessionaires who have contracts with Reclamation. These resorts and marinas provide camping, boat launching, moorage, day use, and marina services (Dirksen and Dirksen, 2003).

Wildlife Refuges and Wildlife Areas

There is a complex of federal and State wildlife refuges in the Sacramento Valley along the Sacramento River that provides fishing, hunting, and wildlife viewing opportunities via auto tours and trails. Hunting is generally limited to upland game and waterfowl. These refuges include the Sacramento, Colusa, Sutter, and Delevan NWRs and Gray Lodge Wildlife Management Area. Gray Lodge is considered the most popular of the five refuges in the region. Fishing and hunting account for approximately 50 percent of the total use. The remaining 50 percent is devoted to hiking and photography. Recreational opportunities at the Colusa NWR include hunting, hiking, wildlife viewing, auto tour routes, and environmental education. The Sacramento NWR is headquarters for the Sacramento Valley Refuge Complex and contains a visitor center. At the Delevan NWR, hunting is allowed and a photo blind is available (CALFED, 2000).

Sutter and Yolo Bypasses

The Sutter Bypass includes the Sutter NWR, part of the larger Sutter Bypass WA. Hunting, fishing, bird watching, photography, and general nature observation are primary recreation activities. Fishing occurs year-round (DFG, 2011a).

The Yolo Bypass includes the 1,461-acre Fremont Weir WA. Although there are no formal facilities in this WA, recreationists fish, bird watch, and view wildlife. Hunting is allowed during spring turkey season and also daily from July 1 through January 31.

The Yolo Bypass also includes the Sacramento Bypass WA. The Sacramento Bypass WA is located along the Sacramento River Deep Water Ship Channel downstream of the City of Sacramento. It is a major public waterfowl and pheasant hunting area, with several duck blinds and parking areas. There are also picnic facilities and trails. This 360-acre area provides fishing and wildlife and bird watching. Hunting is allowed from September 1 to January 31. Fishing occurs at the East Toe Drain and along lower Putah Creek (EDAW, 2010).

Sacramento–San Joaquin Delta, San Francisco Bay, Suisun Bay, and San Pablo Bay

The Sacramento-San Joaquin Delta includes the legal Delta and the Sacramento River from Colusa to the Delta. It is the largest estuary on the west coast and provides more than 500 miles of navigable waterways. Most of the recreation in the Delta is water-dependent or water-enhanced. Although boating and fishing are the most popular activities, people also engage in camping, picnicking, hiking, bicycling, hunting, and wildlife viewing.

San Francisco Bay is used heavily for sailing. Yachting and yacht racing are also popular activities. A bicycle and pedestrian trail circles the shoreline of the bay along with many parks and natural areas.

Suisun Bay is a shallow tidal estuary that provides fishing opportunities year-round. Boat access is available at three marinas, and camping sites for motor homes or trailers are available at the Benicia State Recreation Area. Suisun Bay is surrounded by Suisun Marsh, which is the largest brackish marsh on the west coast and includes 116,000 acres of wetlands. It contains public waterfowl hunting areas and 158 private duck clubs. The marsh’s open space and proximity to major urban areas make it well-suited for wildlife viewing, hiking, canoeing, as well as hunting (DWR, 2011).

San Pablo Bay is a tidal estuary that forms the northern extension of San Francisco Bay. Because of its large size and shallow waters, San Pablo Bay frequently has difficult conditions for boating. Prevailing winds produce large waves and there are few protected areas for most boats. The San Pablo Bay NWR and the Napa-Sonoma Marshes WA are located along the Napa River estuary on the north shore of the bay. Most of the area is accessible to the public by boat only. However, there is enough vehicle access that the area is regularly used by hunters and anglers, as well as bird watchers, photographers, bicyclists, and hikers (USFWS, 2011; DFG, 2011b).

21.2.4 Primary Study Area

21.2.4.1 Recreation Resources, Use, and Capacity

This section describes the existing recreation resources in the Primary Study Area, which includes the footprints of the Project facilities, as well as the construction disturbance area around those proposed facilities.

All Primary Study Area Project Facilities

Most of the Project facility sites are privately owned[5], with no public access. However, the private landowners within Antelope Valley, their guests, and their employees may participate in recreational activities, such as hunting upland game birds, deer, and wild boar, as well as firearm target practice, hiking and picnicking, off-road vehicle use, and primitive camping. Occasional horseback riding has also been observed. Fishing is an infrequent activity because of the intermittent nature of the streams in Antelope Valley; children have been observed fishing in Stone Corral Creek located downstream of the

---

[5] The following proposed Project facility sites are privately owned: Sites Reservoir and Dams, Recreation Areas, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and GCID Canal Connection to the TRR.

proposed Sites Dam site. There are several stock ponds located throughout the proposed Sites Reservoir footprint, and some are large enough to support warmwater fishes; it is not known, however, if these ponds are used for recreational fishing. Estimated recreation use within Antelope Valley is approximately 300 hours annually (Rischbieter and Elkins, 2000; Reclamation, 2012).

Existing recreation activities that occur along the proposed Delevan Pipeline and Delevan Transmission Line alignments are associated with private hunting and fishing clubs; the duck hunting clubs experience high use levels.

The proposed location of the Delevan Pipeline Intake/Discharge facilities, which includes a portion of the bank of the Sacramento River, is currently used for shore fishing, but use is limited because the shore can only be accessed from private land. In addition, the river is used for activities such as boating and boat fishing at this location.

The GCID Canal, facilities, and lateral bank roads are for the use of authorized personnel only. The use of the GCID Canal, facilities and roads for public recreation or other unauthorized activity is prohibited.

Limited recreation activities occur on private lands within the proposed construction disturbance areas for the proposed new roads. Existing county roads are used by the public for access to the local area, including existing reservoirs and the Mendocino National Forest.

The existing Funks Reservoir and the land surrounding the reservoir are owned by Reclamation. Opportunities for public recreation at Funks Reservoir do not exist because the maintenance roads leading into and around it are closed to the public.

21.3 Environmental Impacts/Environmental Consequences

21.3.1 Regulatory Setting

Recreation resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

21.3.1.1 Federal Plans, Policies, and Regulations

- Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area
- Federal Water Project Recreation Act of 1965
- Rehabilitation Act of 1973
- Architectural Barriers Act of 1968
- Americans with Disabilities Act of 1990, as Amended
- San Luis Authorization Act

21.3.1.2 State Plans, Policies, and Regulations

- Davis-Dolwig Act of 1961 and State Water Code Section 11900-11901
- California Public Trust Doctrine
- Folsom Lake State Recreation Area General Plan and Amendment

- Lake Oroville State Recreation Area Resource Management Plan and General Development Plan and Amendment
- San Luis Reservoir State Recreation Area General Development Plan and Amendment

21.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

21.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for recreation resources:

- Would the Project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?
- Does the Project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated.
- Require the construction or expansion of existing recreational facilities, which may have an adverse physical effect on the environment.
- Reduce recreation use levels at existing recreational facilities by providing an alternative new site for recreation visitors.
- Reduce recreation use levels and/or recreation benefits at existing reservoirs or rivers due to changes in operating criteria (significant impacts would be triggered by the loss of use for one month for the lowest boat ramp and two months for intermediate[6] boat ramps over the 82-year period of record within the primary recreation season.; in addition, a one point reduction or more in the recreation-day benefit value for reservoir operation would be considered a significant impact.)
- Reduce recreation use levels at existing recreational facilities during the Project construction period.
- Create hazardous conditions for water-based activities due to changes in operating criteria.

[6] Intermediate boat ramps are all major boat ramps other than the lowest boat ramp.

21.3.3 Impact Assessment Assumptions and Methodology

21.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to recreation resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge facilities would be required.
- The extension of the Bidwell Canyon boat ramp at Lake Oroville that is planned for in the FERC License Renewal Project, which is a project included in the No Project/No Action Alternative, would be implemented.

21.3.3.2 Methodology

Potential impacts to recreation resources were evaluated for the proposed Sites Reservoir and five major reservoirs that would potentially be affected by Project operations (Trinity, Shasta, Oroville, Folsom, and San Luis). End-of-month water surface elevations for each of these reservoirs were evaluated to determine if changes in operation would result in adverse effects to the aesthetic quality of the reservoirs, or would result in reduced availability of boat ramps. The methods used to evaluate these effects are described below.

Recreation-Day Benefit Value for Reservoir Operation

Recreation-day benefit values for reservoirs are based on guidelines described in DWR's Economics and Recreation Planning Manuals and in Supplementary Procedures for Application of Department of Water

Resources Guidelines for Evaluation of General Recreation, developed jointly by the Departments of Parks and Recreation and DWR (California State Parks, 1967).

These guidelines are intended to express the net benefit of a reservoir to a recreationist in terms of two equally weighted factors: (1) variety and quality of recreation, and (2) aesthetic qualities of the site. Factors considered in determining the variety and quality of recreation at a reservoir include the types of activities available, quality of the experience, quality of development, and operation and maintenance of the facilities and area. Aesthetic factors include reservoir operation, geologic, topographic, aquatic, vegetative, climate, and other environmental factors.

For the purposes of this analysis, only the reservoir operation portion of the recreation-day benefit value was evaluated. Reservoir operations were assigned up to 50 points; in general, a full reservoir with no water level fluctuations during the recreation season would receive 50 points, and a reservoir that experiences severe water level fluctuations or drawdowns during the recreation season would receive few points.

Specifically, CALSIM II modeling results (Appendix 6B) were used to obtain the long-term average end of month surface area during the primary recreation season (May 1 through September 30), for each reservoir, for Existing Conditions, the No Project/No Action Alternative, and for each action alternative. Because modeling results represent end-of-month values, results for April through September were analyzed to represent the primary recreation season.

The average end of month surface area was calculated for April through September, and then divided by the maximum normal water elevation surface area of the reservoir to obtain a ratio of average surface area to normal pool surface area. The calculated ratio was compared to a Project Operations –Reservoir Point Rating Graph (California State Parks, 1967) to obtain the associated operation points portion of the recreation-day benefit value. The operation point value was then rounded to the nearest half point (Appendix 21A). A one point reduction or more in the recreation-day benefit value for reservoir operation resulting from changes in reservoir operations was considered a potentially significant impact.

Boat Ramp Availability

CALSIM II modeling results (Appendix 6B) were used to obtain the average end of month water elevations for the reservoirs that could be affected by Project operations. The entire 82-year period of record equates to 984 months; for the purposes of this analysis, only the primary recreation season was evaluated, which includes 492 months of the entire period of record. To analyze the potential impact of changes in reservoir operations on the availability of major boat ramps, average end-of-month reservoir elevations during the primary recreation season were compared to the bottom elevations of the boat ramps (i.e., the elevation when a boat ramp is no longer usable) to determine the number of months that each boat ramp would be dewatered for Existing Conditions and for each of the alternatives (Appendix 21B). Major boat ramps are defined as having two lanes or more; cartop boat ramps and service ramps were not evaluated. The major boat ramps evaluated included the following:

- San Luis Reservoir: Dinosaur Point, Basalt
- Trinity Lake: Stuart Fork, Clark Springs, Bowerman, Fairview, Trinity Center, Cedar Stock, Minersville
- Lake Shasta: Bailey Cove, Antlers, Hirz Bay, Packers Bay, Silverthorn Marina, Digger Bay Marina, Sugarloaf, Bridge Bay Resort, Centimudi, Jones Valley

- Lake Oroville: Loafer Creek, Enterprise, Lime Saddle, Spillway, Bidwell Canyon
- Folsom Lake: Rattlesnake Bar, New Stage Four (Granite Bay), Five Percent (Granite Bay), Folsom Point (Old Dyke 8), Folsom Lake Marina (Brown's Ravine), Old Stage One to Four (Granite Bay), Hobie Cove (Brown's Ravine), Low Water (Granite Bay)
- Proposed Sites Reservoir: Stone Corral, Unnamed

It should be noted that this method of evaluation does not provide the exact number of months or days the boat ramps would be dewatered because six end-of-month estimates of average reservoir elevation are required to define the May 1 to September 30 period. Water levels could reach the bottom of a boat ramp any time during the month, but modeling results only provide elevation information for the end of each month.

21.3.4 Topics Eliminated from Further Analytical Consideration

There is no recreational use directly associated with agricultural, municipal, or industrial water use within the Extended Study Area. As described in the Affected Environment section, there is also no recreation use associated with Spring Creek. Therefore, the potential impacts to recreation use associated with these water supply uses or Spring Creek were not evaluated.

O'Neill Forebay in the Extended Study Area, as well as the regulating reservoirs that are located within the Secondary Study Area (including Lewiston Reservoir, Whiskeytown Reservoir, Keswick Reservoir, Thermalito Complex, and Lake Natoma), have also been eliminated from further consideration. As regulating afterbays, these reservoirs are operated to receive highly variable flows and, as a result, surface water elevations fluctuate significantly on a daily and hourly basis. Therefore, changes in the operation of upstream reservoirs with implementation of any of the alternatives would not affect the monthly mean elevation of these regulating reservoirs. Consequently, no assessment of potential elevation-related impacts on recreation resources in these regulating reservoirs is warranted.

The evaluation of reduced recreation use levels at existing reservoirs or rivers (**Impact Rec-4**) is not applicable to the managed wetlands of the Level 4 wildlife refuges within the Extended Study Area, and is, therefore, not discussed for those refuges.

Project construction activities would occur only with Alternatives A, B, and C at the Red Bluff Pumping Plant (located within the Secondary Study Area) and at Project facilities sites located within the Primary Study Area. Therefore, the effects of Project construction on existing recreation use levels (**Impact Rec-5**) are not discussed for any of the three study areas for the No Project/No Action Alternative, or for the Extended Study Area and the areas beyond the Red Bluff Pumping Plant within the Secondary Study Area for Alternatives A, B, and C.

The only alternative new site for recreation visitors for Alternatives A, B, and C would be Sites Reservoir. Therefore, the effects of a new recreation site on recreation use levels at existing recreational facilities (**Impact Rec-3**) are not discussed for the other proposed Project facilities within the Primary Study Area.

The defined Primary Study Area does not include any existing reservoirs that provide recreational opportunities, and does not include the Sacramento River. Impacts to recreation use levels and recreation benefits resulting from changes in operating criteria (**Impact Rec-4**) are, therefore, not discussed for the Primary Study Area. For these same reasons, hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) are not discussed for the Primary Study Area, with the exception of the Delevan

Pipeline Intake Facilities and Delevan Pipeline Discharge Facility, which would release water into the Sacramento River.

21.3.5 Impacts Associated with the No Project/No Action Alternative

21.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

San Luis Reservoir

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Project operational modeling results indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in the same or slightly decreased water surface elevations during most water years, and increased water surface elevations during Dry and Critical years at San Luis Reservoir. These fluctuations in San Luis Reservoir surface water elevations are not expected to affect recreation use or to increase use of existing facilities. Therefore, these changes in surface water elevations at San Luis Reservoir resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on recreation use at other existing facilities, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. Population growth could result in the increased use of existing recreational facilities such that substantial physical deterioration of the facilities would occur. Therefore, population growth associated with implementation of the No Project/No Action Alternative **could have a substantial adverse effect** on recreation use at existing facilities, when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible fluctuations in San Luis Reservoir surface water elevations would not require the construction or expansion of existing facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, there **would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

It is possible that one or more projects included in the No Project/No Action Alternative could include recreational facilities that could affect recreation use levels at San Luis Reservoir. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Population growth would not be expected to result in reduced recreation use levels. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

San Luis Reservoir surface water elevation is currently drawn down to a level that is below the bottom of the Basalt boat ramp in Above Normal, Dry, and Critical years. Implementation of the No Project/No Action Alternative would result in lower water levels than Existing Conditions in Wet, Above Normal, and Below Normal years, but would average eight feet higher in Dry years and 13 feet higher in Critical years.

Project modeling for the No Project/No Action Alternative indicates that the Dinosaur Point ramp would be dewatered more often during Wet and Below Normal years, but less often during above Normal, Dry, and Critical years over the 82-year period of record within the primary recreation season. Overall, San Luis Reservoir surface water elevations would drop below the Dinosaur Point boat ramp one month less often over the 82-year period of record within the primary recreation season than for Existing Conditions, and below the Basalt Boat Ramp three months less often over the 82-year period of record within the primary recreation season than for Existing Conditions. This decrease in the frequency of dewatering of boat ramps would be a **beneficial effect,** when compared to Existing Conditions. There are no boat-in camps or swimming beaches at San Luis Reservoir because of its existing frequent and severe drawdown pattern (as much as 40 feet in one month during a Critical year, and commonly 70 feet during the recreation season). Based on Project modeling for the No Project/No Action Alternative, the water intake at the Basalt Campground would be dewatered five fewer months over the 82-year period of record within the primary recreation season than with Existing Conditions. This would be a **beneficial effect**, when compared to Existing Conditions

Continued reservoir fluctuations associated with the No Project/No Action Alternative would result in a recreation-day benefit value for reservoir operation of 4 points, which is the same as the value for Existing Conditions. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions**.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible fluctuations in San Luis Reservoir surface water elevations would not be expected to create hazardous conditions for water-based activities. Therefore, there **would not be a substantial adverse effect,** when compared to Existing Conditions.

Other Reservoirs within the Extended Study Area

Tri-Dam Reservoirs, New Melones Reservoir, Don Pedro Reservoir, Lake McClure, Pyramid Lake, Castaic Lake, Silverwood Lake, and Lake Perris

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for San Luis Reservoir. The discussion related to population growth would also apply to these other reservoirs. Recreation use at these other existing reservoirs in the Extended Study Area could be affected by implementation of the No Project/No Action Alternative because modeling results indicate that patterns of Delta exports would change and would be reduced more frequently, including by 10 percent or more during some months of Critical years. Additionally, large decreases in exports would also occur, which could potentially result in large reductions in storage during some years. Reductions in Delta exports and large reductions in reservoir storage would not be expected to result in increased use of existing recreational facilities. Implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** modeling results discussion. Decreases in storage at these other reservoirs in the Extended Study Area would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

It is possible that one or more projects included in the No Project/No Action Alternative could include recreational facilities that could affect recreation use levels at existing recreational facilities at these other existing reservoirs in the Extended Study Area. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Population growth would not be expected to result in reduced recreation use levels. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** modeling results discussion. Decreases in Delta exports and the resulting potential reductions in reservoir storage at these other existing reservoirs in the Extended Study Area could result in reduced recreation use levels and decreased recreation-day benefit values for reservoir operations. These reductions **would have a potentially substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** modeling results discussion. Potential large reductions in reservoir storage at these other existing reservoirs in the Extended Study Area could expose submerged obstacles and create hazardous conditions for boaters and other recreationists participating in water-based activities. Reductions in reservoir storage, therefore, **would have a potentially substantial adverse effect**, when compared to Existing Conditions.

Wildlife Refuge Water Use

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for San Luis Reservoir. The discussion related to population growth would also apply to wildlife refuges. Implementation of the No Project/No Action Alternative is expected to result in a slight increase in water supplies for wildlife refuges. Increased water supplies for the managed wetlands at these refuges could result in increased recreation opportunities, and consequently, increased use of these refuges. However, the slight increase would not be expected to result in the deterioration of existing recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. The potential slight increase in recreation use at these wildlife refuges would not require the construction or expansion of the existing recreational facilities. In addition, if increased use of wildlife refuges associated with population growth resulted in the need to expand refuge facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

It is possible that one or more projects included in the No Project/No Action Alternative could include recreational facilities that could affect recreation use levels at existing recreational facilities at these wildlife refuges. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Population growth would not be expected to result in reduced recreation use levels. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. The potential slight increase in water supplies for wildlife refuges would not be expected to create hazardous conditions for water-based activities and, therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

21.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to Trinity Lake. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in negligible changes to surface water elevations at Trinity Lake. These small fluctuations would not be expected to increase use of existing recreational facilities, and therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible changes in surface water elevations would not be expected to increase recreation use, and consequently, would not require the construction or expansion of existing facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Even though only relatively small changes in operation are expected, Project modeling indicates that the No Project/No Action Alternative would reduce the total number of months that five of the Trinity Lake boat ramps would be dewatered by 40 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions. This increase in availability of these boat ramps at Trinity Lake would be a **beneficial effect,** when compared to Existing Conditions.

Project modeling also indicates that the Cedar Stock boat ramp would be dewatered the same number of months over the 82-year period of record within the primary recreation season with implementation of the No Project/No Action Alternative, when compared to Existing Conditions. This lack of change in the availability of the boat ramp **would not have a substantial adverse effect,** when compared to Existing Conditions.

The No Project/No Action Alternative would, however, dewater the Minersville ramp at the end of August during a Critical year, which, over the 82-year period of record within the primary recreation season, is two weeks sooner than with Existing Conditions. The two weeks of reduced availability does not meet the significance criteria of a one month reduction for a lowest boat ramp with implementation of the No Project/No Action Alternative, and therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impacts on the relatively undeveloped swimming areas at Trinity Lake would be negligible because the swimming areas are always out of the water by late summer. Access impacts to the boat-in campsites are unknown; however, with Existing Conditions, the water is always a considerable distance away from the boat-in sites by September. These negligible decreases in availability associated with implementation of the No Project/No Action Alternative therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Recreation use at Trinity Lake may increase slightly in response to the improvement in reservoir operations associated with implementation of the No Project/No Action Alternative. This improvement in operation would increase the recreation-day benefit value for reservoir operation by one point, when compared to Existing Conditions, resulting in a **beneficial effect.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes in surface water elevations would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect,** when compared to Existing Conditions.

Trinity River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Trinity River. Modeling results for Trinity River flows downstream of Lewiston Lake for the No Project/No Action Alternative, when compared to Existing Conditions, indicate only slight changes in flows during Below Normal, Dry, or Critical water years. Large decreases in flow are indicated during Wet water years, but these decreases would not occur during the primary recreation season. These slight changes in flow would not result in increased use of existing facilities, and therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible changes to the flow regime are expected during the primary recreation season, which would not be expected to result in increased recreation use, or consequently, require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of the No Project/No Action Alternative, decreases in flow are expected during Wet water years during the months of March and April (although the Trinity River Record of Decision (ROD) requirements would always be met), and increases in flows are indicated in Above Normal water years in the month of February. Large increases in flow during February could negatively affect boat and shore anglers, who are the primary recreationists at that time, and may adversely affect early season whitewater boating. However, these changes to the flow regime would not affect recreation during the primary recreation season. These changes therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions, because the previously approved and implemented ROD requirements would always be met.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes to the flow regime would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect,** when compared to Existing Conditions.

Klamath River Downstream of the Trinity River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Klamath River. Modeling results for Klamath River downstream of the Trinity River for the No Project/No Action Alternative, when compared to Existing Conditions, indicate negligible changes in flows. These negligible changes in the flow regime would not result in increased use of existing facilities, and therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible changes in the flow regime would not be expected to result in increased recreation use, and consequently, would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

River flows and levels in the Klamath River would not be changed by implementation of the No Project/No Action Alternative, so there would be no impact to its recreational uses. Changes in the Trinity River temperatures would not extend past Douglas City, and so would have no effect on the Klamath River. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on recreation use levels on the Klamath River.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes in the flow regime would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect,** when compared to Existing Conditions.

Shasta Lake

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to Shasta Lake. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in no change to surface water elevations at Shasta Lake. This lack of change would not result in increased use of existing recreational facilities, and therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. A lack of change in surface water elevations would not be expected to increase recreation use, and consequently, would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Project operation modeling indicates that Shasta Lake water levels associated with implementation of the No Project/No Action Alternative typically would be less than one foot higher or lower than Existing Conditions during most months of the primary recreation season. The only exception would be during August and September in Critical years, when the No Project/No Action Alternative may increase lake levels by two or three feet from Existing Conditions.

However, an evaluation of all 10 major boat ramps at Shasta Lake indicates that the No Project/No Action Alternative would dewater seven ramps several months more over the 82-year period of record within the primary recreation season than with Existing Conditions. Overall, the No Project/No Action Alternative would dewater boat ramps at Shasta Lake 30 months more than Existing Conditions over the 82-year period of record within the primary recreation season, which **would have a potentially substantial adverse effect.**

However, Bridge Bay, Centimudi, and Jones Valley (the lowest ramps) would be dewatered two months less often over the 82-year period of record within the primary recreation season than for Existing Conditions, which is considered a **beneficial effect.**

The relatively small water level changes at Shasta Lake **would not have a substantial adverse effect** on recreation use levels; the recreation-day benefit value for reservoir operation would remain unchanged at

28 points, and therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. A lack of change in surface water elevations would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Sacramento River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Sacramento River. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall negligible change to the flow regime of the Sacramento River, with the exception of decreased flows below Keswick in November during Dry years. The decreases in November would occur outside of the primary recreation season, and the other negligible changes in flow would not result in the increased use of existing recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible changes in the flow regime during the primary recreation season would not be expected to result in increased recreation use, and consequently, would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall minor change to the flow regime of the Sacramento River, with the exception of decreased flows downstream of Keswick Reservoir in November during Dry years. These minor changes in flows on the Sacramento River **would not have a substantial adverse effect** on recreation use levels on the river, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes in the flow regime during the primary recreation season would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Clear Creek

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to Clear Creek. Project operational modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall minor change to the flow regime of Clear Creek, with the exception of large increases in flows during Critical years. The increase in Critical year flows would benefit summer recreation along the creek and could increase use levels, but would not be expected to increase to a level that would cause the deterioration of existing facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. A potential increase in recreation use due to increased flow during Critical years would not be expected to occur at a level that would require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Project operational modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall minor change to the flow regime of Clear Creek, with the exception of large increases in flows during Critical years. The increase in Critical year flows would benefit summer recreation along the creek. This would result in a **potentially beneficial effect,** when compared to Existing Conditions**.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. An overall minor change to the flow regime of Clear Creek would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Lake Oroville

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to Lake Oroville. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in slight decreases in surface water elevations at Lake Oroville. These lower water elevations would not result in the increased use of existing recreational facilities, and therefore, **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Slightly decreased surface water elevations would not be expected to result in increased recreation use, and consequently, would not require the construction or expansions of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

If the No Project/No Action Alternative is implemented, Lake Oroville surface water levels typically would be two or three feet lower during the primary recreation season, when compared to Existing Conditions. The slightly lower lake levels would have relatively minor effects on boat ramp accessibility. Overall, the No Project/No Action Alternative would increase boat ramp availability by five months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions. The No Project/No Action Alternative would increase the number of months that two of the intermediate boat ramps would be dewatered by three to four months over the 82-year period of record within the primary recreation season, which **would have a potentially substantial adverse effect,** when compared to Existing Conditions. Lime Saddle, another intermediate boat ramp that has an associated marina, would be dewatered one additional month over the 82-year period of record within the primary recreation season with implementation of the No Project/No Action Alternative. However, this additional dewatering does not meet the significance criteria of two additional months for intermediate boat ramps.

Enterprise, another intermediate boat ramp, would be dewatered one less month over the 82-year period of record within the primary recreation season with implementation of the No Project/No Action Alternative. In addition, the lowest ramp at Bidwell Canyon would be extended, with implementation of the FERC License Renewal Project included in the No Project/No Action Alternative, to a bottom elevation (640 feet) at which the ramp would always be in the water. This increased availability, especially during Critical years, would be a **beneficial effect,** when compared to Existing Conditions.

Although the lowest boat ramp at Bidwell Canyon would always be available, recreation use at Lake Oroville could be expected to decrease in response to the decreased availability of the intermediate boat ramps, especially Lime Saddle and its associated marina. Therefore, implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect,** when compared to Existing Conditions.

The recreation-day benefit value for reservoir operation with implementation of the No Project/No Action Alternative would decrease by one point from 17.5 to 16.5 points as a result of the overall decrease in surface water levels during the recreation season. This one point reduction **would have a potentially substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Slightly decreased surface water elevations would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Feather River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Feather River. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in many changes to the flow regime of the Feather River downstream of Thermalito, such as increased flows from June through September during most water year types, and decreases in flows during August and September in Dry years. Increased flows during the primary recreation season could result in increased use of the recreational facilities located along the Feather River, but not to a level that would result in the deterioration of those facilities. Decreased flows during Dry years could slightly reduce recreations use levels, but not to a level that would be expected to cause the increased use of other recreational facilities. Therefore, the No Project/No Action Alternative **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. The potential slight increases and decreases in recreation use in response to a fluctuating flow regime would not be expected to occur at a level that would require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Increased flows from June through September during most water year types and decreases in flows during August and September in Dry years could affect use levels or recreation benefits. However, flow levels would remain in an acceptable range of 1,500 to 4,000 cfs (Pike, 2001) downstream of Thermalito for fishery habitat, wading, and recreational boating, except during Below Normal, Dry, and Critical years when May flows would be between 1,000 to 1,500 cfs downstream of Thermalito and 3,000 to 5,000 cfs at Verona. During those times, the No Project/No Action Alternative conditions would be virtually the same as Existing Conditions. Therefore, the No Project/No Action Alternative **would not have a substantial adverse effect** on lower Feather River recreation use levels, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-4** discussion. Changes to the flow regime of the Feather River could create hazardous conditions for water-based activities. However, flow levels would remain in an acceptable range for wading and boating downstream of Thermalito and therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Sutter Bypass and Yolo Bypass

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Sutter and Yolo bypasses. Project operational modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall small change in spills into the Sutter Bypass at Moulton, Tisdale, and Ord Ferry weirs. Colusa Weir would experience an overall decrease in spills during November, especially in Dry years. Modeling results also indicate overall small change in monthly flows into the Yolo Bypass, with the exception of large decreases in flow during late fall in Below Normal and Dry years. These changes would occur in the winter months when little or no recreation use occurs along the bypasses because of hazardous flows and poor road access. Therefore, the reduction in winter flows in the Sutter and Yolo bypasses would not impact its recreational uses and would not increase use at other recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Because changes in weir spills into these bypasses would occur outside of the primary recreation season, these operational changes would not be expected to require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Because these changes in spills would occur in the winter months when little or no recreation use occurs along the bypasses, the changes **would not have a substantial adverse effect** on recreation use levels in the bypasses, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. An overall small change in spills into the Sutter and Yolo Bypass, with the exception of large decreases in flow during late fall in Below Normal and Dry years at the Yolo Bypass, would occur in the winter months when little or no recreation use occurs along the bypasses because of hazardous flows and poor road access. Small changes in spills would not be expected to create additional hazardous conditions, and decreases in flow could potentially reduce existing hazards. These expected changes in flows into the bypasses therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Folsom Lake

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to Folsom Lake. If the No Project/No Action Alternative is implemented, decreases in surface water elevations at Folsom Lake are expected during some months of the year. These decreases could result in reduced recreation use, but these minor decreases would not result in increased use levels that would cause the deterioration of other recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. A potential reduction in recreation use levels would not require the construction or expansion of existing recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Slight decreases in surface water elevations associated with implementation of the No Project/No Action Alternative would dewater the eight major boat ramps (that have two or more lanes) at Folsom Lake a total of 29 months more over the 82-year period of record within the primary recreation season than with Existing Conditions. Most of this impact would occur at the intermediate ramps, with the dewatering occurring seven to 11 months more per boat ramp. This increased amount of dewatering **would have a potentially substantial adverse effect,** when compared to Existing Conditions.

In addition, the lowest ramps (Hobie Cove and Low Water) would be dewatered one additional month each over the 82-year period of record within the primary recreation season. Therefore, these two boat ramps **would have a potentially substantial adverse effect,** when compared to Existing Conditions.

Although any reduction in recreation use from modestly lower lake levels cannot be accurately quantified, it is likely to equal approximately one month of use at these ramps during the peak recreation season. The operational portion of the recreation-day benefit value for Folsom Lake would decline from 25 to 22.5 points due to the lower lake levels. These effects **would have a potentially substantial adverse effect,** when compared to Existing Conditions**.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Decreases in surface water elevations at Folsom Lake could expose submerged obstacles and create hazardous conditions for water-based activities, and therefore **would have a potentially substantial adverse effect,** when compared to Existing Conditions.

American River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the American River. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall decrease in flows on the American River in all months, with the exception of December. Large decreases in flow are also indicated in September of Above Normal years, September and October of Below Normal years, and in August and September in Critically Dry years. This overall reduction in flows could result in decreased recreation use, but not at levels that would be expected to increase use of other recreational facilities or cause the deterioration of those facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. A potential decrease in recreation use would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Flows needed to support recreation uses and fishery production on the American River have been studied extensively. In general, flows of 1,500 to 3,000 cfs are acceptable for general recreation activities, and 3,000 to 5,000 cfs is desirable for boating uses during the primary recreation season (Hinton and Tittel, 1987). The No Project/No Action Alternative would generally reduce flows in the American River downstream of Nimbus Dam and at the H Street Bridge during the primary recreation season in nearly all water year types. These reductions would range from 3 percent to as much as 24 percent in August and September of Critical years at the H Street Bridge. Although streamflows would remain in the desirable ranges during most years with these reductions, flows would generally be less than 1,500 cfs during Critical years, when reductions **would have a potentially substantial adverse effect,** when compared to Existing Conditions**.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. An overall decrease in flows on the American River, especially during critical years, could result in hazardous boating conditions and therefore **would have a potentially substantial adverse effect,** when compared to Existing Conditions**.**

Sacramento-San Joaquin Delta

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Sacramento-San Joaquin Delta. Project modeling indicates that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall minor change in Delta monthly outflow. This minor change would not be expected to increase use levels and cause the deterioration of recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Minor changes in Delta flow would not be expected to result in increased recreation use, and consequently, would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

The overall minor change in Delta monthly outflow associated with implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would not be expected to affect recreation use levels. These minor changes would, **therefore, not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Minor changes in Delta flow would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect,** when compared to Existing Conditions.

Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to the Sacramento-San Joaquin Delta. Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall negligible change in Delta monthly outflow. Therefore, Suisun, San Pablo, and San Francisco bays would also be expected to experience negligible changes. Negligible changes in the flow regime of these bays would not increase use levels or cause the deterioration of recreational facilities. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible changes within the bays would not be expected to result in increased recreation use, and consequently, would not require the construction or expansion of existing recreational facilities. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

The overall minor change in Delta monthly outflow and negligible changes in the flow regime of Suisun, San Pablo, and San Francisco bays **would not have a substantial adverse effect** on recreation use of the bays, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes within the bays would not be expected to create hazardous conditions for water-based activities and therefore **would not have a substantial adverse effect**, when compared to Existing Conditions.

Other Reservoirs within the Secondary Study Area

Lake Almanor, Clear Lake, Lake Berryessa, New Bullard's Bar Reservoir, Englebright Lake, Black Butte, East Park, Stony Gorge, and Indian Valley

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Refer to the **Impact Rec-1** discussion for the Extended Study Area for San Luis Reservoir. The discussion related to population growth would also apply to these other reservoirs within the Secondary Study Area. The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval as of June 2009. Some of those projects may result in indirect effects to recreation opportunities at these other reservoirs within the Secondary Study Area. However, the impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to existing recreation resources and opportunities in the vicinity of those projects has been addressed in those environmental documents. The impact on recreation resources therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. It is possible that one or more projects included in the No Project/No Action Alternative could require the construction or expansion of recreational facilities at these other Secondary Study Area reservoirs that may result in adverse effects on the environment. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. In addition, if increased use of existing recreational facilities associated with population growth resulted in the need to expand those facilities, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-3** discussion for the Extended Study Area for San Luis Reservoir. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

It is possible that other projects included in the No Project/No Action Alternative could include operations that could affect recreation use levels at the existing recreational facilities of these other Secondary Study Area reservoirs. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

It is possible that other projects included in the No Project/No Action Alternative could include operations that would affect water levels within the existing recreational facilities of these other Secondary Study Area reservoirs. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

21.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Population throughout California is expected to increase. Recreation use at existing neighborhood or regional parks also may (or may not) continue to increase, as described and anticipated in City and County General Plans that address areas within the Primary Study Area. However, none of the projects and programs included in the No Project/No Action Alternative are located within the Primary Study Area, and they would not directly affect existing recreation in that area. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. That discussion is also applicable to effects on the environment from the construction or expansion of existing recreational facilities.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to the **Impact Rec-1** discussion. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. That discussion is also applicable to effects on recreation use levels and/or recreation benefits at existing reservoirs or rivers.

21.3.6 Impacts Associated with Alternative A

21.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

San Luis Reservoir

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

San Luis Reservoir currently experiences severe water level fluctuations. Operational modeling results for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicate that operation of the Project would cause San Luis Reservoir water levels to continue to fluctuate, but would occur more often and could be more severe. Water level fluctuations can adversely affect recreation use levels if they occur during the recreation season. However, the water level fluctuations associated with implementation of Alternative A are expected to fall within the historic range of fluctuations during the primary recreation season and, therefore, are not expected to decrease recreation use at San Luis Reservoir or increase or substitute use at other recreational facilities. Therefore, the increased fluctuations in water levels at San Luis Reservoir resulting from implementation of Alternative A would have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Fluctuating surface water elevations would not be expected to increase recreation use at San Luis Reservoir, and consequently would not require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels at San Luis Reservoir because Sites Reservoir would be located approximately 200 miles from this facility. There would, therefore, be **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Changes in operation that would result in increased surface water elevation fluctuations at San Luis Reservoir associated with implementation of Alternative A would make the Dinosaur Boat Ramp available five more months over the 82-year period of record within the primary recreation season than Existing Conditions, and four more months over the 82-year period of record within the primary recreation season than with implementation of the No Project/No Action Alternative. The Basalt Boat Ramp would be usable six months over the 82-year period of record within the primary recreation season more than Existing Conditions and three months over the 82-year period of record within the primary recreation season more than with the No Project/No Action Alternative, including increased availability during Critical years. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would result in a **beneficial effect.**

Implementation of Alternative A would provide sufficient water surface elevations for boating use of the reservoir; in comparison, boating access would not be possible for several months for Existing Conditions and the No Project/No Action Alternative. Recreation use at San Luis Reservoir could be expected to increase by an amount roughly equal to the five additional months over the 82-year period of record within the primary recreation season that the boat ramps would be available, which is considered a **beneficial effect,** when compared to Existing Conditions and the No Project Alternative.

The Basalt Campground water intake would be dewatered three fewer months over the 82-year period of record within the primary recreation season when compared to Existing Conditions, but two more months over the 82-year period of record within the primary recreation season when compared to the No Project/No Action Alternative. This would be a **beneficial effect,** when compared to Existing Conditions, but would be a **potentially significant impact,** when compared to the No Project/No Action Alternative.

The reservoir operations portion of the recreation-day benefit value for existing San Luis Reservoir operations is approximately five out of a possible 50 points because of extensive drawdown nearly every year (averaging 138 feet). Therefore, a few feet of change in water levels with implementation of Alternative A would have only a small effect on the recreation-day benefit value for reservoir operation. Even in the Wet year conditions when the reservoir is expected to average 13 feet lower during the recreation season, or the Critical years when it could be 6 to 16 feet higher during the season, there would be a small change in the recreation-day benefit value for reservoir operation because the value is based on average conditions, rather than specific water years. The recreation-day benefit value for reservoir operation at San Luis Reservoir would be decreased by 0.5 point because the average water surface elevation would be approximately two feet lower with Alternative A than with either Existing Conditions or the No Project/No Action Alternative. This would be a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Fluctuating surface water elevations at San Luis Reservoir could create hazardous conditions for water-based activities by exposing submerged obstacles or concealing obstacles that were previously visible. However, because the water level fluctuations at San Luis Reservoir are expected to fall within the historic range of fluctuations during the primary recreation season, they are not expected to create additional hazardous conditions and therefore would result in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Other Reservoirs within the Extended Study Area

Tri-Dam Reservoirs, New Melones Reservoir, Don Pedro Reservoir, Lake McClure, Pyramid Lake, Castaic Lake, Silverwood Lake, and Lake Perris

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

The increased SWP/CVP exports associated with implementation of Alternative A could potentially result in increased storage at these other existing reservoirs within the Extended Study Area. Small increases in storage at these reservoirs could result in increased recreation use at these reservoirs, but the increase would be negligible and would not cause physical deterioration of existing facilities. The potential slight increases in storage at these service area reservoirs would, therefore, also not be expected to result in increased recreation use at other reservoirs. Implementation of Alternative A would, therefore, have **no impact** on increased recreation use levels at these reservoirs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Slight increases in storage could result in slightly increased recreation use levels, but not at the level that would require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels at these other existing reservoirs located within the Extended Study Area because Sites Reservoir would be located a great distance away from these facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. The potential slight increase in storage at some of these other existing reservoirs within the Extended Study Area could result in increased recreation use and an increased recreation-day benefit value if the increase occurs during the primary recreation season. The slight change in operation would, therefore, not be expected to reduce recreation use levels or other recreation benefits, and would have a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. The potential slight increase in storage at some of these other existing reservoirs within the Extended Study Area would not be expected to create hazardous conditions for water-based activities and therefore would have a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Wildlife Refuge Water Use

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Alternative A would provide an alternate source of Level 4 water deliveries to the wildlife refuges. The provision of an alternate source of water would have **no impact** on recreational use levels, and therefore, would not cause the deterioration of recreational facilities within the wildlife refuges, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. An alternate water supply source would not increase recreational use levels, and consequently, would not require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas (up to five recreation areas are proposed) are not expected to affect recreation use levels at existing wildlife refuges located within the Extended Study Area because Sites Reservoir would be located a great distance away from these facilities and would not offer the same recreational opportunities as a wildlife refuge. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. An alternate water supply source would not create hazardous conditions for water-based activities and would, therefore, have **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Operational modeling results for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicate that Alternative A would provide operational flexibility to Trinity Lake. Storage would be improved in all months of all water year types, including during May through October in Dry and Critical year conditions. In other years, larger releases would be made to stabilize fall flow conditions. Seasonal and monthly improvements in storage would occur, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, operational modeling results indicate that a reduced range of change in fluctuations would occur, resulting in less severe drawdowns. These improved conditions at Trinity Lake are not expected to increase use of existing recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Improved storage conditions are not expected to increase recreation use to a level that would require the construction of new facilities, nor would it require the expansion of the lake's existing facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels at Trinity Lake because Sites Reservoir would be located more than 130 miles away from this facility. In addition, Sites Reservoir would not provide the same recreation experiences as the larger and higher elevation, tributary-filled Trinity Lake. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of Alternative A, average end of month storage at Trinity Lake would increase during nearly all months of the year, when compared to Existing Conditions and the No Project/No Action Alternative. Improved storage could increase recreation use and/or recreation benefits, especially if boat ramps or boat-in campsites are more accessible or accessible for longer periods. There are some months in many water year types when an increase in water level of several feet would make one or more boat ramps available for longer than Existing Conditions during the recreation season.

Implementation of Alternative A would increase Trinity Lake boat ramp accessibility by a total of 87 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and by a total of 47 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. However, the most important change would be in Below Normal, Dry, and Critical years, when the Cedar Stock ramp would be available six more months over the 82-year period of record within the primary recreation season than for Existing Conditions and the No Project/No Action Alternative, and the Minersville ramp would be available three more months over the 82-year period of record within the primary recreation season than for Existing Conditions and four more months over the 82-year period of record within the primary recreation season than for the No Project/No Action Alternative. These increases in boat ramp availability are considered **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

With implementation of Alternative A, boat-in campsites would be more accessible than for Existing Conditions and the No Project/No Action Alternative. There would likely be an increase in recreation use due to increased access to boat ramps and boat in-camps. The increased use would likely be equivalent to or greater than the additional four months of boating use at the Minersville Ramp. This would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

The reservoir operation portion of the recreation-day benefit value with Existing Conditions has a point value of 12 out of 50 possible points, and would have a value of 13 if the No Project/No Action Alternative is implemented. With implementation of Alternative A, the expected increase in water levels during the primary recreation season would increase this value to 15. Thus, the increased recreation-day benefit value for reservoir operation would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Improved storage conditions would not be expected to create hazardous conditions for water-based activities and therefore would have a **less-than-significant** impact, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Trinity River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Project operational modeling results indicate that Trinity River flows would meet or exceed the Trinity River ROD requirements in all scenarios, with or without implementation of Alternative A. Modeling results show little change from the existing flow schedule, and the small amount of change would rarely occur. These occasional small changes to the existing flow schedule are not expected to affect recreation use along the Trinity River, and would not increase use at other recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Occasional small changes to the existing flow schedule are not expected to increase recreation use to a level that would require the construction or expansion of existing recreational facilities along the river. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels on the Trinity River because Sites Reservoir would be located a great distance away from this river and would not provide river recreation opportunities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Project operational modeling results for Alternative A show little change from the existing flow schedule, or from the No Project/No Action Alternative. Cooler water temperatures could improve conditions for anadromous fish and possibly increase Trinity River angling. Conversely, colder water temperatures in the summer months could affect water contact recreation, such as swimming or tubing. However, Project operation studies suggest the temperature change at Lewiston would be less than 1°F, except for one or two months in Critical years when it may be 2°F or 3°F colder. These minor changes in temperature would, therefore, not be likely to improve angling opportunities or adversely affect water contact recreation. This slight change in the flow regime and change in water temperature on the Trinity River would have a **less-than-significant impact** on recreation use levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Occasional small changes to the existing flow regime would not be expected to create hazardous conditions for water-based activities and therefore would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Klamath River downstream of the Trinity River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

River flows and levels in the Klamath River would not be changed by implementation of Alternative A, when compared to Existing Conditions the No Project/No Action Alternative, so there would be **no impact** to its recreational uses.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Because recreational use levels would not be affected, the construction or expansion of existing recreational facilities would not be required. There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels on the Klamath River because Sites Reservoir would be located approximately 300 miles away from this river and would not provide river recreation opportunities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. In addition, any changes in Trinity River temperatures would be negligible past Douglas City and therefore would have no effect on the Klamath River. Therefore, implementation of Alternative A would have **no impact** on recreation use levels on the Klamath River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. A lack of change to the existing flow regime would not create hazardous conditions for water-based activities and therefore would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Shasta Lake

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Operational modeling results for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicate that Alternative A would provide operational flexibility to Shasta Lake, similar to that described for Trinity Lake. Improved storage conditions and reduced water level fluctuations are not expected to reduce recreation use of Shasta Lake and would not increase use at other recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Improved storage conditions are not expected to increase recreation use to a level that would require the construction or expansion of existing facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels at Shasta Lake because Sites Reservoir would be located approximately 115 miles away from this facility. In addition, Sites Reservoir would not provide the same recreation experience as the larger and higher elevation, tributary-filled Shasta Lake. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

For Alternative A, storage at Shasta Lake would increase nearly every month during all water year types, when compared to Existing Conditions and the No Project/No Action Alternative.

There are no obvious major changes to boat ramp accessibility, but implementation of Alternative A would increase accessibility to several ramps in August and September during most water year types (a **beneficial effect**). In Dry years, the Antlers Ramp would go out of service in August and September (an adverse impact), but eight of the remaining major boat ramps would still be accessible. In addition, overall accessibility at Antlers Ramp would improve by 11 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and by 15 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative.

In Critical years, access to Packers Bay and Digger Bay ramps would be increased by nearly one month. Access to Centimudi and Jones Valley ramps would be increased by three months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions and the No Project/No Action Alternative. Access to all major boats ramps would be improved by at least two months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions and the No Project/No Action Alternative. The exception would be the Silverthorn Marina, which would be dewatered two months more over the 82-year period of record within the primary recreation season, when compared to Existing Conditions. Overall, Shasta Lake boat ramp accessibility associated with Alternative A would increase by a total of 56 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and by 86 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. When considering all of the expected changes, implementation of Alternative A would result in a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The USFS provides information on the Whiskeytown-Shasta-Trinity National Recreation Area website indicating how far it is to the water's edge from campgrounds at various water levels. Data specific to each of the 17 campgrounds located at that recreation area are not available, so a detailed analysis of the operational effect of Alternative A on those areas was not performed. However, a 20-foot increase in water level during the recreation season would shorten the distance to the lake by more than 150 feet (USFS, 2011).

In addition to slightly improved boat ramp and boat-in camp accessibility, the increased water levels at Shasta Lake associated with Alternative A would increase the lake's recreation-day benefit value. The Existing Conditions and No Project/No Action Alternative's reservoir operation portion of the benefit value both have a point value of 28 out of 50 possible points. The increase in water levels during the primary recreation season with implementation of Alternative A would increase this value to 33 points. Improved storage at Shasta Lake would have a **beneficial effect** on the recreation-day benefit value for reservoir operation, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Improved storage conditions would not be expected to create hazardous conditions for water-based activities and therefore would have a **less-than-significant** impact, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Sacramento River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

The flow regime modifications on the Sacramento River expected with implementation of Alternative A would not significantly affect river recreation use and would not increase use at other recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Occasional small changes to the existing flow schedule are not expected to increase recreation use to a level that would require the construction or expansion of existing facilities along the river. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels on the Sacramento River because Sites Reservoir would not provide river recreation opportunities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Improved (colder) water temperatures on the Sacramento River resulting from flow regime modifications have the potential to improve conditions for salmon and steelhead, and consequently, increase fishing use on the river. Conversely, colder water temperatures in the summer months may adversely affect water contact recreation, such as swimming and tubing, which is already limited in the Sacramento River. However, Project operation modeling indicates that water temperatures at Balls Ferry, Bend Bridge, and the City of Red Bluff would be essentially unchanged, with differences always less than 1°F. Thus, changes in the flow regime of the Sacramento River would have a **less-than-significant impact** on recreation use levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Occasional small changes to the existing flow regime of the Sacramento River would not be expected to create hazardous conditions for water-based activities. Decreased water temperatures could, however, create hazardous conditions for swimmers or tubers, but these types of recreation are limited on the

Sacramento River and modeling results indicate the changes in temperature would be less than 1°F. Therefore, changes in the flow regime of the Sacramento River would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Pump Installation at the Red Bluff Pumping Plant

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

The installation and operation of an additional pump in an existing bay at the Red Bluff Pumping Plant would result in only minor increases in diversions from the river, when compared to Existing Conditions and the No Project/No Action Alternative. This minor change in flow would have **no impact** on recreation use levels in the Sacramento River near that location and would not increase use at other recreational facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Minor changes in the flow regime would not be expected to affect recreation use levels on the Sacramento River at this location and consequently would not require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

Refer to **Impact Rec-3** for the Sacramento River. That discussion is also applicable to effects on recreation use levels at existing recreational facilities.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Minor changes in the flow regime would not be expected to affect recreation use levels. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-5: Reduce Recreation Use Levels at Existing Recreational Facilities during the Project Construction Period

Construction activities associated with the installation of an additional pump at the Red Bluff Pumping Plant would not occur within the river, and therefore, would have **no impact** on recreation use levels in that area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Minor changes in the flow regime would not be expected to create hazardous conditions for water-based activities and therefore would have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Clear Creek

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Project operational modeling results indicate that Clear Creek flow requirements would be met or exceeded, if Alternative A is implemented, and that changes in Clear Creek flows and water temperatures would be minor. Minor changes in flow would have **no impact** on Clear Creek recreation use levels and would not increase use at other recreational facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Minor changes in flow would not be expected to affect recreation use levels, and consequently, would not require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels on Clear Creek because Sites Reservoir would be located approximately 100 miles away from this creek and would not provide the same type of recreation opportunities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Cooler water temperatures downstream of Whiskeytown Lake in Dry and Critical years could potentially improve conditions for anadromous fish in Clear Creek and ultimately increase Sacramento River angling. However, Project operational modeling results indicate that changes in Clear Creek flows and water temperatures would be minor, so no measureable improvement is anticipated. Therefore, there would be **no impact** on recreation use levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Minor changes in flow would not be expected to create hazardous conditions for water-based activities and therefore would have **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Lake Oroville

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Operational modeling results for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicate that Alternative A would provide operational flexibility to Lake Oroville, similar to that described for Trinity Lake. Improved storage conditions and reduced water level fluctuations are not expected to reduce recreation use at Lake Oroville and would not increase use at other recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Improved storage conditions are not expected to increase recreation use to a level that would require the construction or expansion of existing facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas could affect recreation use levels at Lake Oroville, especially if Sites Reservoir surface water elevations are high when Lake Oroville surface water elevations are low. However, Sites Reservoir would be smaller than Lake Oroville and would not provide the same recreation experience as the larger tributary-filled Lake Oroville; it, therefore, would not be expected to substantially reduce recreation use levels at Lake Oroville. Therefore, there would be **a less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

The Bidwell Canyon low water ramp would always be in the water with implementation of the No Project/No Action Alternative, and would remain in the water with or without implementation of Alternative A. Alternative A would increase access to the remaining four major ramps evaluated at Lake Oroville by 15 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and by 22 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. This situation would result in a **beneficial effect** with implementation of Alternative A when compared to Existing Conditions and the No Project/No Action Alternative.

Typically, the changes in water elevations with Alternative A would not substantially change access to the boat-in campsites, when compared to Existing Conditions and the No Project/No Action Alternative, so there would be **no impact**.

The Existing Conditions operation for Lake Oroville has a recreation-day benefit value of 17.5 points. This value would not change with implementation of Alternative A. However, the operation portion of the recreation-day benefit value for the No Project/No Action Alternative is 16.5 points, so Alternative A would provide an increase of one point. Therefore, implementation of Alternative A would have **no impact** on the recreation-day benefit value when compared to Existing Conditions, and would have a **beneficial effect** when compared to the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Improved storage conditions would not be expected to create hazardous conditions for water-based activities and therefore would have a **less-than-significant** impact, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Feather River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Project operational modeling results indicate that Feather River flows would meet or exceed the FERC Settlement Agreement's minimum flow requirements in all scenarios. When compared to Existing Conditions and the No Project/No Action Alternative, flows in June through September in drier years would be improved. However, flows would generally be decreased during October, November, and December. The flow regime modifications on the Feather River expected with implementation of Alternative A would not significantly affect river recreation use and would not increase use at other recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Increased flows during the recreation season during drier years are not expected to increase recreation use to a level that would require the construction or expansion of existing recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels on the Feather River, as Sites Reservoir would not provide river recreation opportunities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Improved flow and temperature conditions for salmon and steelhead during drier years could result in increased populations; consequently, fishing use would likely increase. Conversely, colder water temperatures in the summer months could affect water contact recreation, such as swimming or tubing. However, Project operational modeling results indicate small changes in flows and water temperatures in the lower Feather River with implementation of Alternative A, with the exception of June through September which would have relatively large increases in flow during drier years. These flow regime changes would have a **less-than-significant impact** on recreation use levels, when compared to Existing Conditions or the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Increased flows during the recreation season during drier years would fall within acceptable levels for water-based activities and would not be expected to create hazardous conditions. These flow regime changes would have a **less-than-significant impact**, when compared to Existing Conditions or the No Project/No Action Alternative.

Sutter Bypass and Yolo Bypass

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

With implementation of Alternative A, winter flood flows that spill into the Sutter Bypass would be reduced by up to 5,900 cfs due to diversions to Sites Reservoir. Flows in the Yolo Bypass would also be reduced in duration and magnitude due to Sites Reservoir diversions. However, these reductions in winter flows in the bypasses would not be expected to substantially impact its recreational uses and would not increase use at other recreational facilities. Therefore, there would be a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Reductions in winter flows would not be expected to substantially affect recreation use levels and consequently would not require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels within the bypasses because Sites Reservoir would not provide the type of recreation opportunities that are available within the bypasses. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Reductions in winter flows would not be expected to substantially affect recreation use levels. There would, therefore, be a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Reductions in winter flows in the bypasses would occur when little or no recreation use occurs because of hazardous flows and poor road access. Decreases in flow would not create hazardous conditions and could potentially reduce existing hazards. These expected changes in flows into the bypasses would, therefore, be **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative. Folsom Lake

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Project operational modeling results for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicate that Alternative A would provide operational flexibility to Folsom Lake, similar to that described for Trinity Lake. Improved storage conditions and reduced water level fluctuations are not expected to reduce recreation use of Folsom Lake and would not increase use at other recreational facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Improved storage conditions are not expected to increase recreation use to a level that would require the construction or expansion of the lake's facilities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas could affect recreation use levels at Folsom Lake, especially if Sites Reservoir surface water elevations are high when Folsom Lake surface water elevations are low. However, Sites Reservoir would not provide the same recreation experiences as Folsom Lake, such as a marina and associated equipment rentals; it, therefore, would not be expected to substantially reduce recreation use levels at Folsom Lake. Therefore, there would be a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Implementation of Alternative A would result in small increases in storage at Folsom Lake during some months of the year. Increased storage and resulting higher water surface elevations could slightly increase recreation use and/or the recreation-day benefit value, especially if boat ramps or boat moorage areas are more accessible.

With implementation of Alternative A, the eight major boat ramps at Folsom Lake would be available 16 additional months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and 45 additional months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. The Low Water Ramp would be available three more months over the 82-year period of record within the primary recreation season than for Existing Conditions and four more months over the 82-year period of record within the primary recreation season than with the No Project/No Action Alternative. These changes would be **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

There are no designated boat-in campgrounds at Folsom Lake. However, boaters can beach their boats and camp overnight up to two nights in unoccupied campsites at Peninsula Campground. There is also a designated swimming beach. The higher water surface elevations during the recreation season resulting from implementation of Alternative A would provide slightly better access from the Peninsula and Beals Point campgrounds to the water surface, and could improve conditions at the swim beach. This would be a **potentially beneficial effect**, when compared to Existing Conditions and the No Project/No Action Alternative.

The modest increases in lake levels with implementation of Alternative A would affect the recreation-day benefit value for Folsom Lake. Existing Conditions has a value of 25 points, and the No Project/No Action Alternative would have a reservoir operation value of 22.5 points; the value would increase to 26.5 points with implementation of Alternative A. The increased recreation-day benefit value would be a **beneficial effect**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Improved storage conditions would not be expected to create hazardous conditions for water-based activities and therefore would have a **less-than-significant** impact, when compared to Existing Conditions and the No Project/No Action Alternative**.**

American River

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Operational changes on the American River related to implementation of Alternative A, when compared to Existing Conditions, would result in a substantial reduction in summer flows, but would have a flow regime similar to the No Project/No Action Alternative. Decreased or similar flows during the primary recreation season would not increase recreational use or cause the deterioration of recreational facilities along the American River. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

The operational changes associated with Alternative A would not require the construction or expansion of existing recreational facilities along the American River. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels along the American River because Sites Reservoir would not provide river recreation opportunities. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Project operational modeling results indicate that American River flows would be similar between Alternative A and the No Project/No Action Alternative, but would be significantly reduced with implementation of Alternative A, especially in Critically Dry years, when compared to Existing

Conditions (adverse impact). However, the significant flow reductions are associated with operational changes that would occur with implementation of the No Project/No Action Alternative, and were carried forward/incorporated into Alternative A. These adverse changes would occur with or without implementation of Alternative A, and are, therefore, not considered to be Project-related impacts. Because the adverse changes in flows would not be caused by implementation of Alternative A, the potential operational impacts on recreation use levels are considered to be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to **Impact Rec-4** discussion. Slight changes in flow would not be expected to create hazardous conditions for water-based activities and would, therefore, be **less than significant**, when compared to the No Project/No Action Alternative. Significant flow reductions could create hazardous boating conditions, however, the significant flow reductions are associated with operational changes that would occur with implementation of the No Project/No Action Alternative, and were carried forward/incorporated into Alternative A. These adverse changes would occur with or without implementation of Alternative A, and are, therefore, not considered to be Project-related impacts. Because the adverse changes in flows would not be caused by implementation of Alternative A, the potential operational impacts are considered to be **less than significant**, when compared to Existing Conditions.

Sacramento-San Joaquin Delta and Suisun Bay

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Alternative A operations would cause minor changes in flows entering the Sacramento-San Joaquin Delta and Suisun Bay, when compared to Existing Conditions and the No Project/No Action Alternative. These changes would be too small to affect its many recreational uses and, therefore, would have **no impact** on recreation use levels.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Negligible changes in flows would not be expected to affect recreation use levels, and consequently, would not require the construction or expansion of existing recreational facilities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels within the Delta because Sites Reservoir would not provide the type of recreation opportunities that are available within the Delta. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes in flows would not be expected to affect recreation use levels. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Negligible changes in flows would not create hazardous conditions for water-based activities and would, therefore, have **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

San Pablo Bay and San Francisco Bay

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Implementation of Alternative A would not result in changes to the hydrology of San Pablo Bay or San Francisco Bay. Therefore, there would be **no impact** to recreation use levels within the bays or at other recreational facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Because recreation use levels would not be affected, the construction or expansion of existing recreational facilities would not be required. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The proposed Sites Reservoir and its associated recreation areas are not expected to affect recreation use levels within the bays because Sites Reservoir would not provide the type of recreation opportunities that are available within the bays. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Because recreation use levels would not be affected, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. A lack of change in the hydrology of the bays would not create hazardous conditions and would, therefore, have **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Other Reservoirs within the Secondary Study Area

Lake Almanor, Clear Lake, Lake Berryessa, New Bullard's Bar Reservoir, Englebright Lake, Black Butte, East Park, Stony Gorge, and Indian Valley

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

No operational changes would occur at these other reservoirs within the Secondary Study Area with implementation of Alternative A. In addition, the availability of a new Sites Reservoir would not be expected to increase use of these reservoirs. Therefore, there would be **no impact** to recreation use levels at these reservoirs, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Because implementation of Alternative A is not expected to affect recreation use levels at these reservoirs, construction or expansion of their existing recreational facilities would not be required. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The new availability of Sites Reservoir would not be expected to reduce recreation use levels at Lake Almanor, Lake Berryessa, New Bullard's Bar Reservoir, or Englebright Lake due to their large distance away from Sites Reservoir. However, Sites Reservoir is likely to reduce recreation use at neighboring Black Butte, East Park, Stony Gorge, and Indian Valley reservoirs, as well as Clear Lake, at least initially. Alternative A would provide a new recreation site (i.e., additional recreation opportunities) for recreation visitors. It is expected that recreationists would want to visit the new reservoir to see what it offers. Fishing in a recently filled reservoir is often outstanding for several years because a newly filled reservoir increases the biological productivity of the inundated lands; this productivity supports rapid fish growth and growth in fish populations. Publicity related to construction of the new reservoir would also create interest and would alert potential recreationists to its existence, which may attract additional visitors to the area.

Construction of a new reservoir could also cause a temporary or even permanent redistribution of recreation use among the nearby recreation sites. The factors that would determine this redistribution of use include access convenience, climate, vegetative cover, available recreation opportunities, user fees, and quality of the recreation development. Sites Reservoir would be closer to I-5 than Clear Lake or East Park, Stony Gorge, or Indian Valley reservoirs, and would be located approximately the same distance from I-5 as Black Butte Reservoir. Climate and vegetative cover are similar at all five sites. The primary differences between the reservoirs would, therefore, be the available recreation opportunities and quality of recreation development.

Sites Reservoir would be smaller than Clear Lake and much larger than the other four reservoirs, which has both positive and negative aspects. Clear Lake offers private resorts and marinas, as well as county, State, and city parks on the lake's perimeter. East Park, Stony Gorge, and Indian Valley reservoirs are minimally developed, and many of their visitors enjoy the relative freedom of movement and ability to camp or picnic more or less wherever they want. Black Butte Reservoir has designated camp and picnic sites and a paved boat ramp. In this regard, it is probably most comparable to the proposed recreation area development level at Sites Reservoir.

The large surface area of Sites Reservoir may be daunting to some boaters and appealing to others. The expected average annual 33-foot drawdown that would occur during the recreation season at Sites Reservoir with implementation of Alternative A is greater than the drawdown typical of neighboring reservoirs and could adversely affect the proposed recreation opportunities due to the increased difficulty of accessing the reservoir, the barren exposed land during the drawdown (i.e., the bathtub ring appearance), and the creation of potential boating hazards. After a few years of Project operation, the distribution of recreation use at all area reservoirs is expected to stabilize, with use of neighboring reservoirs returning to pre-Sites Reservoir levels, i.e., Existing Conditions. Therefore, the temporary redistribution of recreation use resulting from implementation of Sites Reservoir and its associated Recreation Areas would have a **less-than-significant impact** on recreation use levels at existing recreational facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Implementation of Alternative A would not affect the operation of any of these other reservoirs within the Secondary Study Area. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

Refer to the **Impact Rec-1** discussion. Because no operational changes would occur at these other reservoirs within the Secondary Study Area, no hazardous conditions for water-based activities would be created. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

The following Project facility locations do not currently provide public recreation opportunities and would continue to provide little or no recreation opportunities if Alternative A is implemented, so there would be **no impact** to recreation resources at these locations from constructing or operating Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative:

- Sites Reservoir Dams
- Road Relocations and South Bridge
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR

- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline Electrical Switchyard
- Project Buffer

The remaining Project facilities and their potential impacts to recreation resources are described below.

Sites Reservoir Inundation Area and Recreation Areas

The recreation-day benefit value for Sites Reservoir was calculated for the purpose of comparison between Alternatives A, B, and C. Based on the expected operation of the reservoir, the recreation-day benefit value for the Alternative A Sites Reservoir would be 30.

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

The only existing recreational facilities within the Primary Study Area are the private duck clubs located along the proposed Delevan Pipeline. The operation of the Alternative A 1.27-MAF Sites Reservoir and associated recreation areas would not increase the use of those duck clubs. There would, therefore, be **no impact** to the existing recreational facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Because the operation of Sites Reservoir and its associated recreation areas would not increase use levels at existing private duck clubs within the Primary Study Area, the construction or expansion of the existing duck clubs would not be required. There would, therefore, be **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-3: Reduce Recreation Use Levels at Existing Recreational Facilities by Providing an Alternative New Site for Recreation Visitors

The effects to recreation use levels resulting from the provision of a new Sites Reservoir are evaluated within the Extended and Secondary study area discussions for each facility that is included in those study areas.

Sites Reservoir would not be expected to reduce recreation use levels at the private duck clubs located within the Primary Study Area because Sites Reservoir would not offer hunting opportunities. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-5: Reduce Recreation Use Levels at Existing Recreational Facilities during the Period of Construction

There are no existing developed or public recreational facilities within the footprint of the proposed Sites Reservoir Inundation Area or its associated Recreation Areas. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline and Delevan Transmission Line

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

During construction of the Delevan Pipeline, land that the proposed pipeline and transmission line would cross that is owned by private duck clubs would be fallowed, which would reduce the amount of habitat available to waterfowl and, consequently, could reduce hunting opportunities on those lands. In response, it is possible that hunters who hunt on these lands would instead temporarily use other nearby duck clubs during the Alternative A construction period. However, duck clubs impose limits on recreation use levels, so they would not experience a level of use that would result in substantial deterioration of their facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation of the Delevan Pipeline and Transmission Line, these lands would be restored to their original condition and would support the same recreation use levels. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Refer to the **Impact Rec-1** discussion. Because private duck clubs impose limits on recreation use levels, the potential redirected use of these clubs during the construction period for the Delevan Pipeline and Transmission Line would not require the construction or expansion of those facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-5: Reduce Recreation Use Levels at Existing Recreational Facilities during the Period of Construction

There are several private duck clubs located on lands where the Delevan Pipeline and Delevan Transmission Line alignments are proposed to be located. Hunting use at these clubs would be adversely affected during the Alternative A construction period because the fields within the construction disturbance area would be fallowed for at least one season. However, the loss of hunting opportunity would be minimized by the construction schedule for the Alternative A Delevan Pipeline alignment, which, based on other environmental considerations, would minimize the total amount of fields that would be fallowed during each year of construction of Alternative A, rather than fallowing the entire length of the construction disturbance area for the entire Alternative A construction period. In addition, hunting opportunities would still exist on adjacent lands. Therefore, this phased construction approach would have a **less-than-significant impact** on recreation use levels within the Delevan Pipeline and Transmission Line construction disturbance areas, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated

Some fishing currently occurs along the bank of the Sacramento River near the existing Maxwell Irrigation District Pumping Plant, which is adjacent to the proposed Delevan Pipeline Intake Facilities location. The Delevan Pipeline Intake Facilities' fish screen would extend from this portion of the bank, so it would no longer be available for recreational use. However, current use levels along the bank are low because the bank can be accessed only by private roads that connect to the levee road. Any redirected recreation use of other existing recreational facilities resulting from the loss of access to this river bank is expected to be minimal and would not cause the deterioration of those facilities. Therefore, there would be **a less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Physical Effect on the Environment

Because any redirected recreation use of the river bank would be minimal, the redirected use would not require the construction or expansion of existing recreational facilities. Therefore, there would be **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-5: Reduce Recreation Use Levels at Existing Recreational Facilities during the Period of Construction

Refer to the **Impact Rec-1** discussion. The loss of this portion of the river bank during Project construction would eliminate recreation use at this location. However, due to the limited amount of recreation use that occurs there and the alternative opportunities for recreation at nearby areas, the impact would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Boat fishing and recreation in the river would not be affected except within and adjacent to the Project construction disturbance area. Due to this impact being temporary, this impact on recreation use levels would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

During Project operations, releases would be made to the Sacramento River through the Delevan Pipeline Intake Facilities. The increased flows in the immediate vicinity of the facilities could create hazardous boating conditions. However, releases would be made through a fish screen, which would dissipate the energy of the water being released to the river to a velocity of one foot per second. These releases would not be expected to create hazardous boating conditions and would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.7 Impacts Associated with Alternative B

21.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), reduced recreation use levels at existing recreational facilities from providing an alternative new site for recreation visitors (**Impact Rec-3**), and hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) would be the same for San Luis Reservoir, other reservoirs within the Extended Study Area, and wildlife refuges as described for Alternative A.

The impacts associated with Alternative B, as they relate to reduced recreation use levels and recreation benefits at existing reservoirs or rivers (**Impact Rec-4**), would be the same as described for Alternative A for the other reservoirs within the Extended Study Area, but not for San Luis Reservoir. The effects of operational changes at San Luis Reservoir on recreation use levels and recreation benefits resulting from implementation of Alternative B are discussed below.

San Luis Reservoir

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of Alternative B, San Luis Reservoir would be drawn down below the Dinosaur Point Boat Ramp four months fewer over the 82-year period of record within the primary recreation season than with Existing Conditions, and three months fewer over the 82-year period of record within the primary recreation season than with the No Project/No Action Alternative. This would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

Alternative B would dewater the Basalt Boat Ramp, which is the lowest boat ramp, four fewer months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and one less month over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. Thus, impacts on boating resulting from implementation of Alternative B would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The Basalt Campground water intake would be dewatered four fewer months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, but one more month over the 82-year period of record within the primary recreation season, when compared to the No Project / No Action Alternative. This would be a **beneficial effect** when compared to Existing Conditions, but would be a **potentially significant impact,** when compared to the No Project/No Action Alternative.

The recreation-day benefit value of Alternative B on San Luis Reservoir would be 4 points for reservoir operation, the same as with Existing Conditions and the No Project/No Action Alternative, so there would be **no impact** on the recreation-day benefit value with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), reduced recreation use levels at existing recreational facilities from providing an alternative new site for recreation visitors (**Impact Rec-3**), reduced recreation use levels and recreation benefits at existing reservoirs or rivers (**Impact Rec-4**), and hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) would be the same as described for Alternative A for Trinity River, Klamath River, Sacramento River and pump installation at the Red Bluff Pumping Plant, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay. In addition, reduced recreation use levels at existing recreational facilities during the period of construction (**Impact Rec-5**) would be the same as described for Alternative A for the pump installation at the Red Bluff Pumping Plant.

For the remaining facilities, the impacts associated with Alternative B, as they relate to increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), reduced recreation use levels at existing recreational facilities from providing an alternative new site for recreation visitors (**Impact Rec-3**), and hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) would be the same as described for Alternative A. However, the effects of Alternative B operational changes on reduced recreation use levels and recreation benefits at existing reservoirs or rivers (**Impact Rec-4)** would differ from Alternative A at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. These differences are discussed below.

Trinity Lake

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

If Alternative B is implemented, the Trinity Lake boat ramps would be usable 94 more months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and 54 more months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. Also, the low water ramps (Cedar Stock and Minersville) would be usable a few additional months. Although not specifically defined, access to boat-in camps would also be improved. These changes would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

The recreation-day benefit value for reservoir operation with implementation of Alternative B would be 15 points, when compared to 12 points for Existing Conditions and 13 points for the No Project/No Action Alternative. This would also be a **beneficial effect** when compared to Existing Conditions and the No Project Alternative**.**

Shasta Lake

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of Alternative B, Shasta Lake boat ramps would be usable 63 additional months over the 82-year period of record within the primary recreation season when compared to Existing

Conditions, and 93 more months over the 82-year period of record within the primary recreation season than with the No Project/No Action Alternative. The low water ramps (Centimudi and Jones Valley) would be usable for three additional months. Access to boat-in campsites would also be improved. These changes are a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value for Shasta Lake with implementation of Alternative B would be 33 points, when compared to 28 points for Existing Conditions and the No Project/No Action Alternative. This is a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

Lake Oroville

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

The Bidwell Canyon low water ramp would always be in the water with implementation of the No Project/No Action Alternative, and would remain in the water with or without implementation of Alternative B. Alternative B would increase access to the remaining four major boat ramps at Lake Oroville by 15 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and 22 months over the 82-year period of record within the primary recreation season when compared to the No Project/No Action Alternative. Access to boat-in camps would be improved slightly due to slightly increased surface water elevations. These changes would be considered a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value for Lake Oroville operation with implementation of Alternative B would be 17.5 points, when compared to 17.5 points for Existing Conditions and 16.5 points for the No Project/No Action Alternative. This would result in **no impact** for Alternative B, when compared to Existing Conditions, and a **beneficial effect** for Alternative B, when compared to the No Project/No Action Alternative.

Folsom Lake

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Alternative B would increase access to the Folsom Lake boat ramps by nine months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and by 38 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. Access to the Low Water Ramp would be increased by one month over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and two months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. This is considered a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value for operations at Folsom Lake would be 26 points for Alternative B, as compared to 25 points for Existing Conditions and 22.5 points for the No Project/No Action Alternative. This is considered a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities have no current public recreation uses and would continue to provide negligible if any recreation opportunities after the Project is implemented, so there would be **no impact** to recreation resources at these locations:

- Sites Reservoir Dams
- Road Relocations and South Bridge
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline Electrical Switchyard
- Delevan Transmission Line
- Project Buffer

The Alternative B Recreation Areas, which would provide recreation opportunities, and the Delevan Pipeline construction disturbance area, which currently supports private hunting activities along portions of the alignment and would continue to support those activities during Project operation, would have the same design for alternatives A and B. These facilities would, therefore, have the same impacts on increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), and reduced recreation use levels at existing recreational facilities during the period of construction (**Impact Rec-5**) as described for Alternative A.

With implementation of Alternative B, the Delevan Pipeline Discharge Facility would replace the Delevan Pipeline Intake Facilities that were included in Alternative A. Although the Alternative B Delevan Pipeline Discharge Facility would be much smaller than the Alternative A Delevan Pipeline Intake Facilities, the portion of the river bank described for Alternative A would still become unavailable for shore fishing with implementation of Alternative B. Therefore, the impacts on increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), and reduced recreation use levels at existing recreational facilities during the period of construction (**Impact Rec-5**) at that location would be the same as described for Alternative A. However, the design of the release structure differs for each facility. That difference is discussed below as it relates to hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**).

The Alternative B Sites Reservoir would be 1.81 MAF in size, as compared to the 1.27-MAF Alternative A Sites Reservoir. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), and reduced recreation use levels at existing recreational facilities during the period of construction (**Impact Rec-5**) at existing private duck clubs as described for Alternative A. However, changes in reservoir operation would affect the recreation-day benefit value. Those changes are discussed below and provided for the purpose of comparison to Alternative A.

Sites Reservoir Inundation Area

The Alternative B Sites Reservoir Inundation Area would be larger than described for Alternative A. A larger reservoir has the potential to provide improved recreation opportunities, depending on the operation of the reservoir. However, the larger Alternative B Sites Reservoir would have an associated release-only Delevan Pipeline that would change reservoir operation. When compared to Alternative A, water level fluctuations during the primary recreation season would be increased by Alternative B, resulting in adverse effects to recreation resources. Consequently, the recreation-day benefit value for the Alternative B reservoir would be 19, as compared to 30 for the Alternative A reservoir.

Delevan Pipeline Discharge Facility

Impact Rec-6: Create Hazardous Conditions for Water-Based Activities due to Changes in Operating Criteria

During Project operations, releases would be made to the Sacramento River through the Delevan Pipeline Discharge Facility. The increased flows in the immediate vicinity of the facilities could create hazardous boating conditions. However, releases would be made through energy dissipating valves, which would dissipate the energy of the water being released to the river. These releases would not be expected to create hazardous boating conditions and would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.8 Impacts Associated with Alternative C

21.3.8.1 Extended Study Area

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), reduced recreation use levels at existing recreational facilities from providing an alternative new site for recreation visitors (**Impact Rec-3**), and hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) would be the same for San Luis Reservoir, other reservoirs within the Extended Study Area, and wildlife refuges as described for Alternative A.

Impacts associated with Alternative C as they relate to reduced recreation use levels and recreation benefits at existing reservoirs or rivers (**Impact Rec-4**), would be the same as described for Alternative A for the other reservoirs within the Extended Study Area, but not for San Luis Reservoir. The effects of operational changes at San Luis Reservoir on recreation use levels and recreation benefits resulting from implementation of Alternative B are discussed below.

San Luis Reservoir

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of Alternative C, San Luis Reservoir would dewater the Dinosaur Point boat ramp two additional months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions. However, the Basalt boat ramp, which is the lowest ramp and associated with a campground, would be dewatered four fewer months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions. The four-month increase in availability at the lowest boat ramp would outweigh the two-month decrease in availability of the intermediate ramp. This would therefore be a **less-than-significant impact,** when compared to Existing Conditions.

When compared to the No Project/No Action Alternative, operation of San Luis Reservoir with implementation of Alternative C would dewater the Dinosaur Point boat ramp three additional months over the 82-year period of record within the primary recreation season. Although the low water ramp at the Basalt Campground would be dewatered one month less over the 82-year period of record within the primary recreation season than the No Project/No Action Alternative, the loss of three additional months of availability at Dinosaur Point could outweigh this benefit. This would, therefore, be a **potentially significant impact,** when compared to the No Project/No Action Alternative.

The Basalt Campground water intake would be dewatered three fewer months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, but two more months over the 82-year period of record within the primary recreation season, when compared to the No Project / No Action Alternative. This would be a **beneficial effect,** when compared to Existing Conditions, but would be a **potentially significant impact,** when compared to the No Project/No Action Alternative.

The recreation-day benefit for San Luis Reservoir with implementation of Alternative C would be 3 points, as compared to 4 points for Existing Conditions and the No Project/No Action Alternative. This one point decrease in recreation-day benefit would be a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), reduced recreation use levels at existing recreational facilities from providing an alternative new site for recreation visitors (**Impact Rec-3**), reduced recreation use levels and recreation benefits at existing reservoirs or rivers (**Impact Rec-4**), and hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) would be the same as discussed for Alternative A for Trinity River, Klamath River, Sacramento River and pump installation at the Red Bluff Pumping Plant, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay. In addition, reduced recreation use levels at existing recreational facilities during the period of construction (**Impact Rec-5**) would be the same as described for Alternative A for the pump installation at the Red Bluff Pumping Plant.

For the remaining facilities, the impacts associated with Alternative C, as they relate to increased use of existing recreational facilities (**Impact Rec-1**), construction or expansion of existing recreational facilities (**Impact Rec-2**), reduced recreation use levels at existing recreational facilities from providing an alternative new site for recreation visitors (**Impact Rec-3**), and hazardous conditions resulting from changes in operating criteria (**Impact Rec-6**) would be the same as described for Alternative A. The effects of Alternative B operational changes on reduced recreation use levels and recreation benefits at existing reservoirs or rivers (**Impact Rec-4)** would differ from Alternative A at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. These differences are discussed below.

Trinity Lake

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of Alternative C, Trinity Lake boat ramps would be usable 101 more months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and 61 more months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. Alternative C operation of Trinity Lake would make the Cedar Stock and Minersville boat ramps usable for several additional months and access to the boat-in campsites would also be better. This would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value for Trinity Lake operation would be 16 points for Alternative C, as compared to 12 points for Existing Conditions and 13 points for the No Project/No Action Alternative. This would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

Shasta Lake

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

With implementation of Alternative C, Shasta Lake boat ramps would be available 100 additional months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and 130 additional months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. The low water ramps (Centimudi and Jones Valley) would be usable for seven additional months, when comparison to Existing Conditions and the No Project/No Action Alternative. Access to boat-in campsites would be improved. These changes are considered a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value for Shasta Lake operation with implementation of Alternative C would be 33 points, when compared to 28 points for Existing Conditions and the No Project/No Action Alternative. This would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

Lake Oroville

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

The Bidwell Canyon low water ramp would always be in the water with implementation of the No Project/No Action Alternative, and would remain in the water with or without implementation of Alternative C. Operation of Lake Oroville with implementation of Alternative C would increase access to the remaining four major boat ramps at Lake Oroville by 11 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and 18 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. Access to boat-in campsites would be slightly increased, when compared to Existing Conditions and the No Project/No Action Alternative, due to slight changes in surface water elevations. These changes would result in a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value at Lake Oroville with implementation of Alternative C would be 17.5 points, which is the same as for Existing Conditions, resulting in **no impact**. The No Project/No Action Alternative would be 16.5 points; implementation of Alternative C would increase the value by one point, resulting in a **beneficial effect**.

Folsom Lake

Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria

Implementation of Alternative C would increase access to the Folsom Lake boat ramps by 23 months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and by 52 months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. Access to the Low Water Ramp would be increased by four months over the 82-year period of record within the primary recreation season, when compared to Existing Conditions, and five months over the 82-year period of record within the primary recreation season, when compared to the No Project/No Action Alternative. This would be a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

The recreation-day benefit value for operations at Folsom Lake with implementation of Alternative C would be 26.5 points, as compared to 25 points for Existing Conditions and 22.5 points for the No Project/No Action Alternative, resulting in a **beneficial effect,** when compared to Existing Conditions and the No Project/No Action Alternative.

21.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facility sites have no current public recreation uses and would continue to provide negligible if any recreation opportunities after the Project is implemented, so there would be **no impact** to recreation resources at these locations:

- Sites Reservoir Dams
- Road Relocations and South Bridge
- Sites Pumping/Generating Plant

- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline Electrical Switchyard
- Project Buffer

The Alternative B Recreation Areas, which would provide recreation opportunities, and the Delevan Pipeline route, which currently supports private hunting activities along portions of its alignment and would continue to support those activities during Project operation, would have the same design for all three alternatives. These facilities would, therefore, have the same impacts on recreation resources as described for Alternative A.

The Alternative C design of the Delevan Pipeline Intake Facilities and Delevan Transmission Line is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to recreation resources as described for Alternative A.

The Alternative C design for the Sites Reservoir Inundation Area would be the same as described for Alternative B. Despite the larger size, the reservoir would have the same impacts to recreation resources at existing private duck clubs as described for Alternative A. However, changes in reservoir operation would affect the recreation-day benefit value. Those changes are discussed below and provided for the purpose of comparison to Alternatives A and B.

Sites Reservoir Inundation Area

The Alternative C Sites Reservoir would larger than described for Alternative A, but the same size as described for Alternative B. However, the Delevan Pipeline associated with Alternative C would be able to deliver water to the reservoir (rather than being a release-only pipeline, as is the case with Alternative B). When compared to alternatives A and B, water level fluctuations during the primary recreation season associated with Alternative C would result in beneficial effects to recreation resources. Consequently, the recreation-day benefit value for the Alternative C reservoir would be 39.5, as compared to 19 for the Alternative B reservoir and 30 for the Alternative A reservoir.

21.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 21-9 for the impacts that have been identified as significant or potentially significant.

Table 21-9
Summary of Mitigation Measures for
Potential NODOS Project Impacts to Recreation Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Rec-4: Reduce Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria	San Luis Reservoir (Alternative C)	Significant	Mitigation Measure Rec-4a: Extend the Existing Dinosaur Point Boat Ramp at San Luis Reservoir	Less than Significant
	San Luis Reservoir (Alternatives A, B, and C)	Potentially Significant	Mitigation Measure Rec-4b: Extend the Basalt Campground Water Intake at San Luis Reservoir	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Rec-4a: Extend the Existing Dinosaur Point Boat Ramp at San Luis Reservoir

DWR and Reclamation shall coordinate with California State Parks' Division of Boating and Waterways to extend the Dinosaur Point boat ramp to accommodate the decreased water levels associated with Project operation. The boat ramp extension shall be constructed when San Luis Reservoir reaches a water level below 378 feet. The feasibility of this mitigation has not been evaluated.

Mitigation Measure Rec-4b: Extend the Basalt Campground Water Intake at San Luis Reservoir

DWR and Reclamation shall extend the Basalt Campground water intake to accommodate the expected decreased water levels associated with Project operation. The water intake extension shall be constructed when San Luis Reservoir reaches a water level below 345 feet. The feasibility of this mitigation has not been evaluated.

Implementation of **Mitigation Measures Rec-4a and Rec-4b** would reduce the level of significance of Project impacts to recreation resources to **less than significant**.

22. Socioeconomics

22.1 Introduction

This chapter describes the socioeconomic setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Measures of social and economic activity described in this chapter include population, housing, industry earnings[1], income[2], annual jobs[3], unemployment, agricultural economics, and local government fiscal resources, as well as characteristics of the industries in the Primary Study Area. The agricultural industry is discussed for the Extended study areas because of the potential for changes in agricultural water deliveries in those areas, as well as agriculture’s widespread and substantial contribution to the State’s economy. The recreation industry is discussed because of the potential changes in water availability in reservoirs and rivers and the potential for changes in these resources.

The regulatory setting for socioeconomic resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

This chapter focuses primarily on the Primary Study Area. However, potential impacts in the Secondary and Extended study areas were evaluated. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, and because none were identified for this resource, no mitigation is included in this chapter.

22.2 Environmental Setting/Affected Environment

22.2.1 Methodology

The collection of Existing Condition socioeconomic information for the Environmental Setting/Affected Environment and impact assessments was based on available data. It is not uncommon for socioeconomic data to be released on a five- or ten-year interval and for the data to change significantly between intervals. Therefore, the most recent socioeconomic data available at the time this chapter was written was used for the Environmental Setting/Affected Environment and impact assessments.

22.2.2 Extended Study Area

The 39 counties in the Extended Study Area were grouped into five water delivery regions: Bay Area, Central Coast, North Coast, Sacramento Valley, San Joaquin, and Southern (Table 22-1). These regions encompass both small rural counties and large metropolitan counties that receive water from the SWP and CVP and that may be affected by Project-related changes in operations and water delivery.

[1] Industry Earnings: Dollar value of production (sales revenues or gross receipts) from each industry.
[2] Income: Employment income (wages and benefits derived at the workplace, including self-employed income).
[3] Annual Jobs: Total of part-time and full-time hourly wage, salary, and self-employed jobs.

Table 22-1
Counties in Water Delivery Regions – Extended Study Area

Water Delivery Region	Counties Included in Water Delivery Region
Bay Area	Alameda, Contra Costa, Napa, Santa Clara
Central Coast	Monterey, San Benito, San Luis Obispo, Santa Barbara, Santa Cruz
Sacramento Valley	Butte, Colusa, El Dorado, Glenn, Nevada, Placer, Plumas, Sacramento, Shasta, Solano, Sutter, Tehama, Yolo
San Joaquin	Calaveras, Fresno, Kern, Kings, Madera, Merced, San Joaquin, Stanislaus, Tulare, Tuolumne
Southern California	Imperial, Los Angeles, Orange, Riverside, San Bernardino, San Diego, Ventura

22.2.2.1 Population

Historical, current, and projected population estimates for the five water delivery regions in the Extended Study Area are summarized in Table 22-2. Historically, the Southern California region has the highest population concentration, with approximately 62 percent of the total Extended Study Area population. Approximately 24 percent of the population in the water delivery regions resides in the Bay Area and San Joaquin regions. The population in the Central Coast region accounts for approximately four percent of the overall regional population, and the Sacramento Valley region accounts for approximately nine percent.

Table 22-2
Historical, Current, and Projected Population and Average Annual Growth Rate within the Extended Study Area and California

Water Delivery Region	Population			Average Annual Growth Rate (%)	
	2000	2010	2030	2000 to 2010	2010 to 2030
Bay Area	4,199,421	4,477,422	5,598,796	0.64	1.12
Central Coast	1,356,626	1,426,240	1,738,133	0.50	0.99
Sacramento Valley	2,850,909	3,286,206	4,528,515	1.43	1.62
San Joaquin	3,397,847	4,072,602	6,683,874	1.83	2.51
Southern California	19,329,839	21,146,847	27,376,256	0.90	1.30
Extended Study Area Total	**31,134,642**	**34,409,317**	**45,925,574**	**1.01**	**1.45**
California	33,871,648	37,253,956	46,688,407	0.96	1.14

Source: DOF, 2012a.

The water delivery regions ranged in population from 1,426,240 residents in the Central Coast region to more than 21 million residents in the Southern California region in 2010. The Southern California region is projected to continue to have a larger share of the Extended Study Area's future population at 59.6 percent (larger than all other regions combined). The proportion of the Bay Area and San Joaquin regional populations is expected to continue to be approximately the same as it has been in the past, at 27 percent (DOF, 2012a).

Table 22-2 also shows the average annual population growth rate in the water delivery regions for the periods from 2000 to 2010 and 2010 to 2030. Between 2000 and 2010, the population in the water delivery regions grew at an average annual rate of 1.01 percent. Among the five regions, the San Joaquin region had the highest growth rate of 1.83 percent, and the Bay Area and the Central Coast regions had the smallest growth rate of 0.64 and 0.50 percent, respectively. The average annual population growth rate is expected to be highest in the San Joaquin region (2.51 percent) and lowest in the Bay Area and Central Coast regions (1.12 and 0.99, respectively) during the 2010 to 2030 period.

22.2.2.2 Economic Activity

Table 22-3 presents measures of economic activity within the Extended Study Area as of 2009. The 39 counties within the Extended Study Area produced approximately $1 trillion in total industry output and had a labor force of 16,623,040. The unemployment rate varied from 10.9 percent in the Bay Area region to 16.5 percent in the San Joaquin region.

Table 22-3
Economic Activity within the Extended Study Area and California in 2009 (2010 Dollars)

Water Delivery Region	Total Personal Income[a] (Thousand $)	Total Industry Output[b] (Thousand $)	Total Civilian Labor Force[c]	Unemployment Rate (%)
Bay Area	236,896,426	183,603,903	2,226,600	10.9
Central Coast	53,354,289	38,148,252	750,000	12.5
Sacramento Valley	126,584,666	86,712,892	1,517,730	14.9
San Joaquin	119,011,208	79,575,465	1,832,610	16.5
Southern California	855,026,941	627,362,787	10,296,100	14.6
Extended Study Area Total	1,390,873,530	1,015,403,299	16,623,040	13.9
California	1,566,999,086	1,145,167,947	18,176,200	12.4

[a]Total personal income is the sum of income received by all persons from all sources.
[b]Total industry output is the total production from all industries in a region for a given year.
[c]Total civilian labor force is the sum of all persons classified as employed.
Source: BEA, 2009.

22.2.2.3 Agricultural Activity

The average irrigated acreage and annual value of production for the five water delivery regions are listed in Table 22-4. The San Joaquin region had the most irrigated crops, in terms of acreage, at 5.6 million acres (approximately 60 percent of the total for the Extended Study Area). The San Joaquin region also had the largest production value of irrigated crops; livestock, dairy, and apiary; and dryland range with $15.6 billion, $8.4 billion, and $77 million, respectively. Of the water delivery regions, the area with the least agricultural production was the Bay Area region, with approximately 105,000 acres of irrigated crops (1.1 percent of the total acreage for the Extended Study Area). Agricultural production value for the Bay Area region was approximately $796 million for irrigated crops; $30 million for livestock, dairy, apiary; and $8.6 million for dryland range.

Table 22-4
Average Irrigated Acreage and Annual Value of Production (2008 to 2010) within the Extended Study Area (2010 Dollars)

Water Delivery Region	Irrigated Crops		Livestock, Dairy, Apiary	Dryland Range
	Acreage	Value (Thousand $)	Value (Thousand $)	Value (Thousand $)
Bay Area	104,914	796,113	30,107	8,620
Central Coast	683,524	6,366,796	161,108	29,586
Sacramento Valley	1,905,226	3,271,313	431,448	28,720
San Joaquin	5,600,756	15,603,416	8,429,888	77,341
Southern California	944,329	5,498,551	1,093,210	4,083
Extended Study Area Total	**9,238,750**	**31,536,188**	**10,145,761**	**148,350**
California	10,651,347	33,737,268	10,914,904	184,619

Sources: USDA, 2009, 2010, and 2011.

22.2.3 Secondary Study Area

The Secondary Study Area is comprised of 22 counties that are grouped into water delivery regions that use CVP water and could be affected by changes in operation and water delivery resulting from the alternatives (Table 22-5).

Table 22-5
Counties in Water Delivery Regions – Secondary Study Area

Water Delivery Region	Counties Included in the Water Delivery Region
Bay Area	Alameda, Contra Costa, Marin, San Francisco, San Mateo, Santa Clara
Sacramento Valley	Butte, Colusa, El Dorado, Glenn, Placer, Sacramento, Shasta, Solano, Sonoma, Sutter, Tehama, Yolo, Yuba
North Coast	Del Norte, Humboldt, Trinity

22.2.3.1 Population

Historical, current, and projected population estimates for the three water delivery regions in the Secondary Study Area are summarized in Table 22-6. Historically, the Bay Area region had the highest population concentration, with approximately 63 percent of the total regional population in 2000. Approximately 35 percent of the population in the water delivery regions resides in the Sacramento Valley region. The population in the North Coast region accounts for approximately two percent of the overall regional population.

Table 22-6 also shows the average annual population growth rate in the water delivery regions for the periods from 2000 to 2010 and 2010 to 2030. Between 2000 and 2010, the population in the water delivery regions grew at an average annual rate of 0.82 percent. Among the three regions, the Sacramento Valley region had the highest growth rate of 1.35 percent, and the Bay Area and the North Coast regions had smaller growth rates of 0.52 and 0.58 percent, respectively. The average annual population growth rate is expected to be highest in the Sacramento Valley region (1.61 percent) and lowest in the Bay Area and North Coast regions (0.90 percent) during the 2010 to 2030 period.

Table 22-6
Historical, Current, and Projected Population and Average Annual Growth Rate within the Secondary Study Area and California

Water Delivery Region	Population			Average Annual Growth Rate (%)	
	2000	2010	2030	2000 to 2010	2010 to 2030
Bay Area	5,806,325	6,117,033	7,320,957	0.52	0.90
Sacramento Valley	3,256,885	3,723,468	5,123,713	1.35	1.61
North Coast	167,047	177,019	211,773	0.58	0.90
Secondary Study Area Total	9,230,257	10,017,520	12,656,443	0.82	1.18
California	33,871,648	37,253,956	46,688,407	0.96	1.14

Source: DOF, 2012b.

22.2.3.2 Economic Activity

Table 22-7 presents measures of economic activity within the Secondary Study Area as of 2009. The 22 counties within the Secondary Study Area produced approximately $387 billion in total industry output and had a labor force of 4,939,210. The unemployment rate varied from a low of 10.5 percent in the Bay Area region to a high of 12.8 percent in the Sacramento Valley region. Agricultural economic activity is included in Table 22-7. Additional detail is not provided because impacts to agriculture are only modeled for the Extended Study Area.

Table 22-7
Economic Activity within the Secondary Study Area and California in 2009 (2010 Dollars)

Water Delivery Region	Total Personal Income[a] (Thousand $)	Total Industry Output[b] (Thousand $)	Total Civilian Labor Force[c]	Unemployment Rate (%)
Bay Area	358,592,983	285,948,210	3,114,000	10.5
Sacramento Valley	144,689,070	98,058,833	1,747,540	12.8
North Coast	5,401,584	3,098,813	77,670	12.2
Secondary Study Area Total	508,683,637	387,105,856	4,939,210	11.4
California	1,566,999,086	1,145,167,947	18,176,200	12.4

[a]Total personal income is the sum of income received by all persons from all sources.
[b]Total industry output is the total production from all industries in a region for a given year.
[c]Total civilian labor force is the sum of all persons classified as employed.

Source: BEA, 2009.

22.2.4 Primary Study Area

The section summarizes the existing socioeconomic conditions within the Primary Study Area. Socioeconomic conditions that are described for the Primary Study Area include population, housing, employment, labor force, income, fiscal resources, and agricultural economics. The agriculture sector is discussed in greater detail because of its widespread and substantial contributions to the regional economy.

The Primary Study Area is comprised of Colusa and Glenn counties. These two counties are primarily rural with low populations compared to the rest of the State. There are a few small incorporated cities and several unincorporated areas in these counties. Populations vary in the numerous communities, with populations ranging from a few hundred people (e.g., Elk Creek and Stonyford) to a few thousand people (e.g., Orland and Colusa). Surrounding these communities are farms, ranches, and orchards, most of which have residences associated with them that are not in a delineated community, but are socially tied to a community through general proximity or public services (e.g., school district boundaries and public service delivery areas).

Colusa County encompasses approximately 1,151 square miles. The County seat is the City of Colusa. The County has two incorporated cities (Colusa and Williams) and several unincorporated communities: Maxwell, Arbuckle, Stonyford, Princeton, Grimes, and Sites. As of the 2010 census, approximately 70.5 percent of Colusa County's population was 25 years of age or older and had graduated from high school, and approximately 11.7 percent of that population group had a Bachelor's degree or higher education (U.S. Census Bureau, 2012).

Glenn County is located directly north of Colusa County and encompasses 1,314 square miles. The county seat is the City of Willows. The County has two incorporated cities (Willows and Orland) as well as the unincorporated areas of Hamilton City and Elk Creek. As of the 2010 census, approximately 73.9 percent of Glenn County's population was 25 years of age or older and had graduated from high school, and approximately 16.2 percent of that population group had a Bachelor's degree or higher education (U.S. Census Bureau, 2012).

22.2.4.1 Population

The population density in the Primary Study Area is very low. The highest concentration of people is located in the few incorporated towns, and smaller population concentrations are located in the rural communities throughout the Primary Study Area. In addition, numerous residences associated with agricultural parcels are scattered throughout the two counties.

Table 22-8 lists the population and annual growth rate of both counties within the Primary Study Area for 2000, 2010, projections for 2030, the average annual growth rates from 2000 to 2010, and projected growth rate from 2010 to 2030. Population size has increased by approximately one percent per year throughout the Primary Study Area, increasing by approximately 4,300 people in 10 years from 2000 to 2010.

Table 22-8
Historical, Current, and Projected Population and Average Annual Growth Rate within the Primary Study Area and California

Area	2000	2010	2030	Average Annual Growth Rate 2000-2010 (%)	Average Annual Growth Rate 2010-2030 (%)
Glenn County	26,453	28,122	45,181	0.61	2.40
Colusa County	18,804	21,419	34,488	1.31	2.41
Primary Study Area Total	45,257	49,541	79,669	0.91	2.40
California	33,871,648	37,253,956	46,688,407	0.96	1.14

Source: U.S. Census Bureau, 2012.

Age distribution within the Primary Study Area's counties, compared to the State of California, as of 2010 is shown in Table 22-9. The working age population between ages 20 and 64 is approximately 27,500 people. School age children (ages 5 to 19), adults (ages 20 to 64), and senior citizens (ages 65 and older) represented approximately 24, 56, and 12.6 percent, respectively, of the total population in the Primary Study Area in 2010. This age composition is similar to that of the State.

Table 22-9
Age Distribution within the Primary Study Area Counties and California

	2010 Population (Number and Percent of Total)								
		<5 years of age		5 to 19 years of age		20 to 64 years of age		65+ years of age	
Area	Total	Number	%	Number	%	Number	%	Number	%
Colusa County	21,419	1,841	8.6	5,198	24.2	11,885	55.6	2,495	11.6
Glenn County	28,122	2,178	7.7	6,489	23.1	15,709	55.9	3,737	13.2
Primary Study Area Total	49,541	4,019	8.1	11,687	23.6	27,594	55.7	6,232	12.6
California	37,253,956	2,531,333	6.8	7,920,709	21.3	22,555,400	60.5	4,246,514	11.4

Source: U.S Census Bureau, 2012.

22.2.4.2 Housing

Table 22-10 shows the housing distribution, vacancy rates, and persons per household for the incorporated cities and unincorporated areas included in the counties that comprise the Primary Study Area. As of 2010, there were 27,544 housing units within the Primary Study Area, representing 0.2 percent of the housing units in the State. Of the two counties, Glenn County had the highest number of single-family and multi-family homes in 2010, with 11,548 single-family and 2,836 multi-family homes. Colusa County had 8,855 single-family and 1,688 multi-family homes in 2010. Glenn County had a vacancy rate of 7.73 percent and Colusa County had a vacancy rate of 7.12 percent.

Table 22-10
Housing Distribution within the Primary Study Area and California

County/City	Single-Family	Multiple-Family	Mobile Homes	Total Housing Units	Percent Vacant	Persons Per Household
Glenn County						
Incorporated Area						
Orland	2,045	581	71	2,697	5.15	2.92
Willows	1,657	768	8	2,433	9.82	2.88
Incorporated Area Subtotal	3,702	1,349	79	5,130	7.37	2.90
Unincorporated Area	4,144	138	1,480	5,762	8.59	2.90
Glenn County Total	**7,846**	**1,487**	**1,559**	**10,892**	**8.02**	**2.9**

Source: DOF, 2012b.

In 2010, 45 building permits were issued in Glenn County, and 19 building permits were issued in Colusa County (U.S. Census Bureau, 2012).

In 2012, there were nine hotels and two campgrounds/RV parks in Colusa County, and 13 hotels and five campgrounds available in Glenn County (Google Maps, 2012).

22.2.4.3 Economic Activity

Employment and income provide useful insight into an area's economy. A community-level discussion is not provided because employment and income data are available only at the county level.

The Primary Study Area economy is rooted in agriculture. Agriculture became the primary economic driver in the region because of the rich soil, ample water supply, and proximity to urban markets. Today, the agricultural sector is still important in the Primary Study Area, but changes in mechanization and processing have resulted in a much smaller proportion of residents participating in agriculture than during the early part of the 20th century.

Table 22-11 presents measures of economic activity within the Primary Study Area as of 2009. The two counties within the Primary Study Area produced approximately $1.8 billion in total personal income and $1.2 billion in total industry output in 2009. The distribution of the regional personal income was approximately 51 percent and 49 percent for Glenn and Colusa counties, respectively. The distribution of regional earnings by industry was approximately 47 percent and 53 percent for Glenn and Colusa counties, respectively. The Primary Study Area's regional personal income and total industry earnings accounted for approximately one tenth of one percent of California's total personal income and total industry earnings.

Table 22-11
Personal Income and Industry Earnings within the Primary Study Area and California in 2009 (2010 Dollars)

Area	Total Personal Income in 2009 (Thousand $)	Earning by Industry in 2009 (Thousand $)
Glenn County	912,862	586,999
Colusa County	868,203	662,464
Primary Study Area Total	1,781,065	1,249,463
California	1,566,999,086	1,145,167,947

Source: BEA, 2009.

Table 22-12
Employment within the Primary Study Area and California in 2010

Area	Civilian Labor Force	Number of Civilians Employed	Unemployment Rate (%)
Glenn County	12,730	10,660	16.3
Colusa County	11,930	9,500	20.4
Primary Study Area Total	24,660	20,160	18.3
California	18,335,400	16,109,000	12.2

Source: EDD, 2012.

In 2010, the total labor force was 12,730 and 11,930 in Glenn and Colusa counties, respectively. During the same year, there were 18,335,400 people in California's labor force; thus, the labor force in the Primary Study Area comprises approximately 0.13 percent of the State's total labor force. The unemployment rates in 2010 were 16.3 percent for Glenn County and 20.4 percent for Colusa County. In comparison, in 2010, the California unemployment rate was 12.2 percent.

Table 22-13 provides Glenn County's employment by industry, employment share, and annual growth rates. The top three industries in Glenn County in 2010, as measured by the number of employees, were government, agriculture, and services. The retail industry had the highest annual growth rates (at 4.5 percent), followed by the services industry, which had a 1.8 percent annual growth rate. The manufacturing; natural resources, mining, and construction; financial activities, transportation, warehousing, and utilities; and government sectors all experienced negative annual growth rates during that 10-year period.

Table 22-13
Employment by Industry for the Primary Study Area – Glenn County

Industry	2000		2010		2000 to 2010	
	Number of Employees	Employment Share (%)	Number of Employees	Employment Share (%)	Change (%)	Average Annual Growth (%)
Agriculture	1,510	28.7	1,740	32.5	15.2	1.4

Table 22-14 provides Colusa County's employment by industry, employment share, and annual growth rates. The top three industries in Colusa County in 2010, as measured by the number of employees, were agriculture, government, and services. The natural resources, mining, and construction industry had the highest annual growth rate (at 19.2 percent), followed by the wholesale industry, which had a 6.5 percent annual growth rate. The transportation, warehousing, and utilities; manufacturing; retail; and agriculture sectors all experienced negative annual growth rates during that 10-year period.

Total Industry Employment	**7,580**	**100.0**	**8,550**	**100**	**12.8**	**1.2**

Source: EDD, 2012.

In total, the Primary Study Area's combined employment in 2000 and 2010 was 15,020 and 16,030, respectively, representing a 6.7 percent increase from 2000 to 2010.

The 2010 median household income in Colusa County was $48,016 and per capita income was $21,317 (Table 22-15). Both the median household income and per capita income were lower than for California. The percentage of persons below the poverty level, 15 percent, was slightly higher than for the State. Approximately 35.3 percent of the population was considered minority (U.S. Census Bureau, 2010).

Table 22-15
Demographics of the Primary Study Area – 2010

Demographic	Glenn County	Colusa County	California
Median household income	$43,074	$48,016	$60,883
Per capita income	$19,987	$21,317	$29,188
Percentage of persons below poverty level	17.5	15.0	13.7
Minority Population	8,132	7,565	15,800,022
Percent minority population	28.9	35.3	42.4

Source: U.S. Census Bureau, 2010.

The 2010_median household income in Glenn County was $43,074 and per capita income was $19,987 (Table 22-15). Both the median household income and per capita income were lower than for California. The percentage of persons below the poverty level was 17.5 percent, which was higher than for the State. Approximately 28.9 percent of the population was considered minority (U.S. Census Bureau, 2010). The population of the Primary Study Area is relatively ethnically diverse as a result of its unique cultural history, the presence of seasonal farm workers, and agricultural past.

22.2.4.4 County Budgets

Glenn and Colusa counties are the local agencies that have taxing authority for the Primary Study Area. Revenues from property taxes are used to fund county governments, local school districts, county roads, local fire departments, libraries, and emergency medical services.

Table 22-16 presents historical and current general fund revenues and expenditures (2008 to 2012) for Glenn County. As shown, the expenditures exceeded revenues in 2010 and 2011, and are expected to exceed revenues in 2012. The majority of the general fund revenues for 2008 to 2012 were from intergovernmental transfers and other financing sources. Taxes ranged from approximately 6.5 percent in 2012 to 13.8 percent in 2009.

In total, adopted county general fund revenues and expenditures in 2012 for the Primary Study Area were $147,085,576 and $150,657,602, respectively.

22.2.4.5 Agricultural Economics in the Primary Study Area

Agriculture is a major industry in the Primary Study Area. Major commodities include rice, almonds, dairies, walnuts, and prunes. The total value of production for Glenn County irrigated crops, dryland range, livestock, dairy, and apiary was $520 million per year from 2008 to 2010 (Table 22-18). Rice was the top irrigated crop in terms of acreage harvested, tons produced, and production value. Almonds were the next most valuable crop with a value of production that was slightly less than half the production value of rice.

Table 22-18
Glenn County Average Agricultural Production, 2008 to 2010 (2010 Dollars)

Crop	Harvested Acreage	Production (tons)	Value per acre ($)	Value of Production (Thousand $)
Top Six Irrigated Crops				
Rice	85,154	376,441	2,045	174,133
Almonds	31,097	5,686	2,966	92,236
Walnuts	14,831	28,599	3,113	46,165
Plums, Dried	6,676	14,983	3,363	22,454

Livestock, Dairy, Apiary				90,110
Total All				**520,006**

Source: USDA 2009, 2010 and 2011

Agriculture is also a leading industry in Colusa County. The total value of production for Colusa County irrigated crops, dryland range, livestock, dairy, and apiary averaged over $637.5 million per year from 2008 to 2010 (Table 22-19). Rice was the top irrigated crop in terms of acreage harvested, tons produced, and production value. Almonds were the next most valuable crop with a value of production that was approximately 43.7 percent of the production of rice.

Table 22-19
Colusa County Average Agricultural Production, 2008 to 2010 (2010 Dollars)

Crop	Harvested Acreage	Production (tons)	Value per acre ($)	Value of Production (Thousand $)
Top Six Irrigated Crops				
Rice	162,160	696,952	1,926	312,392
Almonds	37,403	40,643	3,653	136,638
Walnuts	14,727	679,548	3,487	51,350

Livestock, Dairy, Apiary				18,070
Total All				**637,571**

Source: USDA 2009, 2010 and 2011.

In total, the average irrigated crop acreage from 2008 to 2010 in the Primary Study Area was 502,162, with an average value per acre of $2,083.

22.3 Environmental Impacts/Environmental Consequences

22.3.1 Regulatory Setting

Socioeconomic resources are regulated at the federal, State, and local levels through goals and policies that regulate population growth, housing development, relocation assistance, and industry creation. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

22.3.1.1 Federal Plans, Policies, and Regulations

- Constitution of the United States: Fifth Amendment Takings Clause
- Uniform Relocation Assistance and Real Property Acquisitions Policies Act of 1970
- Housing and Community Development Act of 1974
- U.S. Department of Agriculture Commodity Programs, Conservation Reserve and Wetland Reserve Programs, Marketing and Credit Assistance, and Crop Insurance and Disaster Assistance

22.3.1.2 State Plans, Policies, and Regulations

- California Constitution: Article 1 Declaration of Rights, Section 19
- California Relocation Assistance Act and the California Relocation Assistance and Real Property Acquisition Guidelines

22.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

22.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for population and housing:

Would the Project:

- Induce substantial population growth in an area either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extensions of roads or other infrastructure)?
- Displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere?
- Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Substantial adverse effects on regional economics.
- Substantial adverse effects on population and housing.

- Substantial adverse effects on local government fiscal conditions.
- Substantial adverse effects on recreation economics.
- Substantial adverse effects on agricultural economics.
- Substantial adverse effects on municipal and industrial (M&I) water use economics.

The determination of impact significance is based on the magnitude of socioeconomic effects that the Project would cause.

- **No impact** indicates no change in socioeconomic conditions would occur.
- A **less-than-significant impact** may or may not be perceptible but is considered a minor (less than five percent) change in socioeconomic conditions.

A **significant impact** with feasible mitigation may be reduced to less-than-significant levels or avoided. Without mitigation measures, a significant impact would cause a major (greater than five percent) change in socioeconomic conditions.

22.3.3 Impact Assessment Assumptions and Methodology

22.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to socioeconomics:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.
- Although the size of the regional economy would likely grow, when comparing Existing Conditions and the No Project/No Action Alternative, Alternative A, Alternative B, and Alternative C, it is assumed that the type of industries and spending patterns by consumers, as examples, would not.

22.3.3.2 Methodology

Part of the socioeconomic analysis is based upon results of hydrologic and water quality analytical model simulations of the Project alternatives, Existing Conditions, and the No Project/No Action Alternative. Operation of Alternatives A, B, and C was analyzed for future conditions that would occur in approximately year 2025. Costs used in the impacts assessment are reported in 2010 dollars (U.S. Department of Commerce, 2012).

The CEQA analysis presents the results of the comparison of socioeconomic conditions associated with construction and operation of Alternatives A, B, and C to those of Existing Conditions. Many of the differences between Alternatives A, B, C, and Existing Conditions are related to the changes that would occur due to assumptions related to the socioeconomic models (such as population growth) and are unrelated to Alternatives A, B, and C. The CEQA analysis also presents the results of a comparison of the No Project/No Action Alternative and Existing Conditions.

The NEPA analysis presents the results of the comparison of socioeconomics conditions associated with operation of Alternatives A, B, and C to those of the No Project/No Action Alternative. In accordance with NEPA, the No Project/No Action Alternative represents the reasonably foreseeable future conditions that may occur if the alternatives are not approved; the future No Project/No Action Alternative conditions include several projects and programs (refer to Chapter 3 Description of Proposed Project//Proposed Action and Alternatives for details). It is important that the No Project/No Action Alternative assumptions are not speculative to avoid causing the results of the impact assessment to misrepresent either the impacts or benefits of the alternatives.

Although Appendix G of the *CEQA Guidelines* indicates that “economic or social effects of a project shall not be treated as significant effects on the environment”, economic and social effects are included in this Draft EIR/EIS for “determining the significance of physical changes caused by the project”. Although significance criteria were applied to the Project-related socioeconomic effects, the physical effects related to the socioeconomic effects were addressed in other chapters of this EIR/EIS. Chapters that address the Project-related physical effects related to the economic and social effects include: Chapter 6 Surface Water Resources, Chapter 7 Surface Water Quality, Chapter 20 Land Use, Chapter 21 Recreation Resources, and Chapter 29 Public Services and Utilities.

This chapter addresses the Project-related socioeconomic effects in relation to:

- Regional economics
- Population and housing
- Local government fiscal conditions
- Recreation economics
- Agricultural economics
- M&I water use economics

The Secondary Study Area is defined as the area of potential operational effects, including SWP and CVP facilities that could experience reservoir water surface elevation fluctuations and stream flow changes downstream from their facilities. These operational effects are included in the analysis of the Extended Study Area. Therefore, no separate impact analyses were undertaken for the economic or social effects of the No Project/No Action Alternative in the Secondary Study Area.

For a summary of the economics analytical framework used for this analysis, see Appendix 22A. Economics model results used in this analysis are included in Appendix 22B.

Regional Economics

Regional economic effects include changes in characteristics such as regional employment and income. The magnitude of the economic effects depends on the initial changes in economic activity within the region (such as construction expenditure or loss of production from existing activities), the interactions within the regional economy, and the "leakage" of economic activity from this regional economy to the larger surrounding economy. Economic linkages create multiplier effects in a regional economy as money is circulated by trade. These linkages are often modeled using large mathematical input-output models such as IMPLAN. IMPLAN, a computer database and modeling system used to create regional economics models for any combination of United States counties, is used in this analysis. For a detailed description of IMPLAN, see Appendix 22C.

An IMPLAN model of the Primary Study Area was used to estimate total changes in employment and income as a result of Project construction and operation, a reduction in temporary and permanent agricultural production, and changes in land use and recreation. Although the size of the economy would change across economic conditions, the structure of the economy would not. The IMPLAN model uses the structural relationship between elements of the economy to identify Project-related socioeconomic impacts. When evaluating temporary impacts, such as Project construction, it is likely that no structural change would occur in the relationship between elements of the economy. Although long-term impacts may incite structural changes, the relatively small Project operation and maintenance impact would not likely do so. Therefore, with no expected change in the structure of the economy across conditions, the Existing Conditions and No Project/No Action Alternative IMPLAN models are the same.

An IMPLAN model was also created for the multi-county Extended Study Area and was used to estimate total changes in employment and income. Changes in employment and income in this study area could result from changes in agricultural production as a result of the operation of the Project. Changes in employment and income in the Secondary Study Area were evaluated as part of the Extended Study Area IMPLAN model. However, Secondary Study Area impacts to employment and income are not reported independent of the Extended Study Area results.

Population and Housing

Estimates of housing demand, both during the construction and operation phases for each alternative, were calculated based on changes in employment that would result from implementation of the Project. The Project is expected to draw from the entire workforce in the Primary Study Area, not merely those workers who are available in the immediate area of construction or operation activity. It is expected that some portion of the construction and operation workforce would be filled by workers in the Primary Study Area who would not demand new housing. However, construction and operation would require specialty occupations that require skills that are not likely available in the local workforce. Thus, out-of-region contractors may import crews to the Project area. These workers may immigrate from outside the Primary Study Area and demand additional housing. Because of the likelihood that specialized occupations and out-of-region contractors would immigrate to the region, it is expected that additional housing demand would occur in the Primary Study Area. The proportion of construction and operation employees that would be locally supplied from within the Primary Study Area was determined through consultations with the engineering staff who developed Project cost estimates.

The estimates of housing demand increases were compared to the Primary Study Area real estate vacancy rates and availability of temporary lodging to assess whether capacity exists in the area to support additional demand for temporary (during construction) and long-term (during operation) housing as a result of the Project.

Total estimated changes in population as a result of the Project were calculated by multiplying the average number of persons per household (DOF, 2012b) by the average number of workers anticipated to be needed for the Project using the results of the Primary Study Area IMPLAN analysis. As with the IMPLAN analysis, the impact assessment is based on the change in conditions, with Existing Conditions and No Project/No Action Alternative considered the same condition. Population changes were assessed for the short-term construction phase and for the longer-term operation phase. The changes in population resulting from construction and operation of an alternative were then compared to the projected population. In instances where population changes are anticipated to deviate from the historical annual average for the Primary Study Area (2000 to 2010), an impact was identified and discussed.

Local Government Fiscal Conditions

Fiscal effects on local governments would occur from changes to property tax revenue resulting from Project-related land acquisition. The fiscal impact analysis evaluated the estimated loss of property tax revenue resulting from potential conversion of existing land uses. An alternative would result in changes to existing land use that, in turn, would affect the property taxes on affected parcels. Tax rolls and redemption rolls were acquired for lands in the footprint of the alternatives and for the Project Buffer. Each county’s tax roll dataset includes an itemization of county and special assessment related taxes. A GIS analysis identified affected parcels and associated property taxes using the tax roll data and parcel boundary information. For the purposes of this analysis, the entire affected parcel is expected to be acquired if it is located in the Project facility footprint. The total annual change in tax revenue associated with the affected parcels was then calculated for each taxing entity for each alternative. As with the IMPLAN analysis, the impact assessment is based on the change in conditions, with Existing Conditions and No Project/No Action Alternative considered the same condition.

Recreational Economics

Recreational economic effects in the Primary Study Area would occur from a change in recreational expenditures. It is expected that recreation visitation and expenditures would increase within the Primary Study Area as a result of increased recreation and visitors drawn from other recreational sites. It is anticipated that recreational numbers and patterns would be similar to those of nearby facilities of similar character, specifically Black Butte Reservoir. Recreation visitation is only a function of reservoir water levels and not adjusted for population growth. Informational surveys completed at Black Butte Reservoir were used to estimate the mix of recreational activities at the proposed Sites Reservoir, type of recreational spending that would occur, and the percentage of expenditures originating outside the Primary Study Area (within approximately 60 miles) (Reclamation, 2012). As with the IMPLAN analysis, the impact assessment is based on the change in conditions, with Existing Conditions and No Project/No Action Alternative considered the same condition. The change in recreation expenditures in the Primary Study Area was used in the Primary Study Area IMPLAN model to identify changes in employment and income.

Agricultural Economics

The analysis of the economic effect of land use changes in the Primary Study Area is based on the changes in acreage resulting from the Project facilities’ construction and operation. Quantitative estimates were also made of the change in the value of agricultural production. Estimates were based on the acreage changes and the per-acre crop revenue summarized in Section 22.2.

The economic analysis of changes in agricultural production in the Extended Study Area used results from changes in SWP and CVP water delivery and changes in water quality. See Appendix 22F for an overview of the analytical approach. Changes in agricultural production in the Secondary Study Area are included in the Extended Study Area results.

Agricultural economic effects from changes in SWP and CVP water delivery were evaluated using the Statewide Agricultural Production (SWAP) model, a regional agricultural production model developed specifically for large-scale analysis of agricultural water supply and cost changes. SWAP is a regional model of irrigated agricultural production and economics that simulates the decisions of agricultural producers (i.e., farmers) in California. The model assumes that farmers maximize profit subject to available resource and economic conditions. Within this framework, the model estimates changes in acreage, crop production, and revenues resulting from changes in CVP and SWP water delivery. For a detailed description of SWAP see Appendix 22F.

Water quality effects were evaluated using a separate analysis of costs associated with managing salts in irrigation water. The economic effects of changes in water quality of irrigation water are complex and may occur in the short term and over the long term. Immediate effects of an improvement in salinity can include reduced quantity of water needed for leaching and subsequent irrigation costs, lower soil salinity, improved crop yields, and greater crop selection. Long-term effects are important in drainage-affected areas of the western and southern San Joaquin. A calculation of the value of changes in leaching requirement was used to illustrate the relative magnitude of short-term economic changes associated with salinity. The long-term value of salinity changes depends upon complex interactions among irrigation management, crop selection, and groundwater conditions. Because of this complexity, this long-term effect was described but not quantified.

Municipal and Industrial Water Use Economics

The economic analysis of changes in M&I water supply and quality in the Extended Study Area used results from changes in SWP and CVP water delivery and changes in salinity levels. See Appendix 22D and 22E for an overview of the analytical approach. Changes in M&I water supply and quality in the Secondary Study Area are included in the Extended Study Area results.

M&I water supply economic effects from changes in SWP and CVP water delivery were evaluated using the Least Cost Planning Simulation Model (LCPSIM) and the Other Municipal Water Economics Model (OMWEM). These models were developed by DWR for use in planning and impact studies related to water supply for SWP and CVP. LCPSIM was used to estimate the direct economic effect of changes in the water supply for M&I purposes in the urban areas of the San Francisco Bay – South and the South Coast hydrologic regions (refer to Chapter 7 Surface Water Quality for a description of California's hydrologic regions). Other affected SWP and CVP delivery regions were modeled using OMWEM. System-related energy costs are included in the assessment of M&I water use economics impacts from changes in SWP and CVP water deliveries and resulting changes in regional water portfolio management. However, the assessment of power- and energy-related impacts is discussed in Chapter 31 Power Production and Energy.

LCPSIM is an annual time-step urban water service system reliability management model. Its objective is to estimate the least-cost water supply management strategy for an area, given the mix of available supplies, and considering the costs of new supply augmentation and use reduction options and the costs of water shortages. OMWEM is a set of individual spreadsheet models that were used to estimate economic benefits of changes in SWP or CVP supplies based on estimated water supply and demand conditions. For a detailed description of LCPSIM and OMWEM see Appendix 22D.

For the M&I water quality assessment, two models corresponding to two regions of M&I water users were used. The Lower Colorado River Basin Water Quality Model (LCRBWQM) covers almost the entire urban coastal region of southern California. LCRBWQM was developed by Reclamation and Metropolitan Water District of Southern California for assessing regional effects of salinity. The Bay Area Water Quality Economics Model (BAWQM) includes the portion of the Bay Area region from Contra Costa County south to Santa Clara County. The model uses estimated relationships between salinity and residential damages to estimate the benefits from changes in salinity. For a detailed description of LCRBWQM and BAWQM see Appendix 22E. Note that water quality impacts are a function of water quality and total volume of SWP and CVP deliveries. This is a result of blending of SWP and CVP deliveries that occurs with other imported and local water supply in a region.

22.3.4 Topics Eliminated from Further Analytical Consideration

This EIR/EIS does not address the Project-related socioeconomic effect of flood control, biological-related resources, and power production and energy. The socioeconomic effects of flood control and biological related resources were not included in this chapter because no direct socioeconomic-related impacts have been estimated. This is, in part, due to the limited Project-related flood control socioeconomic benefits and the indirect methods used to estimate the socioeconomic benefits of biological resources (Reclamation, 2012). Project-related effects of power production and energy are included in other socioeconomic impact discussions, such as M&I water use economics. Specifically, water supply costs in LCPSIM account for the power production required to convey water to the San Francisco Bay – South and the South Coast regions.

22.3.5 Impacts Associated with the No Project/No Action Alternative

22.3.5.1 Extended Study Area – No Project/No Action Alternative

<u>**Construction, Operation, and Maintenance Impacts**</u>

Hydrologic Regions, Water Delivery Regions, and Water Delivery Service Areas

Impact Socio-1: Substantial Adverse Effects on Regional Economics

The No Project/No Action Alternative assumes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential to exceed established standards has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on regional economics, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to change the scale of the economy, increasing overall production in the Extended Study Area, when compared to Existing Conditions, but not its structure. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Socio-2: Substantial Adverse Effects on Population and Housing

It is anticipated that population growth in the Extended Study Area would follow the projections described for Existing Conditions if the No Project/No Action Alternative is implemented. Trends in housing demand and supply correspond to population trends. It is, therefore, expected that the growth in housing would match the growth in population. Therefore, **there would not be a substantial adverse effect** on population and housing, when compared to Existing Conditions.

Impact Socio-3: Substantial Adverse Effects on Local Government Fiscal Conditions

The No Project/No Action Alternative assumes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential to exceed established standards has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on local government fiscal conditions, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to change the scale of the economy, increasing overall production in the Extended Study Area, when compared to Existing Conditions, but not its structure. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Socio-4: Substantial Adverse Effects on Recreation Economics

It is anticipated that, if the No Project/Action Alternative is implemented, recreation expenditure patterns in the Extended Study Area would be similar to those described for Existing Conditions. Growth in population is expected to cause growth in recreation economic activity. However, although the scale of recreation economic activity would increase with population growth, the structure of recreation economic activity would not. Therefore, **there would not be a substantial adverse effect** on recreation economics, when compared to Existing Conditions.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Table 22-20 summarizes irrigated crop acreage and value of agricultural production in the Extended Study Area if the No Project/Action Alternative is implemented, and shows the difference from Existing Conditions. These SWAP model results rely on water deliveries. Results are summarized for long-term and Dry and Critical water year average conditions. Agricultural markets are regional phenomena, so all irrigated crop lands in the Sacramento Valley are included, not just those of SWP and CVP contractors. Changes in crop acreage and value would occur over time in the Extended Study Area regardless of whether the Project is implemented. These changes primarily reflect trends in land use patterns, crop mix, and demands for agricultural products.

In the Extended Study Area, with implementation of the No Project/No Action Alternative, nearly $22 billion in crop value would be generated on approximately 7.5 million irrigated acres. Acreage and value of production would be slightly lower under a Dry and Critical water year average condition than long-term water year average condition as a result of lower water deliveries. This level of production is similar to Existing Conditions, and when comparing the No Project/No Action Alternative to Existing Conditions, the change in total irrigated acres would be negligible. However, the increase in demand and subsequent real price of agricultural output for the No Project/No Action Alternative, when compared to

Existing Conditions, would increase the total value of production, where the value of production is calculated by multiplying price by quantity. Because the Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average, no comparison is made with the No Project/No Action Alternative.

Table 22-20
Comparison of Crop Acres and Value of Agricultural Production for the No Project/No Action Alternative and Existing Conditions

Analysis Metric	No Project/No Action Alternative	Change from Existing Conditions
Long-Term Water Year Average		
Total Irrigated Acreage (Thousand Acres)	**7,484**	**-22**
Sacramento Valley[a]	1,907	2
San Joaquin[a]	5,577	-24
Total Value of Production (Million $)	**21, 996.5**	**3,121.8**
Sacramento Valley	3,711.3	440.0
San Joaquin	18,285.2	2,681.8
Dry and Critical Water Year Average[b]		
Total Irrigated Acreage (Thousand Acres)	**7,453**	**N/A**
Sacramento Valley	1,899	N/A
San Joaquin	5,554	N/A
Total Value of Production (Million $)	**21,995.1**	**N/A**
Sacramento Valley	3,696.1	N/A
San Joaquin	18,299.0	N/A

[a]Water delivery regions.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions.

Notes:

N/A = Not Applicable
SWAP included relevant regions of agricultural production in the Extended Study Area

Value of production is based on prices received by farmers, in 2010 dollars.

Agricultural economic conditions that are not based on results of the SWAP model are included in the M&I Water Use Economics analysis presented in **Impact Socio-6**. These agricultural areas outside of the SWAP model include SWP water used for irrigation in the Central Coast and South Coast hydrologic regions, and CVP irrigation water delivery in the San Felipe Unit of San Benito and Santa Clara counties.

Agricultural production costs and investments per acre in the Extended Study Area for the No Project/No Action Alternative would be similar to those described for Existing Conditions. Salinity levels of irrigation water delivered to SWP and CVP export service areas in the Extended Study Area for the No Project/No Action Alternative would be similar to that described for Existing Conditions (refer to Chapter 7 Surface Water Quality (electrical conductivity levels) Section 7.3.6.1 for detailed analysis). No additional salinity related costs would be imposed on agricultural lands.

Table 22-21 summarizes the volume and cost of groundwater pumped in the Extended Study Area for the No Project/No Action Alternative, and shows the difference from Existing Conditions. More than 6.5 million acre-feet of groundwater would be pumped under long-term water year average conditions for irrigation purposes, at an estimated cost of more than $700 million per year. The volume and cost of groundwater pumping would increase slightly in Dry and Critical water year average conditions, as a result of reduced surface water delivery to growers, if the No Project/No Action Alternative is implemented. When comparing the No Project/No Action Alternative to Existing Conditions, the reduction in groundwater pumping is a result of increased surface water deliveries and real price of groundwater pumping. The increase in the real price of groundwater pumping would increase the total cost of pumping, prompting producers to use other supplies. However, the No Project/No Action Alternative groundwater pumping could still lead to overdraft, adversely affecting and groundwater quality. Because the Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average, no comparison is made with the No Project/No Action Alternative.

Table 22-21
Comparison of Volume and Cost of Groundwater Pumping for the No Project/No Action Alternative and Existing Conditions

Analysis Metric	No Project/No Action Alternative	Change from Existing Conditions
Long-Term Water Year Average		
Annual Groundwater Pumped (TAF)	**6,556.5**	**-411.7**
Sacramento Valley[a]	1,405.1	-123.4
San Joaquina	5,151.4	-288.3
Annual Cost of Pumping (Million $)	**701.6**	**104.6**
Sacramento Valley	117.0	13.1
San Joaquin	584.6	91.5
Dry and Critical Water Year Average[b]		
Annual Groundwater Pumped (TAF)	**7,215.9**	**N/A**
Sacramento Valley	1,431.0	N/A
San Joaquin	5,784.9	N/A
Annual Cost of Pumping (Million $)	**788.0**	**N/A**
Sacramento Valley	118.7	N/A
San Joaquin	669.3	N/A

[a]Water delivery regions.
[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions.

Notes:

N/A = Not Applicable
TAF = thousand acre feet

SWAP includes all relevant regions of agricultural production in the Extended Study Area grouped as Sacramento Valley and San Joaquin

Costs are presented in 2010 dollars.

A change in demand and subsequent real price of agricultural commodities, and the cost of inputs in the agricultural production process, specifically energy prices, are the primary reasons for the increase in the value of agricultural production and cost of groundwater pumping, respectively. However, these changes would be gradual and are offsetting. The relative size of the agricultural economy would not change significantly. Therefore, **there would not be a substantial adverse effect** on agricultural economics, when compared to Existing Conditions.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

The water supply conditions in the Extended Study Area for the No Project/No Action Alternative are discussed in Chapter 6 Surface Water Resources. This discussion focuses on the delivered M&I water supply specific to urban areas with modeled water supply costs. The segmentation of M&I water supply regions within the Extended Study Area is based on past M&I water supply economics models.

The No Project/No Action Alternative water deliveries, other water supply, and total supply costs, including management options (the sum of modeled conservation, recycling, and desalination) are reported for the San Francisco Bay – South hydrologic region for long-term and Dry and Critical water year average conditions, including changes from Existing Conditions, in Table 22-22. These changes would occur in the Bay Area subregion of the Extended Study Area.

When comparing the No Project/No Action Alternative to Existing Conditions, total water supply and costs would increase. The increase in water management options and other supply reflect the adoption of management options and transfers to meet increased demand for the No Project/No Action Alternative. Although shortages costs would decrease, the increase in total cost is expected with increased water supply costs, such as the increase in the real price of energy.

Table 22-22
Comparison of M&I Water Supply Deliveries and Costs for the San Francisco Bay-South Hydrologic Region for the No Project/No Action Alternative and Existing Conditions

Analysis Metric	No Project/No Action Alternative	Change from Existing Conditions
Long-Term Water Year Average		
Total Supply (TAF/Year)	**1,253**	**72**
Project Delivery	426	40
Management Options[a]	10	10
Other Supply	817	22
Total Costs (Million$/Year)	**207,871**	**37,918**
Shortage	5,478	-5,152
Supply[c]	202,394	43,070
Dry and Critical Water Year Average[b]		
Total Supply (TAF/Year)	**1,166**	**89**
Project Delivery	378.8	25
Management Options[a]	10	10
Other Supply	777	54
Total Costs (Million$/Year)	**206,855**	**27,789**
Shortage	15,759	-13,972
Supply[c]	191,096	41,760

[a]Management options include conservation, recycling, and desalinization.

[b]Sacramento River 40-30-30 index.

[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives including conveyance, distribution, treatment, and transfers.

Notes:

M&I = municipal and industrial
TAF = thousand acre feet

Energy costs of conveyance are included in the cost estimates.

Costs are presented in 2010 dollars.

The No Project/No Action Alternative water deliveries, other water supply, and total supply costs, including management options (the sum of modeled conservation, recycling, and desalination) are reported for the South Coast hydrologic region for long-term and Dry and Critical water year average conditions, including changes from Existing Conditions, in Table 22-23. These changes would occur in the Southern California subregion of the Extended Study Area.

When comparing the No Project/No Action Alternative to Existing Conditions, total water supply and costs would increase. The increase in water management options reflects the adoption of conservation, recycling, and desalinization to meet increased demand for the No Project/No Action Alternative. Other supply would decrease, such as transfers, with demand being met by management options. Although shortages costs would decrease, the increase in total cost is expected to occur with increased water supply costs, such as the real price of energy.

Table 22-23
Comparison of M&I Water Supply Deliveries and Costs for the South Coast Hydrologic Region for the No Project/No Action Alternative and Existing Conditions

Analysis Metric	No Project/No Action Alternative	Change from Existing Conditions
Long-Term Water Year Average		
Total Supply (TAF/Year)	**5,019**	**441**
Project Delivery	1,371	49
Management Options[a]	510	510
Other Supply	3,138	-118
Total Costs (Million $/Year)	**1,763,622**	**427,827**
Shortage	109,330	-29,937
Supply[c]	1,654,292	57,763
Dry and Critical Water Year Average[b]		
Total Supply (TAF/Year)	**4,719**	**275**
Project Delivery	1,052	-36
Management Options[a]	510	510
Other Supply	3,157	-199
Total Costs (Million $/Year)	**2,038,745**	**532,548**
Shortage	302,768	-112,212
Supply[c]	1,735,977	644,760

[a]Management options include conservation, recycling, and desalinization.

[b]Sacramento River 40-30-30 index.

[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives including conveyance, distribution, treatment, and transfers.

Notes:

M&I = municipal and industrial
TAF = thousand acre feet

Energy costs of conveyance are included in the cost estimates.

Costs are presented in 2010 dollars.

The average annual water deliveries and associated shortage and supply costs for long-term and Dry and Critical water year average conditions in urban areas modeled outside of the San Francisco Bay-South and South Coast hydrologic regions in the Extended Study Area for the No Project/No Action Alternative, including the difference from Existing Conditions, are listed in Table 22-24. When comparing the No Project/No Action Alternative to Existing Conditions, the change in water deliveries would vary. An increase in water shortages and supply costs is expected from implementation of the No Project/No Action Alternative, with increased demand and water supply costs, such as the real price of energy.

Table 22-24
Comparison of M&I Water Supply Deliveries and Costs Modeled in OMWEM for the No Project/No Action Alternative and Existing Conditions

Water Delivery Region	Average Annual Project Water Deliveries (TAF)		Average Annual Shortage and Supply[c] Cost (Thousand $)	
	No Project/No Action Alternative	Change from Existing Conditions	No Project/No Action Alternative	Change from Existing Conditions
Long-Term Water Year Average				
Delta	54,332	1,193	9,742	4,091
Bay Area[a]	52,450	4,854	5,860	5,831
Central Coast	45,372	-216	2,692	2,637
Sacramento Valley	22,817	127	4,553	3,389
San Joaquin	99,699	-2,937	1,621	787
Southern California[b]	251,867	6,354	22,496	11,593
Dry and Critical Water Year Average[d]				
Delta	40,672	-4,095	19,422	9,406
Bay Area[a]	36,340	709	11,739	11,659
Central Coast	23,822	-3,686	7,449	7,296
Sacramento Valley	20,697	-68	11,117	8,185
San Joaquin	72,847	-2,790	2,921	1,278
Southern California[b]	186,488	-21,104	47,788	26,350

[a]The results shown here are for San Benito County only.

[b]The results shown here exclude South Coast Hydrologic Area, which is shown separately.

[c]This estimate does not include all water supply-related costs. It includes annual shortage costs and supply costs that might be affected by alternatives, including transfers, groundwater pumping, or other water management options

[d]Sacramento River 40-30-30 index.

Notes:

M&I = municipal and industrial
OMWEM = Other Municipal Water Economics Model
TAF = thousand acre feet

Costs are presented in 2010 dollars.

Water quality conditions in the Extended Study Area were evaluated and discussed with a focus on the salinity conditions specific to regions with modeled salinity costs. The No Project/No Action Alternative long-term average export-weighted annual total dissolved solids (TDS) for the Metropolitan Water District of Southern California, long-term average export-weighted annual TDS and chloride for the Contra Costa and Santa Clara Water District service areas, costs associated with the respective water quality levels, and the difference from Existing Conditions are reported in Table 22-25.

When comparing the No Project/No Action Alternative to Existing Conditions, long-term average export-weighted annual TDS and chloride would decrease. The increase in average annual costs is expected with increased service area population, increasing the total households and related water quality related damages.

Table 22-25
Comparison of M&I Salinity Costs for the No Project/No Action Alternative and Existing Conditions[a,c]

Water Delivery Service Area	Analysis Metric	No Project/No Action Alternative	Change from Existing Conditions
Long-Term Water Year Average			
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	239.8	-7.4
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	253.9	-14.5
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	60.6	-10.4
Metropolitan Water District of Southern California	Average Annual Cost (Thousand $)	N/A	547.0
Contra Costa and Santa Clara Water Districts		N/A	110.8
Dry and Critical Water Year Average[b]			
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	313.0	-8.9
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	275.5	-23.9
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	83.9	-20.1
Metropolitan Water District of Southern California	Average Annual Cost (Thousand $)	N/A	563.1
Contra Costa and Santa Clara Water Districts		N/A	108.6

[a]Results include some damages related to agricultural production in Metropolitan Water District of Southern California's Service Area.

[b]Sacramento River 40-30-30 index.

[c]The Lower Colorado River Basin Water Quality Model and was used for the Metropolitan Water District of Southern California service area and the South Bay Water Quality model was used for the Contra Costa and Santa Clara Water District service areas.

Notes:

M&I = municipal and industrial
mg/L = milligrams per liter
N/A = not applicable
TDS= total dissolved solids

Costs are presented in 2010 dollars.

The change in cost related to M&I water supply and quality in the Extended Study Area would primarily be a result of additional demand and the real increase in water supply-related costs, such as the increase in energy prices. Additional demand would increase the total damages associated with water quality even in the absence of a change in water quality. However, increasing demand would be accompanied by corresponding development of water supply projects and use reduction measures, such as conservation, recycling, and desalinization. Therefore, it is expected that the growth in water supply demand would be accompanied by water supply development. Therefore, **there would not be a substantial adverse effect** on M&I water use economics, when compared to Existing Conditions.

22.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Because the operational effects of the No Project/No Action Alternative were included in the analysis of the Extended Study Area, no separate impact analyses were undertaken for the economic or social effects of the No Project/No Action Alternative in the Secondary Study Area.

22.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

If the No Project/No Action Alternative is implemented, the Project would not be constructed, and socioeconomic effects in the Primary Study Area are expected to be similar to that described for Existing Conditions. In addition, projects included in the No Project/No Action Alternative are not located within the Primary Study Area, and therefore **would not have a substantial adverse effect** on socioeconomic resources, when compared to Existing Conditions.

22.3.6 Impacts Associated with Alternative A

22.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Hydrologic Regions, Water Delivery Regions, and Water Delivery Service Areas

Impact Socio-1: Substantial Adverse Effects on Regional Economics

Agricultural production in the Extended Study Area is expected to change from operation of Alternative A and the resulting changes to SWP and CVP deliveries, impacting employment and income. The estimated change in agricultural production is discussed as effects on agricultural economics (Impact Socio-5). The regional economic effects on employment and income from a change in agricultural production during Project construction, operation, and maintenance would not differ between Existing Conditions and the No Project/No Action Alternative (Table 22-26).

Table 22-26
Change in Extended Study Area Regional Employment and Income Associated with Implementation of Alternative A when Compared to the No Project/No Action Alternative[a,b,c]

Impact	Annual Labor Income (Thousand $)[d]		Annual Jobs	
	Direct	Total[e]	Direct	Total[e]
Agriculture	848	1,996	44.7	72.1

[a]Average annual effect based on long-term water year average conditions.
[b]Based on changes in agricultural production (irrigated acreage) and agricultural commodity prices.
[c]IMPLAN results are changes relative to Existing Conditions and the No Project/No Action Alternative.
[d]Income is reported 2010 dollars.
[e]Includes direct, indirect, and induced effects (defined in Appendix 22C).
Source: Pavich, 2012a.

The increased reliability associated with Alternative A water deliveries would be expected to increase agricultural production in the Extended Study Area less than one percent. This, in turn, would increase annual employment by approximately 72 individuals and annual labor income by more than $1.9 million.

Construction, operation, and maintenance activities would affect the regional economic condition of the Extended Study Area through construction and operation expenditures; Project footprint impacts, such as removal of agricultural land from production; and Project-related impacts. However, the magnitude of the impacts is relatively minor, when compared to the regional economy of the Extended Study Area. Therefore, additional regional economic effects related to Alternative A construction, operation, and maintenance are discussed for the Primary Study Area only.

The increase in total employment and income in the Extended Study Area would result from an increase in agricultural production. The increase in employment and income would not be considered an adverse effect on the regional economy of the Extended Study Area. Therefore, a **less-than-significant impact** on regional economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-2: Substantial Adverse Effects on Population and Housing

The expected population and housing changes associated with construction, operation, and maintenance of Alternative A would be minor, when compared to the population and housing in the Extended Study Area. Therefore, a **less-than-significant impact** on population and housing is expected in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-3: Substantial Adverse Effects on Local Government Fiscal Conditions

The expected local government fiscal conditions changes associated with the construction, operation, and maintenance of Alternative A would be minor, when compared to the government fiscal conditions in the Extended Study Area. Therefore, a **less-than-significant impact** on local government fiscal conditions is expected in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-4: Substantial Adverse Effects on Recreation Economics

The expected changes to recreation economics associated with Alternative A would be minor, when compared to the recreation economics in the Extended Study Area. Therefore, a **less-than-significant impact** on recreation economics is expected in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Estimated agricultural economic changes would be driven by changes in water delivery and water quality conditions. Table 22-27 summarizes the expected changes in irrigated acreage and value of agricultural production that would result in the SWP and CVP export areas as a result of Alternative A operation. Changes are described relative to Existing Conditions and the No Project/No Action Alternative.

Changes in acreage and value relative to Existing Conditions would result from a combination of Alternative A and underlying changes in land use and crop mix unrelated to Alternative A. Total value of irrigated crop production in the Extended Study Area would increase on average by over $3.125 billion per year, with total irrigated crop acreage declining by approximately 19,000 acres. The increase in demand and subsequent real price of agricultural output for the No Project/No Action Alternative, when compared to Existing Conditions, is the reason for the increase in total value of production, even with the decline in irrigated acres.

Changes relative to the No Project/No Action Alternative provide an estimate of the changes solely from Alternative A. Total value of irrigated crop production in the Extended Study Area would increase on average by approximately $3.8 million per year, with total irrigated crop acreage increasing by approximately 2,000 acres. In Dry and Critical water year average conditions, the value of production would be approximately $24 million per year higher than for the No Project/No Action Alternative Dry and Critical water year average conditions.

Changes in production costs and investments are a result of, and consistent with, changes in crop acreage. Changes compared to Existing Conditions would be dominated by long-term trends in crop acreage and cropping patterns that are unrelated to Alternative A. Increases in costs and investments relative to the No Project/No Action Alternative would result from the changes in crop acreage shown in Table 22-27. Water supply and crop acreage would increase relative to No Project/No Action Alternative, so no investments in production facilities or growing stock would be lost as a result of implementation.

Table 22-27
Change in Acres and Value of Agricultural Production Associated with Implementation of Alternative A when Compared to the Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Results of Alternative A	Change from Existing Conditions	Change from No Project/No Action Alternative
Long-Term Water Year Average			
Total Crop Acreage (Thousand Acres)	**7,487**	**-19**	**2**
Sacramento Valley[a]	1,908	3	1
San Joaquin[a]	5,579	-22	1
Total Value of Production (Million $)	**22,000.3**	**3,125.7**	**3.8**
Sacramento Valley	3,713.6	442.3	2.3
San Joaquin	18,286.7	2,683.3	1.5
Dry and Critical Water Year Average[b]			
Total Crop Acreage (Thousand Acres)	**7,469**	**N/A**	**17**
Sacramento Valley	1,904	N/A	6
San Joaquin	5,565	N/A	11
Total Value of Production (Million $)	**22,019.4**	**N/A**	**24.4**
Sacramento Valley	3,703.1	N/A	7.0
San Joaquin	18,316.3	N/A	17.4

[a]Water delivery regions.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions

Notes:

N/A = not applicable

Value of production is based on prices received by farmers, in 2010 dollars.

Long-term average export-weighted TDS and electrical conductivity (EC) would decrease if Alternative A is implemented, when compared to Existing Conditions and the No Project/No Action Alternative, resulting in improved water quality for agricultural production. The economic value of the salinity change is the avoided cost of groundwater pumping. For the Extended Study Area as a whole, the value of avoided pumping as it relates to improved water quality would be approximately $0.436 million per year, when compared to No Project/No Action Alternative.

Table 22-28 summarizes the volume and cost of groundwater pumped in the Extended Study Area. Results are based on SWAP model analysis. Changes in volume and cost relative to Existing Conditions would result from a combination of Alternative A and underlying changes in land use and crop mix unrelated to Alternative A. Total volume pumped in the Extended Study Area would decline on average by almost 462 thousand acre feet (TAF) per year, and total cost of pumping would increase by approximately $97 million per year. The decreased groundwater pumping would be a result of additional surface water available to agriculture in the No Project/No Action Alternative, when compared to Existing Conditions. The increase in pumping costs would be a result of the increase in real energy costs in the No Project/No Action Alternative, when compared to Existing Conditions.

Table 22-28
Change in Volume and Cost of Groundwater Pumping Associated with Implementation of Alternative A when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Results of Alternative A	Change from Existing Conditions	Change from No Action Alternative
Long-Term Water Year Average			
Annual Groundwater Pumped (TAF)	**6,506.5**	**-461.7**	**-49.9**
Sacramento Valley[a]	1,395.9	-132.5	-9.1
San Joaquin[a]	5,110.6	-329.2	-40.8
Annual Cost of Pumping (Million $)	**694.6**	**97.4**	**-7.1**
Sacramento Valley	116.4	12.4	-0.6
San Joaquin	578.2	85.0	-6.5
Dry and Critical Water Year Average[b]			
Annual Groundwater Pumped (TAF)	**7,156.7**	**N/A**	**-59.3**
Sacramento Valley	1,418.3	N/A	-12.7
San Joaquin	5,738.4	N/A	-7.0
Annual Cost of Pumping (Million $)	**780.6**	**N/A**	**-7.4**
Sacramento Valley	117.8	N/A	-0.9
San Joaquin	662.8	N/A	-6.5

[a]Water delivery regions.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions

Notes:

TAF = thousand acre feet

Cost of pumping is based on prices received by farmers, in 2010 dollars.

Changes relative to the No Project/No Action Alternative provide an estimate of the changes solely from Alternative A. Total volume pumped in the Extended Study Area would decline on average by approximately 50 TAF per year, and total cost of pumping would decline by approximately $7 million per year. The declines in pumping and cost would be larger in the Dry and Critical water year average condition.

When comparing Alternative A to Existing Conditions, changes in agricultural economics impacts would result from a combination of Alterative A and underlying changes in land use, crop mix, and real energy and agricultural commodity prices unrelated to Alternative A. The changes that would occur solely as a result of Alternative A, an increase in the value of production and a decrease in groundwater pumping cost, are not considered an adverse effect on the agricultural economy in the Extended Study Area (Tables 22-27 and 22-28). Therefore, a **less-than-significant impact** on agricultural economics is expected, when compared to Existing Conditions.

When comparing Alternative A to the No Project/No Action Alternative, the increase in the value of production, along with the decrease in groundwater pumping cost, are not considered an adverse effect on the agricultural economy in the Extended Study Area (Tables 22-27 and 22-28). Therefore, a **less-than-significant impact** on agricultural economics is expected, when compared to the No Project/No Action Alternative.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

Changes in water supply reliability and related water supply costs in the Extended Study Area attributable to Alternative A operations are described relative to Existing Conditions and the No Project/No Action Alternative. Discussion in this section focuses on the change in water supply reliability specific to urban areas in the SWP and CVP service areas, and estimates of associated changes in water supply costs.

Changes in water supply reliability and related water supply costs in the San Francisco Bay – South hydrologic region are shown in Table 22-29. Project deliveries would increase in Alternative A in long-term and Dry and Critical water year average conditions, when compared to Existing Conditions and the No Project/No Action Alternative. No water management options are included in Existing Conditions. Therefore, when comparing Alternative A with Existing Conditions, the change in management options would always be zero or positive. When comparing Alternative A with the No Project/No Action Alternative, the increase in Project deliveries would not reduce the use of management options (conservation, recycling, and desalination) but would decrease the use of other supplies. Other supplies include local surface water and groundwater, imported non-Project water, baseline recycling and desalination, and transfers.

When comparing Alternative A with Existing Conditions, supply costs would increase in the San Francisco Bay – South hydrologic region in long-term and Dry and Critical water year average conditions. The increase in supply costs would result from increases in population and real energy prices that occur in future conditions. This increase in supply cost would overwhelm any decrease in shortage costs, causing total costs to increase. When comparing Alternative A with the No Project/No Action Alternative, the additional Project deliveries, with little change in management options, would increase supply costs. However, shortage costs would decrease enough to offset the increase in supply costs, reducing total costs.

Table 22-29
Change in M&I Water Supply Deliveries and Costs for the San Francisco Bay-South Hydrologic Region Associated with Implementation of Alternative A when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Results of Alternative A	Change from Existing Conditions	Change from No Project/No Action Alternative
Long-Term Water Year Average			
Total Supply (TAF/Year)	**1,272**	**92**	**19**
Project Delivery	434	48	8
Management Options[a]	22	22	12
Other Supply	816	21	-1
Total Costs (Million $/Year)	**206,205**	**36,252**	**-1,666**
Shortage	3,547	-7,083	-1,931
Supply[c]	202,659	43,335	265
Dry and Critical Water Year Average[b]			
Total Supply (TAF/Year)	**1,192**	**115**	**26**
Project Delivery	394	40	16
Management Options[a]	22	22	12
Other Supply	776	52	-2
Total Costs (Million$/Year)	**201,727**	**22,661**	**-5,128**
Shortage	9,921	-19,809	-5,837
Supply[c]	91,806	42,470	710

[a]Management options include conservation, recycling, and desalinization.

[b]Sacramento River 40-30-30 index.

[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives, including conveyance, distribution, treatment, and transfers.

Notes:

M&I = municipal and industrial
TAF = thousand acre feet

Costs are presented in 2010 dollars.

Changes in water supply reliability and related water supply costs in the South Coast hydrologic region are shown in Table 22-30. Project deliveries would increase in Alternative A in long-term and Dry and Critical water year average conditions, when compared to Existing Conditions and the No Project/No Action Alternative. No water management options are included in Existing Conditions. Therefore, when comparing Alternative A with Existing Conditions, the change in management options would always be zero or positive. When comparing Alternative A with the No Project/No Action Alternative, the increase in Project deliveries would allow for increased deliveries to carryover storage and/or reduce the use of management options (conservation, recycling, and desalination) and other supply (transfers).

When comparing Alternative A with Existing Conditions, supply costs would increase in the South Coast hydrologic region in long-term and Dry and Critical water year average conditions. The increase in supply costs would result from population and real energy price increases that occur in future conditions. This increase in supply cost would overwhelm any decrease in shortage costs, causing total costs to increase. When comparing Alternative A with the No Project/No Action Alternative, the additional Project deliveries would reduce the use of management options and other supplies, reducing supply costs. The accompanying reduction in shortage costs would decrease total costs.

Table 22-30
Change in M&I Water Supply Deliveries and Costs for the South Coast Hydrologic Region Associated with Implementation of Alternative A when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Results of Alternative A	Change from Existing Conditions	Change from No Action Alternative
Long-Term Water Year Average			
Total Supply (TAF/Year)	**5,045**	**467**	**26**
Project Delivery	1,434	111	62
Management Options[a]	507	507	-3
Other Supply	3,105	-151	-33
Total Costs (Million $/Year)	**1,702,870**	**367,075**	**-60,752**
Shortage	68,429	-170,837	-40,901
Supply[c]	1,634,441	537,912	-19,851
Dry and Critical Water Year Average[b]			
Total Supply (TAF/Year)	**4,779**	**334**	**59**
Project Delivery	1,189	101	137
Management Options[a]	507	507	-3
Other Supply	3,082	-274	-75

Shortage	206,045	-208,935	-96,723
Supply[c]	1,708,665	617,448	-27,312

[a]Management options include conservation, recycling, and desalinization.

[b]Sacramento River 40-30-30 index.

[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives, including conveyance, distribution, treatment, and transfers.

Notes:

M&I = municipal and industrial
TAF = thousand acre feet

Costs are presented in 2010 dollars

When comparing Alternative A and Existing Conditions in the Extended Service Area outside of the San Francisco Bay – South and South Coast hydrologic regions, Project water deliveries would increase in long-term and Dry and Critical water year average conditions, excluding the Delta. When comparing Alternative A to the No Project/No Action Alternative, Project deliveries would increase in long-term and Dry and Critical water year average conditions (Table 22-31).

When comparing Alternative A and Existing Conditions, shortage and water supply costs would increase in both long-term and Dry and Critical water year average conditions. The increase in supply costs would result from population and real energy price increases that occur in future conditions. When comparing Alternative A to the No Project/No Action Alternative, shortage and water supply costs would decrease, Table 22-31. The increase in Project deliveries would reduce shortage and water supply costs.

Table 22-31
Change in M&I Water Supply Deliveries and Costs Modeled in OMWEM Associated with Implementation of Alternative A when Compared to Existing Conditions and the No Project/No Action Alternative

Water Delivery Region	Analysis Metric					
	Average Annual Project Water Delivery (TAF)			Average Annual Shortage and Supply Cost[c] (Thousand $)		
	Results of Alternative A	Change from Existing Conditions	Change from No Project/No Action Alternative	Results of Alternative A	Change from Existing Conditions	Change from No Project/No Action Alternative

[a]The results shown here are for San Benito County only.

[b]The results shown here exclude South Coast Hydrologic Area, which is shown separately.

[c]This estimate does not include all water supply-related costs. It includes annual shortage costs and supply costs that might be affected by alternatives, including transfers, groundwater pumping, or other water management options

[d]Sacramento River 40-30-30 index.

Notes:

M&I = municipal and industrial
OMWEM = Other Municipal Water Economics Model
TAF = thousand acre feet

Energy costs of conveyance are included in the cost estimates.

Costs are presented in 2010 dollars.

The change in salinity-related costs in the Extended Study Area attributable to Alternative A operations relative to Existing Conditions and the No Project/No Action Alternative is shown in Table 22-32. Discussion in this section focuses on the change in salinity costs specific to regions with modeled salinity costs.

Table 22-32
Change in Water Supply Salinity Costs Associated with Implementation of Alternative A when Compared to Existing Conditions and the No Project/No Action Alternative[a]

Water Delivery Service Area	Analysis Metric	Results of Alternative A	Change from Existing Conditions	Change from No Action Alternative
Long-Term Water Year Average				
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	234.3	-12.9	-5.5
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	59.3	-11.7	-1.4
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	252.4	-16.0	-1.5
Metropolitan Water District of Southern California	Average Annual Cost (Million $)	N/A	$537.1	-$10.0
Contra Costa and Santa Clara Water Districts		N/A	$112.9	-$1.0
Dry and Critical Water Year Average[b]				
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	299.3	-22.6	-13.7
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	81.2	-22.7	-2.7
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	273.6	-25.8	-1.9
Metropolitan Water District of Southern California	Average Annual Cost (Million $)	N/A	$544.9	-$18.1
Contra Costa and Santa Clara Water Districts		N/A	$110.3	-$1.3

[a]Results include some damages related to agricultural production in Metropolitan Water District of Southern California's Service Area.
[b]Sacramento River 40-30-30 index.

Notes:

mg/L = milligrams per liter
N/A = Not applicable
TDS= total dissolved solids

Costs are presented in 2010 dollars. The Lower Colorado River Basin Water Quality Model was used for the Metropolitan Water District of Southern California service area and the South Bay Water Quality model was used for the Contra Costa and Santa Clara Water District service areas.

When comparing Alternative A with Existing Conditions, long-term average export-weighted annual TDS and chloride would decrease in long-term and Dry and Critical water year average conditions across service areas. However, average annual costs would increase. This increase is expected due to population increases that occur in future conditions. When comparing Alternative A with the No Project/No Action Alternative, long-term average export-weighted annual TDS and chloride would decrease in long-term and Dry and Critical water year average conditions in the Metropolitan Water District of Southern California and Contra Costa and Santa Clara Water District service areas. The improvement in water quality would reduce damages in long-term and Dry and Critical water year average conditions.

When comparing Alternative A to Existing Conditions, changes in M&I water use economics impacts would result from a combination of Alterative A and underlying changes in population and the real cost of energy, impacting water system operation costs. The change that would occur solely as a result of Alternative A, decreasing total costs, is not considered an adverse effect on M&I water use economics in the Extended Study Area. Therefore, a **less-than-significant impact** on M&I water use economics is expected, when compared to Existing Conditions.

When comparing Alternative A to the No Project/No Action Alternative, the increase in water supply and quality would decrease total costs, which is not considered an adverse effect on the M&I water use economics in the Extended Study Area. Therefore, a **less-than-significant impact** on water use economics is expected, when compared to the No Project/No Action Alternative.

22.3.6.2 Secondary Study Area – Alternative A

The operational effects within the Secondary Study Area are included in the analysis of the Extended Study Area and/or Primary Study Area. For example, the minor construction- and operation-related activities at the Red Bluff Pumping Plant are expected to have less-than-significant socioeconomic effects, but are included in the overall construction and operational expenditures used in the regional economic analysis for the Extended and Primary study areas.

22.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Socio-1: Substantial Adverse Effects on Regional Economics

The regional economic effects on employment and income in the Primary Study Area were evaluated for Project construction, operation, and maintenance. Changes are shown relative to Existing Conditions and the No Project/No Action Alternative. There is no difference between the Existing Conditions and No Project//No Action Alternative model used in the analysis. The effects of construction, operation, and maintenance expenditures to employment and income are shown in Table 22-33.

The Project footprint and related facilities, such as roads and utilities, would remove some existing agricultural land from production, so the effects on employment and income would be negative. Some agricultural land removed from production would be temporary, and would be restored to its original use following the construction period.

Alternative A would increase economic activity related to land acquisition in the Primary Study Area. This regional economic impact would be temporary, occurring 12 to 18 months prior to construction. The expected regional economic effects to employment and income in the Primary Study Area from land acquisition are reported in Table 22-33.

Table 22-33
Temporary Change in Regional Employment and Income Associated with Implementation of Alternative A when Compared to the No Project/No Action Alternative[a,b]

Impact	Labor Income (Thousand $)		Annual Jobs	
	Direct	Total[c]	Direct	Total[c]
Agriculture	-636	-1,242	-44.0	-62.2
Land Acquisition	625	717	14.7	17.5
Construction	19,940	44,544	95.9	626.1
Total	**19,929**	**44,019**	**66.6**	**581.4**

[a]Average annual effect based on entire period of construction. The duration of each impact will vary.
[b]IMPLAN results are changes relative to Existing Conditions and the No Project/No Action Alternative.
[c]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 2012a.

The expected permanent effects to employment and income from operation and maintenance are shown in Table 22-34. Alternative A would also increase recreational opportunities in the Primary Study Area. The increased recreational expenditures would affect employment and income. The expected regional economic effects to employment and income in the Primary Study Area from the increase in recreational expenditures are reported in Table 22-34.

Table 22-34
Permanent Change in Regional Employment and Income Associated with Implementation of Alternative A when Compared to the No Project/No Action Alternative[a,b]

Impact	Labor Income (Thousand $)		Annual Jobs	
	Direct	Total[c]	Direct	Total[c]
Recreation	487	588	20.1	22.9
Agriculture	-204	-381	-4.7	-9.9
Operation	1,750	2,120	35.0	45.7
Total	**2,033**	**2,327**	**50.4**	**58.7**

[a]Average annual effect based over life of Alternative A.
[b]IMPLAN results are changes relative to Existing Conditions and the No Project/No Action Alternative.
[c]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported in 2010 dollars.

Source: Pavich, 2012a.

Total employment and income in the Primary Study Area would increase as a result of construction, operation, land acquisition, and a change in agricultural production and recreational opportunities. The increase in employment and income would not be considered an adverse effect on the regional economy of the Primary Study Area. Therefore, a **less-than-significant impact** on regional economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-2: Substantial Adverse Effects on Population and Housing

Population

Construction and operation of Alternative A would require an estimated annual average of 96 and 35 workers, respectively, with a maximum of 60 daily workers for operation. It is anticipated that approximately 50 percent of the construction jobs would be filled from within the existing two-county labor force. However, construction may require specialized skills not readily available in the local labor pool. As a result, it is anticipated that some of the non-local workers would be imported from outside of the two-county region.

When considering the multi-year duration of construction, it is anticipated that 20 percent of the imported workers would relocate to the two-county region, adding to the local population. It is anticipated that all of the workers required for operation would relocate to the two-county region. This additional population from construction and operation would constitute a minor increase in the total 2020 projected Primary study area population of 64,605, and would not pose a burden on local public services, utilities, or infrastructure. Therefore, impacts are considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Housing

Changes in housing demand are based on changes in supply resulting from displacement during Project facility construction and changes in housing demand resulting from employment associated with construction and operation of Alternative A.

The construction and operation workforce would most likely commute daily to the Project sites from within the two-county region; however, if needed, there are approximately 2,000 available housing units, as reported in the Environmental Setting/Affected Environment discussion, to accommodate workers who may choose to commute to the Project sites on a workweek basis or who may choose to relocate to the region for the duration of the construction period. In addition to the available housing units, there are recreational vehicle parks within the two-county region to accommodate construction workers. As a result, construction and operation of the Project is not expected to increase the demand for housing within the two-county region.

Within specific local communities, there could be localized effects on housing during construction. However, given the availability of housing within the two-county region, predicting where this impact would occur would be speculative. Construction and operation of Alternative A would result in minor population increases in the Primary Study Area, with adequate housing supply to accommodate the change in population. Therefore, impacts are considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-3: Substantial Adverse Effects on Local Government Fiscal Conditions

Table 22-35 lists the change in annual property tax receipts associated with the implementation of Alternative A. For Glenn County, the annual property tax amount that would be removed from the annual tax revenues would be $28,428, or approximately 0.033 percent of the overall revenues for Glenn County. For Colusa County, the annual property tax amount that would be removed from the annual tax revenues from Alternative A would be $252,366, or approximately 0.415 percent of the overall revenues for Colusa County. The counties may also incur costs associated with increased County services that may become necessary as a result of implementing the Project.

A decrease in property tax receipts in the Primary Study Area would result from Alternative A. However, the decrease in property tax revenue would be less than five percent of the overall county revenues. Therefore, impacts of Alternative A to local government fiscal conditions are considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Table 22-35
Change in Property Tax Receipts Associated with Implementation of Alternative A when Compared to the No Project/No Action Alternative

County	Change in Annual Property Tax 2010 ($)	Percentage of County Revenue 2012 Budget (%)
Glenn	28,428	0.033
Colusa	252,366	0.415

Source: Colusa County, 2012.

Impact Socio-4: Substantial Adverse Effects on Recreation Economics

Alternative A would provide recreational opportunities within the Primary Study Area. Table 22-36 shows the estimated number of visitors to Sites Reservoir if Alternative A is implemented. Also included are recreation expenditures attributable to the portion of visitors outside the Primary Study Area. This recreation expenditure information is used to assess the effects on regional economics, i.e., the impact on employment and income. The anticipated total recreation visitation to Sites Reservoir would be more than 360,000 annual visits, increasing recreation expenditures from outside of the Primary Study Area by almost $3 million.

Table 22-36
Estimated Sites Reservoir Recreation Visitation and Expenditures Associated with Implementation of Alternative A*

Activity / Spending Category	Alternative A	
	Visits (Recreation Visitor Days)	Associated Non-Local Spending
Shore fishing	31,405	$214,838
Boat fishing	16,244	$111,123
Picnicking	83,024	$692,092
Sightseeing	71,473	$605,566
Swimming / beach use	81,580	$680,056
Walking	10,468	$74,794
Bicycling	4,693	$33,528
Boating / water-skiing	56,312	$469,419
Other	2,888	$24,073
Total	**358,087**	**$2,905, 489**

*Based on long-term water year average conditions.

Notes:

Costs are presented in 2010 dollars.

Attributed to reservoir-recreation only; the analysis does not account for changes in recreation spending attributed to river-based recreation.

Source: Pavich, 2012b.

Increased levels of recreation at Sites Reservoir would increase recreation expenditures in the Primary Study Area. An increase in recreation expenditures is not considered an adverse effect on the recreation economy of the Primary Study Area. Therefore, a **less-than-significant impact** on recreation economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Construction of Alternative A would convert land from existing agricultural uses to uses that include Project facility footprints, construction staging areas, temporary and permanent roads, utilities, and open space undeveloped lands.

Changes in crop acreage were used to describe the associated changes in economic values. Table 22-37 summarizes the changes in acreage and value of agricultural production that would result in the Primary Study Area as a result of Alternative A construction. Changes are shown relative to Existing Conditions and the No Project/ No Action Alternative by aggregate crop category (agricultural resources do not differ between Existing Conditions and the No Project/No Action Alternative).

Table 22-37
Change in Crop Acres and Value of Agricultural Production Associated with Implementation of Alternative A when Compared to Existing Conditions and No Project/No Action Alternative

Analysis Metric	Alternative A Baseline[b]	Change from Existing Conditions and the No Project/No Action Alternative	
		Temporary[c]	Permanent[c]
Total Crop Acreage (Thousand Acres)[a]	**889.3**	**-4.5**	**-26.2**
Rice	247.2	-3.1	-0.2
Almonds	109.4	-0.1	0.0
Hay and Forage	94.3	-0.2	-0.6
Wheat	22.5	-0.3	-0.1
Tomatoes, Processing	27.9	-0.1	-0.1
Rangeland	388.1	-0.7	-25.3
Total Value of Production (Million $)[a]	**1,050.9**	**-7.1**	**-1.5**
Rice	486.8	-5.8	-0.3
Almonds	359.4	-0.5	-0.1
Hay and Forage	92.0	-0.2	-0.6
Wheat	12.9	-0.2	0.0
Tomatoes, Processing	96.2	-0.4	-0.3
Rangeland	3.7	-0.1	-0.3

[a]Total crop acreage and value of production differ from the sum of individual categories due to rounding.
[b]Permanent impacts of Alternative A.
[c]Temporary impacts are a result of Project construction. Permanent impacts are a result of Project operation.
Note:
Value of production is based on prices received by farmers, in 2010 dollars.
Source: Pavich, 2012c.

Total value of crop production in the Primary Study Area would be expected to decline on average by $7.1 million per year during the Project construction period, and by $1.5 million per year during Project operation. Total crop acreage would decline by approximately 4,500 acres during Project construction (temporary change) and 26,200 acres during Project operation (permanent change). The majority of the decrease in crop acreage during construction would be associated with rice and almost all of the decrease in crop acreage during Project operation would be associated with rangeland.

Alternative A may also affect production costs on lands even if revenues are largely unaffected. Costs could be associated with operational constraints and longer travel times due to Project construction. Construction designs and costs have provided for such effects in two ways. In most cases, affected lands would be within the Project facilities footprint, and are included in the agricultural acreage and value of production described elsewhere in this chapter. For potentially affected lands not included in the facilities footprint, construction costs include temporary and permanent roads and other facilities, as needed to support agricultural production. There could be some additional travel time and other costs associated with using these facilities, but such costs are not environmental impacts requiring mitigation.

Loss of investments in production facilities would occur as a result of Project facilities construction. The value of structures and equipment potentially affected would vary widely across parcels. Much of the equipment is portable (e.g., machinery, tools, portable sprinkler pipe), and could be sold or used on other lands. Shop and storage buildings and permanent irrigation and drainage equipment may have little or no salvage value. The negotiated purchase of lands for the conveyance and associated facilities would compensate for salvage value accordingly. According to Cooperative Extension cost of production studies, permanent structures, irrigation systems, and drainage systems can represent a wide range in investment, from less than $100 per acre for field and vegetable crops up to more than $3,000 per acre for some orchards (UCCE, 2008 and 2011). Most of the facilities would not be new, so their depreciated values would be substantially lower.

Land improvements, including orchards, would also be considered during negotiations for land purchases. Typical investments required to bring permanent crops into production were described in Section 22.2. Forage crops, such as irrigated pasture and alfalfa, require an establishment cost of approximately $400 per acre. The depreciated values of the growing stock could be substantially below these establishment costs, depending on the ages of the stands that would be affected.

Construction and operation of Alternative A would reduce the total value of agricultural production in the Primary Study Area. DWR and Reclamation would provide compensation to property owners for the fair market value of any property acquired through eminent domain for the Project. The decrease in the total value of agricultural production would be less than five percent of the total value of agricultural production in the Primary Study Area. Therefore, a **less-than-significant impact** is expected to the agricultural economy in the Primary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

Refer to the **Socio-6** discussion for the Extended Study Area. Given the absence of any affected M&I facilities serving the Primary Study Area residents, no M&I water use economic effects are expected in the Primary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative

22.3.7 Impacts Associated with Alternative B

22.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

Hydrologic Regions, Water Delivery Regions, and Water Delivery Service Areas

The impacts associated with Alternative B, as they relate to population and housing (**Impact Socio-2**), local government fiscal conditions (**Impact Socio-3**), and recreation economics (**Impact Socio-4**), would be the same as described for Alternative A for the Extended Study Area.

The operational differences of Alternative B within the Extended Study Area, when compared to Alternative A, for the effects on regional economics (**Impact Socio-1**), agricultural economics (**Impact Socio-5**), and M&I water use economics (**Impact Socio-6**) are discussed below.

Impact Socio-1: Substantial Adverse Effects on Regional Economics

Agricultural production in the Extended Study Area would change from operation of Alternative B and the resulting changes to SWP and CVP project deliveries, impacting employment and income. The estimated change in agricultural production is discussed in effects on agricultural economics (Impact Socio-5). The regional economic effects on employment and income from a change in agricultural production during Project construction, operation, and maintenance would not differ between Existing Conditions and the No Project/No Action Alternative (Table 22-38).

The expected increased reliability associated with Alternative B water deliveries would increase agricultural production in the Extended Study Area less than one percent. This, is turn, would increase annual employment by approximately 60 individuals and annual labor income by more than $1.7 million.

Table 22-38
Change in Extended Study Area Regional Employment and Income Associated with Implementation of Alternative B when Compared to the No Project/No Action Alternative[a,b,c]

Impact	Annual Labor Income (Thousand $)		Annual Jobs	
	Direct	Total[d]	Direct	Total[d]
Agriculture	751	1,708	36.6	59.6

[a]Average annual effect based on long-term water year average conditions.
[b]Based on changes in agricultural production (irrigated acreage) and agricultural commodity prices.
[c]IMPLAN results are changes relative to Existing Conditions or the No Project/No Action Alternative.
[d]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 2012a.

Construction, operation, and maintenance activities would affect the regional economic condition of the Extended Study Area through construction and operation expenditures; Project footprint impacts, such as removal of agricultural land from production; and other Project-related impacts. However, the magnitude of the impacts is relatively minor, when compared to the regional economy of the Extended Study Area. Therefore, additional regional economic effects related to Alternative B construction, operation, and maintenance are discussed for the Primary Study Area only.

The increase in total employment and income in the Extended Study Area would result from an increase in agricultural production. Similar to that described for Alternative A, the increase in employment and income would not be considered an adverse effect on the regional economy of the Extended Study Area. Therefore, a **less-than-significant impact** on regional economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Estimated agricultural economic changes would be driven by changes in water delivery and water quality conditions. Table 22-39 summarizes the expected changes in irrigated acreage and value of agricultural production that would result in the SWP and CVP export areas as a result of operation of Alternative B. Changes are described relative to Existing Conditions and the No Project/No Action Alternative.

Table 22-39
Change in Acres and Value of Agricultural Production Associated with Implementation of Alternative B when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Results of Alternative B	Change from Existing Conditions	Change from No Project/No Action Alternative
Long-Term Water Year Average			
Total Crop Acreage (Thousand Acres)	**7,487**	**-19**	**2**
Sacramento Valley[a]	1,908	3	0
San Joaquin[a]	5,579	-22	1
Total Value of Production (Million $)	**21,999.0**	**3,124.3**	**2.5**
Sacramento Valley	3,711.8	440.5	0.5
San Joaquin	18,287.2	2,683.8	2.0
Dry and Critical Water Year Average[b]			
Total Crop Acreage (Thousand Acres)	**7,462**	**N/A**	**8**
Sacramento Valley	1,903	N/A	4
San Joaquin	5,559	N/A	4
Total Value of Production (Million $)	**22,006.4**	**N/A**	**11.3**
Sacramento Valley	3,699.6	N/A	3.5
San Joaquin	18,306.8	N/A	7.9

[a]Water delivery regions.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions

Notes:

N/A = not applicable

Value of production is based on prices received by farmers, in 2010 dollars.

Changes in acreage and value relative to Existing Conditions would result from a combination of Alternative B and underlying changes in land use and crop mix unrelated to Alternative B. Total value of irrigated crop production in the Extended Study Area would be expected to decline on average by more than $3.124 billion per year, with total irrigated crop acreage declining by approximately 19,000 acres. The increase in demand and subsequent real price of agricultural output for the No Project/No Action

Alternative, when compared to Existing Conditions, is the reason for the increase in total value of production, even with the decline in irrigated acres.

Changes relative to the No Project/No Action Alternative provide an estimate of the changes solely from Alternative B. Total value of irrigated crop production in the Extended Study Area would be expected to increase on average by approximately $2.5 million per year, with total irrigated crop acreage increasing by approximately 2,000 acres. In Dry and Critical water year average conditions, the value of production would be approximately $11.3 million per year higher than for the No Project/No Action Alternative Dry and Critical water year average condition.

Changes in production costs and investments are a result of, and consistent with, changes in crop acreage. Changes compared to Existing Conditions would be dominated by long-term trends in crop acreage and cropping patterns that are unrelated to Alternative B. Increases in costs and investments relative to the No Project/No Action Alternative would result from the changes in crop acreage shown in Table 22-39. Water supply and crop acreage would increase relative to the No Project/No Action Alternative, so no investments in production facilities or growing stock would be lost as a result of implementation.

Long-term average export-weighted TDS and EC would decrease if Alternative B is implemented, when compared to No Project/No Action Alternative and Existing Conditions, resulting in improved water quality for agricultural production. The economic value of the salinity change is the avoided cost of groundwater pumping. For the Extended Study Area as a whole, the value of avoided pumping as it relates to improved water quality would be approximately $0.443 million per year, when compared to No Project/No Action Alternative.

Table 22-40 summarizes the volume and cost of groundwater pumped in the Extended Study Area. Results are based on SWAP model analysis. Changes in volume and cost relative to Existing Conditions would result from a combination of Alternative B and underlying changes in land use and crop mix unrelated to Alternative B. Total volume pumped in the Extended Study Area would decline on average by almost 439 TAF per year, and total cost of pumping would increase by approximately $101 million per year. The decreased groundwater pumping would be a result of additional surface water available to agriculture in the No Project/No Action Alternative, when compared to Existing Conditions. The increase in pumping costs would be a result of the increase in real energy costs in the No Project/No Action Alternative, when compared to Existing Conditions.

Changes relative to the No Project/No Action Alternative provide an estimate of the changes solely from Alternative B. Total volume pumped in the Extended Study Area would decline on average by approximately 27 TAF per year, and total cost of pumping would decline by more than $3 million per year. The declines in pumping and cost would be larger in the Dry and Critical water year average condition.

When comparing Alternative B to Existing Conditions, changes in agricultural economics impacts would result from a combination of Alterative B and underlying changes in land use, crop mix, and real energy and agricultural commodity prices unrelated to Alternative B. Similar to that described for Alternative A, the changes that would occur solely as a result of Alternative B, an increase in the value of production and a decrease in groundwater pumping cost, are not considered an adverse effect on the agricultural economy in the Extended Study Area (Tables 22-39 and 22-40). Therefore, a **less-than-significant impact** on agricultural economics is expected, when compared to Existing Conditions.

Table 22-40
Change in Volume and Cost of Groundwater Pumping Associated with Implementation of Alternative B when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative B	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Annual Groundwater Pumped (TAF)	**6,529.2**	**-438.9**	**-27.3**
Sacramento Valley[a]	1,399.4	-129.1	-5.7
San Joaquin[a]	5,129.9	-309.9	-21.6
Annual Cost of Pumping (Million $)	**698.3**	**101.2**	**-3.3**
Sacramento Valley	116.6	12.7	-0.4
San Joaquin	581.7	12.8	-2.9
Dry and Critical Water Year Average[b]			
Annual Groundwater Pumped (TAF)	**7,177.0**	**N/A**	**-38.9**
Sacramento Valley	1,427.2	N/A	-3.8
San Joaquin	5,749.8	N/A	-35.1
Annual Cost of Pumping (Million $)	**782.4**	**N/A**	**-5.6**
Sacramento Valley	118.4	N/A	-0.3
San Joaquin	664.0	N/A	-5.3

[a]Water delivery regions.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions.

Notes:

N/A = not applicable
TAF = thousand acre feet

Cost of pumping is based on prices received by farmers, in 2010 dollars.

When comparing Alternative B to the No Project/No Action Alternative, the increase in the value of production, along with the decrease in groundwater pumping cost, are not considered an adverse effect on the agricultural economy in the Extended Study Area (Tables 22-39 and 22-40). Therefore, a **less-than-significant impact** on agricultural economics is expected, when compared to the No Project/No Action Alternative.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

Changes in water supply reliability and related water supply costs in the Extended Study Area attributable to Alternative B operations are described relative to Existing Conditions and the No Project/No Action Alternative. This discussion focuses on the change in water supply reliability specific to urban areas in the SWP and CVP service areas, and estimates of associated changes in water supply costs.

Changes in water supply reliability and related water supply costs in the San Francisco Bay – South hydrologic region are shown in Table 22-41. Project deliveries would be expected to increase if Alternative B is implemented in long-term and Dry and Critical water year average conditions, when compared to Existing Conditions and the No Project/No Action Alternative. No water management options are included in Existing Conditions. Therefore, when comparing Alternative B with Existing Conditions, the change in management options would always be zero or positive. When comparing Alternative B with the No Project/No Action Alternative, the increase in Project deliveries would allow for increased deliveries to carryover storage and/or not reduce the use of management options (conservation, recycling, and desalination) but would decrease the use of other supplies (transfers).

Table 22-41
Change in M&I Water Supply Deliveries and Costs for the San Francisco Bay-South Hydrologic Region Associated with Implementation of Alternative B when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative B	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Total Supply (TAF/Year)	**1,272**	**91**	**19**
Project Delivery	433	47	7
Management Options[a]	22	22	12
Other Supply	817	22	0
Total Costs (Million $/Year)	**206,324**	**36,370**	**-1,547**
Shortage	3,583	-7,047	-1,895
Supply[c]	202,741	43,418	348
Dry and Critical Water Year Average[b]			
Total Supply (TAF/Year)	**1,190**	**113**	**24**
Project Delivery	392	38	13
Management Options[a]	22	22	12
Other Supply	776	53	-1
Total Costs (Million $/Year)	**201,597**	**22,531**	**-5,258**
Shortage	9,416	-20,314	-6,342
Supply[c]	192,181	42,845	1,085

[a]Management options include conservation, recycling, and desalinization.

[b]Sacramento River 40-30-30 index.

[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives including conveyance, distribution, treatment, and transfers.

Notes:

M&I = municipal and industrial
TAF = thousand acre feet

Costs are presented in 2010 dollars.

When comparing Alternative B with Existing Conditions, supply costs would increase in the San Francisco Bay – South hydrologic region in long-term and Dry and Critical water year average conditions. The increase in supply costs would result from increases in population and real energy prices that occur in future conditions. This increase in supply cost would overwhelm any decrease in shortage costs, causing total costs to increase. When comparing Alternative B with the No Project/No Action Alternative, the additional Project deliveries, with little change in management options, would increase supply costs. However, shortage costs would decrease enough to offset the increase in supply costs, reducing total costs.

Changes in water supply reliability and related water supply costs in the South Coast hydrologic region are shown in Table 22-42. Project deliveries would be expected to increase in Alternative B in long-term and Dry and Critical water year average conditions, when compared to Existing Conditions and the No

Project/No Action Alternative. No water management options are included in Existing Conditions. Therefore, when comparing Alternative B with Existing Conditions, the change in management options would always be zero or positive. When comparing Alternative B with the No Project/No Action Alternative, the increase in Project deliveries would reduce the use of management options (conservation, recycling, and desalination) and other supply (local surface and groundwater, imported non-Project, baseline recycling and desalination, and transfers).

Table 22-42
Change in M&I Water Supply Deliveries and Costs for the South Coast Hydrologic Region Associated with Implementation of Alternative B when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative B	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Total Supply (TAF/Year)	**5,043**	**465**	**24**
Project Delivery	1,438	115	66
Management Options[a]	502	502	-8
Other Supply	3,104	-152	-34
Total Costs (Million $/Year)	**1,700,990**	**365,195**	**-62,632**
Shortage	72,857	-166,409	-36,472
Supply[c]	1,628,133	531,604	-26,160
Dry and Critical Water Year Average[b]			
Total Supply (TAF/Year)	**4,757**	**313**	**38**
Project Delivery	1,179	91	126
Management Options[a]	502	502	-8
Other Supply	3,077	-279	-80
Total Costs (Million $/Year)	**1,910,843**	**404,646**	**-127,902**
Shortage	225,830	-189,151	-76,938
Supply[c]	1,685,013	593,796	-50,964

[a]Management options include conservation, recycling, and desalinization.
[b]Sacramento River 40-30-30 index.
[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives including conveyance, distribution, treatment, and transfers.

Notes:
M&I = municipal and industrial
TAF = thousand acre feet
Costs are presented in 2010 dollars.

When comparing Alternative B with Existing Conditions, supply costs would be expected to increase in the South Coast hydrologic region in long-term and Dry and Critical water year average conditions. The increase in supply costs would result from population and real energy price increases that occur in future conditions. This increase in supply cost would overwhelm any decrease in shortage costs, causing total costs to increase. Comparing Alternative B with the No Project/No Action Alternative, the additional Project deliveries would reduce the use of management options and other supply, reducing supply costs. The accompanying reduction in shortage costs would decrease total costs.

When comparing Alternative B and Existing Conditions in the Extended Service Area outside of the San Francisco Bay – South and South Coast hydrologic regions, Project water deliveries would increase in long-term and Dry and Critical water year average conditions, excluding the Delta. When comparing Alternative B to the No Project/No Action Alternative, Project deliveries would increase in long-term and Dry and Critical water year average conditions in most regions (Table 22-43).

Table 22-43
Change in M&I Water Supply Deliveries and Costs Modeled in OMWEM Associated with Implementation of Alternative B when Compared to Existing Conditions and the No Project/No Action Alternative

Water Delivery Region	Analysis Metric: Average Annual Project Water Delivery (TAF)			Analysis Metric: Average Annual Shortage and Supply Cost[c] (Thousand $)		
	Alternative B	Change from Existing Conditions	Change from the No Project/No Action Alternative	Alternative B	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average						
Delta	56	3	2	9,287	3,636	-454
Bay Area[a]	54	6	1	5,791	5,763	-69
Central Coast	47	2	2	1,634	1,579	-1,058

Sacramento Valley	21	0	0	10,986	8,054	-131
San Joaquin	81	5	8	2,836	1,194	-85
Southern California[b]	213	5	26	27,861	6,423	-19,927

[a]The results shown here are for San Benito County only.

[b]The results shown here exclude South Coast Hydrologic Area, which is shown separately.

[c]This estimate does not include all water supply-related costs. It includes annual shortage costs and supply costs that might be affected by alternatives, including transfers, groundwater pumping, or other water management options.

[d]Sacramento River 40-30-30 index.

Notes:

M&I = municipal and industrial
OMWEM = Other Municipal Water Economics Model
TAF = thousand acre feet

Costs are presented in 2010 dollars.

When comparing Alternative B and Existing Conditions, shortage and water supply costs would be expected to increase in both long-term and Dry and Critical water year average conditions. The increase in supply costs would result from population and real energy price increases that occur in future conditions. When comparing Alternative B to the No Project/No Action Alternative, shortage and water supply costs would decrease (Table 22-43). The increase in Project deliveries would reduce shortage and water supply costs.

The expected change in salinity-related costs in the Extended Study Area attributable to Alternative B operations relative to Existing Conditions and the No Project/No Action Alternative is shown in Table 22-44. Discussion in this section focuses on the change in salinity costs specific to regions with modeled salinity costs.

Table 22-44
Change in Water Supply Salinity Costs Associated with Implementation of Alternative B when Compared to the Existing Conditions and the No Project/No Action Alternative[a]

Water Delivery Service Area	Analysis Metric	Alternative B	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average				
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	233.9	-13.3	-5.9
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	59.2	-11.8	-1.5
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	252.2	-16.2	-1.6
Metropolitan Water District of Southern California	Average Annual Cost (Million $)	N/A	$536.2	-$10.8
Contra Costa and Santa Clara Water Districts		N/A	$112.8	-$1.1
Dry and Critical Water Year Average[b]				
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	298.2	-23.7	-14.8
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	80.8	-23.2	-3.1
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	273.0	-26.3	-2.4
Metropolitan Water District of Southern California	Average Annual Cost (Million $)	N/A	$542.7	-$20.4
Contra Costa and Santa Clara Water Districts		N/A	$110.0	-$1.6

[a]Results include some damages related to agricultural production in Metropolitan Water District of Southern California's Service Area.

[b]Sacramento River 40-30-30 index.

Notes:

mg/L = milligrams per liter
N/A = not applicable
TDS= total dissolved solids

Costs are presented in 2010 dollars. The Lower Colorado River Basin Water Quality Model was used for the Metropolitan Water District of Southern California service area and the South Bay Water Quality model was used for the Contra Costa and Santa Clara Water District service areas.

When comparing Alternative B with Existing Conditions, long-term average export-weighted annual TDS and chloride would be expected to decrease in long-term and Dry and Critical water year average conditions across service areas. However, average annual costs would increase. This increase is expected due to population increases that occur in future conditions. When comparing Alternative B with the No Project/No Action Alternative, long-term average export-weighted annual TDS and chloride would decrease in long-term and Dry and Critical water year average conditions in the Metropolitan Water District of Southern California and Contra Costa and Santa Clara Water District service areas. The improvement in water quality would reduce damages in long-term and Dry and Critical water year average conditions.

When comparing Alternative B to Existing Conditions, expected changes in M&I water use economics impacts would result from a combination of Alterative B and underlying changes in population and the real cost of energy, impacting water system operation costs. Similar to that described for Alternative A, the change that would occur solely as a result of Alternative B, decreasing total costs, is not considered an adverse effect on M&I water use economics in the Extended Study Area. Therefore, a **less-than-significant impact** on M&I water use economics is expected, when compared to Existing Conditions.

When comparing Alternative B to the No Project/No Action Alternative, the expected increase in water supply and quality would decrease total costs, which is not considered an adverse effect on the M&I water use economics in the Extended Study Area. Therefore, a **less-than-significant impact** on water use economics is expected, when compared to the No Project/No Action Alternative.

22.3.7.2 Secondary Study Area – Alternative B

The operational effects within the Secondary Study Area are included in the analysis of the Extended Study Area and/or Primary Study Area, similar to that described for Alternative A.

22.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Socio-1: Substantial Adverse Effects on Regional Economics

The regional economic effects on employment and income in the Primary Study Area were evaluated during construction, operation, and maintenance. Changes are shown relative to Existing Conditions and the No Project/No Action Alternative. There is no difference between Existing Conditions and the No Project//No Action Alternative model used in the analysis. The expected effects of construction, operation, and maintenance expenditures to employment and income are shown in Table 22-45.

The Project footprint and related facilities, such as roads and utilities, would remove some existing agricultural land from production, so the effects on employment and income would be negative. Some agricultural land removed from production would only be temporary, and restored to its original use following the construction period.

Alternative B would also increase economic activity related to land acquisition in the Primary Study Area. This regional economic impact would be temporary, occurring 12 to 18 months prior to construction. The regional economic effects to employment and income in the Primary Study Area from land acquisition are reported in Table 22-45.

Table 22-45
Temporary Change in Regional Employment and Income Associated with Implementation of Alternative B when Compared to the No Project/No Action Alternative[a,b]

Impact	Labor Income (Thousand $) Direct	Labor Income (Thousand $) Total[c]	Annual Jobs Direct	Annual Jobs Total[c]
Agriculture	-636	-1,242	-44.0	-62.2
Land Acquisition	615	706	14.4	17.2
Construction	20,518	45,253	98.7	631.7
Total	**20,497**	**44,717**	**69.1**	**586.7**

[a]Average annual effect based on entire period of construction. The duration of each impact would vary.
[b]IMPLAN results are changes relative to Existing Condition and the No Project/No Action Alternative.
[c]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 2012a.

The expected permanent effects to employment and income from Alternative B operation and maintenance are shown in Table 22-46. The Project would also increase recreational opportunities in the Primary Study Area. The increased recreational expenditures would affect employment and income. The regional economic effects to employment and income in the Primary Study Area from the increase in recreational expenditures are reported in Table 22-46.

Table 22-46
Permanent Change in Regional Employment and Income Associated with Implementation of Alternative B when Compared to the No Project/No Action Alternative[a,b]

Impact	Labor Income (Thousand $) Direct	Labor Income (Thousand $) Total[c]	Annual Jobs Direct	Annual Jobs Total[c]
Recreation	483	583	19.9	22.7
Agriculture	-199	-372	-4.6	-9.7
Operation	1,500	1,838	30.0	39.7
Total	**1,784**	**2,049**	**45.3**	**52.7**

[a]Average annual effect based over life of Alternative B.
[b]IMPLAN results are changes relative to Existing Conditions and the No Project/No Action Alternative.
[c]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 2012a.

Total employment and income in the Primary Study Area would increase as a result of construction, operation, land acquisition, and a change in agricultural production and recreational opportunities. Similar to that described for Alternative A, the increase in employment and income would not be considered an adverse effect on the regional economy of the Primary Study Area. Therefore, a **less-than-significant impact** on regional economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-2: Substantial Adverse Effects on Population and Housing

Population

Construction and operation of Alternative B would require an estimated annual average of 99 and 30 workers, respectively, with a maximum of 60 daily workers for operation. It is anticipated that approximately 50 percent of the construction jobs would be filled from within the existing two-county labor force. However, construction may require specialized worker skills not readily available in the local labor pool. As a result, it is anticipated that some of the non-local workers would be imported from outside the two-county region.

When considering the multi-year duration of construction, it is anticipated that 20 percent of the imported workers would relocate to the two-county region, adding to the local population. It is anticipated that all of the workers required for operation would relocate to the two-county region. Similar to that described for Alternative A, this additional population from construction and operation would constitute a minor increase in the total 2020 projected regional population of 64,605, and would not pose a burden on local public services, utilities, or infrastructure. Therefore, impacts are considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Housing

Alternative B construction, operation, and maintenance impacts to housing conditions within the Primary Study Area would be the same as described for Alternative A.

Impact Socio-3: Substantial Adverse Effects on Local Government Fiscal Conditions

Alternative B construction, operation, and maintenance impacts to local government fiscal conditions within the Primary Study Area would be the same as described for Alternative A.

Impact Socio-4: Substantial Adverse Effects on Recreation Economics

Alternative B would provide recreational opportunities within the Primary Study Area. Table 22-47 shows the estimated number of visitors to Sites Reservoir if Alternative B is implemented. Also included are recreation expenditures attributable to the portion of visitors outside the Primary Study Area. This recreation expenditure information is used to assess the effects on regional economics, i.e., the impact on employment and income. Anticipated total recreation visitation to Sites Reservoir would be more than 360,000 annual visits, increasing recreation expenditures from outside of the Primary Study Area by almost $3 million.

Increased levels of recreation at the Sites Reservoir would increase recreation expenditures in the Primary Study Area. Similar to that described for Alternative A, an increase in recreation expenditures is not considered an adverse effect on the recreation economy of the Primary Study Area. Therefore, a **less-than-significant impact** on recreation economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Table 22-47
Estimated Sites Reservoir Recreation Visitation and Expenditures Associated with Implementation of Alternative B*

Activity / Spending Category	Alternative B	
	Visits (Recreation Visitor Days)	Associated Non-Local Spending
Shore fishing	31,150	$213,096
Boat fishing	16,112	$110,222
Picnicking	82,351	$686,480
Sightseeing	70,894	$600,656
Swimming / beach use	80,919	$674,542
Walking	10,383	$74,187
Bicycling	4,655	$33,256
Boating / water-skiing	55,856	$465,613
Other	2,864	$23,878
Total	**355,184**	**$2,881,930**

*Based on long-term water year average conditions.

Notes:

Costs are presented in 2010 dollars.

Attributed to reservoir-recreation only; the analysis does not account for changes in recreation spending attributed to river-based recreation.

Source: Pavich, 2012b.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Construction of Alternative B would convert land from existing agricultural uses to uses that include direct Project facility footprints, construction staging areas, temporary and permanent roads, utilities, and open space undeveloped lands.

Changes in crop acreage were used to describe the associated changes in economic values. Table 22-48 summarizes the expected changes in acreage and value of agricultural production that would result in the Primary Study Area as a result of Alternative B construction. Changes are shown relative to Existing Conditions and the No Project/ No Action Alternative by aggregate crop category (agricultural resources do not differ between Existing Conditions and the No Project/No Action Alternative).

Total value of crop production in the Primary Study Area would be expected to decline on average by $7.1 million per year during the Project construction period, and by $1.5 million per year during Project operation. Total crop acreage would decline by approximately 4,500 acres during Project construction (temporary change) and 26,100 acres during Project operation (permanent change). The majority of the decrease in crop acreage during construction would be associated with rice and almost all of the decrease in crop acreage during Project operation would be associated with rangeland.

Alternative B may also affect production costs on lands even if revenues are largely unaffected. Costs could be associated with operational constraints and longer travel times due to construction. Construction designs and costs have provided for such effects in two ways. In most cases, affected lands would be within the Project facilities footprint, and are included in the agricultural acreage and value of production described elsewhere in this chapter. For potentially affected lands not included in the facilities footprint, construction costs include temporary and permanent roads and other facilities as needed to support agricultural lands. There could be some additional travel time and other costs associated with using these facilities, but such costs are not environmental impacts requiring mitigation.

Loss of investments in production facilities would occur as a result of facilities construction. The value of structures and equipment potentially affected would vary widely across parcels. Much of the equipment is portable (e.g., machinery, tools, portable sprinkler pipe), and could be sold or used on other lands. Shop and storage buildings and permanent irrigation and drainage equipment may have little or no salvage value. The negotiated purchase of lands for the conveyance and associated facilities would compensate for salvage value accordingly. According to Cooperative Extension cost of production studies, permanent structures, irrigation systems, and drainage systems can represent a wide range in investment, from less than $100 per acre for field and vegetable crops up to over $3,000 per acre for some orchards (UCCE, 2008 and 2011). Most such facilities would not be new, so their depreciated values would be substantially lower.

Table 22-48
Change in Crop Acres and Value of Agricultural Production Associated with Implementation of Alternative B when Compared to Existing Conditions and No Project/No Action Alternative

Analysis Metric	Alternative B Baseline[b]	Change from Existing Conditions and the No Project/No Action Alternative	
		Temporary[c]	Permanent[c]
Total Crop Acreage (Thousand acres)[a]	**889.4**	**-4.5**	**-26.1**
Rice	247.2	-3.1	-0.2
Almonds	109.4	-0.1	0.0
Hay and Forage	94.3	-0.2	-0.6
Wheat	22.5	-0.3	-0.1
Tomatoes, Processing	27.9	-0.1	-0.1
Rangeland	388.1	-0.7	-25.3
Total Value of Production (Million $)[a]	**1,047.9**	**-7.1**	**-1.5**
Rice	486.2	-5.8	-0.3
Almonds	359.3	-0.5	0.0
Hay and Forage	90.9	-0.2	-0.6
Wheat	12.8	-0.2	0.0
Tomatoes, Processing	95.5	-0.4	-0.3
Rangeland	3.1	-0.1	-0.3

[a]Total crop acreage and value of production differ from the sum of individual categories due to rounding.
[b]Permanent impacts of Alternative A.
[c]Temporary impacts are a result of Project construction. Permanent impacts are a result of Project operation.

Note:
Value of production is based on prices received by farmers, in 2010 dollars.

Source: Pavich, 2012c.

Land improvements, including orchards, would also be considered during negotiations for land purchases. Typical investments required to bring permanent crops into production were described in Section 22.2. Forage crops, such as irrigated pasture and alfalfa, require an establishment cost of approximately $400 per acre. The depreciated values of the growing stock could be substantially below these establishment costs, depending on the ages of the stands that would be affected.

Construction and operation of Alternative B would reduce the total value of agricultural production in the Primary Study Area. DWR and Reclamation would provide compensation to property owners for the fair market value of any property acquired through eminent domain for the Project. Similar to that described for Alternative A, the expected decrease in the total value of agricultural production would be less than five percent of the total value of agricultural production in the Primary Study Area. Therefore, a **less-than-significant impact** is expected to the agricultural economy in the Primary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

Refer to the **Impact Socio-6** discussion for the Extended Study Area. That discussion also applies to the Primary Study Area.

22.3.8 Impacts Associated with Alternative C

22.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

Hydrologic Regions, Water Delivery Regions, and Water Delivery Service Areas

The impacts associated with Alternative C, as they relate to population and housing (**Impact Socio-2**), local government fiscal conditions (**Impact Socio-3**), and recreation economics (**Impact Socio-4**), would be the same as described for Alternative A for the Extended Study Area.

The operational differences for Alternative C within the Extended Study Area, when compared to Alternative A, for the effects on regional economics (**Impact Socio-1**), agricultural economics (**Impact Socio-5**), and M&I water use economics (**Impact Socio-6**) are discussed below.

Impact Socio-1: Substantial Adverse Effects on Regional Economics

Agricultural production in the Extended Study Area would be expected to change from operation of Alternative C and the resulting changes to SWP and CVP project deliveries, impacting employment and income. The estimated change in agricultural production is discussed in effects on agricultural economics (Impact Socio-5). The regional economic effects on employment and income from a change in agricultural production during Project construction, operation, and maintenance would not differ between Existing Conditions and the No Project/No Action Alternative Table 22-49.

The expected increased reliability associated with Alternative C water deliveries would increase agricultural production in the Extended Study Area less than one percent. This, is turn, would increase annual employment by approximately 77 individuals and annual labor income by more than $2.1 million.

Construction, operation, and maintenance activities would affect the regional economic condition of the Extended Study Area through construction and operation expenditures; Project footprint impacts, such as removal of agricultural land from production; and other Project-related impacts. However, the magnitude of the impacts is relatively minor when compared to the regional economy of the Extended Study Area. Therefore, additional regional economic effects related to Alternative C construction, operation, and maintenance are discussed for the Primary Study Area only.

Table 22-49
Change in Extended Study Area Regional Employment and Income Associated with Implementation of Alternative C when Compared to the No Project/No Action Alternative[a,b,c]

Impact	Annual Labor Income (Thousand $)		Annual Jobs	
	Direct	Total[d]	Direct	Total[d]
Agriculture	918	2,176	47.3	77.3

[a]Average annual effect based on long-term water year average conditions.
[b]Based on changes in agricultural production (irrigated acreage) and agricultural commodity prices.
[c]IMPLAN results are changes relative to Existing Condition and the No Project/No Action Alternative.
[d]Includes direct, indirect, and induced effects defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 2012a.

The expected increase in total employment and income in the Extended Study Area would result from an increase in agricultural production. Similar to that described for Alternative A, the increase in employment and income would not be considered an adverse effect on the regional economy of the Extended Study Area. Therefore, a **less-than-significant impact** on regional economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Estimated agricultural economic changes would be driven by changes in water delivery and water quality conditions. Table 22-50 summarizes the expected changes in irrigated acreage and value of agricultural production that would result in the SWP and CVP export areas as a result of operation of Alternative C. Changes are described relative to Existing Conditions and the No Project/No Action Alternative.

Expected changes in acreage and value relative to Existing Conditions would result from a combination of Alternative C and underlying changes in land use and crop mix unrelated to Alternative C. Total value of irrigated crop production in the Extended Study Area would decline on average by over $3.125 billion per year, with total irrigated crop acreage declining by approximately 18,000 acres. The increase in demand and subsequent real price of agricultural output for the No Project/No Action Alternative, when compared to Existing Conditions, is the reason for the increase in total value of production, even with the decline in irrigated acres.

Changes relative to the No Project/No Action Alternative provide an estimate of the changes solely from Alternative C. Total value of irrigated crop production in the Extended Study Area would be expected to increase on average by approximately $4.1 million per year, with total irrigated crop acreage increasing by approximately 2,000 acres. In Dry and Critical water year average conditions, the value of production would be approximately $21 million per year higher than in the No Project/No Action Alternative Dry and Critical water year average condition.

Changes in production costs and investments are a result of, and consistent with, changes in crop acreage. Expected changes compared to Existing Conditions are dominated by long-term trends in crop acreage and cropping patterns that are unrelated to Alternative C. Increases in costs and investments relative to the No Project/No Action Alternative would result from the changes in crop acreage shown in Table 22-50. Water supply and crop acreage would increase relative to the No Project/No Action Alternative, so no investments in production facilities or growing stock would be lost as a result of implementation.

Table 22-50
Change in Acres and Value of Agricultural Production Associated with Implementation of Alternative C when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Total Crop Acreage (Thousand Acres)	**7,488**	**-18**	**2**
Sacramento Valley[a]	1,909	3	1
San Joaquin[a]	5,579	-22	2
Total Value of Production (Million $)	**22,000.7**	**3,125.9**	**4.1**
Sacramento Valley	3,713.6	442.3	2.3
San Joaquin	18,287.0	2,683.6	1.8
Dry and Critical Water Year Average[b]			
Total Crop Acreage (Thousand Acres)	**7,468**	**N/A**	**15**
Sacramento Valley	1,905	N/A	5
San Joaquin	5,564	N/A	9
Total Value of Production (Million $)	**22,016.5**	**N/A**	**21.4**
Sacramento Valley	3,702.6	N/A	6.5
San Joaquin	18,313.9	N/A	14.9

[a]Water delivery region.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions.

Notes:

N/A = not applicable

Value of production is based on prices received by farmers, in 2010 dollars.

Long-term average export-weighted TDS and EC would be expected to decrease if Alternative C is implemented, when compared to No Project/No Action Alternative and Existing Conditions, resulting in improved water quality for agricultural production. The economic value of the salinity change is the avoided cost of groundwater pumping. For the Extended Study Area as a whole, the value of avoided pumping as it relates to improved water quality would be approximately $0.616 million per year, when compared to the No Project/No Action Alternative.

Table 22-51 summarizes the volume and cost of groundwater pumped in the Extended Study Area. Results are based on SWAP model analysis. Changes in volume and cost relative to Existing Conditions would result from a combination of Alternative C and underlying changes in land use and crop mix unrelated to Alternative C. Total volume pumped in the Extended Study Area would decline on average by almost 455 TAF per year, and total cost of pumping would increase by approximately $99 million per year. The decreased groundwater pumping would be a result of additional surface water available to agriculture in the No Project/No Action Alternative, when compared to Existing Conditions. The increase in pumping costs would be a result of the increase in real energy costs in the No Project/No Action Alternative, when compared to Existing Conditions.

Table 22-51
Change in Volume and Cost of Groundwater Pumping Associated with Implementation of Alternative C when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Annual Groundwater Pumped (TAF)	**6,513.5**	**-454.7**	**-43.0**
Sacramento Valley[a]	1,396.5	-131.9	-8.5
San Joaquin[a]	5,116.9	-322.8	-34.5
Annual Cost of Pumping (Million $)	**695.8**	**98.7**	**-5.8**
Sacramento Valley	116.4	12.5	-0.6
San Joaquin	579.4	86.3	-5.2
Dry and Critical Water Year Average[b]			
Annual Groundwater Pumped (TAF)	**7,155.2**	**N/A**	**-60.8**
Sacramento Valley	1,418.6	N/A	-12.4
San Joaquin	5,736.5	N/A	-48.4
Annual Cost of Pumping (Million $)	**780.1**	**N/A**	**-7.9**
Sacramento Valley	117.9	N/A	-0.8
San Joaquin	662.3	N/A	-7.0

[a]Water delivery regions.

[b]The Existing Conditions SWAP model run is based on long-term water year average conditions and does not report Dry and Critical water year average conditions.

Notes:

N/A = not applicable
TAF = thousand acre feet

Cost of pumping is based on prices received by farmers, in 2010 dollars.

Changes relative to the No Project/No Action Alternative provide an estimate of the changes solely from Alternative C. Total volume pumped in the Extended Study Area would be expected to decline on average by approximately 43 TAF per year, and total cost of pumping would decline by approximately $6 million per year. The declines in pumping and cost would be larger in the Dry and Critical water year average condition.

When comparing Alternative C to Existing Conditions, expected changes in agricultural economics impacts would result from a combination of Alterative C and underlying changes in land use, crop mix, and real energy and agricultural commodity prices unrelated to Alternative C. Similar to that described for Alternative A, the changes that would occur solely as a result of Alternative C, i.e., an increase in the value of production and a decrease in groundwater pumping cost, are not considered an adverse effect on the agricultural economy in the Extended Study Area (Tables 22-50 and 22-51). Therefore, a **less-than-significant impact** on agricultural economics is expected, when compared to Existing Conditions.

When comparing Alternative C to the No Project/No Action Alternative, the expected increase in the value of production along with the decrease in groundwater pumping cost are not considered an adverse effect on the agricultural economy in the Extended Study Area (Tables 22-50 and 22-51). Therefore, a **less-than-significant impact** on agricultural economics is expected, when compare to the No Project/No Action Alternative.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

Changes in water supply reliability and related water supply costs in the Extended Study Area attributable to Alternative C operations are described relative to Existing Conditions and No Project/No Action

Alternative. Discussion in this section focuses on the change in water supply reliability specific to urban areas in the SWP and CVP service areas, and estimates of associated changes in water supply costs.

Expected changes in water supply reliability and related water supply costs in the San Francisco Bay – South hydrologic region are shown in Table 22-52. Project deliveries would increase in Alternative C in long-term and Dry and Critical water year average conditions, when compared to Existing Conditions and the No Project/No Action Alternative. No water management options are included in Existing Conditions. Therefore, when comparing Alternative C with Existing condition, the change in management options would always be zero or positive. When comparing Alternative C with the No Project/No Action Alternative, the increase in Project deliveries would allow for increased deliveries to carryover storage and/or not reduce the use of management options (conservation, recycling, and desalination) but would decrease use of other supplies (transfers).

Table 22-52
Change in M&I Water Supply Deliveries and Costs for the San Francisco Bay-South Hydrologic Region Associated with Implementation of Alternative C when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Total Supply (TAF/Year)	**1,274**	**93**	**21**
Project Delivery	435	49	9
Management Options[a]	22	22	12
Other Supply	817	22	0
Total Costs (Million $/Year)	**206,067**	**36,113**	**-1,804**
Shortage	3,341	-7,289	-2,137
Supply[c]	202,726	43,402	333
Dry and Critical Water Year Average[b]			
Total Supply (TAF/Year)	**1,195**	**117**	**28**
Project Delivery	397	43	18
Management Options[a]	22	22	12
Other Supply	776	52	-2
Total Costs (Million $/Year)	**201,273**	**22,206**	**-5,582**
Shortage	9,282	-20,449	-6,477
Supply[c]	191,991	42,655	895

[a]Management options include conservation, recycling, and desalinization.

[b]Sacramento River 40-30-30 index.

[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives including conveyance, distribution, treatment, and transfers.

Notes:

M&I = municipal and industrial
TAF = thousand acre feet

Costs are presented in 2010 dollars.

When comparing Alternative C with Existing Conditions, supply costs would increase in the San Francisco Bay – South hydrologic region in long-term and Dry and Critical water year average conditions. The increase in supply costs would result from increases in population and real energy prices that occur in future conditions. This increase in supply cost would overwhelm any decrease in shortage costs, causing total costs to increase. When comparing Alternative C with the No Project/No Action Alternative, the additional Project deliveries, with little change in management options, would increase supply costs. However, shortage costs would decrease enough to offset the increase in supply costs, reducing total costs.

Expected changes in water supply reliability and related water supply costs in the South Coast hydrologic region are shown in Table 22-53. Project deliveries would increase in Alternative C in long-term and Dry and Critical water year average conditions, when compared to Existing Conditions and the No Project/No Action Alternative. No water management options are included in Existing Conditions. Therefore, when comparing Alternative C with Existing Conditions, the change in management options would always be zero or positive. When comparing Alternative C with the No Project/No Action Alternative, the increase in Project deliveries would reduce the use of management options (conservation, recycling, and desalination) and other supply (local surface water and groundwater, imported non-Project water, baseline recycling and desalination, and transfers).

Table 22-53
Change in M&I Water Supply Deliveries and Costs for the South Coast Hydrologic Region Associated with Implementation of Alternative C when Compared to Existing Conditions and the No Project/No Action Alternative

Analysis Metric	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average			
Total Supply (TAF/Year)	**5,043**	**464**	**23**
Project Delivery	1,440	117	68
Management Options[a]	500	500	-10
Other Supply	3,103	-153	-35
Total Costs (Million $/Year)	**1,698,063**	**362,267**	**-65,559**
Shortage	68,089	-171,177	-41,241
Supply[c]	1,629,974	533,445	-24,319
Dry and Critical Water Year Average[b]			
Total Supply (TAF/Year)	**4,775**	**331**	**56**
Project Delivery	1,199	111	146
Management Options[a]	500	500	-10
Other Supply	3,076	-280	-81
Total Costs (Million $/Year)	**1,884,947**	**378,750**	**-153,798**
Shortage	197,360	-217,620	-105,408
Supply[c]	1,687,587	596,371	-48,390

[a]Management options include conservation, recycling, and desalinization.
[b]Sacramento River 40-30-30 index.
[c]This estimate does not include all water supply-related costs. It includes annual costs that might be affected by alternatives including conveyance, distribution, treatment, and transfers.

Notes:
M&I = municipal and industrial
TAF = thousand acre feet
Costs are presented in 2010 dollars.

When comparing Alternative C with Existing Conditions, supply costs would be expected to increase in the South Coast hydrologic region in long-term and Dry and Critical water year average conditions. The increase in supply costs would result from population and real energy price increases that occur in future conditions. This increase in supply cost would overwhelm any decrease in shortage costs, causing total costs to increase. When comparing Alternative C with the No Project/No Action Alternative, the additional Project deliveries would reduce the use of management options and other supply, reducing supply costs. The accompanying reduction in shortage costs would decrease total costs.

When comparing Alternative C and Existing Conditions in the Extended Service Area outside of the San Francisco Bay – South and South Coast hydrologic regions, Project water deliveries would be expected to increase in long-term and Dry and Critical water year average conditions, excluding the Delta. When comparing Alternative C to the No Project/No Action Alternative, Project deliveries would increase in long-term and Dry and Critical water year average conditions (Table 22-54).

Table 22-54
Change in M&I Water Supply Deliveries and Costs Modeled in OMWEM Associated with Implementation of Alternative C when Compared to Existing Conditions and the No Project/No Action Alternative

Water Delivery Region	Analysis Metric					
	Average Annual Project Water Delivery (TAF)			Average Annual Shortage and Supply Cost[c] (Thousand $)		
	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average						
Delta	56	3	2	9,222	3,571	-519
Bay Area[a]	54	7	2	5,671	5,642	-189

Dry and Critical Water Year Average[d]						
Delta	45	0	4	18,170	8,154	-1,252
Bay Area[a]	39	3	3	11,263	11,183	-476
Central Coast	28	1	4	3,758	3,604	-3,691
Sacramento Valley	21	0	0	10,761	7,829	-356
San Joaquin	83	7	10	2,796	1,154	-125
Southern California[b]	218	10	32	23,930	2,491	-23,858

[a]The results shown here are for San Benito County only.

[b]The results shown here exclude South Coast Hydrologic Area, which is shown separately.

[c]This estimate does not include all water supply-related costs. It includes annual shortage costs and supply costs that might be affected by alternatives, including transfers, groundwater pumping, or other water management options.

[d]Sacramento River 40-30-30 index.

Notes:

M&I = municipal and industrial
OMWEM = Other Municipal Water Economics Model
TAF = thousand acre feet

Costs are presented in 2010 dollars.

When comparing Alternative C and Existing Conditions, shortage and water supply costs would be expected to increase in both long-term and Dry and Critical water year average conditions. The increase in supply costs would result from population and real energy price increases that occur in future conditions. When comparing Alternative C to the No Project/No Action Alternative, shortage and water supply costs would decrease (Table 22-54). The increase in Project deliveries would reduce shortage and water supply costs.

The expected change in salinity-related costs in the Extended Study Area attributable to Alternative C operations relative to Existing Conditions and the No Project/No Action Alternative is shown in Table 22-55. Discussion in this section focuses on the change in salinity costs specific to regions with modeled salinity costs.

Table 22-55
Change in Water Supply Salinity Costs Associated with Implementation of Alternative C when Compared to Existing Conditions and the No Project/No Action Alternative[a]

Water Delivery Service Area	Analysis Metric	Alternative C	Change from Existing Conditions	Change from the No Project/No Action Alternative
Long-Term Water Year Average				
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	232.0	-15.2	-7.8
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	58.6	-12.4	-2.0
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	251.6	-16.8	-2.3
Metropolitan Water District of Southern California	Average Annual Cost (Million $)	N/A	$534.2	-$12.9
Contra Costa and Santa Clara Water Districts		N/A	$112.4	-$1.5
Dry and Critical Water Year Average[b]				
Metropolitan Water District of Southern California	Long-Term Average Export-Weighted Annual TDS (mg/L)	295.1	-26.8	-17.9
Contra Costa and Santa Clara Water Districts	Average Annual Chloride (mg/L)	80.4	-23.6	-3.5
Contra Costa and Santa Clara Water Districts	Long-Term Average Export-Weighted Annual TDS (mg/L)	272.7	-26.6	-2.7
Metropolitan Water District of Southern California	Average Annual Cost (Million $)	N/A	$539.6	-$23.5
Contra Costa and Santa Clara Water Districts		N/A	$109.8	-$1.9

[a]Results include some damages related to agricultural production in Metropolitan Water District of Southern California's Service Area.

[b]Sacramento River 40-30-30 index.

Notes:

mg/L = milligrams per liter
N/A = not applicable
TDS= total dissolved solids

Costs are presented in 2010 dollars. The Lower Colorado River Basin Water Quality Model was used for the Metropolitan Water District of Southern California service area and the South Bay Water Quality model was used for the Contra Costa and Santa Clara Water District service areas.

When comparing Alternative C with Existing Conditions, long-term average export-weighted annual TDS and chloride would be expected to decrease in long-term and Dry and Critical water year average conditions across service areas. However, average annual costs would increase. This increase is expected due to population increases that occur in future conditions. When comparing Alternative C with the No Project/No Action Alternative, long-term average export-weighted annual TDS and chloride would decrease in long-term and Dry and Critical water year average conditions in the Metropolitan Water District of Southern California and Contra Costa and Santa Clara Water District service areas. The improvement in water quality would reduce damages in long-term and Dry and Critical water year average conditions.

When comparing Alternative C to Existing Conditions, expected changes in M&I water use economics impacts would result from a combination of Alterative C and underlying changes in population and the real cost of energy, impacting water system operation costs. Similar to that described for Alternative A, the change that would occur solely as a result of Alternative C, i.e., decreases in total costs, is not considered an adverse effect on M&I water use economics in the Extended Study Area. Therefore, a **less-than-significant impact** on M&I water use economics is expected, when compared to Existing Conditions.

When comparing Alternative C to the No Project/No Action Alternative, the expected increase in water supply and quality would decrease total costs, which is not considered an adverse effect on the M&I water use economics in the Extended Study Area. Therefore, a **less-than-significant impact** on water use economics is expected, when compared to the No Project/No Action Alternative.

22.3.8.2 Secondary Study Area – Alternative C

The operational effects within the Secondary Study Area are included in the analysis of the Extended Study Area and/or Primary Study Area, similar to that described for Alternative A.

22.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Socio-1: Substantial Adverse Effects on Regional Economics

The regional economic effects on employment and income in the Primary Study Area were evaluated during Project construction, operation, and maintenance. Changes are shown relative to Existing Conditions and the No Project/No Action Alternative. There is no difference between Existing Conditions and the No Project/No Action Alternative model used in the analysis. The expected effects of construction, operation, and maintenance expenditures to employment and income are shown in Table 22-56.

The Project footprint and related facilities, such as roads and utilities, would remove some existing agricultural land from production, so the effects on employment and income would be negative. Some agricultural land removed from production would only be temporary, and restored to its original use following the construction period.

Table 22-56
Temporary Change in Regional Employment and Income Associated with Implementation of Alternative C when Compared to the No Project/No Action Alternative[a,b]

Impact	Labor Income (Thousand $)		Annual Jobs	
	Direct	Total[c]	Direct	Total[c]
Agriculture	-636	-1,242	-44.0	-62.2
Land Acquisition	625	717	14.7	17.5
Construction	22,219	49,441	106.9	693.3
Total	**22,208**	**48,916**	**77.6**	**648.6**

[a]Average annual effect based on entire period of construction. The duration of each impact will vary.
[b]IMPLAN results are changes relative to Existing Conditions and the No Project/No Action Alternative.
[c]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 2012a.

Alternative C would increase economic activity related to land acquisition in the Primary Study Area. This regional economic impact would be temporary, occurring 12 to 18 months prior to construction. The regional economic effects to employment and income in the Primary Study Area from land acquisition are reported in Table 22-56.

The expected permanent effects to employment and income from operation and maintenance are shown in Table 22-57. Alternative C would also increase recreational opportunities in the Primary Study Area. The increased recreational expenditures would affect employment and income. The regional economic effects to employment and income in the Primary Study Area from the increase in recreational expenditures are reported in Table 22-57.

Table 22-57
Permanent Change in Regional Employment and Income Associated with Implementation of Alternative C when Compared to the No Project/No Action Alternative[a,b]

Impact	Labor Income (Thousand $)		Annual Jobs	
	Direct	Total[c]	Direct	Total[c]
Recreation	504	608	20.8	23.7
Agriculture - Permanent	-204	-381	-4.7	-9.9
Operation	1,750	2,120	35.0	45.7
Total	**2,050**	**2,347**	**51.1**	**59.5**

[a]Average annual effect based over life of Alternative C.
[b]IMPLAN results are changes relative to Existing Condition and the No Project/No Action Alternative.
[c]Includes direct, indirect, and induced effects (defined in Appendix 22C).

Note:
Income is reported 2010 dollars.

Source: Pavich, 20112a.

Total employment and income in the Primary Study Area would increase as a result of construction, operation, land acquisition, and a change in agricultural production and recreational opportunities. The increase in employment and income would not be considered an adverse effect on the regional economy of the Primary Study Area. Therefore, a **less-than-significant impact** on regional economics is expected, similar to that described for Alternative A.

Impact Socio-2: Substantial Adverse Effects on Population and Housing

Population

Construction and operation of Alternative C would require an estimated annual average of 107 and 35 workers, respectively, with a maximum of 60 daily workers for operation. It is anticipated that approximately 50 percent of the construction jobs would be filled from within the existing two-county labor force. However, construction may require specialized worker skills not readily available in the local labor pool. As a result, it is anticipated that some of the non-local workers would be imported from outside the two-county region.

Considering the multi-year duration of construction, it is anticipated that 20 percent of the imported workers would relocate to the two-county region, adding to the local population. It is anticipated that all of the workers required for operation would relocate to the two-county region. Similar to that described for Alternative A, this additional population from construction and operation would constitute a minor increase in the total 2020 projected regional population of 64,605, and would not pose a burden on local public services, utilities, or infrastructure. Therefore, impacts are considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Housing

Alternative C construction, operation, and maintenance impacts to housing conditions within the Primary Study Area would be the same as described for Alternative A.

Impact Socio-3: Substantial Adverse Effects on Local Government Fiscal Conditions

Alternative C construction, operation, and maintenance impacts to local government fiscal conditions within the Primary Study Area would be the same as described for Alternative A.

Impact Socio-4: Substantial Adverse Effects on Recreation Economics

Alternative C would provide recreational opportunities within the Primary Study Area. Table 22-58 shows the estimated number of visitors to Sites Reservoir if Alternative C is implemented. Also included are recreation expenditures attributable to the portion of visitors outside the Primary Study Area. This recreation expenditure information is used to assess the effects on regional economics, i.e., the impact on employment and income. Anticipated total recreation visitation would be more than 370,000 annual visits, increasing recreation expenditures from outside the Primary Study Area by more than $3 million.

Increased levels of recreation at the Sites Reservoir would increase recreation expenditures in the Primary Study Area. An increase in recreation expenditures is not considered an adverse effect on the recreation economy of the Primary Study Area. Therefore, a **less-than-significant impact** on recreation economics is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Table 22-58
Estimated Sites Reservoir Recreation Visitation and Expenditures Associated with Implementation of Alternative C*

Activity / Spending Category	Alternative C	
	Visits (Recreation Visitor Days)	**Associated Non-Local Spending**
Shore fishing	32,508	$222,386
Boat fishing	16,815	$115,027
Picnicking	85,941	$716,409
Sightseeing	73,984	$626,843
Swimming / beach use	84,447	$703,949
Walking	10,836	$77,422
Bicycling	4,858	$34,706
Boating / water-skiing	58,291	$485,912
Other	2,989	$24,919
Total	**370,669**	**$3,007,573**

*Based on long-term water year conditions.

Note:

Costs are presented in 2010 dollars. Spending attributed to reservoir-recreation only; the analysis does not account for changes in recreation spending attributed to river-based recreation.

Source: Pavich, 2012b.

Impact Socio-5: Substantial Adverse Effects on Agricultural Economics

Construction of Alternative C would convert land from existing agricultural uses to uses that include Project facility footprints, construction staging areas, temporary and permanent roads, utilities, and open space undeveloped lands.

Changes in crop acreage were used to describe the associated changes in economic values. Table 22-59 summarizes the expected changes in acreage and value of agricultural production that would result in the Primary Study Area as a result of Alternative C construction. Changes are shown relative to Existing Conditions and the No Project/ No Action Alternative; by aggregate crop category (agricultural resources do not differ between Existing Conditions and the No Project/No Action Alternative).

Total value of crop production in the Primary Study Area would be expected to decline on average by $7.1 million per year during the Project construction period, and by $1.5 million per year during Project operation. Total crop acreage would decline by approximately 4,500 acres during Project construction (temporary change) and 26,200 acres during Project operation (permanent change). The majority of the decrease in crop acreage during construction would be associated with rice and almost all of the decrease in crop acreage during Project operation would be associated with rangeland.

Alternative C may also affect production costs on lands even if revenues are largely unaffected. Costs could be associated with operational constraints and longer travel times due to Project construction. Construction designs and costs have provided for such effects in two ways. In most cases, affected lands fall within the Project facilities footprint, and are included in the agricultural acreage and value of production described elsewhere in this chapter. For potentially affected lands not included in the facilities footprint, construction costs include temporary and permanent roads and other facilities as needed to support agricultural production. There could be some additional travel time and other costs associated with using these facilities, but such costs are not environmental impacts requiring mitigation.

Table 22-59
Change in Crop Acres and Value of Agricultural Production Associated with Implementation of Alternative C when Compared to Existing Conditions and No Project/No Action Alternative

Analysis Metric	Alternative C Baseline[b]	Change from Existing Conditions and No Action Alternative	
		Temporary[c]	Permanent[c]
Total Crop Acreage (Thousand acres)[a]	**889.3**	**-4.5**	**-26.2**
Rice	247.2	-3.1	-0.2
Almonds	109.4	-0.1	0.0
Hay and Forage	94.3	-0.2	-0.6
Wheat	22.5	-0.3	-0.1
Tomatoes, Processing	27.9	-0.1	-0.1
Rangeland	388.1	-0.7	-25.3
Total Value of Production (Million $)[a]	**1,047.9**	**-7.1**	**-1.5**
Rice	486.2	-5.8	-0.3
Almonds	359.3	-0.5	-0.1
Hay and Forage	90.9	-0.2	-0.6
Wheat	12.8	-0.2	0.0
Tomatoes, Processing	95.5	-0.4	-0.3
Rangeland	3.1	-0.1	-0.3

[a]Total crop acreage and value of production differ from the sum of individual categories due to rounding.
[b]Permanent impacts of Alternative A.
[c]Temporary impacts are a result of Project construction. Permanent impacts are a result of Project operation.

Note:
Value of production is based on prices received by farmers, in 2010 dollars.

Source: Pavich, 2012c.

Loss of investments in production facilities would occur as a result of facilities construction. The value of structures and equipment potentially affected would vary widely across parcels. Much of the equipment is portable (e.g., machinery, tools, portable sprinkler pipe), and could be sold or used on other lands. Shop and storage buildings and permanent irrigation and drainage equipment may have little or no salvage value. The negotiated purchase of lands for the conveyance and associated facilities would compensate for salvage value accordingly. According to Cooperative Extension cost of production studies, permanent structures, irrigation systems, and drainage systems can represent a wide range in investment, from less than $100 per acre for field and vegetable crops up to more than $3,000 per acre for some orchards (UCCE, 2008 and 2011)). Most of these facilities would not be new, so their depreciated values would be substantially lower.

Land improvements, including orchards, would also be considered during negotiations for land purchases. Typical investments required to bring permanent crops into production were described in Section 22.2. Forage crops, such as irrigated pasture and alfalfa, would require an establishment cost of approximately $400 per acre. The depreciated values of the growing stock could be substantially below these establishment costs, depending on the ages of the stands that would be affected.

Construction and operation of Alternative C would reduce the total value of agricultural production in the Primary Study Area. DWR and Reclamation would provide compensation to property owners for the fair market value of any property acquired through eminent domain for the Project. Similar to that described for Alternative A, the expected decrease in the total value of agricultural production would be less than five percent of the total value of agricultural production in the Primary Study Area. Therefore, a **less-than-significant impact** is expected to the agricultural economy in the Primary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Socio-6: Substantial Adverse Effects on M&I Water Use Economics

Refer to the **Impact Socio-6** discussion for the Extended Study Area. That discussion also applies to the Primary Study Area.

22.4 Mitigation Measures

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

23. Environmental Justice

23.1 Introduction

This chapter describes the ethnic and income characteristics of the populations within the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Environmental Justice is the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies (USEPA, 2013).

The regulatory setting for environmental justice is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Specifically, the chapter discusses whether the alternatives would have disproportionately high and adverse human health or environmental effects on minority and/or low-income populations, as defined by State and federal regulations that address environmental justice. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate. Because none were identified for this resource, no mitigation is included in this chapter.

23.2 Environmental Setting/Affected Environment

23.2.1 Introduction

Executive Order (EO) 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations* (59 Federal Register No. 32), was signed on February 11, 1994, by President Clinton. EO 12898 requires that each federal agency make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations (Federal Register, 1994).

The intent of EO 12898 is to assess potential impacts from the implementation of development projects, subject to federal permitting requirements, to confirm that no person in the United States shall, on the basis of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving federal financial assistance. Where possible, measures should be taken to avoid negative impacts to these communities or mitigate the adverse effects.

The U. S. Census Bureau provides a definition of minority and low-income populations. The term "minority population" includes persons who identify themselves as African American, Asian or Pacific Islander, American Indian or Alaskan Native, or Hispanic (U.S. Census Bureau, 2009a). Race refers to census respondents' self-identification of racial background. Hispanic origin refers to ethnicity and language, not race, and may include persons whose heritage is Puerto Rican, Cuban, Mexican, or Central or South American, and other Spanish cultures (Office of Management and Budget, 1997).

According to the Council on Environmental Quality (CEQ), to be considered a minority population, the population of the affected area must either exceed 50 percent minority, or the minority population percentage of the affected area must be meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. To be considered a low-income population, the low-income populations in an affected area should be identified using the annual statistical poverty thresholds from the U.S. Census Bureau. A minority population also exists if there is more than one minority group present and the minority percentage, as calculated by aggregating all minority persons, meets one of the above-stated thresholds (CEQ, 1997). In addition, according to USEPA guidelines, similar to the CEQ, a minority population refers to a minority group that has a population of greater than 50 percent of the affected area's general population; or the minority population percentage of the affected area must be meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis (USEPA, 1998).

The U. S. Census Bureau does not provide a specific definition for "low-income." Rather, the term "poverty" is used, and poverty thresholds are established each year for statistical purposes (U.S. Census Bureau, 2009b). The U.S. Department of Health and Human Services issues poverty guidelines each year that are a simplification of the U.S. Census Bureau's poverty thresholds. The guidelines are another version of the federal poverty measure; they are used for administrative purposes (for example, such as determining financial eligibility for certain federal programs) (IRP, 2008).

23.2.2 Extended Study Area

23.2.2.1 Methodology

To characterize the population, race, and ethnicity of the Extended Study Area, data from the U.S. Census Bureau were obtained for each of the 39 counties that are located within that study area. Table 23-1 presents the total population and population breakdown by race and ethnicity for the counties that are located within the Extended Study Area, as well as for the State of California, based on the 2005 to 2009 Census Bureau American Community Survey (U.S. Census Bureau, 2009c).

23.2.3 Secondary Study Area

23.2.3.1 Methodology

To characterize the population, race, and ethnicity of the Secondary Study Area, data from the U.S. Census Bureau were obtained for each of the 22 counties that are located within that study area. Table 23-2 lists the total population and population breakdown by race and ethnicity, based on the 2005 to 2009 Census Bureau American Community Survey (U.S. Census Bureau, 2009c). Fourteen of the 22 counties in the Secondary Study area are also located in the Extended Study Area (Table 23-1), and are not repeated in Table 23-2.

23.2.4 Primary Study Area

23.2.4.1 Methodology

To characterize the population, race, ethnicity, income, poverty, unemployment, and housing characteristics of the Primary Study Area, data from the U.S. Census Bureau were obtained for the two counties that are located within that study area.

23.2.4.2 Race and Ethnic Character

Table 23-3 lists the population and percent minority population for Glenn and Colusa counties, as well as for the State of California. It also provides the race breakdown and Hispanic or Latino ethnicity percentages (U.S. Census Bureau, 2009c).

Table 23-3
Race and Ethnicity 2005-2009 Five-Year Estimate - Glenn and Colusa Counties and the State of California

Parameter	Glenn County	Colusa County	California
Total Population	27,891	21,001	36,308,527
Percent Minority[a]	27.9	33.4	38.7
White			
Number	20,120	13,982	22,258,042
Percent	72.0	66.6	61.3
Black or African American			
Number	193	241	2,249,404
Percent	0.69	1.1	6.2
American Indian and Alaska Native[b]			
Number	613	185	283,031
Percent	2.2	1.7	0.78
Asian			
Number	863	185	4,473,292
Percent	3.1	0.88	12.3
Native Hawaiian and Other Pacific Islander			
Number	10	62	132,535
Percent	0.04	0.3	0.37
Some Other Race			
Number	5,025	5,311	5,639,234
Percent	18.0	22.1	15.5
Two or More Races			
Number	1,067	855	1,272,989
Percent	3.8	4.0	3.5
Hispanic or Latino (any race)			
Number	9,648	10,663	13,102,161
Percent	34.6	50.17	36.1

[a]Minority population was calculated by subtracting the white population parameter from the total county or state population numbers to conservatively estimate minority population and avoid double-counting mixed-race individuals.

[b]The tribes known to be present in the Primary Study Area include the Hill and River Patwin and, to a lesser extent, in areas belonging to the Nomlaki and the Konkow Maidu.

Source: U.S. Census Bureau, 2009c.

As shown in Table 23-3, the Hispanic population in Colusa County is just over the 50 percent threshold (50.1 percent) indicating that a majority of the County population identifies itself as a minority population. For Glenn County and the State of California, none of the minority population parameters approach the 50 percent threshold. A review of the U.S. Census blocks in the vicinity of all proposed Project facilities within the Primary Study Area was conducted. This review confirmed that the Primary Study Area is sparsely populated. It further confirmed that all Project facilities would be located in primarily areas that are unpopulated or have less than a 25 percent minority population. The exception to this is the easternmost three miles of the proposed Delevan Transmission Line and Delevan Pipeline alignments, in which 75.1 to 100 percent of the population is identified as being minority. In addition, all Project facilities would be located in areas where 25 percent or less of the population is identified as low income.

23.2.4.3 Income, Poverty, Unemployment, and Housing Characteristics

Table 23-4 provides income, poverty, unemployment, and housing data for Glenn and Colusa counties, as well as for the State of California.

Table 23-4
Income, Poverty, Unemployment, and Housing 2005-2009 Five-Year Estimate - Glenn and Colusa Counties and the State of California

Parameter	Glenn County	Colusa County	California
Median Family Income	$47,618	$51,637	$53,760
Per Capita Income	$19,257	$20,381	$22,973
Families Below Poverty Level (#/%)	566/2%	2,520 /12.2%	110,663/7.3%
Individuals Below Poverty Level (#/%)	390/14.2%	9,280/15.7%	612,370/10.6%
Percent Unemployed	4.2	8.2	6.2
Housing: 1.01 or More Occupants per Room* (%)	3.6	3.7	5.1
Housing: Lacking Complete Plumbing Facilities (%)	0.9	0.4	0.5

*This parameter is an indicator of how crowded the living facilities are.

Note:

It is noted that the 2012-2013 Community Action Plan for the Community Services Block Grant for Colusa, Glenn, and Trinity counties reports these poverty and unemployment rates: 2010 poverty rate in Colusa County of 15.7 percent and Glenn County of 17.8 percent; and April 2011 unemployment rate in Colusa County of 21 percent and in Glenn County of 16.5 percent (Community Action Partnership, 2011).

Source: U.S. Census Bureau, 2009c.

As shown in Table 23-4[1], both counties have lower median family and per capita incomes than the State of California. The percentages of individuals living below the poverty level are higher in both counties when compared to the State; however, the percentage of families living below the poverty level in Glenn County is lower than Colusa County and the State. The unemployment rate in Colusa County is higher than the State, and Glenn County's unemployment rate is lower than the State. In addition, the percentage of people who are living together in individual rooms is lower in both counties than the State. The percentage of homes that lack plumbing facilities in Glenn County is greater than the State, and the percentage in Colusa County is less than the State.

[1] It is acknowledged that there are likely undocumented workers within Glenn and Colusa counties that are not included in U.S. Census Bureau data.

23.3 Environmental Impacts/Environmental Consequences

23.3.1 Regulatory Setting

Environmental justice is regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

23.3.1.1 Federal Plans, Policies, and Regulations

- Executive Order 12898 (EO 12898) regarding "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations" (1994)
- Council on Environmental Quality Guidance (1997)
- U.S. Department of the Interior Environmental Compliance Memorandum No. ECM 95-3 (National Environmental Policy Act [NEPA] Responsibilities Under the Environmental Justice Policy, 1995)
- U.S. Department of the Interior Environmental Justice Strategic Plan (1995)
- U.S. Environmental Protection Agency Office of Environmental Justice's Environmental Justice Implementation Plan (1997)
- Title VI of the Civil Rights Act of 1964
- U.S. Environmental Protection Agency Final Guidance for Incorporating Environmental Justice Concerns in EPA's NEPA Compliance Analyses (1998)

23.3.1.2 State Plans, Policies, and Regulations

- Delta Vision Strategic Plan (October 2008)
- Senate Bill 115 (Solis) (1999)
- California Government Code Section 65040.12
- California State Lands Commission Environmental Justice Policy (October 1, 2002)
- California Public Resources Code Sections 71110 to 71116
- CALFED Environmental Justice Statement (as declared in August 2000, Record of Decision [ROD] CALFED Bay Delta Program Programmatic EIS/EIR)

23.3.1.3 Regional and Local Plans, Policies, and Regulations

- Tehama County General Plan
- Glenn County General Plan
- Colusa County General Plan

23.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* does not address environmental justice or minority and low-income populations specifically. Its Mandatory Findings of Significance Question (c) is relevant to the general population, as follows:

- Does the Project have environmental effects which will cause substantial adverse effects on human beings, either directly or indirectly?

EO 12898 specifies that, “each federal agency shall analyze the environmental effects, including human health, economic, and social effects, of federal actions, including effects on minority communities and low-income communities, when such analysis is required by NEPA.” For the purposes of this analysis, an alternative would result in a significant environmental justice impact if it would result in the following:

- A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures.

Potential adverse environmental impacts associated with this type of major infrastructure project include construction-, operation-, or maintenance-related nuisance effects (e.g., traffic, noise, dust, and/or hazards); and construction, operation, or maintenance effects on local employment opportunities.

23.3.3 Impact Assessment Assumptions and Methodology

23.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to minority and low-income populations:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.

23.3.3.2 Methodology

The analysis characterizes the distributional patterns of minority and low-income populations in the Primary Study Area and describes whether Project impacts to minority and/or low-income populations would be disproportionately high and adverse.

In accordance with CEQ and USEPA guidelines established to assist federal and State agencies, the first step undertaken in this environmental justice analysis was to define minority and low-income populations. For this analysis, a minority population was defined to be present in the Primary Study Area if: (1) the minority population of the affected area exceeds 50 percent, or (2) the minority population percentage of the affected area is at least 10 percentage points greater than that of the general population in the State. By the same rule, a low-income population exists in the Primary Study Area if it consists of 50 percent or more people living below the poverty threshold, as defined by the U.S. Census Bureau, or is significantly greater than the poverty percentage of the general population or other appropriate unit of geographic analysis.

The second step undertaken in this environmental justice analysis was to determine if a “high and adverse” impact would occur. The CEQ guidance indicates that, when determining whether the effects are high and adverse, agencies are to consider whether the risks or rates of impact “are significant or above generally accepted norms.”

The final step undertaken in this analysis was to determine if the impact on the minority or low-income population would be disproportionately high and adverse. The CEQ includes a non-quantitative definition stating that an effect is disproportionate if it appreciably exceeds the risk or rate to the general population.

23.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

23.3.5 Impacts Associated with the No Project/No Action Alternative

23.3.5.1 Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Env Jus-1: A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures Impacts

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, when evaluated pursuant to NEPA, and their potential for environmental justice impacts has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on a minority and/or low-income population, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to result in more minority and/or low-income people living throughout the three study areas. The projects that are included in the No Project/No Action Alternative would already have been in place for most of the Project analysis period; therefore, the future population (including its minorities and low-income population) that chooses to relocate near the projects included in the No Project/No Action Alternative would not experience new impacts and **there would not be a substantial adverse effect**, when compared to Existing Conditions.

In addition, projects considered within the No Project/No Action Alternative are not located within the Primary Study Area, and therefore, **there would not be a substantial adverse effect** on a minority and/or low-income population within that study area, when compared to Existing Conditions.

23.3.6 Impacts Associated with Alternative A

23.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Env Jus-1: A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures Impacts

There would be no direct Project-related construction or maintenance occurring within the CVP and SWP service areas of the Extended Study Area. As a result, there would be no traffic, noise, dust, hazards, and/or socioeconomic effects in the Extended Study Area that would affect a minority and/or low-income population. Therefore, there would be **no impact** on a minority and/or low-income population, when compared to Existing Conditions and the No Project/No Action Alternative.

Improvement in surface water supply reliability for agricultural, municipal, and industrial users, and the provision of an alternate Level 4 water supply source for wildlife refuge users resulting from Project operation would reduce the need for extracting groundwater and/or provide some additional applied water for deep percolation recharge of the aquifer system. Operation at San Luis Reservoir would be altered to accommodate Project operation, which would result in more frequent and larger surface water elevation fluctuations at the reservoir than currently occurs there. These operational changes would not have a disproportionately high or adverse impact on a minority or low-income population, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

23.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Env Jus-1: A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures Impacts

There would be no direct Project-related construction or maintenance occurring at any of the above-listed facilities or areas within the Secondary Study Area. Therefore, **no impact** on a minority and/or low-income population would occur, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operational activities would result in improved surface water storage in reservoir facilities within the Secondary Study Area, and also changes to the flow regime of the rivers, creeks, and bypasses within that area. These changes are not expected to result in substantial increases in the amount of water (surface or groundwater) that would be available to people (including minority and/or low-income populations) residing within the Secondary Study Area. Additionally, changes in flow regime or surface water elevations would not result in traffic, noise, air quality, hazards, and/or socioeconomic impacts to people (including minority and/or low-income populations). Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Pump Installation at the Red Bluff Pumping Plant

Impact Env Jus-1: A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures Impacts

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing pump bay at the Red Bluff Pumping Plant. The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the removal of sediment from the existing GCID Canal and Red Bluff Pumping Plant intakes. Neither of these activities would result in traffic, noise, air quality, hazards, and/or socioeconomic impacts to people (including minority and/or low-income populations) due to the facilities' locations away from residences and businesses (e.g., they are separated from the Red Bluff Pumping Plant construction site by streets and an elevated railroad track). There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

23.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Env Jus-1: A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures Impacts

Minority Population

Project construction impacts would occur during the defined construction period at each Project facility. The distribution and location of minority population relative to all Project facility locations is shown on the figures included in Appendix 23A. Construction of the proposed Sites Reservoir would require the demolition of all existing structures within the reservoir inundation area and the surrounding Project Buffer, and the relocation of all residents within those boundaries. Sites Reservoir would be located in an area that has a very low population; many areas of the reservoir footprint are unpopulated. A total of 26 residences and two mobile homes would be displaced by Sites Reservoir.

In the areas that are populated, most of the reservoir site has 10 percent or less minority population, with a few areas having 10.1 to 25 percent minority population, and a very small area having 25.1 to 50 percent minority population.

All other Project facilities would be located in areas classified as being unpopulated, or having 25 percent or less minority in areas that have population, except for the easternmost three miles of the proposed Delevan Transmission Line and Delevan Pipeline, in which the area is classified as being 75.1 to 100 percent minority (U.S. Census Bureau, 2000). The easternmost three miles of proposed Delevan Transmission Line/Pipeline alignment has one residence in the vicinity. Siting of transmission line towers and pipeline installation would not affect that residence, resulting in **no impact** to residents, and particularly **no disproportionate impact** to a minority population, when compared to Existing Conditions and the No Project/No Action Alternative.

Low-Income Population

The distribution and location of low-income population relative to all Project facility locations is shown on the figures included in Appendix 23B. Sites Reservoir would be located in an area that is classified as primarily 10.1 to 25 percent low income, with a small area that is 0 to 10 percent low income (U.S. Census Bureau, 2000). All Project facilities, other than Sites Reservoir, would be located in areas classified as being 10.1 to 25 percent low income (U.S. Census Bureau, 2000). The areas where Project facilities would be constructed do not have high percentages of the two counties' populations or of low-income populations. Therefore, there would be **no impact** to residents, and particularly **no disproportionate impact** to a low-income population, from construction, operation, or maintenance in the Primary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Hispanic Population

Although the Hispanic population in Colusa County is greater than 50 percent of the County's population, as shown in Table 23-3, the County's population is low and widely distributed. As discussed above, the areas where Project facilities would be constructed do not have high percentages of the two counties' populations, or of minorities or low-income populations. Along the portion of the Delevan Transmission Line/Pipeline alignment, which is classified as being high minority percentage by the U.S. Census Bureau, there is one residence, which would not be affected during Project construction, operation, or maintenance. Therefore, there would be **no impact** to residents at this location within the Primary Study Area, and particularly **no disproportionate impact** to a minority or low-income population, from construction, operation, or maintenance in the Primary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Job and Recreational Opportunities

In addition, this alternative has the potential to create jobs for minorities who have the appropriate construction, operation, or maintenance skillset for the Project. Further, this alternative would increase recreational opportunities in Glenn and Colusa counties for all recreationists, including minority and low-income populations, resulting in a **potentially beneficial effect**, when compared to Existing Conditions and the No Project/No Action Alternative.

23.3.7 Impacts Associated with Alternative B

23.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to disproportionate adverse impacts on a minority or low-income population (**Impact Env Jus-1**), would be the same as described for Alternative A for the Extended and Secondary study areas.

23.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to a minority or low-income population:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road

- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprint or construction disturbance area of Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge; the Road Relocations and TRR Pipeline Road; the Delevan Transmission Line; and the Electrical Distribution Lines would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility. However, these differences in the size of the footprint or alignment of the construction disturbance area would require the same type of construction, operation, and activities as was described for Alternative A. They would, therefore, have the same impact on a minority and/or low-income population (**Impact Env Jus-1**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities, and associated impacts on a minority and/or low-income population (**Impact Env Jus-1**) as described for Alternative A.

23.3.8 Impacts Associated with Alternative C

23.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to disproportionate adverse impacts on a minority or low-income population (**Impact Env Jus-1**), would be the same as described for Alternative A for the Extended and Secondary study areas.

23.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to a minority or low-income population:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant

- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to a minority or low-income population (**Impact Env Jus-1**) as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area, Sites Reservoir Dams, and South Bridge; Road Relocations and TRR Pipeline Road; and the Electrical Distribution Lines is the same as described for Alternative B. These facilities would require the same construction, operation, and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to a minority or low-income population (**Impact Env Jus-1**) as described for Alternative B.

The boundary of the Project Buffer would be the same for all alternatives, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on a minority or low-income population (**Impact Env Jus-1**) as described for Alternative A.

23.4 Mitigation Measures

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

24. Air Quality

24.1 Introduction

This chapter describes the air quality setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas[1] are provided in Chapter 1 Introduction.

The regulatory setting for air quality is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the counties in the Primary Study Area, with greatest emphasis on the existing air quality conditions and potential Project-related emissions and impacts in Glenn and Colusa counties. Air quality conditions and potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

24.2 Environmental Setting/Affected Environment

24.2.1 Extended Study Area

The California Air Resources Board (ARB) and the U.S. Environmental Protection Agency (USEPA) use ambient air quality monitoring data to determine whether geographic areas throughout the State achieve the standards that regulators have established for criteria pollutants[2]. Areas that achieve standards are designated as attainment areas[3], and areas that do not achieve standards are nonattainment areas[4], in accordance with the National Ambient Air Quality Standards (NAAQS)[5] and California Ambient Air Quality Standards (CAAQS)[6]. Table 24-1 lists the NAAQS and CAAQS.

---

[1] For this resource, the Extended Study Area consists of 39 counties that are located in the following air basins: San Francisco Bay Area, Sacramento Valley, Mountain Counties, San Joaquin Valley, Salton Sea, Mojave Desert, South Coast, North Central Coast, San Diego County, Lake Tahoe, and South Central Coast. The Secondary Study Area consists of 22 counties that are located in the Sacramento Valley Air Basin, San Francisco Bay Area Air Basin, Mountain Counties Air Basin, and North Coast Air Basin. The Primary Study Area consists of portions of the Sacramento Valley Air Basin (SVAB), in Glenn and Colusa counties only.

[2] Criteria Pollutant: An air pollutant for which acceptable levels of exposure can be determined and for which an ambient air quality standard has been set (ARB, 2010). The criteria pollutants are ozone (O_3), carbon monoxide (CO), nitrogen oxides (NOx), sulfur dioxide (SO_2), particulate matter less than 10 microns in aerodynamic diameter (PM_{10}), particulate matter less than 2.5 microns in aerodynamic diameter ($PM_{2.5}$), and lead.

[3] Attainment Area: A geographic area considered to have air quality as good as or better than the national and/or State ambient air quality standards (NAAQS and CAAQS, respectively) (USEPA, 2006).

[4] Nonattainment Area: A geographic area identified by the USEPA and/or ARB as not meeting either NAAQS or CAAQS standards for a given pollutant (ARB, 2010).

[5] NAAQS: Standards established by USEPA that apply to ambient air throughout the country (USEPA, 2006).

[6] California Ambient Air Quality Standard (CAAQS): A legal limit that specifies the maximum level and time of exposure in the ambient air for a given air pollutant and which is protective of human health and public welfare (Health and Safety Code section 39606b). CAAQSs are recommended by the California Office of Environmental Health Hazard Assessment and adopted into regulation by the ARB. CAAQS are the standards which must be met per the requirements of the California Clean Air Act (ARB, 2010).

Table 24-1
Ambient Air Quality Standards

Pollutant	Averaging Time	California Standards (CAAQS)[a]	National Standards (NAAQS)[b]	
			Primary[c]	Secondary[d]
Ozone	8 Hour 1 Hour	0.07 ppm 0.09 ppm	0.075 ppm —	0.075 ppm —
Carbon monoxide	8 Hour 1 Hour	9.0 ppm 20 ppm	9 ppm 35 ppm	— —
Nitrogen dioxide	Annual Arithmetic Mean 1 Hour	0.30 ppm 0.18 ppm	0.053 ppm 100 ppb	0.053 ppm —
Sulfur dioxide[e]	Annual Arithmetic Mean 24 Hour 3 Hour 1 Hour	— 0.04 ppm — 0.25 ppm	0.030 ppm 0.14 ppm — 75 ppb	— — 0.5 ppm —
PM_{10}	Annual Arithmetic Mean 24 Hour	20 μg/m^3 50 μg/m^3	— 150 μg/m^3	— 150 μg/m^3
$PM_{2.5}$[f]	Annual Arithmetic Mean 24 Hour	12 μg/m^3 —	12 μg/m^3 35 μg/m^3	12 μg/m^3 35 μg/m^3
Sulfates	24 Hour	25 μg/m^3	—	—
Lead[g]	30 Day Average Calendar Quarter Rolling 3-Month Average	1.5 μg/m^3 — —	— 1.5 μg/m^3 0.15 μg/m^3	— 1.5 μg/m^3 0.15 μg/m^3
Hydrogen sulfide	1 Hour	0.03 ppm	—	—
Vinyl chloride	24 Hour	0.01 ppm	—	—
Visibility-reducing particles	8 Hour	See Note[h]	—	—

[a]California Ambient Air Quality Standards (CAAQS) for ozone, carbon monoxide, sulfur dioxide (1-hour and 24-hour), nitrogen dioxide, suspended particulate matter (PM_{10}, $PM_{2.5}$, and visibility reducing particles), are values that are not to be exceeded. All others are not to be equaled or exceeded.

[b]National Ambient Air Quality Standards (NAAQS), other than ozone, particulate matter, and those based on annual averages or annual arithmetic means, are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest eight hour concentration in a year, averaged over three years, is equal to or less than the standard. For PM_{10}, the 24-hour standard is attained when the expected number of days per calendar year with a 24-hour average concentration above 150 μg/m^3 is equal to or less than one. For $PM_{2.5}$, the 24-hour standard is attained when 98 percent of the daily concentrations, averaged over three years, are equal to or less than the standard.

[c]National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.

[d]National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

[e]On June 2, 2010, a new 1-hour SO_2 standard was established and the existing 24-hour and annual primary standards were revoked. The 1971 SO_2 national standards (24-hour and annual) remain in effect until one year after an area is designated for the 2010 standard, except for areas designated nonattainment for the 1971 standards, where the 1971 standards remain in effect until implementation plans to attain or maintain the 2010 standards are approved.

[f]On December 14, 2012, USEPA lowered the federal primary $PM_{2.5}$ annual standard from 15.0 micrograms per cubic meter to 12.0 micrograms per cubic meter.

[g]The national standard for lead was revised on October 15, 2008, to a rolling three-month average. The 1978 lead standard (1.5 μg/m^3 as a quarterly average) remains in effect until one year after an area is designated for the 2008 standard, except for areas designated nonattainment for the 1978 standard, where the 1978 standard remains in effect until implementation plans to attain or maintain the 2008 standard are approved.

[h]Insufficient amount to produce an extinction coefficient of 0.23 per kilometer due to particles when the relative humidity is less than 70 percent.

Notes:

ppm = parts per million (by volume)
ppb = parts per billion (by volume)
μg/m^3 = micrograms per cubic meter

Source: ARB, 2012e.

Table 24-2 lists the 39 counties within the Extended Study Area that are designated as nonattainment areas pursuant to the NAAQS and CAAQS. An area may be an attainment area for one pollutant and a non-attainment area for others (USEPA, 2006). The table also lists the air basin and air district for each county. Nonattainment designations are provided for two timeframes: an earlier assessment of nonattainment status based on information available from the USEPA and the State of California in 2009 (the baseline date for the proposed Project), and more current data obtained in 2012.

The relative locations of the air basins, air districts, and proposed Project are shown on Figure 24-1.

[a]These counties are located in both the Extended and Secondary study areas.
[b]These two counties (Glenn and Colusa) are located in all three study areas (Extended, Secondary, and Primary).
[c]National Ambient Air Quality Standards
[d]California Ambient Air Quality Standards

Notes:
NO_x = nitrogen oxides.
$PM_{2.5}$ = Includes particles with an aerodynamic diameter less than or equal to a nominal 2.5 microns. This fraction of particulate matter penetrates most deeply into the lungs.
PM_{10} = Particulate matter consisting of small particles with an aerodynamic diameter less than or equal to a nominal 10 microns (about 1/7 the diameter of a single human hair). Their small size allows them to make their way to the air sacs deep within the lungs, where they may be deposited and result in adverse health effects. PM_{10} emissions also cause visibility reduction.

Source: ARB, 2007 and 2012b; USEPA, 2009 and 2012a.

24.2.2 Secondary Study Area

The Secondary Study Area includes lands within 22 counties. Fourteen of the 22 counties in the Secondary Study Area are also located within the Extended Study Area (Table 24-2), and information for these counties is not repeated in Table 24-3. Table 24-3 lists the remaining counties in the Secondary Study Area that are designated as nonattainment areas pursuant to the NAAQS and CAAQS. The table also lists the air basin and air district for each county.

Table 24-3
Counties Designated as Nonattainment Areas Pursuant to the National Ambient Air Quality Standards and the California Ambient Air Quality Standards for the Secondary Study Area[a]

24.2.3 Primary Study Area

24.2.3.1 Sacramento Valley Air Basin and County Air Quality Characteristics

Table 24-4 provides the State attainment status for each of the criteria pollutants in the two counties (Glenn and Colusa) that comprise the Primary Study Area. Glenn and Colusa counties are designated as unclassified or attainment for all NAAQS. The pollutants of greatest concern in the Primary Study Area are ozone and the ozone precursors, NO_x and reactive organic gases (ROG[7]), primarily from vehicle and equipment exhaust, and particulate matter (PM_{10}) from soil disturbance and wind erosion (fugitive dust). Glenn and Colusa counties are designated as nonattainment for the CAAQS for these pollutants.

[7] The terms ROG (reactive organic gases), VOC (volatile organic compounds), and hydrocarbons (HC) are used synonymously in this document.

Table 24-4
State Attainment Status for the Two Counties that Comprise the Primary Study Area (Glenn and Colusa)

Lead	A	A	A	A
Hydrogen sulfide	U	U	U	U
Visibility-reducing particles	U	U	U	U

*California Ambient Air Quality Standards

Notes:
A = Attainment.
N = Nonattainment.
N-T = Nonattainment-Transitional: a subcategory of the nonattainment designation category for State air quality standards that signals progress and implies the area is nearing attainment. Districts with nonattainment-transitional status may revise their attainment plans to delay adoption of control measures if they anticipate attainment without the measures.
$PM_{2.5}$ = Includes particles with an aerodynamic diameter less than or equal to a nominal 2.5 microns. This fraction of particulate matter penetrates most deeply into the lungs.
PM_{10} = Particulate matter consisting of small particles with an aerodynamic diameter less than or equal to a nominal 10 microns (about 1/7 the diameter of a single human hair). Their small size allows them to make their way to the air sacs deep within the lungs, where they may be deposited and result in adverse health effects. PM_{10} emissions also cause visibility reduction.
U = Unclassified.

Source: ARB, 2007 and 2012b.

The ARB compiles annual average emissions of total organic gases, ROG, CO, NO_x, sulfur oxides, particulate matter, PM_{10}, and $PM_{2.5}$ for areas throughout the State. Table 24-5 lists the estimated annual average emission inventory for stationary sources, area-wide sources, and mobile sources for each of these pollutants in 2010 for the Sacramento Valley Air Basin (SVAB), and for Glenn and Colusa counties. As shown, each of the counties' contributions to the emissions was minor, when compared to the emissions for the SVAB as a whole.

The region's topographic features restrict air movement through and out of the basin. As a result, the northern SVAB is highly susceptible to pollutant accumulation over time. In addition, transport of pollutants into the northern SVAB from the Sacramento Metropolitan Area is primarily influenced by air movement northward. These sources contribute to the region's poorest air quality, which typically occurs during the summer months.

Table 24-5
2010 Estimated Annual Average Emissions (tons per day) for the Sacramento Valley Air Basin and Glenn and Colusa Counties

Pollutant	Area		
	2010 SVAB[d]	2010 Glenn County	2010 Colusa County
Stationary Sources[a]			
Total organic gases	176.5	11.3	5.6

Tables 24-6 and 24-7 summarize the ambient concentrations for the nonattainment pollutants ozone and PM_{10} in the Primary Study Area over the eight-year period of 2004 to 2011. Ozone concentrations and the number of days the ozone standard(s) are exceeded each year are presented in comparison to the State 1-hour and 8-hour standards, and the federal 8-hour standards (data for both the 1997 and 2008 federal 8-hour standards are provided). PM_{10} concentrations are presented in comparison to the State and federal 24-hour standards. The reported data in these tables were taken from the Colusa-Sunrise Boulevard ARB monitoring station in Colusa County, and the Willows East Laurel Street and Willows 720 North Colusa Street ARB monitoring stations in Glenn County.

Table 24-6
Number of Days State 1-Hour and 8-Hour and Federal 8-Hour Ozone Standards Were Exceeded, and Maximum Ozone Concentrations Measured, in Glenn and Colusa Counties (2004 to 2011)

[a]Based on 1-Hour Year Coverage.

[b]Data from Willows-E Laurel Street ARB monitoring station in Glenn County.

[c]Data from Willows-720 N Colusa Street ARB monitoring station in Glenn County.

[d]Data were available for both Glenn County ARB monitoring stations. The Willows-E Laurel Street station data were assumed to be more representative because this station had a yearly coverage of 80 percent, while the Willows-720 N Colusa station only had a yearly coverage of 18 percent.

[e]Parts per million

Notes:

California 1-hour Ozone Standard = 0.09 ppm (ARB, 2012e).

California 8-hour Ozone Standard = 0.070 ppm (ARB, 2012e). Effective May 17, 2006.

Federal 8-hour Ozone Standard (1997) = 0.08 ppm; the Federal 8-hour Standard was reduced to 0.075 ppm in March 2008 (USEPA, 2008).

The national 1-hour ozone standard was revoked in June 2005 and is no longer in effect.

[a]The national annual PM_{10} standard was revoked in December 2006, and is no longer in effect. The statistic shown here applies only to that standard and is included only for retrospective use.

[b]There were insufficient (or no) data available to determine the value.

[c]Data from Willows-E Laurel Street ARB monitoring station in Glenn County.

[d]Data from Willows-720 N Colusa Street ARB monitoring station in Glenn County.

[e]Data were available for both Glenn County ARB monitoring stations. The Willows-E Laurel Street station date were assumed to be more representative because this station had a yearly coverage of 62 percent, while the Willows-720 N Colusa station only had a yearly coverage of 27 percent.

[f]microgram per cubic meter

Notes:

California 24-hour PM_{10} Standard = 50 µg/m3 (ARB, 2012e).
California Annual Arithmetic Mean Standard = 20 µg/m3 (ARB, 2012e).
Federal 24-hour PM_{10} Standard = 150 µg/m3 (ARB, 2012e).

Source: ARB, 2012d.

The higher ozone concentrations, including those that exceed standards, typically occur during the months of May through October in the northern SVAB. NO_x and ROG are chemical precursors for ground-level ozone (or smog) formation. Motor vehicles, power plants, factories, chemical solvents, and various combustion sources are leading emitters of these pollutants.

Table 24-7 shows the PM_{10} concentrations from 2004 to 2011. Particulate matter can cause damage to human lungs when it enters the body through the respiratory system. The extent of the damage depends on the toxicity of the substance and the particle size. Sources of these pollutants include industries that emit airborne pollution, agricultural operations, dust resulting from high winds and soil erosion, dust from construction, vehicular travel on paved and unpaved roads, and vehicular exhaust emissions. As shown in Table 24-7, monitoring stations in both counties recorded PM_{10} levels exceeding the State standard.

In 2011, there were no days in Glenn County when the PM_{10} measurements were above the national or State 24-hour standard. In 2011, there were no days in Colusa County when the PM_{10} measurements were above the national 24-hour standard; there were 17.6 days in 2011 when air in Colusa County exceeded the State 24-hour PM_{10} standard (ARB, 2012d).

24.2.3.2 Regional Haze and Visibility Impairment

Natural and human-caused pollution in the atmosphere can degrade visibility, resulting in what is known as regional haze (ARB, 2008). Particulate pollution, including sulfates, nitrates, organics, soot, fine soil dust, and particles, contribute to the regional haze that impairs visibility, in addition to affecting public health.

24.2.3.3 Toxic Air Contaminant/Hazardous Air Pollutant Emissions

In addition to the criteria air pollutants, toxic air contaminants are another group of airborne pollutants that may be hazardous to human health, even in small quantities. Toxic air contaminants can cause or contribute to an increase in deaths or serious illness, or can pose a present or potential hazard to human health (ARB, 2011). Substances that have been identified as hazardous air pollutants pursuant to Section 112 (b) of the federal Clean Air Act are also included in the ARB list of toxic air contaminants. Toxic air contaminants can cause short-term (acute) and long-term (chronic or carcinogenic) adverse human health effects. They can be emitted from a variety of common sources, including gasoline stations, automobiles, dry cleaners, industrial operations, and painting operations. Agricultural and construction activities can also contribute to toxic air emissions. In 1998, the ARB identified particulate emissions from diesel-fueled engines (i.e., diesel PM) as a toxic air contaminant.

24.2.3.4 Existing Sensitive Receptors

A sensitive receptor is generically defined as a location where human populations (especially children, seniors, or ill persons) are found, and there is reasonable expectation of human exposure to air pollutants of concern. Examples of sensitive receptors include residences, hospitals, day-care centers, and schools. The Primary Study Area is rural, for the most part, with a few residences located near areas proposed for construction.

24.2.3.5 Odors

Odors may result from construction and operation of projects, especially if activities involve or would result in anaerobic decomposition of organic materials. Odors rarely cause physical health effects but may be unpleasant and may result in complaints from the public. Odor impacts vary in frequency and severity, depending on the nature, frequency, and intensity of the source, the wind speed and direction, and the sensitivity and location of the receptors. Projects may result in objectionable odors if located near receptors. Air districts typically regulate odor sources under nuisance regulations, and base the level of significance of odors on the number of complaints received.

24.3 Environmental Impacts/Environmental Consequences

24.3.1 Regulatory Setting

Air quality throughout California is regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations that were in effect as of June 2009. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

24.3.1.1 Federal Plans, Policies, and Regulations

- Federal Clean Air Act (FCAA)
- National Ambient Air Quality Standards and Federal Air Quality Designations
- Federal General Conformity Requirements[8]
- Prevention of Significant Deterioration/New Source Review and New Source Performance Standards
- Federal Regulations for Hazardous Air Pollutants
- Federal Standards for Mobile Sources

24.3.1.2 State Plans, Policies, and Regulations

- California Clean Air Act (CCAA)
- Mulford-Carrell Act
- California Ambient Air Quality Standards and State Air Quality Designations
- State Implementation Plans
- California Air Toxics Programs
- California Mobile Source Emission Control Programs

24.3.1.3 Regional and Local Plans, Policies, and Regulations

- Regional and Local Air Quality Management Plans
- Local Air District CEQA Guidance Documents Pertaining to Air Quality
- Glenn and Colusa County General Plans

24.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for air quality:

Would the Project:

- Conflict with or obstruct implementation of the applicable air quality plan?
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation?
- Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or State ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors)?
- Expose sensitive receptors to substantial pollutant concentrations?
- Create objectionable odors affecting a substantial number of people?

[8] Glenn and Colusa counties are designated as unclassified or attainment for all the NAAQS, so the general conformity rule does not apply to the Project or alternatives. General conformity applies to only federal actions that are in areas that are designated as nonattainment or maintenance for one or more of the NAAQS.

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Conflict with an applicable air quality plan, contribute substantially to an air quality violation, and/or result in a cumulatively considerable net increase of nonattainment pollutants.
- Expose sensitive receptors to substantial pollutant concentrations.
- Create objectionable odors affecting a substantial number of people.

The CEQA Guidelines for air quality in Appendix G indicate that, where available, the thresholds of significance established by the applicable air quality management or air pollution control district may be relied upon to make the significance determinations.

The Tehama County Air Pollution Control District (TCAPCD) has developed specific air quality guidelines and criteria for compliance with CEQA[9] (TCAPCD, 2009). TCAPCD has established recommended significance thresholds for Project construction and/or operation. Projects with the potential to have higher emission levels are subject to increasingly more stringent environmental review and mitigation requirements.

Projects with the potential to exceed ambient air quality standards and projects with the potential to emit toxic or hazardous air pollutants may be required to conduct dispersion modeling and/or a health risk assessment to evaluate modeled emission concentration values, or allow comparison to health-risk related thresholds. Emissions of toxic or hazardous air pollutants would be considered significant if they result in ambient concentrations and human exposures that exceed acceptable levels or contribute significantly to the area's excess lifetime cancer risk values, cancer burden, or health hazard indices.

The pollutants of greatest concern in the Primary Study Area are ozone and the ozone precursors (NO_x and ROG) primarily from vehicle and equipment exhaust, and particulate matter (PM_{10}) from soil disturbance and wind erosion (fugitive dust). Glenn and Colusa counties are designated as nonattainment for the CAAQS for these pollutants, and the significance thresholds established by the nearby local air districts are mass-based emission rates for these pollutants of concern. As a result, the discussion of environmental consequences focuses on NO_x, ROG, and PM_{10} pollutants as indicators of potential Project-related air quality impacts.

The thresholds of significance for these pollutants of concern are presented in Table 24-8. General Conformity de minimis levels are not applicable in Primary Study Area because Glenn and Colusa counties are designated as unclassified or attainment for all NAAQS, and general conformity applies only to federal actions in areas designated as nonattainment or maintenance for any of the NAAQS.

[9] The Glenn County Air Pollution Control District (GCAPCD) does not have CEQA guidelines for assessing air quality impacts; it would instead defer to the Butte County guidelines, if necessary (Ledbetter, 2009). In 2008, the Butte County AQMD published its CEQA Air Quality Handbook, *Guidelines for Assessing Air Quality Impacts for Projects Subject to CEQA Review* (Butte County AQMD, 2008). In addition, the Colusa County Air Pollution Control District (CCAPCD) does not have CEQA guidelines other than its New Source Review rules; thresholds developed by the Tehama County Air Pollution Control District (TCAPCD) would represent similar values (Gomez, 2009). The Butte County and Tehama County thresholds are the same values.

Table 24-8
Tehama County Air Pollution Control District Thresholds of Significance for Criteria Pollutants of Concern

Pollutant	Level A[a]	Level B[b]	Level C[c]
NO_x	≤ 25 lbs/day	> 25 lbs/day	> 137 lbs/day
ROG	≤ 25 lbs/day	> 25 lbs/day	> 137 lbs/day
PM_{10}	≤ 80 lbs/day	> 80 lbs/day	> 137 lbs/day
Level of Significance	Potentially Significant Impacts	Potentially Significant Impacts	Significant Impacts

[a]**Level A:** Any project that has the potential to emit the Level A thresholds would be subject to Standard Mitigation Measures (SMM). Guidelines are recommended to assist in reducing air quality impacts to a level of insignificance.

[b]**Level B: Greater than 25 pounds per day of ROG and/or NO_x and greater than 80 pounds per day of PM_{10} Emissions.** Projects that exceed Level B thresholds have the potential to cause significant air quality impacts, and should be submitted to TCAPCD for review. Projects proponents can select as many Best Available Mitigation Measures (BAMM) as needed, in addition to the recommended list of SMM. If all feasible mitigation measures are incorporated into the Project and emissions are still greater than Level B, additional mitigation measures, including off-site mitigation, may be required.

[c]**Level C: Greater than 137 pounds per day of Emissions.** If emissions from a Project would exceed the Level C thresholds, mitigation measures (BAMMs and SMMs), including off-site mitigation measures following the guidelines, may be required to reduce the overall air quality impacts of the project to a level of insignificance (TCAPCD, 2009).

Notes:

NO_x = nitrogen oxides.
PM_{10} = Particulate matter consisting of small particles with an aerodynamic diameter less than or equal to a nominal 10 microns (about 1/7 the diameter of a single human hair).
ROG = reactive organic gases.

Source: TCAPCD, 2009.

24.3.3 Impact Assessment Assumptions and Methodology

24.3.3.1 Assumptions

The following assumptions were made regarding Project-related impacts (construction, operation, and maintenance impacts) to air quality:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.

24.3.3.2 Methodology

Air quality impacts from implementation of the alternatives were evaluated in terms of how construction and operations of proposed Project facilities would result in criteria pollutant, toxic air contaminant, and odor emissions. The TCAPCD thresholds were used to evaluate the significance of Project-related air quality impacts because these values have been formally or informally adopted by other air districts in the area (i.e., Glenn County APCD, Butte County AQMD, and Colusa County APCD). Appendix 24A provides the methodology, assumptions, and information used to evaluate the potential air quality impacts associated with construction, and operations and maintenance, of the alternatives. In addition, Appendix 24A includes the emission calculations, emission factors, and summary tables.

Indirectly, the expected changes in operation of power production facilities at Oroville, Shasta, Trinity, and Folsom may affect Project-related emissions. The direct and indirect emissions associated with changes in water operations, power generation, and pumping in the Extended and Secondary study areas were quantified for NO_x as an indicator of criteria pollutant impacts; other pollutants and other indirect effects were evaluated on a qualitative basis.

24.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

24.3.5 Impacts Associated with the No Project/No Action Alternative

24.3.5.1 Extended and Secondary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants

The No Project/No Action Alternative assumes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts on air quality has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on air quality, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to cause increases in emissions of criteria pollutants. Air quality impacts that would occur as a result of the increased population would be managed in accordance with the regulations that are in effect at the time by various levels of government. Mitigation measures are outlined in local and regional air quality plans prepared by the local air districts and USEPA. Therefore, **there would not be a substantial adverse effect** associated with population growth, when compared to Existing Conditions.

If the No Project/No Action Alternative is implemented, ongoing systemwide net generation and consumption of electricity by the existing CVP and SWP facilities would occur. Energy use by SWP pumping facilities is predicted to increase in the future, resulting in a net decrease in CVP and SWP electrical generation, when compared to Existing Conditions[10]. For a further discussion of the power impacts, refer to Table 31-7 and Section 31.3.5.1 in Chapter 31 Power Production and Energy.

To evaluate the potential indirect air quality impacts of systemwide increases in electricity use and decreases in generation, NO_x emissions were estimated for the predicted systemwide net generation of electricity by CVP, SWP, and other related facilities for Existing Conditions and the No Project/No Action Alternative (Table 24-9). NO_x emissions were estimated as an indicator of potential indirect emissions impacts; the other criteria pollutant emissions associated with electricity generation were not estimated. The expected increased net energy consumption associated with the No Project/No Action Alternative would result in NO_x emissions of up to 210 pounds per day above Existing Conditions. These emission levels have been estimated to represent the maximum potential indirect effects and could potentially be lower, due to multiple sources of uncertainty and the assumptions used to estimate energy consumption. These potential electricity-related impacts would depend on how and where the electricity is generated. Increased energy efficiency and use of electricity generated by renewable energy sources would result in lower levels of emissions. The electrical generating facilities producing the power would be subject to stringent air quality permitting and emission control requirements, and the systemwide incremental increase in emissions would occur over a large geographic area. As a result, electricity-related emissions of criteria pollutants associated with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on air quality, when compared to Existing Conditions.

[10] These impacts are attributable to increases in demands associated with water rights and CVP contracts north of the Delta and increases in demands associated with SWP contracts south of the Delta. The result of these changes in demands is increased long-term average pumping at the SWP Banks Pumping Plant and related pump stations throughout the California Aqueduct.

Table 24-9
Indirect NO_x Emissions from CVP, SWP, and Other Related Electricity Use for Existing Conditions and the No Project/No Action Alternative

Alternative	Long-Term CVP and SWP Electricity Net Use (GWh/yr)[a]	Total NO_x Emissions (lb/day)[b]	Systemwide Incremental Increase (Compared to Existing Conditions) NO_x Emissions (lb/day)
Existing Conditions	-51	(59)	Not Applicable
No Project/No Action Alternative	132	152	210

[a]Source for Project Electricity Net Use: Power and Pumping Cost Reporting Metrics-Summary, NODOS ADEIR/S and FS Alternatives, February 8, 2011, as presented in Appendix 31B. Negative values for net electricity use indicate net electricity generation, and emission values in parenthesis indicated a net emissions benefit. Other related energy use includes energy use for Glenn-Colusa Irrigation District Canal pumping facilities.

[b]Source for NO_x Emission Factor: USEPA, 2012b.

Notes:

CVP = Central Valley Project
GWh/yr = gigawatt hours per year
lb/day = pounds per day
NO_x = nitrogen oxides
SWP = State Water Project

Impact Air Qual-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations

Refer to the **Impact Air Qual-1** discussion. That discussion also applies to substantial pollutant concentrations.

Impact Air Qual-3: Create Objectionable Odors Affecting a Substantial Number of People

Refer to the **Impact Air Qual-1** discussion. That discussion also applies to objectionable odors.

24.3.5.2 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants

Refer to the **Impact Air Qual-1** discussion for the Extended and Secondary study areas. In addition, projects included in the No Project/No Action Alternative are not located within the Primary Study Area and therefore, **would not have a substantial adverse effect** on air quality in the Primary Study Area, when compared to Existing Conditions.

Impact Air Qual-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations

Refer to the **Impact Air Qual-1** discussion for the Extended and Secondary study areas. That discussion also applies to substantial pollutant concentrations.

Impact Air Qual-3: Create Objectionable Odors Affecting a Substantial Number of People

Refer to the **Impact Air Qual-1** discussion for the Extended and Secondary study areas. That discussion also applies to objectionable odors.

24.3.6 Impacts Associated with Alternative A

24.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants

No direct Project-related construction or maintenance activities would occur in the Extended Study Area, so there would be no direct Project-related emissions or impacts. It is not possible to quantify the indirect air quality emissions or impacts associated with more reliable water supplies for agriculture, municipal and industrial use, and reservoirs, or the provision of an alternate source of refuge water supply; however, these impacts would likely be beneficial because these systems would be maintained in a healthier, more productive state. Potential fugitive dust impacts due to continued fluctuating reservoir levels at San Luis Reservoir would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative, because exposure of shorelines would be intermittent, and dust emissions from exposed areas would not be substantial. Therefore, air quality impacts in the Extended Study Area would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Air Qual-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations

Refer to the **Impact Air Qual-1** discussion. That discussion also applies to substantial pollutant concentrations.

Impact Air Qual-3: Create Objectionable Odors Affecting a Substantial Number of People

Refer to the **Impact Air Qual-1** discussion. That discussion also applies to objectionable odors.

24.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay.

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants

The only Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing concrete pump bay at the Red Bluff Pumping Plant, located on the Sacramento River. Construction would require limited operation of construction equipment, such as one mobile crane, and would not be expected to involve earthmoving or land disturbance. Air quality impacts from this minimal construction activity would be minor. Therefore, when compared to Existing

Conditions and the No Project/No Action Alternative, the construction-related air quality impacts in the Secondary Study Area would result in a **less-than-significant impact**.

Operation of the additional pump at the Red Bluff Pumping Plant, as part of Alternative A, would not significantly change the air emissions that are currently generated at the plant. The only Project-related maintenance activity that would occur in the Secondary Study area is related to the removal of sediment from the existing GCID Canal and Red Bluff Pumping Plant intakes. The additional pump at the Red Bluff Pumping Plant would not increase the frequency of existing maintenance activities at the pumping plant, and would not require additional personnel. More frequent dredging of the pumping plant forebay may be required, but this dredging and the additional pumping activities would not be expected to result in a substantial increase in air emissions when compared to existing activities. When compared to Existing Conditions and the No Project/No Action Alternative, Alternative A would result in minor increases in emissions from operations and maintenance activities in the Secondary Study Area, resulting in a **less-than-significant impact**.

When compared to Existing Conditions and the No Project/No Action Alternative, potential changes in the locations and types of recreational use due to the expected improved reservoir storage conditions with implementation of Alternative A may result in changes in emissions, but systemwide recreation-related emissions and impacts would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

The expected improved reservoir storage conditions would leave less exposed barren land at the reservoir's edges. Therefore, incremental, intermittent dust emissions and related impacts from exposed areas would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Air quality impacts associated with systemwide increases in electrical use and decreases in net electrical generation would depend on how and where the replacement electricity is generated[11]. For a further discussion of the power impacts, refer to Table 31-8 and Section 31.3.6.1 in Chapter 31 Power Production and Energy. The electrical generating facilities producing the power would be subject to stringent air quality permitting and emission control requirements, and the systemwide incremental increase in emissions would occur over a large geographic area. As a result, electricity-related emissions of criteria pollutants would result in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Air Qual-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations

Refer to the **Impact Air Qual-1** discussion. That discussion also applies to substantial pollutant concentrations.

Impact Air Qual-3: Create Objectionable Odors Affecting a Substantial Number of People

Refer to the **Impact Air Qual-1** discussion. That discussion also applies to objectionable odors.

[11] As a result of the increased storage of Sites Reservoir, CVP and SWP water supply deliveries and exports from the Delta would be increased. There would be increased long-term average pumping at the SWP Banks Pumping Plant and related pump stations throughout the California Aqueduct. There would also be increased generation at system reservoirs and at Sites Reservoir, but the increase in pumping would be larger than the increase in generation, and therefore, the net generation would decrease for the action alternatives.

24.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Construction and operation of proposed Project facilities would result in criteria pollutant emissions. Emissions of NO_x, PM_{10}, $PM_{2.5}$, ROG, CO, SO_x, and CO_2[12] would result from combustion of fuels in construction equipment and material transport trucks. Construction of facilities would result in emissions of PM_{10} and $PM_{2.5}$ from fugitive dust, generated primarily during earthmoving activities. Other sources of fugitive dust include vehicle travel on paved and unpaved roads, creation and management of quarries and borrow sites, concrete batch plants, and material handling, storage, and transport. Similar emissions, at lower levels, may result from operations and maintenance of proposed Project facilities.

All Primary Study Area Project Facilities

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an ***Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants***

Alternative A would involve the construction of proposed surface water storage reservoirs, water intakes, conveyance facilities (canals, pipelines, tunnels, and pumping plants), service roads, dams, buildings, recreation facilities, transmission lines, and hydroelectric generation facilities in the Primary Study Area.

Fuel combustion in construction equipment, trucks, and construction worker vehicles would generate criteria air pollutant emissions as exhaust. Emissions of the ozone precursors, ROG and NO_x, from these emissions sources would temporarily contribute to regional atmospheric ozone problems during the proposed construction period. Construction activities would also generate fugitive dust from sources such as unpaved roads, concrete batch plants, grading, and excavation. Fugitive dust emissions refer to emissions of PM_{10} and $PM_{2.5}$. Stationary sources that would be needed to support construction activities, such as rock quarries, asphalt plants, and concrete batch plants, would be subject to local air district permitting programs. These permitting programs would keep emissions from permitted equipment within acceptable limits.

Table 24-10 presents the estimated construction emissions for Alternative A, providing average daily construction emissions by construction year, with comparison to significance thresholds established by TCAPCD (TCAPCD, 2009). Detailed calculation spreadsheets and supporting documentation are provided in Appendix 24A.

Alternative A would involve construction, operations, and maintenance of a 1.27-MAF reservoir, Sites and Golden Gate dams, and seven saddle dams. Construction equipment utilization was assumed to be directly related to volume of materials used for dam construction (Barnes pers. comm., 2011), and fugitive dust emissions would be directly related to the area of disturbance.

When compared to Existing Conditions, estimated construction-related emissions for Alternative A would be **significant**, because they would exceed thresholds of significance for NO_x, PM_{10}, and ROG established by TCAPCD (TCAPCD, 2009).

[12] A discussion of greenhouse gases, such as CO_2, and related CEQA significance criteria and impacts, is presented in Chapter 25 Climate Change and Greenhouse Gas Emissions.

Table 24-10
Estimated Average Daily Emission Rates for Criteria Pollutants by Year for Construction of Alternative A Within the Primary Study Area

Construction Year	Emissions (lbs/day)[a,d]					
	NO_x	PM_{10}	$PM_{2.5}$	ROG	CO	SO_x
2013	**2,171**[b]	**344**	124	**247**	833	3
2014	**4,114**	**750**	247	**467**	1,604	5
2015	**3,639**	**655**	219	**414**	1,420	4
2016	**3,688**	**661**	222	**420**	1,448	4
2017	**1,913**	**419**	125	**216**	775	2
2018	**617**	**209**	55	68	267	1
2019	**617**	**209**	55	68	267	1
2020	**519**	**188**	48	57	215	1
2021	98	21	8	11	52	0
Significance Threshold (lb/day)[c]	137	137	-	137	-	-

[a]The average daily construction emission rates for each criteria pollutant (in lb/day) for each construction year are the sum of the average daily emission rates estimated for each of the proposed Project features that would be constructed in the indicated construction year.

[b]**Bolded** values indicate an exceedance of the Significance Threshold.

[c]Significance Threshold is from TCAPCD Level C: Greater than 137 pounds per day of emissions. If emissions from a project would exceed the Level C thresholds, all feasible mitigation measures, including Suggested Mitigation Measures (SMMs), Best Available Mitigation Measures (BAMMs), and off-site mitigation measures, may be required to reduce the overall air quality impacts of the project to a level of insignificance (TCAPCD, 2009).

[d]Fugitive dust emissions from grading were assumed to include daily watering of disturbed areas to control dust, and vehicles traveling on unpaved roads were assumed to be limited to 15 miles per hour.

Notes:

CO = carbon monoxide.
lb/day = pounds per day.
NO_x = nitrogen oxides.
PM_{10} = Particulate matter consisting of small particles with an aerodynamic diameter less than or equal to a nominal 10 microns (about 1/7 the diameter of a single human hair). Their small size allows them to make their way to the air sacs deep within the lungs, where they may be deposited and result in adverse health effects. PM_{10} emissions also cause visibility reduction.
$PM_{2.5}$ = Includes particles with an aerodynamic diameter less than or equal to a nominal 2.5 microns. This fraction of particulate matter penetrates most deeply into the lungs.
ROG = reactive organic gases.
SO_x = sulfur oxides.

Construction of the Alternative A proposed facilities would result in higher levels of emissions than implementation of the No Project/No Action Alternative in the Primary Study Area. Implementation of Alternative A would result in temporary construction-related increases in pollutant emissions, resulting in a **significant impact** on air quality in the Primary Study Area, when compared to the No Project/No Action Alternative.

Operation and maintenance of Alternative A would include activities that must occur to operate and maintain each proposed facility. These activities and their associated impacts would be long-term and permanent. Operation activities would include those related to the use of roads during operations and maintenance activities, recreation activities, the movement of water (such as Sites Reservoir level fluctuations, or the intake or release of water through the Delevan Pipeline Intake Facilities), and the generation and transmission of electricity.

Emissions associated with operations and maintenance of the Alternative A proposed facilities would depend on the size and type of facility, the number of employees and types of equipment, the increased traffic on the local and regional roadway network (including additional haul trucks and workers), and the level of operations activities. Emissions similar to those expected during construction, but at lower levels, would likely result from facility operations and maintenance. For example, operational sources of fugitive dust would primarily be maintenance equipment and truck movement over paved and unpaved surfaces. Stationary sources, such as electrical generators, would be subject to permitting requirements to limit emissions. Required mitigation and operating conditions would be reflected in needed permits and approvals for the proposed Project.

Table 24-11 presents the estimated daily emissions for operations and maintenance of the Alternative A proposed facilities, with comparison to significance thresholds established by TCAPCD (TCAPCD, 2009). Detailed calculation spreadsheets and supporting documentation are provided in Appendix 24A.

Table 24-11
Estimated Total Emission Rates in lb/day for Operations and Maintenance of Alternative A Proposed Facilities Within the Primary Study Area

	NO_x	PM_{10}	$PM_{2.5}$	ROG	CO	SO_x
Total Average Daily Emissions (lb/day)	33	7	7	38	1308	0.1
TCAPCD Threshold (lb/day), Level A	< 25	< 25	-	< 25	-	-
Threshold Exceeded?	Yes	No	-	Yes	-	-
TCAPCD Threshold (lb/day), Level B	> 25	> 25	-	> 25	-	-
Threshold Exceeded?	Yes	No	-	Yes	-	-
TCAPCD Threshold (lb/day), Level C	> 137	> 137	-	> 137	-	-
Threshold Exceeded?	No	No	-	No	-	-

Notes:

It was assumed that sedans/pickups would travel at a speed of 15 mph which equates to 3 roundtrips per hour at a distance of 5 miles per roundtrip.

An estimated total of 60 employees would support operations and maintenance work at all facilities.

CO = carbon monoxide.
lb/day = pounds per day.
NO_x = nitrogen oxides.
PM_{10} = Particulate matter consisting of small particles with an aerodynamic diameter less than or equal to a nominal 10 microns (about 1/7 the diameter of a single human hair). Their small size allows them to make their way to the air sacs deep within the lungs, where they may be deposited and result in adverse health effects. PM_{10} emissions also cause visibility reduction.
$PM_{2.5}$ = Includes particles with an aerodynamic diameter less than or equal to a nominal 2.5 microns. This fraction of particulate matter penetrates most deeply into the lungs.
ROG = reactive organic gases.
SO_x = sulfur oxides.
TCAPCD = Tehama County Air Pollution Control District

Implementation of Alternative A would provide increased opportunities for recreational uses in the Primary Study Area. The expected increase in recreational opportunities and recreation visitor days would generate additional vehicle trips to and from the area. These vehicle trips would add to the significant emissions and impacts estimated for operations and maintenance of Alternative A facilities.

Operations of the proposed Sites Reservoir, Holthouse Reservoir, and the TRR could result in significant fluctuations of water levels, leaving exposed barren land at the reservoirs' edges when the water level is lowered. Exposed areas may be sources of fugitive dust, depending on local conditions of temperature, humidity, and wind. Because these dust emissions would be intermittent, they are expected to result in a **less-than-significant impact** on air quality.

Operations of proposed Project facilities would generate electricity, but would also result in additional electricity consumption due to pumping and facility operations. Alternative A would have greater operations-related emissions than Existing Conditions and the No Project/No Action Alternative, because it would result in net energy consumption, and would require additional electricity generation. To evaluate the potential indirect impacts on air quality, NO_x emissions were estimated for the predicted systemwide net generation and consumption of electricity by CVP, SWP, and proposed Project facilities associated with Alternative A. NO_x emissions were estimated as an indicator of potential indirect emissions impacts; the other criteria pollutant emissions associated with electricity generation were not estimated.

Table 24-12 summarizes the NO_x emissions estimated for each of the action alternatives, when compared to emissions estimated for the net generation and consumption of electricity for Existing Conditions and the No Project/No Action Alternative. Emissions associated with Alternatives B and C are presented in Table 24-12 for the purpose of comparison and are evaluated in their respective discussions. Increased energy consumption associated with Alternative A would result in indirect NO_x emissions of up to 632 pounds per day above Existing Conditions, and up to 422 pounds per day above the No Project/No Action Alternative. These emission levels have been estimated to represent the maximum potential indirect effects, and could potentially be lower, due to multiple sources of uncertainty and the assumptions used to estimate electricity generation. These potential electricity-related impacts may add to emissions and significant air quality impacts in the Primary Study Area, depending on how and where the electricity is generated.

Table 24-12
Indirect NO_X Emissions from Electricity Use for Existing Conditions, the No Project/No Action Alternative, and Alternatives A, B, and C

Scenario	Electricity Long-Term Net Use (GWh/yr)[a]	Total NO_x Emissions (lb/day)[b]	Incremental Increase (Compared to Existing Conditions) NO_x Emissions (lb/day)	Incremental Increase (Compared to No Project/No Action Alternative) NO_x Emissions (lb/day)
Existing Conditions	-51	(59)	Not Applicable	Not Applicable
No Project/No Action Alternative	132	152	210	Not Applicable
Alternative A	499	573	632	422
Alternative B	498	572	631	420
Alternative C	543	624	682	472

[a]Source for Project Electricity Net Use: Power and Pumping Cost Reporting Metrics-Summary, NODOS ADEIR/S and FS Alternatives, February 8, 2011, as presented in Appendix 31B. All values include electricity use associated with CVP and SWP operations. Existing Conditions and No Project/No Action Alternative values include other related energy use for Glenn-Colusa Irrigation District Canal pumping facilities. Alternative A, B, and C values include electricity use associated with operation of the proposed Project facilities.

[b]Source for NO_x Emission Factor: USEPA, 2012b.

Notes:

Negative values for net electricity use indicate net electricity generation, and emission values in parentheses indicate a net emissions benefit.

NO_x = nitrogen oxides
CVP = Central Valley Project
SWP = State Water Project
GWh/yr = gigawatt hours per year
lb/day = pounds per day

When compared to Existing Conditions in the Primary Study Area, emissions and air quality impacts associated with long-term operations and maintenance of Alternative A would result in a **significant impact**. This finding is based on the CEQA guidance, thresholds of significance, and attainment plans for the TCAPCD (TCAPCD, 2009). Additional exceedances of significance thresholds could occur when other operational or maintenance activities occur, e.g., the proposed Holthouse Reservoir would be dredged to remove sediment periodically during the proposed Project duration, resulting in an additional 705 pounds per day of NO_x for 167 days, during dredging years, and periodic dredging would also occur at the proposed TRR and Delevan Pipeline Intake Facilities, and at the existing T-C Canal and GCID Canal intakes.

When compared to the No Project/No Action Alternative, operations and maintenance of Alternative A would result in higher levels of emissions, and a **significant impact**. For example, increased electricity consumption associated with Alternative A implementation would result in NO_x emissions of up to 422 pounds per day more than the No Project/No Action Alternative, on a systemwide basis. These potential electricity-related emissions would potentially add to emissions and significant air quality impacts in the Primary Study Area, depending on how and where the electricity is generated.

Impact Air Qual-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations

Construction-related activities for large surface water reservoirs and related facilities would require the use of heavy equipment, such as excavators, graders, scrapers, bulldozers, backhoes, and concrete mixing and pumping trucks. Haul trucks would be used to move borrow and/or spoils and other materials. Emissions of CO and toxic air contaminants (TACs) could result from fuel combustion to support site preparation and construction activities required for the proposed Project. TACs that could be generated by the combustion of fuels include benzene, formaldehyde, acrolein, and other products of incomplete combustion. Health impacts from human exposure to localized CO emissions and TACs from construction are dependent on the magnitude of the concentrations that sensitive receptors may be exposed to, the duration of exposure, and the relative toxicities of the individual pollutants.

Due to the rural nature of most of the proposed Project construction activities, CO hot spots are not expected to result from construction-related changes in traffic patterns.

Emissions of airborne naturally occurring asbestos are not expected to result from proposed land disturbance activities. Ultramafic rocks likely to contain naturally occurring asbestos are not found within the Primary Study Area or in the watersheds draining into the Primary Study Area (see Chapter 16 Geology, Minerals, Soils, and Paleontology for more details).

Preparation of the proposed Sites Reservoir Inundation Area for filling would involve demolition of several structures. To avoid adverse Project-related air quality impacts, construction contractors conducting demolition and disposal of asbestos-containing material (ACM) must comply with various regulatory requirements, such as the Asbestos National Emission Standard for Hazardous Air Pollutants (NESHAP) (40 CFR 61, Subpart M).

Diesel PM from diesel-fueled on-road haul trucks and off-road equipment would be the primary TAC of concern for proposed Project construction activities. Because of the variable nature of construction activity, the generation of TAC emissions in most cases would be temporary, especially considering the short amount of time such equipment is typically within an influential distance that would result in the exposure of sensitive receptors to substantial concentrations. In its CEQA Guidelines, the Bay Area Air Quality Management District (BAAQMD) cites studies by ARB that show concentrations of mobile-source diesel PM are typically reduced by 70 percent at a distance of approximately 500 feet from the source. In addition, current models and methodologies for conducting health risk assessments are associated with longer-term exposure periods of nine, 40, and 70 years, which do not correlate well with the temporary and highly variable nature of project construction activities. This results in difficulties with producing accurate estimates of health risk during construction (BAAQMD, 2011).

Most of the proposed construction activities and exhaust emissions from equipment would occur in rural areas, typically more than 1,000 feet from sensitive receptors. Diesel-fueled construction equipment would operate only a limited period of time at any given location, and would be subject to stringent regulatory requirements. When compared to Existing Conditions and the No Project/No Action Alternative, sensitive receptors would not be exposed to substantial pollutant concentrations from Project-related construction equipment exhaust emissions, and the associated impacts would be **less than significant**.

Emission sources similar to those expected during proposed Project construction, but at lower levels, would likely result from operations and maintenance of the proposed Project. Activities associated with operations and maintenance of proposed Project facilities would occur intermittently and generate emissions sporadically over the lifetime of the proposed Project. In addition, particulate matter emissions are anticipated to occur away from sensitive receptors and at levels below the TCAPCD thresholds of significance (Table 24-11). It is assumed that CO and TAC emissions from stationary sources would be subject to air district permitting requirements to limit exposure to sensitive receptors. In addition, mobile sources would be subject to ARB emission standards and Airborne Toxic Control Measures. Therefore, when compared to Existing Conditions, sensitive receptors would not be exposed to substantial pollutant concentrations and the impact would be **less than significant**.

Implementation of Alternative A would result in greater construction- and operations and maintenance-related emissions than the No Project/No Action Alternative in the Primary Study Area. However, these emissions would not be expected to expose sensitive receptors to substantial pollutant concentrations, resulting in **a less-than-significant impact**.

Impact Air Qual-3: Create Objectionable Odors Affecting a Substantial Number of People

Odors may result from construction and operation of the proposed Project, especially if activities involve or would result in anaerobic decomposition of organic materials. Alternative A operations would result in large fluctuations in water surface elevations at the proposed Sites Reservoir. Under very low reservoir elevations, algal growth may contribute to localized odors. The reservoir would be located in a rural area with no permanent residents living near the water's edge. In addition, when the reservoir would be drawn down to a very low level, it is unlikely that many recreationists would visit it, so any odors that would be generated by algal growth would be unlikely to affect a substantial number of people.

Odors may be generated through exhaust emissions from diesel equipment, but the emission sources would not remain in one location for long periods of time, and the emissions would be intermittent and would dissipate from the source rapidly. In addition, the types of land uses that typically result in odor problems include agriculture, wastewater treatment plants, food processing and rendering plants, chemical plants, landfills, composting facilities, and dairies. Alternative A does not include construction or operation of any of these land use activities or any similar land uses.

When compared to Existing Conditions, construction and operation of Alternative A would not generate objectionable odors affecting a substantial number of people and the impact would be **less than significant**.

When compared to the No Project/No Action Alternative, Alternative A would have greater construction-, operations-, and maintenance-related impacts. However, construction, operations, and maintenance activities for Alternative A are not anticipated to create objectionable odors affecting a substantial number of people because of the lack of permanent residents around the reservoir's edge, and because it is unlikely that many recreationists would visit the reservoir when it is drawn down to a very low level. This would, therefore, result in a **less-than-significant impact**.

24.3.7 Impacts Associated with Alternative B

24.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to compliance with air quality standards (**Impact Air Qual-1**), substantial pollutant concentrations (**Impact Air Qual-2**), and objectionable odors (**Impact Air Qual-3**), would be the same as those described for Alternative A for the Extended and Secondary study areas.

24.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following proposed Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to air quality:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

Alternative B includes the construction of a proposed 1.81-MAF Sites Reservoir. The increased reservoir size would require a larger footprint for the proposed Sites and Golden Gate dams and necessitate the construction of nine saddle dams. However, similar to that described for Alternative A, there are no sensitive receptors located within one mile of these facilities.

The proposed Alternative B Delevan Transmission Line would differ from Alternative A. There would be no transmission line alignment between the Sacramento River and the PG&E or WAPA transmission line. The transmission line would be approximately three miles long, from the proposed Sites Electrical Switchyard to the PG&E or WAPA transmission line, which would be located west of the proposed TRR.

Similar to that described for Alternative A, there are no sensitive receptors located within 0.5 mile of this construction area.

The proposed Alternative B Road Relocations and South Bridge would differ slightly from those described for Alternative A. The lengths of the saddle dam access roads included in Alternative A would be reduced in Alternative B because the dams would be larger and would be located closer to the main roads. In addition, an extension of an access road would be constructed for Alternative B to provide access from Saddle Dam 3 to Saddle Dams 1 and 2. However, there are no sensitive receptors located within a 0.5-mile radius of these portions of the road relocations.

Alternative B would replace the proposed Delevan Pipeline Intake Facilities with the smaller proposed Delevan Pipeline Discharge Facility. The proposed Delevan Pipeline would be operated as a release-only pipeline, so the associated Delevan Pipeline Discharge Facility would not include a fish screen or any of the facilities needed for the pumping and generating operations that were described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

These changes in facility design would result in similar construction-, operation-, and maintenance-related impacts to sensitive receptors from substantial pollutant concentrations **(Impact Air Qual-2)** and objectionable odors **(Impact Air Qual-3)** as described for Alternative A. However, emissions associated with Alternative B would be more than those estimated for Alternative A, due to the proposed Project design features included in Alternative B that would differ from Alternative A (refer to above discussion). The increased emissions are presented and discussed below.

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants

Table 24-13 presents the results for emission calculations for construction of Alternative B, providing average daily construction emissions by construction year, with comparison to significance thresholds established by TCAPCD (TCAPCD, 2009). Detailed calculation spreadsheets and supporting documentation are provided in Appendix 24A. As indicated in Table 24-13, emissions estimated for construction of Alternatives B and C would be the same because there are only minor differences between the two alternatives with regard to overall construction requirements. For example, Alternative B does not include construction of the proposed Delevan Transmission Line from the PG&E or WAPA line to the Sacramento River, and the proposed Alternative C Delevan Pipeline Intake Facilities would be replaced by the smaller proposed Alternative B Delevan Pipeline Discharge Facility. These differences in required construction activities are not expected to result in substantial differences in the estimated construction emissions.

When compared to Existing Conditions in the Primary Study Area, impacts associated with temporary construction-related emissions of criteria air pollutants and precursors for Alternative B would be **significant**. Construction of Alternative B facilities would result in higher levels of emissions than for the No Project/No Action Alternative. These impacts would be temporary and adverse, resulting in a **significant impact**.

When compared to Existing Conditions in the Primary Study Area, emissions and air quality impacts associated with long-term operation and maintenance of Alternative B would result in a **significant impact**. Refer to Tables 24-11 and 24-12, and the discussion for **Impact Air Qual-1** for Alternative A in the Primary Study Area.

When compared to the No Project/No Action Alternative, Alternative B would have increased emissions. Increased electricity consumption associated with Alternative B would result in NO_x emissions of up to 420 pounds per day more than the No Project/No Action Alternative, on a systemwide basis. These electricity-related emissions would potentially add to emissions and significant impacts in the Primary Study Area, depending on how and where the electricity is generated.

Table 24-13
Estimated Average Daily Emission Rates for Criteria Pollutants by Year for Construction of Alternatives B and C

Construction Year	Emissions (lbs/day)[a,d]					
	NO_x	PM_{10}	$PM_{2.5}$	ROG	CO	SO_x
2013	**2,171**[b]	**344**	124	**247**	833	3
2014	**4,487**	**860**	274	**508**	1,749	6
2015	**4,012**	**765**	246	**455**	1,565	5
2016	**4,061**	**770**	250	**460**	1,593	5
2017	**2,286**	**528**	153	**257**	920	3
2018	**990**	**319**	83	109	412	1
2019	**990**	**319**	83	109	412	1
2020	**892**	**298**	76	98	360	1
2021	98	21	8	11	52	0
Significance Threshold (lb/day)[c]	137	137	-	137	-	-

[a]The average daily construction emission rates for each criteria pollutant (in lb/day) for each construction year are the sum of the average daily emission rates estimated for each of the Project features that would be constructed in the indicated construction year.

[b]**Bolded** values indicate an exceedance of the Significance Threshold.

[c]Significance Threshold is from TCAPCD Level C: Greater than 137 pounds per day of emissions. If emissions from a project would exceed the Level C thresholds, all feasible mitigation measures, including Suggested Mitigation Measures (SMMs), Best Available Mitigation Measures (BAMMs), and off-site mitigation measures, may be required to reduce the overall air quality impacts of the project to a level of insignificance (TCAPCD, 2009).

[d]Fugitive dust emissions from grading were assumed to include daily watering of disturbed areas to control dust, and vehicles traveling on unpaved roads were assumed to be limited to 15 miles per hour.

Notes:

CO = carbon monoxide.
lb/day = pounds per day.
NO_x = nitrogen oxides.
PM_{10} = Particulate matter consisting of small particles with an aerodynamic diameter less than or equal to a nominal 10 microns (about 1/7 the diameter of a single human hair). Their small size allows them to make their way to the air sacs deep within the lungs, where they may be deposited and result in adverse health effects. PM_{10} emissions also cause visibility reduction.
$PM_{2.5}$ = Includes particles with an aerodynamic diameter less than or equal to a nominal 2.5 microns. This fraction of particulate matter penetrates most deeply into the lungs.
ROG = reactive organic gases.
SO_x = sulfur oxides.
TCAPCD = Tehama County Air Pollution Control District.

Additional exceedances of significance thresholds and significant impacts could occur when other operational and/or maintenance activities occur, e.g., the proposed Holthouse Reservoir would be dredged to remove sediment at least once during the proposed Project duration, resulting in an additional 705 pounds per day of NO_x for 167 days during dredging years, and periodic dredging would also occur at the proposed TRR and Delevan Pipeline Intake and the existing T-C Canal and GCID Canal intakes.

24.3.8 Impacts Associated with Alternative C

24.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to compliance with air quality standards (**Impact Air Qual-1**), substantial pollutant concentrations (**Impact Air Qual-2**), and objectionable odors (**Impact Air Qual-3**), would be the same as those described for Alternative A for the Extended and Secondary study areas.

24.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following proposed Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to air quality:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the proposed Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to air quality as described for Alternative A.

The Alternative C design of the proposed Sites Reservoir Inundation Area and Dams and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to transportation air quality as described for Alternative B.

The boundary of the proposed Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the proposed Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

Alternative C would, therefore, result in similar construction-, operation-, and maintenance-related impacts to sensitive receptors from substantial pollutant concentrations **(Impact Air Qual-2)** and objectionable odors **(Impact Air Qual-3)** as described for Alternative A. However, emissions associated with Alternative C would differ from those estimated for Alternative A. The differences in emissions are discussed below.

Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants

Alternative C would result in a **significant impact** to air quality in the Primary Study Area from proposed Project construction, similar to that described for Alternative A. Refer to **Impact Air Qual-1** for Alternative A in the Primary Study Area. Construction emissions associated with Alternative C would be more than those estimated for Alternative A, due to the proposed Project design features included in Alternative C that would be different than Alternative A (refer to above discussion).

As presented in Table 24-13, emissions estimated for construction of Alternatives B and C would be the same, because there are only minor differences between the two alternatives with regard to construction requirements. For example, Alternative C includes construction of a transmission line from the PG&E or WAPA line to the Sacramento River and a pumping plant at the proposed Delevan Pipeline Intake Facilities, but these activities are not expected to result in substantial differences in construction emissions. Therefore, when compared to Existing Conditions, impacts associated with temporary construction-related emissions of criteria air pollutants or precursors for Alternative C in the Primary Study Area would be the same as those described for Alternative B.

Construction of Alternative C facilities would result in higher levels of emissions than for the No Project/No Action Alternative. These impacts would be the same as those described for Alternative B.

When compared to Existing Conditions in the Primary Study Area, impacts associated with long-term operation and maintenance-related emissions of criteria air pollutants and precursors associated with Alternative C would be similar to the **significant impact** described for Alternative A. Refer to Tables 24-11 and 24-12, and the discussion for **Impact Air Qual-1** for Alternative A in the Primary Study Area.

When compared to the No Project/No Action Alternative, Alternative C would result in increased emissions and significant air quality impacts. Increased electricity consumption associated with Alternative C would result in NO_x emissions of up to 472 pounds per day more than the No Project/No Action Alternative, on a systemwide basis. These electricity-related emissions would potentially add to emissions and significant impacts in the Primary Study Area, depending on how and where the electricity is generated.

24.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 24-14 for the impacts that have been identified as significant or potentially significant.

Table 24-14
Summary of Mitigation Measures for Potential NODOS Project Impacts to Air Quality

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS[a] After Mitigation
Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants	All Primary Study Area Project Facilities (construction)	Significant	Mitigation Measure Air Qual-1a: Develop a Fugitive Dust Control Plan	Significant and Unavoidable for Emissions of PM_{10}
			Mitigation Measure Air Qual-1b: Implement Measures to Reduce Equipment and Vehicle Exhaust Emissions	Significant and Unavoidable for Emissions of NO_x, PM_{10}, and ROG
				Less than Significant for Emissions of SO_x, CO, and $PM_{2.5}$
	All Primary Study Area Project Facilities (operation and maintenance)[b]	Significant	Mitigation Measure Air Qual-1a: Develop a Fugitive Dust Control Plan	Less than Significant
			Mitigation Measure Air Qual-1b: Implement Measures to Reduce Equipment and Vehicle Exhaust Emissions	Less than Significant

[a]LOS = Level of Significance

[b]Approaches and mitigation measures to address the electricity-related emissions associated with State Water Project and Central Valley Project operational changes are discussed in Chapter 25 Climate Change and Greenhouse Gas Emissions.

Mitigation Measure Air Qual-1a: Develop a Fugitive Dust Control Plan

The Fugitive Dust Control Plan shall include the following information and measures to reduce fugitive PM_{10} and $PM_{2.5}$ emissions:

- Name(s), address(es), and phone number(s) of person(s) responsible for the preparation, submission, and implementation of the plan.
- Description and location of construction activities.
- Listing of all fugitive dust emissions sources.

Land Clearing/Earth Moving:

- Water shall be applied by means of truck(s), hoses, and/or sprinklers as needed prior to any land clearing or earth movement to minimize dust emission.
- Haul vehicles transporting soil into or out of the property shall be covered.
- Water shall be applied to disturbed areas a minimum of two times per day or more as necessary.

- A publicly visible sign shall be posted with the telephone number and person to contact regarding dust complaints. This person shall respond and take corrective action within 24 hours. The telephone number of the local air district shall also be included and visible on the sign.
- All excavation, grading, and/or earth moving activities shall be suspended when average wind speeds exceed 25 mph.

Visibly Dry Disturbed Soil Surface Areas:

- All visibly dry disturbed soil surface areas of operation shall be treated with a dust palliative agent and/or watered to minimize dust emission.

Paved Road Track-Out:

- Existing roads and streets adjacent to the Project shall be cleaned at least once per day unless conditions warrant a greater frequency.

Visibly Dry Disturbed Unpaved Roads:

- All visibly dry disturbed unpaved road surface areas of operation shall be watered to minimize dust emission.
- Unpaved roads shall be graveled to reduce dust emissions, to the extent feasible.
- Water shall be applied to disturbed areas a minimum of two times per day or more as necessary.
- On-site vehicles shall be limited to a speed of 15 miles per hour on unpaved roads.
- Haul roads shall be sprayed down at the end of the work shift to form a thin crust. This application of water shall be in addition to the minimum rate of application.

Vehicles Entering/Exiting Construction Area:

- Vehicles entering or exiting the construction area shall travel at a speed which minimizes dust emissions.

Employee Vehicles:

- Construction workers shall park in designated parking areas(s) to help reduce dust emissions.

Soil Piles:

- Soil pile surfaces shall be moistened if dust is being emitted from the pile(s). Adequately secured tarps, plastic, or other material may be required to further reduce dust emissions. This includes materials stored in piles for use in the concrete batch plant.

Mitigation Measure Air Qual-1b: Implement Measures to Reduce Equipment and Vehicle Exhaust Emissions

- All construction equipment shall be maintained according to manufacturer's specifications.
- Idling times shall be minimized either by shutting equipment off when not in use or reducing the maximum idling time to five minutes (as required by the California airborne toxics control measure Title 13, Section 2485 of California Code of Regulations [CCR]).

- During all construction activities, diesel-fueled portable equipment with maximum power greater than 25 horsepower shall be registered under the ARB's Statewide Portable Equipment Registration Program.
- All fleets of diesel-fueled off-road vehicles shall comply with the emissions standards pursuant to CCR Title 13, Section 2449. To the extent feasible, operate off-road vehicles with engines certified to the Tier 2 or newer emissions standards.
- All on-road trucks shall be operated in compliance with the emission standards per CCR Title 13, Section 2025. To the extent feasible, operate on-road trucks with engines certified to the 2007 model year or newer heavy-duty diesel engine emissions standards.
- To the extent feasible, electric equipment shall be operated.
- Alternatively fueled construction equipment shall be used, to the extent feasible, such as compressed natural gas (CNG), liquefied natural gas (LNG), propane, or biodiesel.
- Electricity used to power facilities and equipment shall be generated by renewable energy sources with state-of-the-art emissions control systems, to the extent feasible.

Implementation of **Mitigation Measures Air Qual-1a** and **Air Qual-1b** would reduce the level of significance of potential proposed Project impacts to air quality to **less-than-significant** for emissions of SO_x, CO, and $PM_{2.5}$ during Project construction and for all emissions during operation and maintenance.

Implementation of **Mitigation Measures Air Qual-1a** and **Air Qual-1b** would lessen the effects of proposed Project-related NO_x, PM_{10}, and ROG emissions on air quality, but impacts would remain **significant and unavoidable** for emissions of NO_x, PM_{10}, and ROG during Project construction.

25. Climate Change and Greenhouse Gas Emissions

25.1 Introduction

This chapter includes (1) an environmental setting/affected environment for greenhouse gases and climate change, (2) a GHG impact analysis of the potential environmental effects of GHGs emitted by construction, operation, and maintenance of the proposed Project, and (3) a climate change sensitivity analysis of the projected changes in future climate and its expected effects on the proposed Project, as well as the environmental effects on climate from the proposed Project.

The GHG impact analysis and climate change sensitivity analysis presented in this chapter provide two related analyses of the proposed Project. The greenhouse gas emissions portion of this chapter is presented first, and focuses on the effect of the proposed Project's alternatives on climate change, including an evaluation of greenhouse gases produced as a result of implementation of the proposed Project alternatives. The impact analysis provides the analysis required by CEQA (*CEQA Guidelines* §15064.4) to determine whether the proposed Project would have an adverse impact on the environment by emitting GHGs that could contribute to further global climate change.

The regulatory setting for GHG emissions and climate change is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

The existing and potential changes in water operations, power generation, and pumping in the Extended and Secondary study areas as a result of construction, operation, and maintenance of the proposed Project were evaluated, and the associated changes in GHG emissions were estimated. GHG emissions are not directly linked to specific impacts at geographic locations; instead, emissions from individual sources around the globe, including those potential sources of emissions described as part of the proposed Project, result in contributions to global GHG concentrations in the atmosphere, which may result in impacts that manifest themselves at global, regional, and local scales. As a result, this chapter is not separated into analyses of the Extended, Secondary, and Primary study areas. Instead, GHG emissions were analyzed for the proposed Project in terms of short-term construction emissions and long-term operational and maintenance emissions. GHG emissions from implementation of the proposed Project were analyzed as a cumulative environmental impact; therefore, GHG emissions from the proposed Project have been placed in the context of the statewide, national, and global GHG emissions and global atmospheric concentrations of GHGs.

GHG emissions from the proposed Project are not tied directly to potential impacts of climate change. Instead, GHG emissions from the proposed Project and potential impacts of climate change on the proposed Project are handled separately.

The climate change sensitivity analysis provides an analysis of how projected future climate change could impact the performance and environmental impacts of the proposed Project with a focus on water resources and related systems. The climate change sensitivity analysis provides a discussion of the potential effects of climate change on the proposed Project alternatives, including the No Project/No Action Alternative and Alternatives A, B, and C.

25.2 Background

Climate is the average of conditions (based on averages of 20 to 30 years) of temperature, seasonality, precipitation, humidity, and types and frequency of extreme events, such as tornadoes or heat waves. For example, the climate of California's Central Valley is a Mediterranean climate, which is hot and dry during the summer and cool and damp in winter, with the majority of precipitation falling as rain in the winter months and tornadoes rarely occurring. Climate is unique to a particular location and changes on timescales of decades to centuries or millennia.

Climate change is a term used to describe large-scale shifts in existing (i.e., historically observed) patterns in Earth's climate system. Although the climate can and has changed in the past in response to natural drivers, recent climate change has been unequivocally linked to increasing concentrations of greenhouse gases (GHGs) in Earth's lower atmosphere and the rapid timescale on which these gases have accumulated (IPCC, 2007a). The major causes of this rapid loading of GHGs into the atmosphere include the burning of fossil fuels since the industrial revolution, agricultural practices, increases in livestock grazing, and deforestation.

The phenomenon known as the *greenhouse effect* keeps the atmosphere near the Earth's surface warm enough for the successful habitation of humans and other life forms. GHGs present in the Earth's lower atmosphere play a critical role in maintaining the Earth's temperature; GHGs trap some of the long-wave infrared radiation emitted from the Earth's surface that would otherwise escape to space (Figure 25-1). The Kyoto Protocol, which was adopted in December 1997, addresses the following six GHGs: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), perfluorinated carbons (PFCs), sulfur hexafluoride (SF_6), and hydrofluorocarbons (HFCs). CEQA Guidelines §15364.5 also identifies these six gases as GHGs.

Higher concentrations of heat-trapping GHGs in the atmosphere result in increasing global surface temperatures, a phenomenon commonly referred to as *global warming*. Higher global surface temperatures, in turn, result in changes to Earth's climate system, including, but not limited to: the jet stream; El Niño; the Indian monsoon; ocean temperature and acidity; the extent of alpine glaciers, sea ice and polar ice sheets; the extent of deserts; atmospheric water content; and the extent and health of boreal and tropical forests (IPCC, 2007a, 2007b).

The Intergovernmental Panel on Climate Change (IPCC) has been established by the World Meteorological Organization and United Nations Environment Programme to assess scientific, technical, and socioeconomic information relevant to the understanding of climate change, its potential impacts, and options for adaptation and mitigation. The IPCC is an organization of more than 800 scientists from around the world. It regularly publishes summary documents that analyze and consolidate all recent peer-reviewed scientific literature, providing a consensus of the state of the science. Thus, IPCC is viewed by governments, policymakers, and scientists as the leading international body on the science of climate change, and its summaries are considered to be the best available science. IPCC documents address change at the global and super-regional scales. Both IPCC studies and California-specific studies (e.g., California Air Resources Board [ARB], California Energy Commission [CEC], DWR, California Natural Resources Agency [CNRA], and U.S. Bureau of Reclamation [Reclamation]) that are based on IPCC data are referenced throughout this chapter.

The IPCC estimates that the average global temperature rise between the years 2000 and 2100 could range from 1.1°C, with no increase in GHG emissions above year 2000 levels, to 6.4°C, with substantial increase in GHG emissions (IPCC, 2007a). Large increases in global temperatures could have substantial adverse effects on the natural and human environments on the planet and in California.

25.3 Regulatory Setting

GHGs are evaluated and regulated at the federal, State, and local levels. In addition, climate change vulnerability assessment and adaptation and resiliency planning are encouraged (although not regulated or required) at the federal, State, and local levels. Provided below is a list of the applicable climate change and GHG laws, policies, guidance, and plans. These are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this DEIR/EIS.

25.3.1 Federal Plans, Policies, and Regulations

- Draft National Environmental Policy Act Guidance on Consideration of the Effects of Climate Change and Greenhouse Gas Emissions (February 2010)
- Greenhouse Gas Reporting (Rule, January 2010)
- Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act (January 2010)

25.3.2 State Plans, Policies, and Regulations

- California Environmental Quality Act Guidelines
- Senate Bill 97 (2007)
- Governor’s Office of Planning and Research Technical Advisory on CEQA and Climate Change (2008)
- Executive Order S-3-05 (2005)
- California Renewables Portfolio Standard Program
- Assembly Bill 32 (California Global Warming Solutions Act of 2006)
- Senate Bill 1368
- Executive Order S-01-07 (2007)
- Executive Order S-13-08 (2008)
- Senate Bill 1771
- Climate Change Scoping Plan (2008)
- California Climate Change Adaptation Strategy (2009)
- California Cap and Trade Program
- Climate Action Plan Phase 1: Greenhouse Gas Emissions Reduction Plan
- California Air Pollution Control Officers Association Guidance Documents on Addressing GHGs under CEQA (2008) and Quantifying GHG Mitigation Measures (2010)

25.3.3 Regional and Local Plans, Policies, and Regulations

- Regional and Local Air District Programs
- County General Plans

All of the above laws, policies, guidance, and plans show California’s commitment to reducing GHG emissions and climate change planning and will have important influences on current and future development patterns, behavior, and investments. With respect to the regulation of GHG emissions, California law is already more stringent than federal law, therefore, California entities that meet State level requirements will also comply with federal regulations at this time. California’s key GHG regulation, AB 32, and the regulations and GHG emissions reduction programs that are in place to achieve the goals of AB 32, provide the regulatory framework under which all current and future projects will proceed and the GHG emissions restrictions with which projects will have to comply.

25.4 Greenhouse Gas Emissions

25.4.1 Environmental Setting/Affected Environment

25.4.1.1 Global GHG Emissions

Global GHG emissions due to human activities have increased since pre-industrial times, with an increase of 70 percent occurring between 1970 and 2004. Carbon dioxide (CO_2) is the most important anthropogenic GHG. Its annual emissions grew by approximately 80 percent between 1970 and 2004. An estimated 49 billion metric tons of CO_2 equivalent (CO_2e) per year were emitted by global anthropogenic sources in 2004 (IPCC, 2007a).

Global atmospheric concentrations of CO_2, CH_4, and N_2O have increased markedly as a result of human activities since 1750, and now far exceed pre-industrial values determined from ice cores spanning many thousands of years. Atmospheric concentrations of CO_2 (379 parts per million) and CH_4 (1,774 parts per billion) in 2005 exceed by far the natural range over the last 650,000 years. Global increases in CO_2 concentrations are due primarily to fossil fuel use, with land use change providing another significant, but smaller, contribution (IPCC, 2007a).

25.4.1.2 Principal GHG Emissions that Would be Generated by the Proposed Project

The primary GHGs that would be generated by the proposed Project are CO_2, CH_4, N_2O, and SF_6. Each of these gases is discussed below. Note that PFCs and HFCs are not discussed because these gases are primarily generated by industrial processes, which are not anticipated as part of the proposed Project.

To simplify reporting and analysis, methods have been set forth to describe emissions of GHGs in terms of a single gas. The most commonly accepted method to compare GHG emissions is the global warming potential (GWP) methodology defined in the IPCC reference documents (IPCC, 1996, 2001). The IPCC defines the GWP of various GHG emissions on a normalized scale that recasts all GHG emissions in terms of CO_2e, which compares the gas in question to that of the same mass of CO_2 (CO_2 has a global warming potential of one by definition).

Table 25-1 lists the global warming potential of CO_2, CH_4, N_2O, and SF_6; their lifetimes; and abundances in the atmosphere in parts per trillion.

Table 25-1
Lifetimes and Global Warming Potential of Several Greenhouse Gases

Greenhouse Gas	Global Warming Potential (100 Years)	Lifetime (Years)	1998 Atmospheric Abundance (ppt)*
Carbon dioxide (CO_2)	1	50 to 200	365,000,000
Methane (CH_4)	21	9 to 15	1,745
Nitrous oxide (N_2O)	310	120	314
Sulfur hexafluoride (SF_6)	23,900	5.6	3,200

*ppt = parts per trillion; 1 ppt is a mixing ratio unit indicating the concentration of a pollutant in ppt by volume.
Source: IPCC, 1996, 2001.

Carbon Dioxide

CO_2 is the most important anthropogenic GHG and accounts for more than 75 percent of all GHG emissions caused by humans. Its atmospheric lifetime of 50 to 200 years ensures that atmospheric concentrations of CO_2 will remain elevated for decades even after mitigation efforts to reduce

GHG concentrations are promulgated (IPCC, 2007a). The primary sources of anthropogenic CO_2 in the atmosphere include the burning of fossil fuels (including motor vehicles), gas flaring, cement production, and land use changes (including deforestation).

Methane

CH_4, the main component of natural gas, is the second most abundant GHG and has a GWP of 21 (IPCC, 1996). Sources of anthropogenic emissions of CH_4 include growing rice, raising cattle, combusting natural gas, landfill off-gassing, and mining coal (NOAA, 2005). Atmospheric CH_4 has increased from a pre-industrial concentration of 715 parts per billion to 1,774 parts per billion in 2005 (IPCC, 2007b).

Nitrous Oxide

N_2O is a powerful GHG, with a GWP of 310 (IPCC, 1996). Anthropogenic sources of N_2O include agricultural processes (e.g., fertilizer application), nylon production, fuel-fired power plants, nitric acid production, and vehicle emissions. N_2O also is used in rocket engines, race cars, and as an aerosol spray propellant. In the United States, more than 70 percent of N_2O emissions are related to agricultural soil management practices, particularly fertilizer application. N_2O concentrations in the atmosphere have increased 18 percent from pre-industrial levels of 270 parts per billion to 319 parts per billion in 2005 (IPCC, 2007b).

Sulfur Hexafluoride

SF_6, a human-made chemical, is used as an electrical insulating fluid for power distribution equipment, in the magnesium industry, in semiconductor manufacturing, and also as a tracer chemical for the study of oceanic and atmospheric processes (USEPA, 2013). In 2005, atmospheric concentrations of SF_6 were 5.6 parts per billion and steadily increasing in the atmosphere. SF_6 is the most powerful of all GHGs listed in IPCC studies, with a GWP of 23,900 (IPCC, 1996).

25.4.1.3 GHG Emissions Inventories

A GHG inventory is a quantification of all GHG emissions and sinks within a selected physical and/or economic boundary. GHG inventories can be performed on a large scale (i.e., for global and national entities) or on a small scale (i.e., for a particular building or person). Although many processes are difficult to evaluate, several agencies have developed tools to quantify emissions from certain sources.

Table 25-2 outlines the most recent global, national, and Statewide GHG inventories to provide context of the magnitude of potential proposed Project-related emissions.

Table 25-2
Global, National, and Statewide Annual GHG Emissions Inventories

Emissions Inventory	CO_2e (Metric Tons)
2004 IPCC Global GHG Emissions Inventory	49,000,000,000
2011 USEPA National GHG Emissions Inventory	5,797,300,000
2011 ARB State GHG Emissions Inventory	448,110,000

Notes:

ARB = California Air Resources Board
CO_2e = carbon dioxide equivalent
GHG = greenhouse gas
IPCC = Intergovernmental Panel on Climate Change
USEPA = U.S. Environmental Protection Agency

Source: IPCC, 2007a; USEPA, 2013; ARB, 2013.

25.4.2 Environmental Impacts/Environmental Consequences

25.4.2.1 Proposed Project Greenhouse Gas Emissions Analysis

Evaluation Criteria and Thresholds of Significance

Significance criteria represent the environmental thresholds that were used to identify whether an impact would be significant. *CEQA Guidelines* §15064.4 indicates:

(a) The determination of the significance of greenhouse gas emissions calls for a careful judgment by the Lead Agency consistent with the provisions in §15064. A Lead Agency should make a good faith effort, based to the extent possible on scientific and factual data, to describe, calculate, or estimate the amount of greenhouse gas emissions resulting from a project. A Lead Agency shall have discretion to determine, in the context of a particular project, whether to:

  (1) Use a model or methodology to quantify greenhouse gas emissions resulting from a project, and which model or methodology to use. The Lead Agency has discretion to select the model or methodology it considers most appropriate provided it supports its decision with substantial evidence. The Lead Agency should explain the limitations of the particular model or methodology selected for use; and/or

  (2) Rely on a qualitative analysis or performance-based standards.

(b) A Lead Agency should consider the following factors, among others, when assessing the significance of impacts from greenhouse gas emissions on the environment:

  (1) The extent to which the project may increase or reduce greenhouse gas emissions as compared to the existing environmental setting.

  (2) Whether the project emissions exceed a threshold of significance that the Lead Agency determines applies to the project.

  (3) The extent to which the project complies with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of greenhouse gas emissions. Such requirements must be adopted by the relevant public agency through a public review process and must reduce or mitigate the project's incremental contribution of greenhouse gas emissions. If there is substantial evidence that the possible effects of a particular project are still cumulatively considerable notwithstanding compliance with the adopted regulations or requirements, an EIR must be prepared for the project.

For the purposes of this analysis, an alternative would result in a significant impact if it would result in the following:

- Generation of Cumulative GHG Emissions

Neither the CEQA nor NEPA Lead Agencies have established quantitative significance thresholds for GHG emissions; instead the proposed Project is evaluated on a case-by-case basis using up-to-date calculation and analysis methods. By enacting the Global Warming Solutions Act of 2006 (AB 32), the State Legislature has established statewide GHG emissions reduction targets. Further, the Legislature has determined that GHG emissions, as they relate to global climate change, are a source of adverse environmental impacts in California and should be addressed pursuant to CEQA. AB 32 did not amend CEQA, although the legislation identifies the myriad environmental problems in California caused by global warming (Health and Safety Code, Section 38501(a)). SB 97, in contrast, added explicit requirements that CEQA analysis address the impacts of GHG emissions (PRC Sections 21083.05 and 21097).

With respect to significance thresholds established for GHG emissions, no State or federal agency with jurisdiction over the NEPA or CEQA Lead Agencies has established a significance threshold that would apply to the proposed Project. Many regional air pollution control districts have established GHG emissions significance thresholds for CEQA purposes. However, these thresholds apply to only stationary sources, such as power plants or factories or to residential or commercial developments. Because the proposed Project is neither a stationary source, nor a residential or commercial development, these thresholds of significance would not apply.

Scientific studies (as best represented by the IPCC's periodic reports) demonstrate that climate change is already occurring due to past GHG emissions. Evidence suggests that global emissions must be reduced below current levels to avoid the most severe climate change impacts. Given the seriousness of climate change and the regional significance of the proposed Project, the proposed Project Lead Agencies have determined that, for the purposes of the proposed Project, any substantial increase in GHG emissions above net zero (0) would result in a significant impact. A net zero threshold represents the most conservative assessment of emissions. Proposed Project Lead Agencies have selected a net zero threshold to be cautious and to avoid under-representing potential impacts.

In accordance with scientific consensus regarding the cumulative nature of GHGs, the analysis provides a cumulative evaluation of GHG emissions. Unlike traditional cumulative impact assessments, this analysis is still project-specific in that it evaluates only direct emissions generated by the proposed Project. Because of the global nature of GHG emissions and impacts that result from those emissions, proposed Project emissions are placed into the context of current *global* atmospheric GHG concentrations and projections of future concentrations. The analysis does not specifically analyze emissions from past, present, and reasonably foreseeable projects in the Primary, Secondary, and Extended study areas.

Impact Assessment Assumptions and Methodology

Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts from greenhouse gas emissions:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., Glenn-Colusa Irrigation District [GCID] Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect

effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the proposed Delevan Pipeline Intake/Discharge facilities would be required.
- Construction activities are anticipated to occur between the hours of 6:00 a.m. and 7:00 p.m. Monday through Friday. Nighttime and weekend construction are not planned, but may occur on an as-needed basis.

Methodology

The proposed Project was evaluated to determine how construction and operations of proposed Project facilities would generate GHG emissions. GHG emissions associated with the proposed Project could contribute to the cumulatively considerable impact of global climate change by adding GHGs to the atmosphere. The discussion below reviews potential generation of GHG emissions for each of the proposed Project's action alternatives. For the purpose of this analysis, only changes in GHG emissions caused by construction and operation of the proposed Project are discussed. The GHG emissions estimated for the proposed Project's Alternatives A, B, and C were compared to Existing Conditions (for CEQA) and to future conditions associated with the No Project/No Action Alternative (for NEPA). Construction-related GHG emissions would result primarily from fuel combustion in construction equipment, trucks, and worker vehicles. To support calculations of GHG emissions, lists of the types and numbers of construction equipment and number of days required for construction of each proposed Project facility were developed by Project engineers, and assumptions were developed about hours of operation for each type of equipment (Barnes pers. comm., 2011).

Equipment-specific hours of use were multiplied by equipment-specific CO_2 emission factors to calculate total equipment emissions for construction of each proposed Project facility. Total CO_2 emissions for each proposed Project facility were estimated by summing the results of the equipment emissions.

For construction, emissions of other GHGs, such as CH_4 and N_2O, were not estimated, due to the lack of equipment-specific emission factors for GHGs other than CO_2. Emissions of CH_4 and N_2O from fuel combustion would be much lower than emissions of CO_2, contributing in the range of two to four percent of total CO_2 emissions. Therefore, it was assumed that CH_4 and N_2O emissions would not substantially contribute to the construction-related GHG emissions.

To estimate GHG emissions from maintenance activities, proposed Project facilities were grouped to reflect activities, personnel, and equipment that might be shared to optimize efficiency. Emissions were estimated for maintenance of the following proposed Project facilities:

- Pumping Plants, Intake and Outlet Facilities, Pumping/Generating Plants
- Reservoirs, Recreation Facilities, Dams, Roads, and Bridges
- Electrical Switchyards and Transmission Lines
- Tunnels, Pipelines, and Canals

DWR has developed estimates of the numbers and types of equipment, vehicles, and personnel needed for maintenance of the facilities (DWR, 2011). Equipment and personnel requirements for maintenance of facilities were assumed to be the same for proposed Project's Alternatives A, B, and C. Maintenance activities include both routine activities and major inspections. Routine activities would occur on a daily basis throughout the year, whereas major inspections would occur annually. Exhaust emissions from equipment and vehicles were calculated using the EMFAC2011 (ARB, 2011) and CalEEMod (CAPCOA, 2013) models, respectively.

Estimating emissions from operation of the alternatives is complex and involves assumptions about the amount and timing of pumping and generating activities, the fuel source used to power pumping operations (fossil sources or renewable sources), and changes in the operation of existing State Water Project (SWP) and Central Valley Project (CVP) facilities as operations of the alternatives are integrated into the existing water delivery system and the California electrical distribution and balancing system. As discussed in Chapter 31 Power Production and Energy and summarized below, the proposed Project's action alternatives would consume energy during the pumping phase of operations, would generate electricity during the release phase of operations, and would be able to provide resource shifting and renewable integration services during pumpback operations. In addition, the seasonal operations of the proposed Project's action alternatives would make them highly conducive to operations during the pumping and generating phases that would likely result in reductions in GHG emissions.

Emissions from operation of the proposed Project's action alternatives were estimated by post processing the CALSIM II modeling runs used to analyze the impacts of the proposed Project's action alternatives throughout this document. CALSIM II provides estimates of the amount of water that would be pumped and released at each of the facilities during each month of the year for various water year types and hydrologic conditions. The pumping and releasing of water can be converted to electricity use and electricity generation by applying assumptions about efficiency of each pumping or generating plant. Chapter 31 Power Production and Energy describes assumptions of the proposed Project's power and energy operations, including pumpback operations and renewable integration services.

Operation of Proposed Project Alternatives

Although each of the proposed Project alternatives has different features and would operate slightly differently, all alternatives share some commonalities among their operations that are important for analysis of GHG emissions.

As discussed in greater detail in Chapter 31 Power Production and Energy, during winter and spring, the proposed Project alternatives would typically function in the pumping phase when excess water flows down the Sacramento River. This is the time of year when hydroelectric generation and wind generation increase and demand for electricity decreases, thus much of the increased electricity load required to pump water out of the Sacramento River and into the reservoirs could be served by renewable electricity sources. Further, the largest electricity load from the proposed Project alternatives comes from lifting water from the proposed Holthouse Reservoir to the proposed Sites Reservoir. The proposed Holthouse Reservoir has been sized to accommodate a large amount of storage (up to six days of fill operations) allowing pumping operations to move water from the proposed Holthouse Reservoir to the proposed Sites Reservoir to occur at night or during other non-peak electricity demand periods or when renewable power is available.

During the summer and fall, the proposed Project alternatives would typically function in the generating phase, as water is released from the reservoirs to meet water supply and water quality objectives. This is the time of year that electricity demand increases to satisfy summer cooling requirements. The release of water from the proposed Sites Reservoir to the proposed Holthouse Reservoir could be timed to meet peak daytime demand for electricity, thereby displacing the need to operate high emissions power plants.

During times of the year when the proposed Project is not functioning in the pumping or generating phase, it could be operated to perform daily pumpback operations. Daily pumpback operations would allow the proposed Project to use power from various high efficiency sources, including renewables, to pump water from the proposed Holthouse Reservoir to the proposed Sites Reservoir typically during the nights and other low demand periods. Then, during higher demand periods, the water could be released back from the proposed Sites Reservoir to the proposed Holthouse Reservoir to generate electricity. Although this operation would actually consume more electricity than is generated, the net result would typically be reduced GHG emissions because electricity used to pump the water would be very low or zero GHG emissions sources, such as ultra efficient baseload gas fired power plants, nuclear, or renewable, and the generated electricity would displace the least efficient peaking power plants that emit higher levels of GHGs.

In addition to operation of the proposed Project's action alternatives' facilities, the implementation of any of the action alternatives would also result in changes to operations of existing CVP and SWP facilities including:

- Shasta Lake
- San Luis Reservoir
- Folsom Lake
- Trinity Lake
- Lake Oroville
- Banks Pumping Plant
- Jones Pumping Plant

Changes to operations of these facilities as a result of proposed Project operations are described in Chapter 6 Surface Water Resources.

Pumping at Banks and Jones pumping plants would likely increase because of increased water supply reliability created by the proposed Project's alternatives. Thus, additional electricity would be needed to operate the facilities to accommodate integration of the proposed Project facilities and operations.

The combined results of all changes in operation of SWP and CVP facilities are described below for each of the proposed Project's action alternatives.

Appendix 24A provides detailed equipment and emissions tables, emissions factors, and GHG emission calculations for proposed Project construction, operations, and maintenance activities for each of the proposed Project's action alternatives.

GHG Emissions Reduction Project Commitments

Consistent with the requirements of the DWR Greenhouse Gas Emissions Reduction Plan (GGERP) (DWR, 2012a), all construction activities undertaken for the proposed Project would implement DWR's Construction Best Management Practices (BMPs). DWR's Construction BMPs are included in Appendix 25A.

In addition, as described in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives, the proposed Project would: (1) obtain at least 20 percent of the power used for pumping water from the Sacramento River and the proposed Holthouse Reservoir into the proposed Sites Reservoir from wind and/or solar energy, and (2) use at least 20 percent of the proposed Project's generated power and/or served pump load to provide integration services needed to firm up highly variable wind and/or solar generation.

Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

Impacts Associated with the No Project/No Action Alternative

Impact GHG-1: Generation of Cumulative GHG Emissions

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and if these analyses were completed in the past three years, their potential for GHG emissions impacts has been addressed in those environmental documents.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to cause increases in GHG emissions from human activities. It is also expected that improved emissions controls and lower-emitting technologies would be developed in the future to reduce these emissions, consistent with State goals.

If the No Project/No Action Alternative is implemented, no proposed Project-related facilities would be constructed or operated. Therefore, this alternative would have no direct Project-related construction- or operations-related GHG emissions, when compared to Existing Conditions. In addition, no operations and maintenance of proposed Project-related facilities would occur if the No Project/No Action Alternative is implemented, other than the ongoing systemwide generation and use of electricity by the CVP and SWP facilities. Therefore, **there would not be a substantial adverse effect** from GHG emissions, when compared to Existing Conditions.

Impacts Associated with Alternative A

Impact GHG-1: Generation of Cumulative GHG Emissions

Construction, Operation, and Maintenance of the Proposed Project

Project Construction Emissions

Construction-related GHG emissions would result primarily from fuel combustion in construction equipment, trucks, and worker vehicles, from the production of concrete used for construction, and from the generation of electricity used during construction. Total estimated GHG emissions resulting from construction of Alternative A are summarized in Table 25-3.

Table 25-3
Estimated Total GHG Emissions from Construction of Alternative A (Metric Tons CO_2e)*

Emissions from Mobile Construction Equipment*	Emissions From Concrete Production	Emissions from Construction Electricity Usage/Tunnel Boring Machine	Total Construction-Related Emissions
184,206	47,017	4,297	235,520

*Calculated emissions based on Table 24A. A-5 in Appendix 24A.

The GHG emissions shown in Table 25-3 are the estimated total cumulative CO_2e emissions that would occur over the nine-year construction period of Alternative A. Within the nine-year construction period, annual GHG emissions would fluctuate. Because GHG emissions are well dispersed in the atmosphere and persist for long periods of time (hundreds or thousands of years), estimates of emissions on a yearly basis are less meaningful than the total amount of emissions released during the discrete construction period. After construction is complete, emissions from these sources would cease.

Project Operation and Maintenance Emissions

Once construction is complete, the proposed Alternative A facilities would begin to operate. Unlike construction emissions, operations emissions would occur over a long period of time, i.e., the useful life of the proposed Project. Operation of the proposed Alternative A facilities would involve both the use and generation of electricity, as described in Chapter 31 Power Production and Energy. The amount of GHG emissions from operation of Alternative A would depend on the specific sources of energy used for pumping water into the proposed reservoirs and other operational parameters. Further, electricity needed to pump water into the reservoirs and electricity generated by releasing water from the reservoirs would vary annually and seasonally, depending on hydrologic conditions.

As shown in Table 25-4, operation of the proposed Alternative A facilities (without consideration of pumpback operations) would result in an estimated long-term average net generation of -90 GWh/year (i.e., to operate the Alternative A facilities, all of the energy generated at the facilities would be needed and an additional 90 GWh of energy would be needed from other sources).

Table 25-4
Estimated Electricity Generation and Use from Operation of Alternative A Facilities without Consideration of Pumpback Operations (GWh/Year)[a]

		Existing Conditions	No Project/No Action Alternative	Alternative A	Alternative A Minus Existing Conditions	Alternative A Minus No Project/No Action Alternative
Project Facilities[b]						
Energy Generation	Long-Term[c]	0	0	126	126	126
	Dry and Critical[d]	0	0	129	129	129
Pumping Energy Use	Long-Term	13	13	229	217	216

[a]Results are estimated using the NODOS Power model using data from the CALSIM II model.
[b]Other related Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities are included; this results in non-zero values for Existing Conditions and the No Project/No Action Alternative.
[c]Long-Term is the average quantity for the calendar years 1922 to 2002.
[d]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Note:
GWH/year = gigawatt hours per year

Although operation of the proposed Alternative A facilities would result in a long-term average net use of electricity, the way the facilities would be operated and integrated into the California electricity market would actually result in annual reductions in GHG emissions. As discussed in Chapter 31 Power

Production and Energy, water pumping would occur to the extent possible during times when renewable (zero emissions) electricity is available, and releases of water, which generate electricity, would be done to the extent possible when electricity is in high demand. Therefore, electricity generated at the proposed Alternative A facilities – with no emission of GHGs – would offset some of the most inefficient and highest emitting generating resources in the electricity market.

In addition to the analysis provided above, the proposed Alternative A facilities would be configured to allow substantial pumpback operations; i.e., pumping water from the proposed Holthouse Reservoir into the proposed Sites Reservoir during nighttime hours (when excess clean/cheap electricity is available) and then releasing the water back from the proposed Sites Reservoir to the proposed Holthouse during peak demand hours during the day (when the electricity generated can displace high emitting/high cost sources).

Alternative A would also be able to provide critical renewable integration services to the California grid that would facilitate additional renewable energy generation and further reduce GHG emissions. Solar and wind power are intermittent electricity sources; the electricity generated at a solar or wind power station fluctuates unpredictably as clouds obscure the sun or wind speeds decrease. To effectively integrate solar and wind power into an electricity grid, there must be appropriate backup power supplies to ensure that fluctuations in solar or wind generation are smoothed out so that sufficient supply exists in the grid to meet demand. Alternative A could provide this renewable integration service. Both in the pumping and generating phase, Alternative A would have the flexibility to modify its operations to balance generation from intermittent renewable electricity supplies. In the pumping phase, Alternative A would have ample storage at the proposed Holthouse Reservoir and variable speed pumps at the proposed Sites Pumping Plant that could quickly ramp up or down so that pumping from the proposed Holthouse Reservoir to the proposed Sites Reservoir could be slowed or delayed for up to several days to coincide with available renewable electricity. In the generation phase, the proposed Sites Pumping Plant's variable speed turbines could quickly ramp up or ramp down to provide additional generation when renewable electricity decreases or additional pumping load when renewable generation increases.

Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives describes the commitment of the proposed Project to obtain at least 20 percent of the power used for pumping water from the Sacramento River and the proposed Holthouse Reservoir into the proposed Sites Reservoir from wind and/or solar energy, and to use at least 20 percent of the proposed Project's generated power and/or served pump load to provide integration services needed to firm up highly variable wind and/or solar generation. At this level of renewables use and renewable integration service, operational analyses indicate that implementation of Alternative A would result in GHG emissions reductions of approximately 22,200 metric tons of CO_2e per year (Appendix 25A). This represents a very conservative estimate of the level of renewables that would be used to operate Alternative A and the level of renewable integration service that Alternative A could provide. If Alternative A were operated with 80 percent renewable power for pumping and provided 20 percent of pumping load for integration services, and 100 percent of generated electricity was used for integration services, operational analyses indicate that Alternative A would result in GHG emissions reductions of more than 138,000 metric tons of CO_2e per year. Although operations would vary each year, all of these features would contribute to reducing overall GHG emissions from Alternative A and from the larger California electrical power grid. These two data points represent the likely potential range of GHG emissions reductions that would result from operation of Alternative A.

Maintenance of Alternative A facilities would include regular inspections, land management activities, sediment removal from forebays, and servicing of pumping plants. Estimated emissions from maintenance activities are detailed in Appendix 24A and would total approximately 1,500 metric tons of CO_2e per year.

As discussed in Section 25.4.1, any increase in emissions above net zero associated with Alternative A would be adverse. Construction of Alternative A would generate approximately 236,000 metric tons of CO_2e emissions over the nine-year construction period. Once operations begin, maintenance activities would increase GHG emissions by 1,500 metric tons of CO_2e; however, operations of Alternative A would be expected to reduce annual GHG emissions by between 22,000 and 138,000 metric tons of CO_2e per year (Appendix 25A). Thus, it would take between two and 14 years of operation to completely offset the GHG emissions released during construction. After that time period, operation of Alternative A would contribute to lowering California's GHG emissions and would help California achieve its AB 32 GHG emissions reduction goals.

Because increases in GHG emissions associated with construction of Alternative A would be more than offset by reductions in GHG emissions from operation, there would be no long-term increase over the net-zero threshold. Over the life of the proposed Project, Alternative A would be likely to substantially reduce GHG emissions. Therefore, implementation of Alternative A would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Existing State Water Project Facilities Operational Emissions

Operation of Alternative A would result in modifications to the operations of existing SWP facilities, including Lake Oroville and the Thermalito Complex, and pumping and generating facilities along the California Aqueduct.

Table 25-5 shows that net generation (the amount of energy generated at hydroelectric generating facilities minus the amount of energy used at pumping facilities) would be negative, i.e., Alternative A operation would result in a net increase in the amount of energy needed annually to operate the SWP.

Alternative A operation would add approximately 429 GWh of additional net electricity demand over Existing Conditions on a long-term annual basis and 249 GWh of additional net electricity demand over the No Project/No Action Alternative on a long-term annual basis.

Additional energy needed to operate existing SWP facilities would be purchased by DWR as part of its ongoing energy purchasing and scheduling responsibilities for the SWP. Thus, analysis of the GHG impact of this additional electricity will be analyzed pursuant to the DWR GGERP framework (DWR, 2012a).

Operation of Alternative A would result in additional SWP energy demands in excess of 15 GWh/year; therefore, the GGERP procedure has been followed for projects that would increase SWP energy demand by 15 GWh/year or more.

In the GGERP, DWR developed estimates of historical, current, and future GHG emissions. Figure 25-2 shows those emissions as they were projected in the GGERP and how those emissions projections would change with the additional electricity demands needed to operate the SWP with the addition of Alternative A. As shown in Figure 25-2, in 2022 (the year that Alternative A is projected to go online), DWR total emissions would increase from approximately 977,000 metric tons of CO_2e to nearly 1.16 million metric tons of CO_2e. This elevated level would be approximately 150,000 metric tons of

Table 25-5
Electricity Generation and Use from Expected Changes in Operation at Existing State Water Project Facilities as a Result of Implementation of Alternative A (GWh/Year)[a]

SWP = State Water Project

CO_2e below DWR's designated GHG emissions reduction trajectory red line, which is the linear interpolation between DWR's 2020 GHG emissions goal and DWR's 2050 GHG emissions goal. The projection indicates DWR has already included sufficient excess GHG emissions reductions into its future activities, so that with the addition of 429 GWh of demand associated with Alternative A implementation, DWR would remain below its emissions reduction trajectory and would maintain its downward trajectory toward achieving its GHG emissions reduction goals. The calculations associated with projected emissions are included in Appendix 25A.

Given the scale of additional emissions that Alternative A would add to DWR's total GHG emissions, DWR finds that no additional actions or commitments would be required to implement Alternative A.

As shown in the analysis above and consistent with the analysis contained in the GGERP and associated Initial Study and Negative Declaration for the GGERP, Alternative A would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the GGERP and would not conflict with any of the specific action GHG emissions reduction measures set forth in the GGERP. Consistent with the programmatic analysis framework set up in the GGERP, Alternative A would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Existing Central Valley Project Facilities Operational Emissions

DWR's GGERP cannot be used to evaluate environmental impacts associated with increased CVP pumping because emissions associated with CVP are not under DWR's control and are not included in the GGERP. Accordingly, GHG emissions resulting from increased CVP energy use are evaluated separately from GHG emissions generated as a result of SWP energy use.

Table 25-6 shows that under Existing Conditions and No Project/No Action Alternative, the CVP would generate approximately 3,590 GWh of excess hydroelectric power. This electricity would be sold into the California electricity market or directly to CVP power users.

Implementation of Alternative A would result in an increase in CVP electricity use of 25 to 28 GWh/year. This additional demand would be served by energy generated at CVP hydroelectric facilities that emit no GHGs, and therefore, would result in no GHG emissions.

With implementation of Alternative A, operation of the CVP would continue to yield a large net generation of clean GHG-emissions-free hydroelectric energy. However, the small increase in electricity usage to operate the CVP with Alternative A would result in a corresponding reduction in the supply of GHG-emissions-free electricity available to sell to California electricity users. This reduction in hydroelectric energy available for sale could result in a potential indirect effect of Alternative A, as electricity users acquire substitute electricity supplies that may result in GHG emissions (although additional conservation is also a possible outcome as well).

Table 25-6
Electricity Generation and Use from Expected Changes in Operation at Existing Central Valley Project Facilities as a Result of Implementation of Alternative A (GWh/Year)[a]

[c]Long-Term is the average quantity for the calendar years 1922 to 2002.
[d]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Notes:
CVP = Central Valley Project
GWh/year = gigawatt hours per year

It is unknown what type of power source (e.g., renewable, natural gas) would be substituted for CVP electricity or if some of the lost power would be replaced by higher efficiency power. Given State mandates for renewable energy and incentives for energy efficiency, it is possible that a considerable amount of this power would be replaced by renewable resources or would cease to be needed as a result of higher efficiency. However, to ensure a conservative analysis, indirect emissions were quantified for the entire quantity of electricity (28 GWh) using the current and future statewide energy mix (adjusted to reflect the Renewable Portfolio Standard [RPS]). The RPS requires investor-owned utilities to meet a minimum requirement percentage of their power that is provided by renewable sources each year.

Substitution of 28 GWh of electricity with a mix of sources similar to the current statewide mix (emissions factor of 300.0 metric tons of CO_2e/GWh[1]) would result in emissions of 8,400 metric tons of

1 eGrid 2012 Version 1.0 (Year 2009 data) CAMX subregion emissions factor for total output emissions rate. http://www.epa.gov/cleanenergy/documents/egridzips/eGRID2012V1_0_year09_SummaryTables.pdf

CO_2e; however, under expected future conditions (after full implementation of the RPS), emissions would be 6,460 metric tons of CO_2e[2].

These emissions could contribute to a cumulatively considerable effect, and could, therefore, be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. However, these emissions would be caused by dozens of independent electricity users making decisions about different ways to substitute for the lost power. Power purchases by private entities or public utilities in the private marketplace necessitated by a reduction in available CVP-generated hydroelectric power are beyond the control of the Lead Agencies. Further, monitoring to determine the actual indirect change in emissions as a result of Alternative A implementation would not be feasible.

Open Water Surfaces and Tailraces Emissions

Implementation of Alternative A would include the construction of a surface storage reservoir and would result in the conversion of land that is currently used predominantly for cattle grazing to an open water surface. Research indicates that the surfaces of some reservoirs may be emitting or absorbing GHGs at material rates as a result of diffusion of CO_2 and CH_4 from the water into the atmosphere or from the atmosphere into the water. In addition, as stored water passes through hydroelectric turbines, GHGs that had been dissolved in the water come out of solution and are released to the atmosphere (also known as tailrace emissions). These types of emissions could represent sources or sinks of emissions from Alternative A; however, there are several factors that are not yet fully understood that make it difficult to adequately quantify potential emissions rates from the proposed Alternative A surface storage facilities.

These factors have been identified in both the absorption and emission of GHGs from reservoirs and other aquatic systems. In general, organic inputs, soil type and vegetation inundated, water quality parameters (dissolved oxygen, CO_2, and CH_4, temperature, pH), and duration of inundation have all been found to affect the GHG absorption and emissions characteristics of aquatic systems. In addition to these factors, natural aquatic systems have been shown to be the primary pathway in the global carbon cycle for transmitting carbon sequestered at the watershed level back to the atmosphere, into sediment deposition, or as dissolved carbon to the oceans (Cole et al., 2007). Thus, even if emissions from the surface and tailraces of reservoirs could be accurately quantified, it would not be clear whether the emissions of GHGs measured at the reservoir were different from the emissions that would have occurred within the watershed had the reservoir not been built. Because rivers are significant GHG emissions pathways, it is necessary to compare pre-reservoir watershed emissions with post-reservoir watershed emissions to determine the effect of the reservoir.

Recent studies have provided useful information about the potential scale of emissions from open water systems in temperate areas. Fifty-nine hydropower reservoirs, natural lakes, and rivers in the western and southwestern United States have been sampled to date (Soumis et al., 2004). This sampling shows that some reservoirs in California, Oregon, and Washington are GHG sinks and others have gross emissions equal to or less than natural lakes and rivers of the region (Tremblay et al., 2005). These studies suggest that the proposed Sites Reservoir, Holthouse Reservoir, and other open water facilities associated with Alternative A are unlikely to produce substantial GHG emissions.

[2] Assumes a total output emissions rate of 230 $mtCO_2e$/GWh based on shift in generation to 33 percent renewables for retail load.

Further, ARB has determined that, for the purpose of AB 32 Mandatory GHG Accounting, generation of hydroelectric power shall be excluded from the regulation[3]. The USEPA in its eGrid database (USEPA, 2012) of emissions factors for electricity generating facilities also associates a zero emissions factor to hydroelectric power generation. And finally, excluding biogenic sources of emissions from short-term changes in the form of carbon at stages of the active carbon cycle is a widely accepted practice in GHG accounting as indicated by the lack of protocols, guidance, and tools provided for accounting for these emissions in several important GHG protocols including: The GHG Protocol (www.ghgprotocol.org), The Climate Registry (www.theclimateregistry.org), and The American Carbon Registry (www.americancarbonregistry.org).

Based on these studies of emissions from open water systems and considering the zero emissions factor typically assigned to hydroelectric power generation, emissions associated with Alternative A's open water surfaces and tailraces would likely be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. DWR has not quantified emissions from the surface or tailraces of proposed Alternative A facilities because the quantification would be speculative, considering the lack of protocols, guidance, and tools to do so.

Impacts Associated with Alternative B

Impact GHG-1: Generation of Cumulative GHG Emissions

Construction, Operation, and Maintenance of the Proposed Project

Project Construction Emissions

Construction-related GHG emissions associated with Alternative B would result primarily from fuel combustion in construction equipment, trucks, and worker vehicles, and also from the production of concrete used for construction and from the generation of electricity used during construction. Total estimated GHG emissions resulting from construction of Alternative B are summarized in Table 25-7.

Table 25-7
Estimated Total GHG Emissions from Construction of Alternative B (Metric Tons CO_2e)*

Emissions from Mobile Construction Equipment*	Emissions From Concrete Production	Emissions from Construction Electricity Usage/Tunnel Boring Machine	Total Construction-Related Emissions
228,475	50,376	4,297	283,148

*Calculated emissions based on Table 24A. B-5 in Appendix 24A.

The emissions shown in Table 25-7 are the estimated total cumulative CO_2e emissions that would occur over the nine-year construction period of Alternative B. Within the nine-year construction period, annual emissions would fluctuate. Because GHG emissions are well dispersed in the atmosphere and persist for long periods of time (hundreds or thousands of years), estimates of emissions on a yearly basis are less meaningful than the total amount of emissions released during the discrete construction phase. After construction is complete, emissions from these sources would cease.

Once construction is complete, proposed Alternative B facilities would begin to operate. Unlike construction emissions, operations emissions would occur over a long period of time, i.e., the useful life of the proposed Project. Operation of the proposed Alternative B facilities would involve both the use and

[3] California Code of Regulations, Title 17, Division 3, Chapter 1, Subchapter 10, Article 2, Section 95100.

generation of electricity, as described in Chapter 31 Power Production and Energy. The amount of GHG emissions from operation of Alternative B would depend on the specific sources of energy used for pumping water into the reservoir and other operational parameters. Further, electricity needed to pump water into the reservoirs and electricity generated by releasing water from the reservoirs would vary annually and seasonally, depending on hydrologic conditions.

As shown in Table 25-8, operation of the proposed Alternative B facilities (without consideration of pumpback operations) would result in a long-term average net generation of -79 GWh/year (i.e., to operate the Alternative B facilities, all of the energy generated at the facilities would be needed and an additional 79 GWh of energy would be needed from other sources).

Table 25-8
Estimated Electricity Generation and Use from Operation of Alternative B Facilities without Consideration of Pumpback Operations (GWh/Year)[a]

		Existing Conditions	No Project/No Action Alternative	Alternative B	Alternative B minus Existing Conditions	Alternative B minus No Project/No Action Alternative
Project Facilities[b]						
Energy Generation	Long-Term[c]	0	0	104	104	104
	Dry and Critical[d]	0	0	100	100	100
Energy Use	Long-Term	13	13	195	183	182
	Dry and Critical	11	12	106	95	95
Net Generation	Long-Term	-13	-13	-91	-79	-78
	Dry and Critical	-11	-12	-6	5	6

[a]Results are estimated using the NODOS Power model using data from the CALSIM II model.
[b]Other related Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities are included; this results in non-zero values for Existing Condition and No Project/No Action Alternative. Tehama-Colusa Canal pumping facilities are also reported as CVP facilities in Table 25-10.
[c]Long-Term is the average quantity for the calendar years 1922 to 2002.
[d]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Note:
GWh/year = gigawatt hours per year

Although operation of the proposed Alternative B facilities would result in a long-term average net use of electricity, the way the facilities would be operated and integrated into the California electricity market would actually result in annual reductions in GHG emissions. As discussed in Chapter 31 Power Production and Energy, water pumping would occur to the extent possible during times when renewable (zero emissions) electricity is available, and releases of water, which generate electricity, would be done to the extent possible when electricity is in high demand. Therefore, electricity generated at the proposed Alternative B facilities – with no emission of GHGs – would offset some of the most inefficient and highest emitting generating resources in the electricity market.

In addition to the analysis provided above, the proposed Alternative B facilities would be configured to allow substantial pumpback operations; i.e., pumping water from the proposed Holthouse Reservoir into the proposed Sites Reservoir during nighttime hours (when excess clean/cheap electricity is available) and then releasing the water back from the proposed Sites Reservoir to the proposed Holthouse Reservoir during peak demand hours during the day (when the electricity generated can displace high emitting/high cost sources).

Alternative B would also be able to provide critical renewable integration services to the California grid that would facilitate additional renewable energy generation and further reduce GHG emissions. Solar and wind power are intermittent electricity sources; the electricity generated at a solar or wind power station fluctuates unpredictably as clouds obscure the sun or wind speeds decrease. To effectively integrate solar and wind power into an electricity grid, there must be appropriate backup power supplies to ensure that fluctuations in solar or wind generation are smoothed out so that sufficient supply exists in the grid to meet demand. Alternative B could provide this renewable integration service. Both in the pumping and generating phase, Alternative B would have the flexibility to modify its operations to balance generation from intermittent renewable electricity supplies. In the pumping phase, the Alternative B would have ample storage at the proposed Holthouse Reservoir and variable speed pumps at the proposed Sites Pumping Plant that could quickly ramp up or down so that pumping from the proposed Holthouse Reservoir to the proposed Sites Reservoir could be slowed or delayed for up to several days to coincide with available renewable electricity. In the generation phase, the proposed Sites Pumping Plant's variable speed turbines could quickly ramp up or ramp down to provide additional generation when renewable electricity decreases or additional pumping load when renewable generation increases.

Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives describes the proposed Project's commitment to obtain at least 20 percent of the power used for pumping water from the Sacramento River and the proposed Holthouse Reservoir into the proposed Sites Reservoir from wind and/or solar energy, and to use at least 20 percent of the proposed Project's generated power and/or served pump load to provide integration services needed to firm up highly variable wind and/or solar generation. At this level of renewables use and renewable integration service, operational analyses indicate that implementation of Alternative B would result in GHG emissions reductions of approximately 29,400 metric tons of CO_2e per year (Appendix 25A). This represents a very conservative estimate of the level of renewables that would be used to operate Alternative B and the level of renewable integration service that Alternative B could provide. If Alternative B were operated with 80 percent renewable power for pumping and provided 20 percent of pumping load for integration services, and 100 percent of generated electricity was used for integration services, operational analyses indicate that Alternative B would result in GHG emissions reductions of more than 135,600 metric tons of CO_2e per year. Although operations would vary each year, all of these features would contribute to reducing overall GHG emissions from Alternative B and from the larger California electrical power grid. These two data points represent the likely potential range of GHG emissions reductions that would result from operation of Alternative B.

Maintenance of Alternative B facilities would include regular inspections, land management activities, sediment removal from forebays, and servicing of pumping plants. Estimated emissions from maintenance activities are detailed in Appendix 24A and would total approximately 1,500 metric tons of CO_2e per year.

As discussed in Section 25.4.2.1, any increase in emissions above net zero associated with Alternative B would be adverse.

Construction of Alternative B would generate approximately 283,000 metric tons of CO_2e emissions over the nine-year construction period. Once operations begin, maintenance activities would increase GHG emissions by 1,500 metric tons of CO_2e; however, operations of Alternative B would be expected to reduce annual GHG emissions by between 29,400 and 135,600 metric tons of CO_2e per year (Appendix 25A). Thus, it would take between two and 10 years of operation to completely offset the GHG emissions released during construction. After that time period, operation of Alternative B would contribute to lowering California's GHG emissions and would help California achieve its AB 32 GHG emissions reduction goals.

Because increases in GHG emissions from construction would be more than offset by reductions in GHG emissions from operation, there would be no long-term increase over the net-zero threshold. Over the life of the proposed Project, Alternative B would be likely to substantially reduce GHG emissions. Therefore, Alternative B would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Operation and Maintenance Emissions

Existing State Water Project Facilities Operational Emissions

Operation of Alternative B would result in modifications to the operations of existing SWP facilities including Lake Oroville and the Thermalito Complex, and pumping and generating facilities along the California Aqueduct.

Table 25-9 shows that net generation (the amount of energy generated at hydroelectric generating facilities minus the amount of energy used at pumping facilities) would be negative, i.e., Alternative B would result in a net increase in the amount of energy needed annually to operate the SWP.

Table 25-9
Electricity Generation and Use from Expected Changes in Operation at Existing State Water Project Facilities as a Result of Implementation of Alternative B (GWh/Year)[a]

		Existing Conditions	No Project/No Action Alternative	Alternative B	Alternative B minus Existing Conditions	Alternative B minus No Project/No Action Alternative

	Dry and Critical	-3,321	-3,104	-3,599	-277	-494

[a]Results are estimated using the SWP Power model using data from the CALSIM II model.
[b]Long-Term is the average quantity for the calendar years 1922 to 2002.
[c]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Notes:
GWh/year = gigawatt hours per year
SWP = State Water Project

Alternative B would add approximately 449 GWh of additional net electricity demand over Existing Conditions on a long-term annual basis and 269 GWh of additional net electricity demand over the No Project/No Action Alternative on a long-term annual basis.

Additional energy needed to operate existing SWP facilities would be purchased by DWR as part of its ongoing energy purchasing and scheduling responsibilities for the SWP. Thus, analysis of the GHG impact of this additional electricity will be analyzed pursuant to the DWR GGERP framework (DWR, 2012a).

Operation of Alternative B would result in additional SWP energy demands in excess of 15 GWh/year; therefore, the GGERP procedure has been followed for projects that would increase SWP energy demand by 15 GWh/year or more.

In the GGERP, DWR developed estimates of historical, current, and future GHG emissions. Figure 25-3 shows those emissions as they were projected in the GGERP and how those emissions projections would change with the additional electricity demands needed to operate the SWP with the addition of Alternative B. As shown in Figure 25-3, in 2022 (the year that Alternative B is projected to go online), DWR total emissions would increase from approximately 977,000 metric tons of CO_2e to nearly 1.17 million metric tons of CO_2e. This elevated level would be approximately 145,000 metric tons of CO_2e below DWR's designated GHG emissions reduction trajectory red line, which is the linear interpolation between DWR's 2020 GHG emissions goal and DWR's 2050 GHG emissions goal. The projection indicates DWR has already built in sufficient excess GHG emissions reductions into its future activities that even with the addition of 449 GWh of demand, DWR would remain below its emissions reduction trajectory and would maintain its downward trajectory toward achieving its GHG emissions reduction goals. The calculations associated with projected emissions are included in Appendix 25A.

Given the scale of additional emissions that Alternative B would add to DWR's total GHG emissions, DWR finds that no additional actions or commitments are required to implement Alternative B.

As shown in the analysis above and consistent with the analysis contained in the GGERP and associated Initial Study and Negative Declaration for the GGERP, Alternative B would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the GGERP and would not conflict with any of the specific action GHG emissions reduction measures set forth in the GGERP. Consistent with the programmatic analysis framework set up in the GGERP, Alternative B would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Existing Central Valley Project Facilities Operational Emissions

DWR's GGERP cannot be used to evaluate environmental impacts associated with increased CVP pumping because emissions associated with CVP are not under DWR's control and are not included in the GGERP. Accordingly, GHG emissions resulting from increased CVP energy use are evaluated separately from GHG emissions generated as a result of SWP energy use.

Table 25-10 shows that under Existing Conditions and No Project/No Action Alternative, the CVP would generate approximately 3,590 GWh of excess hydroelectric power. This electricity would be sold into the California electricity market or directly to energy users.

Implementation of Alternative B would result in an increase of 14 to 17 GWh per year in CVP electricity use. This additional demand would be served by energy generated at CVP hydroelectric facilities that emit no GHGs, and therefore, would result in no GHG emissions.

With implementation of Alternative B, operation of the CVP would continue to yield a large net generation of clean GHG-emissions-free hydroelectric energy. However, the small increase in electricity usage to operate the CVP with Alternative B would result in a corresponding reduction in the supply of GHG-emissions-free electricity available to sell to California electricity users. This reduction in hydroelectric energy available for sale could result in a potential indirect effect from Alternative B, as electricity users acquire substitute electricity supplies that may result in GHG emissions (although additional conservation is also a possible outcome as well).

It is unknown what type of power source (e.g., renewable, natural gas) would be substituted for CVP electricity or if some of the lost power would be made up with higher efficiency. Given State mandates for renewable energy and incentives for energy efficiency, it is possible that a considerable amount of this power would be replaced by renewable resources or would cease to be needed as a result of higher efficiency. However, to ensure a conservative analysis, indirect emissions were quantified for the entire quantity of electricity (32 GWh) using the current and future statewide energy mix (adjusted to reflect the RPS).

Table 25-10
Electricity Generation and Use from Expected Changes in Operation at Existing Central Valley Project Facilities as a Result of Implementation of Alternative B (GWh/Year)[a]

[d]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Notes:
CVP = Central Valley Project
GWh/year = gigawatt hours per year

Substitution of 32 GWh of electricity with a mix of sources similar to the current statewide mix (emissions factor of 300.0 mtCO_2e/GWh[4]) would result in emissions of 9,600 metric tons of CO_2e; however, under expected future conditions (after full implementation of the RPS), emissions would be 7,360 metric tons of CO_2e[5].

These emissions could contribute to a cumulatively considerable effect, and could, therefore, be a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative. However, these emissions would be caused by dozens of independent electricity users making decisions about different ways to substitute for the lost power. Power purchases by private entities or public utilities in the private marketplace necessitated by a reduction in available CVP-

4 eGrid 2012 Version 1.0 (Year 2009 data) CAMX subregion emissions factor for total output emissions rate. http://www.epa.gov/cleanenergy/documents/egridzips/eGRID2012V1_0_year09_SummaryTables.pdf
5 Assumes a total output emissions rate of 230 mtCO_2e/GWh based on shift in generation to 33 percent renewables for retail load.

generated hydroelectric power are beyond the control of the Lead Agencies. Further, monitoring to determine the actual indirect change in emissions as a result of Alternative B would not be feasible.

Open Water Surfaces and Tailraces Emissions

Refer to the **Impact GHG-1** discussion for Alternative A for open water surfaces and tailraces. That discussion also applies to Alternative B.

Impacts Associated with Alternative C

Impact GHG-1: Generation of Cumulative GHG Emissions

Construction, Operation, and Maintenance of the Proposed Project

Project Construction Emissions

Construction-related GHG emissions would result primarily from fuel combustion in construction equipment, trucks, and worker vehicles, and also from the production of concrete used for construction and from the generation of electricity used during construction. Total GHG emissions resulting from construction of Alternative C are summarized in 25-11.

Table 25-11
Estimated Total GHG Emissions from Construction of Alternative C (Metric Tons CO_2e)*

Emissions from Mobile Construction Equipment*	Emissions From Concrete Production	Emissions from Construction Electricity Usage/Tunnel Boring Machine	Total Construction-Related Emissions
228,475	50,376	4,297	283,148

*Calculated emissions based on Table 24A. B-5 in Appendix 24A.

The emissions shown in Table 25-11 are the estimated total cumulative CO_2e emissions that would occur over the nine-year construction period of Alternative C. Within the nine-year construction period, annual emissions would fluctuate. Because GHG emissions are well dispersed in the atmosphere and persist for long periods of time (hundreds or thousands of years), estimates of emissions on a yearly basis are less meaningful than the total amount of emissions released during the discrete construction phase. After construction is complete, emissions from these sources would cease.

Once construction is complete, proposed Alternative C facilities would begin to operate. Unlike construction emissions, operations emissions would occur over a long and unknown period of time, i.e., the useful life of the proposed Project. Operation of the proposed Alternative C facilities would involve both the use and generation of electricity, as described in Chapter 31 Power Production and Energy. The amount of GHG emissions from operation of Alternative C would depend on the specific sources of energy used for pumping water into the reservoir and other operational parameters. Further, electricity needed to pump water into the reservoirs and electricity generated by releasing water from the reservoirs would vary annually and seasonally, depending on hydrologic conditions.

As shown in Table 25-12, operation of the Alternative C facilities (without consideration of pumpback operations) would result in a long-term average net generation of -108 GWh/year (i.e., to operate the Alternative C facilities, all of the energy generated at the facilities would be needed and an additional 108 GWh of energy would be needed from other sources).

Although operation of the Alternative C facilities would result in a long-term average net use of electricity, the way the facilities would be operated and integrated into the California electricity market would actually result in annual reductions in GHG emissions. As discussed in Chapter 31 Power Production and Energy, water pumping would occur to the extent possible during times when renewable (zero emissions) electricity is available, and releases of water, which generate electricity, would be done to the extent possible when electricity is in high demand. Therefore, electricity generated at the proposed Alternative C facilities – with no emission of GHGs – would offset some of the most inefficient and highest emitting generating resources in the electricity market.

Table 25-12

[a]Results are estimated using the NODOS Power model using data from the CALSIM II model.
[b]Other related Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities are included; this results in non-zero values for Existing Condition and No Project/No Action Alternative. Tehama-Colusa Canal pumping facilities are also reported as CVP facilities in Table 25-14.
[c]Long-Term is the average quantity for the calendar years 1922 to 2002.
[d]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Note:
GWh/year = gigawatt hours per year

In addition to the analysis provided above, the proposed Alternative C facilities would be configured to allow substantial pumpback operations; i.e., pumping water from the proposed Holthouse Reservoir into the proposed Sites Reservoir during nighttime hours (when excess clean/cheap electricity is available) and then releasing the water back from the proposed Sites Reservoir to the proposed Holthouse Reservoir during peak demand hours during the day (when the electricity generated can displace high emitting/high cost sources).

Alternative C would also be able to provide critical renewable integration services to the California grid that would facilitate additional renewable energy generation and further reduce GHG emissions. Solar and wind power are intermittent electricity sources; the electricity generated at a solar or wind power station fluctuates unpredictably as clouds obscure the sun or wind speeds die down. To effectively integrate solar and wind power into an electricity grid, there must be appropriate backup power supplies to ensure that fluctuations in solar or wind generation are smoothed out so that sufficient supply exists in the grid to meet demand. Alternative C could provide this integration service. Both in the pumping and generating phase, the Alternative C would have the flexibility to modify its operations to balance generation from intermittent renewable electricity supplies. In the pumping phase, has Alternative C would have ample storage at the proposed Holthouse Reservoir and variable speed pumps at the proposed Sites Pumping Plant that could quickly ramp up or down so that pumping from the proposed Holthouse Reservoir to the proposed Sites Reservoir could be slowed or delayed for up to several days to coincide with available renewable electricity. In the generation phase, the proposed Sites Pumping Plant's variable speed turbines could quickly ramp up or ramp down to provide additional generation when renewable electricity decreases or additional pumping load when renewable generation increases.

Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives describes the proposed Project's commitment to obtain at least 20 percent of the power used for pumping water from the Sacramento River and the proposed Holthouse Reservoir into the proposed Sites Reservoir from wind and/or solar energy, and to use at least 20 percent of the proposed Project's generated power and/or served pump load to provide integration services needed to firm up highly variable wind and/or solar generation. At this level of renewables use and renewable integration service, operational analyses indicate that Alternative C would result in GHG emissions reductions of approximately 25,000 metric tons of CO_2e per year (Appendix 25A). This represents a very conservative estimate of the level of renewables that would be used to operate Alternative C and the level of renewable integration service that Alternative C could provide. If Alternative C were operated with 80 percent renewable power for pumping and provided 20 percent of pumping load for integration services, and 100 percent of generated electricity was used for integration services, operational analyses indicate that Alternative C would result in GHG emissions reductions of more than 147,500 metric tons of CO_2e per year. Although operations would vary each year, all of these features would contribute to reducing overall GHG emissions from Alternative C and from the larger California electrical power grid. These two data points represent the likely potential range of GHG emissions reductions that would result from operation of Alternative C.

Maintenance of Alternative C facilities would include regular inspections, land management activities, sediment removal from forebays, and servicing of pumping plants. Estimated emissions from maintenance activities are detailed in Appendix 24A and would total approximately 1,500 metric tons of CO_2e per year.

As discussed in Section 25.4.2.1, any increase in emissions above net zero associated with Alternative C would be adverse.

Construction of Alternative C would generate approximately 283,000 metric tons of CO_2e emissions over the nine-year construction period. Once operations begin, maintenance activities would increase GHG emissions by 1,500 metric tons of CO_2e; however, operations of Alternative C would be expected to reduce annual GHG emissions by between 25,000 and 147,500 metric tons of CO_2e per year (Appendix 25A). Thus, it would take between two and 12 years of operation to completely offset the GHG emissions released during construction. After that time period, operation of Alternative C would contribute to lowering California's GHG emissions and would help California achieve its AB 32 GHG emissions reduction goals.

Because increases in GHG emissions from construction would be more than offset by reductions in GHG emissions from operation, there would be no long-term increase over the net-zero threshold. Over the life of the proposed Project, Alternative C would be likely to substantially reduce GHG emissions. Therefore, Alternative C would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Operation and Maintenance Emissions

Existing State Water Project Facilities Operational Emissions

Operation of Alternative C would result in modifications to the operations of existing SWP facilities including Lake Oroville and the Thermalito Complex, and pumping and generating facilities along the California Aqueduct.

Table 25-13 shows that net generation (the amount of energy generated at hydroelectric generating facilities minus the amount of energy used at pumping facilities) would be negative, i.e., Alternative C would result in a net increase in the amount of energy needed annually to operate the SWP.

Table 25-13
Electricity Generation and Use from Expected Changes in Operation at Existing State Water Project Facilities as a Result of Implementation of Alternative C (GWh/Year)[a]

		Existing Conditions	No Project/No Action Alternative	Alternative C	Alternative C Minus Existing Conditions	Alternative C Minus No Project/No Action Alternative

	Dry and Critical	-3,321	-3,104	-3,679	-358	-575

[a]Results are estimated using the SWP Power model using data from the CALSIM II model.
[b]Long-Term is the average quantity for the calendar years 1922 to 2002.
[c]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Notes:
GWh/year = gigawatt hours per year
SWP = State Water Project

Alternative C would add approximately 455 GWh of additional net electricity demand over Existing Conditions on a long-term annual basis and 275 GWh of additional net electricity demand over the No Project/No Action Alternative on a long-term annual basis.

Additional energy needed to operate existing SWP facilities would be purchased by DWR as part of its ongoing energy purchasing and scheduling responsibilities for the SWP. Thus, analysis of the GHG impact of this additional electricity will be analyzed pursuant to the DWR GGERP framework (DWR, 2012a).

Operation of Alternative C would result in additional SWP energy demands in excess of 15 GWh/year; therefore, the GGERP procedure has been followed for projects that would increase SWP energy demand by 15 GWh/year or more.

In the GGERP, DWR developed estimates of historical, current, and future GHG emissions. Figure 25-4 shows those emissions as they were projected in the GGERP and how those emissions projections would change with the additional electricity demands needed to operate the SWP with the addition of Alternative C. As shown in Figure 25-4, in 2022 (the year that Alternative C is projected to go online), DWR total emissions would increase from approximately 977,000 metric tons of CO_2e to nearly 1.18 million metric tons of CO_2e. This elevated level is still approximately 140,000 metric tons of CO_2e below DWR's designated GHG emissions reduction trajectory red line, which is the linear interpolation between DWR's 2020 GHG emissions goal and DWR's 2050 GHG emissions goal. The projection indicates DWR has already built in sufficient excess GHG emissions reductions into its future activities that even with the addition of 455 GWh of demand, DWR would remain below its emissions reduction trajectory and would maintain its downward trajectory toward achieving its GHG emissions reduction goals. The calculations associated with projected emissions are included in Appendix 25A.

Given the scale of additional emissions that Alternative C would add to DWR's total GHG emissions, DWR finds that no additional actions or commitments are required to implement Alternative C.

As shown in the analysis above and consistent with the analysis contained in the GGERP and associated Initial Study and Negative Declaration for the GGERP, Alternative C would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the GGERP and would not conflict with any of the specific action GHG emissions reduction measures set forth in the GGERP. Consistent with the programmatic analysis framework set up in the GGERP, Alternative C would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Existing Central Valley Project Facilities Operational Emissions

DWR's GGERP cannot be used to evaluate environmental impacts associated with increased CVP pumping, as emissions associated with CVP are not under DWR's control and are not included in the GGERP. Accordingly, GHG emissions resulting from increased CVP energy use are evaluated separately from GHG emissions generated as a result of SWP energy use.

Table 25-14 shows that under Existing Conditions and No Project/No Action Alternative, the CVP would generate approximately 3,590 GWh of excess hydroelectric power. This electricity would be sold into the California electricity market or directly to energy users.

Table 25-14
Electricity Generation and Use from Expected Changes in Operation at Existing Central Valley Project Facilities as a Result of Implementation of Alternative C (GWh/Year)[a]

[c]Long-Term is the average quantity for the calendar years 1922 to 2002.
[d]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
Notes:
CVP = Central Valley Project
GWh/year = gigawatt hours per year

Implementation of Alternative C would result in an increase of 26 to 28 GWh per year in CVP electricity use. This additional demand would be served by energy generated at CVP hydroelectric facilities that emit no GHGs, and therefore, would result in no GHG emissions.

With implementation of Alternative C, operation of the CVP would continue to yield a large net generation of clean GHG-emissions-free hydroelectric energy. However, the small increase in electricity usage to operate the CVP with Alternative C would result in a corresponding reduction in the supply of GHG-emissions-free electricity available to sell to California electricity users. This reduction in hydroelectric energy available for sale could result in a potential indirect effect from Alternative C, as electricity users acquire substitute electricity supplies that may result in GHG emissions (although additional conservation is also a possible outcome as well).

It is unknown what type of power source (e.g., renewable, natural gas) would be substituted for CVP electricity or if some of the lost power would be made up with higher efficiency. Given State mandates for renewable energy and incentives for energy efficiency, it is possible that a considerable amount of this power would be replaced by renewable resources or would cease to be needed as a result of higher efficiency. However, to ensure a conservative analysis, indirect emissions were quantified for the entire quantity of electricity (28 GWh) using the current and future statewide energy mix (adjusted to reflect the RPS).

Substitution of 28 GWh of electricity with a mix of sources similar to the current statewide mix (emissions factor of 300.0 mtCO_2e/GWh[6]) would result in emissions of 8,400 metric tons of CO_2e; however, under expected future conditions (after full implementation of the RPS), emissions would be 6,460 metric tons of CO_2e[7].

These emissions could contribute to a cumulatively considerable effect, and could, therefore, be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. However, these emissions would be caused by dozens of independent electricity users making decisions about different ways to substitute for the lost power. Power purchases by private entities or public utilities in the private marketplace necessitated by a reduction in available CVP-generated hydroelectric power are beyond the control of the Lead Agencies. Further, monitoring to determine the actual indirect change in emissions as a result of Alternative C would not be feasible.

Open Water Surfaces and Tailraces

Refer to the **Impact GHG-1** discussion for Alternative A for open water surfaces and tailraces. That discussion also applies to Alternative C.

Mitigation Measures

Mitigation measures are provided below and summarized in Table 25-15 for the impacts that have been identified as significant or potentially significant.

Because monitoring to determine the actual indirect change in emissions as a result of proposed Project operations would not be feasible, and because power purchases by private entities or public utilities in the private marketplace necessitated by a reduction in available CVP-generated hydroelectric power are beyond the control of the Lead Agencies, there are no feasible mitigation measures that could reduce this

[7] Assumes a total output emissions rate of 230 mtCO_2e/GWh based on shift in generation to 33 percent renewables for retail load.

potential impact to a less-than-significant level. This impact would, therefore, remain **potentially significant and unavoidable.**

25.5 Climate Change

25.5.1 Environmental Setting/Affected Environment

25.5.1.1 Climate

Hot dry summers and mild rainy winters characterize the Mediterranean climate of the Sacramento Valley. During the year, the temperature ranges from 25°F to 105°F, with average annual rainfall approximately 20 inches and snowfall very rare (CIMIS, 2011 and WRCC, 2011). The prevailing winds are moderate in strength, and vary from moist clean breezes from the south to dryland flows from the north. Summer conditions in the northern Sacramento Valley Air Basin are typically characterized by high temperatures and low humidity, with prevailing winds from the south. Winter conditions are characterized by rainstorms interspersed with stagnant and sometimes foggy weather. Winter daytime temperatures average in the low 50s and nighttime temperatures average in the high 30s. During winter, north winds become more frequent, but winds from the south predominate. Rainfall occurs mainly from late October to early May.

Table 25-16 provides climate summaries for selected locations in Glenn and Colusa counties. As shown, the counties are similar in temperature, but differ in levels of precipitation and snowfall.

Table 25-16
Climatic Conditions in Glenn and Colusa Counties

Parameter	Glenn County (Willows)[a]	Colusa County (Colusa)[b]
Average Maximum Temperature (°F)	75.0	75.0
Average Minimum Temperature (°F)	47.5	47.6
Average Total Precipitation (inches)	18.29	16.43
Average Total Snowfall (inches)	0.5	0.1

[a]Period of record for the City of Willows: 7/1/1948 to 12/31/2005.
[b]Period of record for the City of Colusa: 10/1/1948 to 12/31/2005.

25.5.1.2 Global Climate Trends

Recent Trends

A vast amount of scientific research on climate change, both its causes and effects, at all geographic scales has been conducted during the last 50 years. Scientific measurements have shown that changes in the *global* climate system are already occurring. These include: rising air temperatures; rising ocean temperatures; rising ocean salinity; rising global sea levels; changes in precipitation patterns; and increased intensity and frequency of extreme events such as storms, droughts, and wildfires (IPCC, 2007b; DWR 2009).

The Earth's average surface temperature rose by 0.74±0.18 °C (1.33±0.32°F) over the period 1906 to 2005. The rate of warming over the last half of that period was almost double that for the period as a whole (IPCC, 2007a). Fourteen of the 15 years from 1997 to 2011 rank among the 15 warmest years in the instrumental record of global average temperature (going back to 1880) (Blunden and Arndt, 2012).

During the same period over which this increased global warming has occurred, many other changes have occurred in other natural systems. Sea levels have risen on average 1.8 millimeters (0.07 inch) per year; precipitation patterns throughout the world have shifted, with some areas becoming wetter and others drier; tropical cyclone activity in the North Atlantic has increased; peak runoff timing of many glacial and snowfed rivers has shifted earlier; and numerous other changed conditions have been observed. Although it is difficult to prove a definitive cause and effect relationship between global warming and other observed changes to natural systems, there is high confidence in the scientific community that these changes are a direct result of increased global temperatures (IPCC, 2007a).

Much of the western United States has experienced warming during the 20th century (roughly 2°F [1.1°C]) and is projected to experience further warming during the 21st century with central estimates varying from roughly 5°F to 7°F (2.8°C to 3.8°C), depending on location (Reclamation, 2011a). Historical trends in annual precipitation are less apparent. Future projections suggest that the northwestern and north-central portions of the United States gradually may become wetter (e.g., Columbia Basin and Missouri River basin) while the southwestern and south-central portions may gradually become drier (e.g., San Joaquin, Truckee, and Rio Grande river basins and the Middle to Lower Colorado River Basin). Areas in between have median projected changes closer to no change, meaning they have roughly equal chances of becoming wetter or drier (e.g., Klamath and Sacramento basins and the Upper Colorado Basin). These summary statements refer to median projected changes in temperature and precipitation, characterized generally across the western United States. Projections show that there is significant variability and uncertainty about these projected conditions both geographically and with time (Reclamation, 2011a).

Warming trends appear to have led to a shift in cool season precipitation toward more rain and less snow, which has caused increased rainfall runoff volume during the cool season accompanied by less snowpack accumulation in some western United States locations (Reclamation, 2011a). Hydrologic analyses-based future climate projections suggest that warming and associated loss of snowpack will persist over much of the western United States. However, there are some geographic contrasts. Snowpack losses are projected to be greatest where the baseline climate is closer to freezing thresholds (e.g., lower lying valley areas and lower altitude mountain ranges). It also appears that, in high altitude and high latitude areas, there is a chance that cool season snowpack actually could increase during the 21st century (e.g., Columbia headwaters in Canada, Colorado headwaters in Wyoming), because precipitation increases are projected and appear to offset the snow-reduction effects of warming in these locations (Reclamation, 2011a).

Average sea level rise over the period 1961 to 2003 was 1.8 millimeters (0.07 inch) per year. Over the period of 1993 to 2003, the rate of sea level rise increased to 3.1 millimeters (0.12 inch) per year. Total average worldwide sea level rise over the 20th century has been 6.7 inches (IPCC, 2007a). Observed trends in sea level rise can be attributed to both thermal expansion of the world's oceans and the melting of ice sheets (polar and alpine). Also during a similar period (1900 to 2007), measurements have shown increases in global ocean temperature (since 1961); a decline in the extent of mountain glaciers and global snow cover; increased atmospheric water vapor content; loss in mass of the polar ice sheets; decreased extent of Arctic sea ice; increased precipitation in the eastern portions of North and South America, northern Europe and northern and central Asia; drying conditions in the Sahel region of the Sahara Desert in Africa, the Mediterranean, and southern Africa; strengthening in mid-latitude westerly winds (since the 1960s); more intense and longer drought conditions in the tropics and sub-tropics (since the 1970s); increased frequency of extreme precipitation events over land areas; higher average night time temperatures; decreased frost days and increased frequency and duration of extreme heat events (since the 1950s); and increased tropical cyclone activity in the North Atlantic (IPCC, 2007a). There may also be additional synergistic impacts of extreme weather events, such as the sea level rise coupled with high tide and extreme storm surges. The above listed changes are, in turn, resulting in changes to the climate of California as the regional climate is moderated by sea surface temperature, westerly wind patterns, the El Niño Southern Oscillation (ENSO), and Pacific storm patterns.

Projections to 2100

Climate models indicate that global average surface temperature will increase at a rate of approximately 0.4°F (0.2°C) per decade for the period 2000 to 2020, and will increase by at least that amount per decade during the period 2020 to 2080. Based on a number of emissions scenarios, the IPCC projected an average increase in surface temperatures of 3.2 to 7.2°F by 2100 compared to 1980 through 1999 levels, with a likely range of 2.0 to 11.5°F when accounting for the uncertainty in climate science (IPCC, 2007a). Approximately half of this warming is the result of past GHG emissions and will occur even if GHG emissions were halted at 2000 levels. Some regions of the globe, particularly high latitudes, will experience much larger changes relative to Existing Conditions. Corresponding global average sea level rise during the period 2000 to 2100 are estimated to be between seven inches (18 centimeters) and 23 inches (58 centimeters) (IPCC, 2007a). However, recent scientific data now strongly suggests that these sea level rise projections are likely too low and that actual sea level rise may be significantly greater than initially estimated (Rahmstorf, 2007; NRC, 2012).[8]

The following additional changes to the global climate system are projected: increased ocean acidity due to increased carbon dioxide uptake by the oceans; reduced global snow cover; increased thaw depth in permafrost regions; decrease in sea ice with potential full disappearance in summer months; increased frequency in heat waves and heavy precipitation events; increased intensity of tropical cyclone events; northward movement of extra-tropical storm tracks; increased precipitation at high latitudes and decreased precipitation in tropical and sub-tropical regions; and increased melting of the ice sheets (IPCC, 2007a).

[8] California agencies, including the Bay Conservation and Development Commission (BCDC) and DWR, are using the more recent data of Rahmstorf et al. 2007 in their sea level rise planning efforts in lieu of the estimates reported by IPCC in the Fourth Assessment Report.

25.5.1.3 Climate Change Effects on California

Recent Trends

Scientific measurements and observations indicate that California's climate is already changing in a manner consistent with what would be expected from global climate change. Since 1920, California's average temperature has been increasing, although this change, or any climate change impact, is not uniform across California. Nighttime temperatures are rising across California and at a higher rate than daytime temperatures. Further, daytime and nighttime heat wave events throughout California have increased in intensity, particularly the nighttime component (Moser et al., 2009).

Water level measurements from the San Francisco gage (CA Station ID: 9414290) indicate that mean sea level rose by an average of 2.01 millimeters (mm) (0.08 inch) per year from 1897 to 2006, equivalent to a change of eight inches in the last century (CCCC, 2009).

California's water supply system is dependent on snowpack storage in the Sierra Nevada. Temperatures over the Sierra Nevada have increased during the last 100 years, resulting in less snowfall (and more rainfall) and an earlier snowmelt (Moser et al., 2009). From 1930 to 2009, the peak timing of Sierra Nevada runoff analyzed by Kapnick and Hall (2009) exhibited a trend toward earlier in the season of 0.4 day per decade. The average early spring snowpack in the Sierra Nevada has decreased by approximately 10 percent since the early 20th century, a loss of 1.5 million acre-feet of snowpack storage (DWR, 2008).

Data also show evidence for the following additional changes to California climate and conditions during the last 50 years: the warming of Lake Tahoe; decreasing chill hours and increased stresses on California agriculture; shifts and disturbances in managed landscapes; increased frequency of wildfire; changes in Santa Ana winds; increases in photochemical smog production in southern California; increased frequency and intensity of heat wave events; changes in the El Niño Southern Oscillation and the impact on California temperatures; and changes in extreme precipitation events and daily average precipitation (CEC, 2011).[9]

Plants and animals around the globe are already reacting to changes caused by increasing temperatures. In California, species are also reacting to extreme conditions, including heat waves (and the fires generated by that heat), cold snaps, droughts (and the Delta saltwater intrusion that droughts often cause), floods, and coastal upwelling. Observed changes also include altered timing of animal and plant lifecycles (phenology), disruption of biotic interactions, changes in physiological performance, species range and abundance, increase in invasive species, altered migration patterns of fishes, aquatic-breeding amphibians, birds and mammals, changes in forage base, local extinction of plant and animal populations, and changes in habitat, vegetation structure, and plant and animal communities (DFG, 2010).

Projections to 2100

Average annual surface temperatures for California are projected to increase by between 2°F and 5°F by 2050 and between 4°F and 9°F by 2100, depending on the GHG emissions scenario assumed. Warming will not be uniform seasonally or across California. Climate models project a greater amount of warming during summer months, during nighttime, and in the interior regions of California. Chill hours in the Central Valley are expected to decrease, but unprecedented extremes of cold weather are still possible (Gershunov, 2011). Changes in temperature and humidity have implications for agriculture in the Central

[9]The State of California under the auspices of the California Energy Commission (CEC) is conducting comprehensive and detailed research into a range of climate change impacts in California as well as research aimed at developing adaptation strategies to deal with impacts already underway and that can no longer be avoided. The majority of this research is available through the California Climate Change Portal. Available at: <http://www.climatechange.ca.gov/>.

Valley; as the climate warms, crop diversity and production will be affected by unpredictability associated with the changing climate (Jackson et al., 2011). Extreme events will also stress California's energy system (Auffhammer, 2011).

Best available data indicate that California, as a whole, will experience changes in precipitation. It is likely that some areas in California will experience higher annual rainfall amounts and precipitation in other regions will decrease (Gershunov, 2011). Cayan et al. (2009) estimates California, particularly southern California, will be 15 to 35 percent drier by 2100. Snowpack volumes are expected to diminish by 25 percent by 2050 (DWR, 2008).

Frequency and intensity of large storms and precipitation events may be influenced by changes in atmospheric rivers. An atmospheric river is a narrow band of concentrated moisture in the atmosphere that transports large amounts of water vapor. In California, nearly all major historic flood events have been associated with the presence of atmospheric rivers, which form in fall and winter and transport warm moister air from the tropical Pacific near Hawaii to the Pacific coast of the continental United States. It is estimated that future changes in climate will increase the frequency of years with atmospheric river storms, but the number of storms per year is not likely to be affected. More importantly, occasional "much-larger-than-historical-range storm intensities" are projected to occur under most warming scenarios. Changes in the frequency and magnitude of atmospheric rivers may result in increases in major flood and storm events (Dettinger, 2011).

Sea level rise along the California coast is expected to accelerate during the 21st century. A recent study completed by the National Research Council (NRC) looked at both global (e.g., thermal expansion, land ice melting) and local (e.g., tectonic land movement, localized subsidence) factors affecting sea level relative to land surface. Table 25-17 shows the projection and the range of uncertainty for expected sea level rise along the coast of San Francisco at 2030, 2050, and 2100.

Table 25-17
Sea Level Rise Projections and Ranges for San Francisco, California 2030, 2050, and 2100

Location	Units	2030		2050		2100	
		Projection	Range	Projection	Range	Projection	Range
San Francisco	cm	14.4 ± 5.0	4.3 to 29.7	28.0 ± 9.2	12.3 to 60.8	91.9 ± 25.5	42.4 to 166.4
	in	5.7±2	1.7 to 11.7	11±3.6	4.84 to 23.9	36.2±10	16.7 to 65.5

Sea level rise will continue to threaten coastal lands and infrastructure, increase flooding at the mouths of rivers, place additional stress on levees in the Sacramento-San Joaquin Delta (Delta), and will intensify the difficulty of managing the Delta as the heart of the State's water supply system (DWR, 2008).These changes in temperature, precipitation, and sea level may have substantial effects on other resources areas. Potential effects of climate change anticipated in California (and discussed in this chapter) are listed below (CNRA, 2009):

- Increased average temperatures (air, water, and soil)
- Changes in annual precipitation amounts

- Change from snowfall (and spring snowmelt) to rainfall
- Decreased Sierra snowpack (earlier runoff, reduced maximum storage)
- Increased evapotranspiration
- Increased frequency and intensity of Pacific storms (flood events)
- Increased severity of droughts
- Increased frequency and severity of extreme heat events
- Increased frequency and severity of wildfire events
- Sea level rise (with increased salt water intrusion in the Delta)
- Changes in species distribution and ranges
- Decreased number of species
- Increased number of vector-borne diseases and pests (including impacts to agriculture)
- Altered timing of animal and plant lifecycles (phenology)
- Disruption of biotic interactions
- Changes in physiological performance, including reproductive success and survival of plants and animals
- Increase in invasive species
- Altered migration patterns of fishes, aquatic-breeding amphibians, birds, and mammals
- Changes in food (forage) base
- Changes in habitat, vegetation structure, and plant and animal communities

These changes have significant implications for water quality, water supply, flooding, aquatic ecosystems, energy generation, and recreation throughout the State. Several guidance documents have been drafted or have been published to discuss strategies to protect resources from climate change in California, such as the 2009 California Climate Adaptation Strategy (CNRA, 2009).

25.5.1.4 Climate Change and Sea Level Rise Effects on California's Water Resources

Although measured effects of climate change are occurring, significant uncertainty remains about the specific magnitude and in some cases even the direction of changes expected in the future. Temperature, precipitation, and sea level are all expected to change and will affect California's water resources in measureable ways.

Numerous studies and publications have noted the importance of considering climate change in water resources planning. The California Water Plan update 2009 states, "planning for and adapting to [climate] changes … will be among the most significant challenges facing water and flood managers this century" (DWR, 2009). Both DWR and Reclamation have noted the need to consider climate change effects in water resources planning studies. For the purposes of this Draft EIR/EIS and the companion Draft Feasibility Report, the potential effects of climate change on California's water resources, as well as on the proposed Project alternatives, are considered.

25.5.1.5 Water Management and Climate

Water management includes the development and fulfillment of operating schemes on a variety of time scales from days to decades (Reclamation, 2011a). Within water management planning, climate characterization informs estimations of future water supplies, future water demands, and boundaries of system operation. Climate information influences evaluation of resource management strategies through assumptions or characterization of future potential temperature, precipitation, and runoff conditions among other weather information. Water supply estimates are developed by making determinations of what Wet, Dry, and Normal periods may be like in the future and include the potential for hydrologic extremes that can create flood risks and droughts. Water demand estimates are developed across water management system uses, which include both the natural and the socioeconomic systems, including agriculture, municipal and industrial, environmental, and hydroelectric power generation.

25.5.1.6 Water Management, Climate Change Effects, and Associated Challenges

There are climate change effects and challenges that are especially relevant to water resources. These effects and challenges are described below as background to the climate change sensitivity analysis.

Reclamation Literature Synthesis

To support longer-term planning processes, Reclamation has created a region-specific literature synthesis of studies relating to climate change implications for Reclamation operations and activities in the 17 western states (Reclamation, 2011b). This report summarizes recent literature on the past and projected effects of climate change on hydrology and water resources, and summarizes implications for key resource areas featured in Reclamation planning processes. The Mid-Pacific Region section of the report describes scientific studies related to climate change for an area that includes most of California, as well as the Klamath River watershed that originates in southern Oregon and the Lahontan watershed that is mainly in Nevada. The Colorado River basin of California is not included within the region. Several observations from the Mid-Pacific Region literature synthesis are listed below by category:

Historical Climate and Hydrology

- Western United States spring temperatures increased 1 to 3°C (1.8 to 5.4°F) between the 1970s and late 1990s. Increasing winter temperature trends observed in central California averaged approximately 0.5°C (0.9°F) per decade from the late 1940s to the early 1990s (Dettinger and Cayan 1995).
- Increased winter precipitation trends are noted during 1950 to 1999 at many western United States sites, including several in California's Sierra Nevada; but a consistent region-wide trend is not apparent.
- Coincident with these trends, the western United States and Mid-Pacific Region also experienced a general decline in spring snowpack, reduced snowfall to winter precipitation ratios, and earlier snowmelt runoff from the late 1940s to early 2000s.
- On explaining historical trends in regional climate and hydrology, several studies indicate that most observed trends for snow water equivalent (SWE), soil moisture, and runoff in the western United States are the result of increasing temperatures rather than precipitation effects (Lettenmaier et al., 2008).
- In many Mid-Pacific Region headwater basins, even with precipitation being equal, warmer temperatures in these watersheds cause reduced snowpack development during winter, more runoff during the winter season, and earlier spring peak flows associated with an earlier snowmelt.

Projected Future Climate and Hydrology

- Several studies have been conducted to relate potential future climate scenarios to Mid-Pacific Region runoff and water resources management impacts. In general, there is greater agreement reported between model projections of temperature and, thus, higher confidence in future temperature change relative to precipitation change.
- Several studies have examined potential hydrologic impacts associated with projected climate change. Analyses show that runoff could occur as much as two months earlier than what currently occurs, and

earlier runoff timing of at least 15 days in early-, middle-, and late-season flow is projected for almost all mountainous areas where runoff is snowmelt driven.

- Future impacts on hydrology have been shown to have implications for water resources management. Management of western United States reservoir systems is very likely to become more challenging as net annual runoff decreases and interannual patterns continue to change as the result of climate change.
- Recently developed climate projection scenarios (Moser et al., 2009) suggest that current climate projections for California would lead to decreased snowpack by the end of the century (20 to 40 percent, depending on emissions scenarios), increased risk of winter flooding, earlier timing of meltwater runoff and greater vulnerability to summer shortfalls, decreased hydropower generation (under dry warming), and decreased quality of winter recreation.

Studies of Impacts on Natural Resources

- Biodiversity may be affected by climate change (Janetos et al., 2008), and many studies have been published about the impacts of climate change on individual species and ecosystems. Climate change also has affected forest insect species range and abundance through changes in insect survival rates, increases in life cycle development rates, facilitation of range expansion, and the effect on host plant capacity to resist attack (Ryan et al., 2008). Predicted future impacts are primarily associated with projected increases in air and water temperatures and are expected to result in poleward shifts in the range of many species, adjustment of migratory species arrival and departure, amphibian population declines, and effects on pests and pathogens in ecosystems.
- Studies of the effects of climate change on agriculture and water resources focus on the many issues associated with future agricultural water demands; only a few studies have attempted to predict climate change impacts on irrigation demands. Limited study findings suggest significant irrigation requirement increases for corn and alfalfa, demand decreases due to crop failures caused by pests and disease exacerbated by climate change, and demand increases if growing seasons become longer or farming practices are adapted by planting more crop cycles per growing season.
- Increased air temperatures could increase aquatic temperatures and affect fisheries habitat. In general, studies of climate change impacts on freshwater ecosystems are more straightforward with streams and rivers, which are typically well mixed and track air temperature closely, as opposed to lakes and reservoirs, where thermal stratification and depth affect habitat (Allan et al., 2005).
- Warmer water temperatures also could exacerbate invasive species issues (e.g., quagga mussel reproduction cycles would respond favorably to warmer water temperatures); moreover, climate change could decrease the effectiveness of chemical or biological agents used to control invasive species (Hellmann et al., 2008). Warmer water temperatures also could facilitate the growth of algae, which could result in eutrophic conditions in lakes, declines in water quality (Lettenmaier et al., 2008), and changes in species composition.
- Another potential effect of climate change impacts on ecosystems and watershed hydrology involves changes in vegetation disturbances due to wildfires and forest dieback. In the western United States, increases in spring-summer temperatures lead to reduced snow melt, soil moisture, and fuel moisture conditions. These reductions, in turn, affect wildland fire activity.

Studies on Historical Sea Level Trends and Projected Sea Level Rise Under Climate Change

- Sea level conditions at San Francisco Bay's Golden Gate Bridge (Golden Gate) affect water level and salinity conditions in the upstream Delta. Throughout the 20th century, sea levels near San Francisco Bay increased by more than 0.21 meters (8 inches) (Anderson et al., 2006).Veermeer and Rahmstorf, (2009) present a dual component relationship with short- and long-term sea level response components to temperature change. Based on this work and applying the IPCC emission scenarios, by 2100, sea levels are predicted to be 1 to 2 meters (39.4 to 78.7 inches) higher than at present.

Climate Change Challenges

DWR has noted similar anticipated effects and associated challenges for California's water resources. The trends of the last century – especially the increases in hydrological variability – will likely intensify this century, and abrupt changes in climate could also occur (DWR, 2008). DWR's list of climate change challenges includes the following:

- **Loss of Natural Snowpack Storage**: One of the most critical impacts for California water management may be the projected reduction in the Sierra Nevada snowpack – California's largest surface "reservoir." Snowmelt currently provides an annual average of 15 million acre-feet of water, slowly released between April and July each year. Much of the State's water infrastructure was designed to capture the slow spring runoff and deliver it during the drier summer and fall months. Based upon historical data and modeling, DWR projects that the Sierra snowpack will experience a 25 to 40 percent reduction from its historic average by 2050.

- **Drought:** Warming temperatures, combined with changes in rainfall and runoff patterns will exacerbate the frequency and intensity of droughts. Regions that rely heavily upon surface water (rivers, streams, and lakes) could be particularly affected as runoff becomes more variable, and more demand is placed on groundwater. Along with drier soils, forests will experience more frequent and intense fires, resulting in subsequent changes in vegetation, and eventually a reduction in the water supply and storage capacity benefits of a healthy forest. Climate change will also affect water demand. Warmer temperatures will likely increase evapotranspiration rates and extend growing seasons, thereby increasing the amount of water that is needed for the irrigation of many crops, urban landscaping and environmental water needs. Other challenge factors related to drought include stress upon the State's forests, environment, non-irrigated agriculture and rangeland, and recreation.

- **Floods:** The amount of snow is critical for water supply and environmental needs, but so is the timing of snowmelt runoff into rivers and streams. Rising snowlines caused by climate change will allow more of the Sierra Nevada watersheds to contribute to peak storm runoff. Along with reductions in the amount of the snowpack and accelerated snowmelt, scientists project greater storm intensity, resulting in more direct runoff and flooding. Other related challenge factors include erosion, habitat, and water quality. Flood planners will need to factor a new level of safety into the design, operation, and regulation of flood protection facilities such as dams, floodways, bypasses and levees, as well as the design of local sewers and storm drains.

- **Water Quality:** Changes in the timing of river flows and warming atmospheric temperatures may affect water quality and water uses in many different ways. Among other water quality effects, warmer water will distress many fish species and could require additional cold water reservoir releases.

- **Sea Level Rise:** Sea levels are rising, and it is generally accepted that this trend will continue and likely accelerate. However, the exact rate of rise is unknown, due to ongoing scientific uncertainty about the melting of ice sheets on western Antarctica and Greenland and the potential for abrupt changes in ocean conditions.

The Delta (i.e., channels and waterways) serves as an integral component of California's water supply system. Much of the Delta is located at or near sea level and is influenced by tidal conditions. Delta water supplies and aquatic habitat will be affected by sea level rise due to saltwater intrusion. An increase in the penetration of seawater into the Delta will further degrade drinking and agricultural water quality and alter ecosystem conditions. More freshwater releases from upstream reservoirs will be required to maintain salinity levels for municipal, industrial, agricultural, and existing ecological water uses.

- **Hydroelectric Generation:** Climate change will reduce the reliability of California's hydroelectricity operations, which, according to the California Climate Action Registry and the California Air Resources Board, is the State's largest source of greenhouse gas emissions-free energy. Changes in the timing of inflows to reservoirs may exceed generation capacity, forcing water releases over spillways and resulting in lost opportunities to generate hydropower. Higher snow elevations, decreased snowpack, and earlier snowmelt may result in less water available for clean power generation during hot summer months, when energy demand is highest. The impact is compounded overall by anticipated increased energy consumption due to higher temperatures and greater water demands in summer when less water is available.

25.5.2 Environmental Impacts/Environmental Consequences

25.5.2.1 Climate Change and Sea Level Rise Sensitivity Analysis

Climate Change Effects on the Proposed Project

A detailed and comprehensive analysis of the effects of the proposed Project alternatives, assuming current climate and variability, is presented in each of the resource chapters of this document (i.e., Chapters 6 though 31). The sensitivity analysis of potential climate change effects on the proposed Project alternatives is described below. The climate change sensitivity analysis and results are described in greater detail in Appendix 25B. The sensitivity analysis uses a methodology that was selected because of its ability to depict both a trend and a potential range of effects.

This sensitivity analysis attempts to help answer the following questions:

- How would climate change and sea level rise effects (especially modified runoff and hydrology) influence diversion to proposed Project storage?
- How would climate change and sea level rise affect the proposed Project's ability to provide system flexibility (i.e., water in storage)?
- How would climate change and sea level rise affect the ability of the proposed Project to provide primary objective benefits, including water supply reliability, fish survival, Delta water quality, and flexible hydropower generation?
- How would climate change and sea level rise affect the environmental effects of the proposed Project?

The NODOS climate change and sea level rise sensitivity analysis has been prepared as a tool for planners, resources specialists, stakeholders, and the public to consider the influence of climate change and sea level rise on the performance of the proposed Project and on the potential effects of the proposed

Project. The sensitivity analysis provides a context for consideration of uncertainty and anticipated trends due to climate change throughout the planning horizon for the proposed Project. A comparison of the No Project/No Action Alternative, with and without climate change and sea level rise, is intended to help the reader understand the trend and potential range of effects upon California's major water systems associated with climate change and sea level rise. In addition, the sensitivity analysis is intended to help the reader understand how the trend and range of potential climate change and sea level rise effects will impact the performance of the proposed Project action alternatives.

Provided below is a description of the methodology used for the sensitivity analysis and some of the results and findings of the sensitivity analysis.

Approach and Assumptions

NODOS Project Detailed Evaluation Scenarios

In the detailed evaluation of the proposed Project alternatives in the DEIR/EIS and Draft Feasibility Report, the SWP and CVP operations model (CALSIM II) was used to simulate the following scenarios, assuming the current climate and sea level condition:

- Existing Conditions
- No Project/No Action Alternative
- **Alternative A:** includes a 1.27-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing Tehama-Colusa (T-C) and GCID canals and a new Delevan Pipeline (2,000 cfs diversion/1,500-cfs release)
- **Alternative B:** includes a 1.81-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals, and a new release-only Delevan Pipeline (1,500-cfs release)
- **Alternative C:** includes a 1.81-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals and a new Delevan Pipeline (2,000-cfs diversion/1,500-cfs release)

The detailed evaluation of the proposed Project alternatives also used several hydrologic, operations, water quality, fisheries, riverine geomorphic and sediment, power, and economics models. The detailed evaluation involved the simulation and analysis of more than 100 parameters describing water flow, storage, diversion, temperature, salinity, fish population and mortality, power generation and use, and various revenues and costs associated with the water system included in the three study areas. A more detailed description of the suite of models that were used is presented in Appendix 6B.

For the climate change and sea level rise sensitivity analysis, the No Project/No Action Alternative and Alternatives A, B, and C were simulated for four additional climate and sea level scenarios. However, the modeling for the sensitivity analysis included only the CALSIM II operations simulation model. The CALSIM II model description, assumptions, and results are included in Appendix 6A and Appendix 6C.

Climate and Sea Level Scenarios

The climate and sea level scenarios used in this sensitivity analysis were previously developed for the Bay Delta Conservation Plan[10] (BDCP) Effects Analysis and DEIR/S[11] and documented in the BDCP Effects Analysis Appendix 5.A.2 (DWR, 2012b) and the BDCP DEIR/S Appendix 5A (DWR, 2012c).The DWR modeling team developed climate and sea level scenarios for evaluation of the BDCP alternatives. The Lead Agencies for the BDCP collaborated on the methodology and approved the selection and use of scenarios for the Effects Analysis and DEIR/S for that program. The BDCP appendix describes the methodology and selection of the climate and sea level scenarios and the development of the inputs and modifications for the CALSIM II model. This methodology separates potential climate futures into quadrants (Q1to Q4 and a central or median "quadrant" called Q5), where temperature increase and precipitation varies. A more detailed discussion of the quadrants is found below in the Climate Scenarios discussion. The concept of the quadrants is illustrated in Figure 25-5, which shows an example of using the quadrants to describe climate in the Feather River basin.

For the NODOS Project sensitivity analysis, four climate and sea level scenarios, in addition to the current climate and sea level scenario (Current), were selected for comparative analyses:

- The Early Long Term (ELT) scenario assuming the median (Q5) of an ensemble of Global Climate Model (GCM) projections at a point in time 15 years into the future (from the baseline date of 2009 for BDCP and also referred to as approximately 2025) and a sea level rise of 15 cm (6 inches). The ELT Q5 scenario is referred to later in this section as one point in the climate change trend.
- The Late Long Term (LLT) Q5 scenario assuming the median of an ensemble of GCM projections at a point in time 50 years into the future (~2060) and a sea level rise of 45 cm (18 inches). The LLT Q5 scenario is also referred to later in this section as one point in the climate change trend.
- The LLT Q2 scenario assuming the "drier, more warming" lower bound (Q2) of an ensemble of GCM projections at a point in time 50 years into the future (~2060) and a sea level rise of 45 cm (18 inches). The LLT Q2 scenario is referred to later in this section as the Lower potential range of effect associated with climate change.
- The LLT Q4 scenario assuming the "wetter, less warming" upper bound (Q4) of an ensemble of GCM projections at a point in time 50 years into the future (~2060) and a sea level rise of 45 cm (18 inches). The LLT Q4 scenario is referred to later in this section as the Upper potential range of effect associated with climate change.

An example parameter showing the relationship between the Current, ELT Q5, LLT Q5, LLT Q2, and LLT Q4 scenarios is shown in Figure 25-6. The figure shows the CALSIM II model results for the No Project/No Action Alternative for Shasta Lake end-of-September storage conditions, and how these conditions are affected by climate change. This graphic indicates, in part, an anticipated trend as well as potential range of effect of climate change for one parameter (Shasta Lake end-of-September storage). The trend of climate change effect is indicated by the blue line that is described by the Current, ELT Q5,

---

[10] As of 2013, the Bay Delta Conservation Plan (BDCP) is being prepared by a group of local water agencies, environmental and conservation organizations, State and federal agencies, and other interest groups. DWR and Reclamation are the State and federal lead agencies, respectively.

11 The BDCP is being developed in compliance with the Federal Endangered Species Act and the California Natural Communities Conservation Planning Act. When complete, the BDCP will provide the basis for the issuance of endangered species permits for the operation of the State and federal water projects. The plan would be implemented over the next 50 years. The heart of the BDCP is a long-term conservation strategy that sets forth actions needed for a healthy Sacramento-San Joaquin Delta.

and LLT Q5 scenarios. The nomenclature "trend" is used because Q5 is the median climate change projection at 15 and 50 years. Thus, Q5 represents a central tendency of potential climate futures. The potential range of effects associated with climate change is described by the Q2 and Q4 climate change projections. As might be anticipated, for Shasta Lake end-of-September storage, LLT Q5 falls between the range Q2 (Lower) and Q4 (Upper). This result, where LLT Q5 falls between LLT Q2 and LLT Q4, is often, but not always, true.

Current, ELT Q5, and LLT Q5 Trend

The trend in climate and sea level conditions over the next 50 years is shown by the results of the three point trend of Current, ELT Q5, and LLT Q5 in climate and sea level conditions. Because this chapter seeks to describe a trend in the performance and impacts of the proposed Project alternatives under potential future climate and sea level conditions, comparisons were made between the proposed Project action alternatives (Alternative C in this chapter, as described below, and Alternatives A, B, and C in Appendix 25B) and the No Project/No Action Alternative with the same climate and sea level assumptions. The trend is described by the following data points for a given metric:

- NODOS action alternative (Current) minus No Project/No Action Alternative (Current)
- NODOS action alternative at ELT Q5 minus No Project/No Action Alternative at ELT Q5
- NODOS action alternative at LLT Q5 minus No Project/No Action Alternative at LLT Q5

In this section, the analysis of alternatives without climate change is referred to as Current because these analyses use current or historic hydrology and sea level conditions. These analyses, comparing proposed Project action alternatives to the No Project/No Action Alternative, with consistent climate and sea level scenarios, highlights potential future conditions that would exist with implementation of each of the proposed alternatives if climate changed consistent with the scenarios described. The use of three different climate scenarios (Current, ELT Q5, and LLT Q5) represent a central estimate of climate and sea level rise conditions that would persist at each time period, referred to as the climate change and sea level rise trend.

LLT Q2 and LLT Q4 Uncertainty Range

Because this chapter seeks to also describe a range in the performance and impacts of the proposed Project alternatives under a potential range of projected future climate and sea level conditions, comparisons were made between the proposed Project action alternatives (Alternative C in this chapter, as described below, and Alternatives A, B, and C in Appendix 25B) and the No Project/No Action Alternative with the same climate and sea level assumptions. The range is described by the following data points for a given metric:

- NODOS action alternative at LLT Q2 minus No Project/No Action Alternative at LLT Q2
- NODOS action alternative at LLT Q4 minus No Project/No Action Alternative at LLT Q4

Selected model inputs and results for the No Project/No Action Alternative are compiled in Appendix 25B. This compilation is helpful to understand the magnitude of potential changes associated exclusively with climate change and sea level rise without proposed Project implementation.

Model results for all proposed Project alternatives are compiled in Appendix 25B. This compilation is helpful to understand the magnitude of potential changes in the performance and effects of the proposed Project alternatives due to climate change and sea level rise.

The results of the sensitivity analysis are not intended to be used for detailed evaluation of proposed Project alternatives, and are subject to some limitations.

Use of Analytical Tools

The analytical process for incorporating climate and sea level scenarios into the CALSIM II simulation model includes the use of several sequenced analytical tools. These tools and the analytical process are shown conceptually in Figure 25-7. This process includes modified hydrologic inputs (inflow time-series) and modified flow-salinity relationships for Delta salinity compliance modeling.

Climate Scenarios

For the NODOS Project sensitivity analysis, ELT and LLT scenario representations (called scenarios) were selected. These scenarios were developed from a larger set of projections and were statistically derived from those projections. The ELT scenario considers climate conditions (temperature and precipitation) for a period of 30 years centered on analysis year 2025 (years 2011 to 2040) and projected sea level conditions at year 2025. Likewise, the LLT scenario considers climate conditions for a period of 30 years centered on analysis year 2060 (years 2046 to 2075) and projected sea level conditions at year 2060.

Consistent with the projections used in the IPCC Fourth Assessment Report (IPCC, 2007a), a collection of 112 future climate scenario projections (i.e., Global Climate Models) based on multiple models and multiple emission scenarios was used in the development of the ELT and LLT scenarios. The 112 future climate projections and the resultant five ensembles (Q1 through Q5) are graphically depicted in an example in Figure 25-5 using downscaled climate projections for a region in the Feather River watershed.

Based on the median (50th percentile) change of both annual temperature and annual precipitation (dashed blue lines in Figure 25-5), the state of change for a 30-year climate period can be broken into quadrants (or regions) representing Q1: drier, less warming; Q2: drier, more warming; Q3: wetter, more warming; and Q4: wetter, less warming. In addition, a fifth region Q5 can be described using samples from inner-quartiles (25th to 75th percentile) of the collection. In each of the five regions, the ensemble of climate change projections, made up of those contained within the region bounds, is identified. The Q5 ensemble was derived from the central trending climate projections and thus favors the consensus of the collection. Additional technical information related to the climate change scenarios used for the NODOS Project sensitivity analysis can be found in Appendix 25B.

Using ensembles, one ELT scenario and three LLT scenarios were selected to describe the sensitivity of California’s water resources systems and the sensitivity of the proposed Project alternatives. For evaluating proposed Project alternatives along the trend in climate and sea level conditions over the next 50 years, the ELT and LLT Q5 scenarios were selected. For evaluating proposed Project alternatives throughout the potential range of climate and sea level conditions at 50 years, near the mid-point of the proposed Project planning period, the LLT Q2 (drier, more warming) and Q4 (wetter, less warming) scenarios were selected because these scenarios would likely capture the bounding conditions of climate change and sea level rise relevant to the proposed Project alternatives being considered.

For a climate scenario, the statistics of the appropriate ensemble of downscaled climate change projections were used to develop modified hydrology for the 22 tributary watersheds of the Central Valley. The downscaled climate projections were used to create modified temperature and precipitation inputs for the Variable Infiltration Capacity (VIC) hydrology model. The VIC model simulates hydrologic processes on the one-eighth degree scale spatial resolution to produce statistics of watershed runoff. The changes in reservoir inflows and downstream accretions/depletions were translated into modified input time series for the CALSIM II model.

Sea Level Scenarios

Sea level projections were based on an existing empirical method (Rahmstorf, 2007). This method better reproduces historical sea levels and generally produces larger estimates of sea level rise than those indicated by the IPCC (IPCC, 2007a). When evaluating all projections of global air temperature, this method projects a mid-range sea level rise of 70 to 100 cm (28 to 40 inches) by the end of the century, and when factoring the full range of uncertainty, the projected rise is 50 to 140 cm (20 to 55 inches). Using this method, the projected sea level rise at year 2025 would be approximately 12 to18 cm (5 to 7 inches), and at year 2060 would be approximately 30 to 60 cm (12 to 24 inches). These sea level rise estimates are also consistent with those outlined in the recent USACE guidance circular for incorporating sea-level changes in civil works programs (USACE, 2009). For the proposed Project sensitivity analysis, a sea level rise of 15 cm (6 inches) was assumed for the ELT scenario and a sea level rise of 45 cm (18 inches) was assumed for all LLT scenarios.

Limitations of Sensitivity Analysis

There are limitations associated with the application and use of the NODOS Project climate change and sea level rise sensitivity analysis. The limitations are summarized below and described in greater detail in Appendix 25B.

The NODOS Project sensitivity analysis is limited by uncertainty related to climate change and sea level rise modeling. There is uncertainty in each sequenced step depicted in Figure 25-7. There are also specific uncertainties related to how operations may need to be modified to adapt to climate change, especially to mitigate the frequency of dead storage conditions at reservoirs caused by climate change and sea level rise. In addition, proposed Project operations may need to be modified to adapt to climate change and sea level rise effects to maximize the effectiveness of the additional storage provided by potential proposed Project implementation. These latter two limitations are related to the adjustment of operations that occur over time. Operators have learned how to operate the system of reservoirs and delivery facilities effectively with historic and current climate. Operators, as well as modelers, understand and learn what works and what does not work for the current climate, system requirements, and commitments. Consequently, operations effectively become “tuned” to the current climate. As climate change effects intensify, modified operations, or refinements, will likely be necessary to meet the multiple objectives of the CVP, SWP, and Central Valley systems. Also, proposed Project operations have been refined for the current climate analysis associated with the detailed evaluation of reasonably foreseeable conditions described in the remainder of the DEIR/EIS. As described below, information available as a result of the detailed and iterative modeling of the current climate was helpful in developing operations that minimize impacts and maximize benefits associated with adding offstream surface storage north of the Delta. In contrast, the refining of proposed Project operations for the ELT Q5, LLT Q5, LLT Q2, and LLT Q4 scenarios was less precise and of less quality because detailed modeling was not used.

NODOS Project Assumptions and Operating Criteria

As described above, the CALSIM II simulations of the proposed Project action alternatives were developed and refined to the conditions of the existing water resources system and current climate. This process was iterative using the full suite of hydrologic, operations, water quality, fisheries, power, and economics models applied to the detailed evaluation of proposed Project action alternatives. A description of the suite of models is provided in Appendix 6B. This refinement process was performed for each individual operational element that depends on the proposed Sites Reservoir, and included definition of metrics, assessment of beneficiary performance, modification of assumptions and inputs to improve performance, and prioritization of beneficiary performance.

However, only the CALSIM II model was used for the sensitivity analysis; therefore, much of the information required to provide feedback to the NODOS Project operating criteria was not available. There was limited consideration of how potential benefits may have been impacted due to climate change and sea level rise; therefore, additional refinements of NODOS Project operating criteria under climate change and sea level rise conditions were limited as well.

Following the initial set of sensitivity analyses simulations, with only the CALSIM II model results available, it was evident that some significant changes would occur in the performance of the proposed Project action alternatives. Based upon these observed changes, a minor alternative refinement was made for the NODOS climate change sensitivity analysis. An increased need for improved storage and maintenance of coldwater pools under ELT Q5 and substantially more under LLT Q2 and Q5 climate and sea level conditions was identified. A decision was made to limit other operations that put the higher priority Ecosystem Enhancement Storage Account (EESA) actions related to coldwater pools at risk. These variations in the NODOS Project operating criteria assumed throughout the climate and sea level rise scenarios are shown in Appendix 25B, Table 25-2. This limited refinement is reflected in the action alternative results discussed below.

Limitations Considerations

The results of the sensitivity analysis should be considered as a tool to provide a comparative understanding of the trend of climate change effects and the relative performance of NODOS Project alternatives with climate change. Any conclusions derived from the sensitivity analysis results should be considered to be qualitative and as an indicator of potential changes related to climate change and sea level rise. Consequently, the results of this analysis should not be used independently for decision making purposes, but rather as supplemental to the detailed evaluations in the Draft Feasibility Report and DEIR/EIS.

In the CALSIM II model, dead pool conditions are assumed at 240 TAF for Trinity Lake, 550 TAF for Shasta Lake, 30 TAF for Lake Oroville, and 90 TAF for Folsom Lake. These are extreme operational limits and are well below the range of reasonable reservoir operations. In real-time reservoir operations, operators and regulators would significantly modify operations to avoid a dead pool condition. As storage in a reservoir approaches dead pool, operators and regulators would initiate an emergency consultation and agree on a modified operational strategy to meet various commitments in a more limited way. This type of modified operation is not included in the CALSIM II operations simulation since the circumstances of an emergency consultation can vary in significant ways. While CALSIM II results are not considered to be predictive generally, the limitations regarding results that indicate dead pool conditions at a reservoir are especially important to understand. Dead pool occurrences in this document should be understood to mean that a reservoir, and more broadly a system of reservoirs, would likely be operating in an emergency condition. The ability to meet one or more system objectives will be impaired and normal operations cannot be sustained.

Analysis Results

The results of the NODOS Project climate change and sea level rise sensitivity analysis include both an effect trend as well as a potential range of effect related to climate change and sea level rise.

Model inputs and results for the No Project/No Action Alternative and for all proposed Project action alternatives are compiled in Appendix 25B. Some additional results and findings are presented below.

No Project/No Action Alternative Findings

The No Project/No Action Alternative findings are based on a sensitivity analysis of changes in the SWP/CVP/Delta system that are expected to occur over the next 50 years as a result of a changing climate only (i.e., without implementation of a proposed Project).

The following observations related to the effect of climate change and sea level rise are primarily based on the Current, ELT Q5, and LLT Q5 scenario trend differences. Generally, these observations are consistent with water management and climate change effects expected and described previously. They are based on the results of VIC simulations of the climate and sea level scenarios selected and the subsequent results of CALSIM II simulations of the No Project/No Action Alternative:

- Increased runoff in late winter/early spring and reduced runoff in late spring and summer
- Increased salinity in the western and central Delta
- Reduced river and Delta inflow due to decreases in runoff, specifically in summer months and Dry and Critically Dry year conditions
- Increased Delta outflow requirements in Dry and Critically Dry year conditions due to increased salinity conditions
- Increased use of reservoir storage to maintain flow, temperature, and Delta salinity requirements
- Decreased use of reservoir storage to meet demands for agricultural and urban water use
- Decreased reservoir storage conditions in summer and fall and uncertain changes in frequency of annual refilling of existing reservoirs
- Increased variability and overall decreased water allocations for SWP and CVP Delta exports and other diversions
- Increased occurrence of dead pool[12] storage at reservoirs and potential operational interruptions

The CALSIM II results indicate changes in flows and storage conditions from the Current, ELT Q5, and LLT Q5 scenario trend, and to some extent the potential range of LLT Q2 and Q4 scenarios, such that the following is expected (but has not been confirmed with detailed modeling):

- Increased water temperatures in reservoirs and rivers
- Reduced suitable riverine habitat for coldwater fish due to warmer water temperatures throughout all seasons and lower flows during late spring and summer
- Modified peak and natural pulse flow conditions

Of particular importance is the finding of increased salinity in the western and central Delta. This salinity effect would be caused primarily by sea level rise, where sea water from San Francisco Bay would intrude into the Delta. The observed trend and range of effects to the X2 position is almost exclusively eastward,

[12] For the purposes of this analysis, "dead pool" occurs when the operating storage in a reservoir equals zero. For most reservoirs, some water would remain in storage as described previously, but it could not be released for any downstream purpose because the water is at or below the lowest intake level.

indicating increased salinity. As shown in Table 25B-20 of Appendix 25B, X2 movement associated with climate change ranges between -0.3 km (0 percent) in October to 3.6 km (5 percent) in May. All months except October show positive or eastward movement, indicating diminished water quality. This result is indicated by comparing average X2 position associated with the No Project/No Action Alternative using current climate and the LLT Q5 trend. Consequently, Delta outflow would need to be increased because more water would be required to meet water quality requirements. The result would be a reduced amount of water available in storage to manage the system for all other uses. Consequently, storage in the major CVP and SWP reservoirs north of the Delta (including Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake) would decrease, and exports from the Delta would be reduced. These results are consistent with previous studies finding that CVP and SWP operations would be most affected by annual runoff through mid-century, and then sea level rise becomes the most critical factor by the end of the century (Wang et al., 2011).

In addition, the climate change sensitivity analysis findings indicate that California's major water systems would become increasingly vulnerable to operational interruptions. For example, the occurrence of dead pool conditions at system reservoirs would increase with climate change. This type of vulnerability to operational interruptions is discussed in greater detail below and in Appendix 25B.

Proposed Project Action Alternatives Findings

Model results for all alternatives are compiled in Appendix 25B. The results in the appendix are shown in tables as seasonal, annual, and selected monthly values; differences with the Current climate and sea level scenario; and differences with the No Project/No Action Alternative for Current, ELT Q5, and LLT Q5 climate and sea level scenarios. The results are presented for long-term and upper, above median, below median, and lower quartile range averages. The results are also shown graphically as seasonal, annual, and selected monthly values ranked and charted against probability of exceedance; exceedance figures show the entire range of probability.

The following conclusions were made based on the comparison of the results of the CALSIM II simulations for the proposed Project action alternatives with the No Project/No Action Alternative evaluated for Current, ELT, and all LLT climate and sea level scenarios:

- The ability to divert water into proposed Project storage would be the same or slightly increased due to changes in the timing of snowmelt runoff and the continued opportunity to use the intakes under a wide range of climate scenarios.
- The proposed Project action alternatives could provide a similar array of potential benefits under a range of climate and sea level scenarios, including the primary objectives of (1) increasing survival of anadromous fish populations, (2) improving water supply reliability for agricultural, urban, and environmental uses, and (3) improving drinking and environmental water quality in the Delta.
- The proposed Project action alternatives would improve system storage conditions and could mitigate some of the effects of climate change and sea level rise specifically related to impacts on storage operations and associated increase in vulnerability of the water resources system to operational interruption.

The sensitivity analysis did not include the full suite of models that are listed in Appendix 6B, such as daily operations, temperature, fisheries, and economics modeling. However, the CALSIM II results do indicate changes in flows and storage conditions between the proposed Project action alternatives and the

No Project/No Action Alternative throughout the Current, ELT, and all LLT scenarios such that the following is expected (but has not been confirmed with modeling):

- The proposed Project with climate change would likely improve the temperature regime of the upper Sacramento River for salmonids, when compared to the No Project/No Action Alternative with climate change.
- As observed, the No Project/No Action Alternative performance of the CVP and SWP systems (for the purposes of water supply, water quality maintenance, and maintenance of aquatic habitats) would decrease with climate change and sea level rise because the systems would have less water to manage. Because the reliability of the SWP and CVP would be diminished with climate change, the economic value of additional water would likely be enhanced. The total value of proposed Project benefits may be greater as well.

Specific Effects of Climate Change and the Proposed Project

The analysis and discussion of effects to proposed Project action alternatives associated with climate change and sea level rise included both the trend (which includes the Current, ELT Q5, and LLT Q5 scenarios) and the range of potential effects (which includes LLT Q2 and LLT Q4 scenarios). The analysis and discussion focused on the sensitivity effects upon Alternative C. As shown in the comprehensive presentation of effects based upon detailed modeling, Alternative C consistently has the greatest effect upon resources, when compared to the No Project/No Action Alternative. Consequently, Alternative C likely reflects the greatest effect associated with climate change and sea level rise. The following observations were made based upon analyses and review of the sensitivity analysis results. A change in the trend of a metric of greater than five percent was considered to be a sensitive response to that metric. A change of less than five percent was considered to be minimally sensitive. Where appropriate, the cases where results support the anticipated effects described in the preliminary sections are identified.

1. Diversion to proposed Project storage for improved flexibility and benefits appears resilient to climate change and sea level rise effects. Diversion to proposed Project storage would be minimally sensitive to climate change and sea level rise, as shown in Figure 25-8. The trend in diversion to proposed Project storage indicates that there would be a reduction of less than one percent in the ELT Q5 scenario, and increases in diversion for all LLT scenarios. The observed LLT Q5 trend of diversion to proposed Project storage indicates an increase of 4.4 percent, when compared to the Current scenario. The increase in diversion to fill the proposed Sites Reservoir under all LLT climate and sea level scenarios demonstrates the resilience of the proposed Project in capturing excess flows for later use. This finding is consistent with and supported by the finding of increased runoff in late winter/early spring due to increased temperature effects on the timing of snowmelt runoff in the ELT and LLT scenarios.

   The proposed Project would rely on water from a combination of sources, including the Sacramento River that flows into and through Shasta Lake, the Trinity River, and the tributaries between Shasta Lake and the proposed Delevan Pipeline. The result described above associated with proposed Project diversion capability indicates more specifically the resilience of the source waters for the proposed Project as their runoff pattern is modified by climate change and sea level rise. Meanwhile, a downward trend in north-of-the-Delta storage (at Trinity, Shasta, Oroville, and Folsom) was observed in the No Project/No Action Alternative and all proposed Project action alternative scenarios for the ELT Q5 and LLT Q5 climate and sea level scenarios. The rate of decline in storage conditions would be slowed by the addition of the proposed Sites Reservoir to the water system. The expected increase of diversion to fill Sites Reservoir, for proposed Project action alternatives under all climate and sea level scenarios, coupled with the observed decrease in Sites Reservoir storage conditions relative to the Current scenario indicates that Sites Reservoir would fill and release at higher rates, potentially producing greater levels of benefits as climate change and sea level rise worsen.

2. System flexibility improvements (previously identified as a system need), as measured by end-of-May additional water in storage, would be minimally sensitive to climate change and sea level rise. Water in storage in May was shown because it represents the quantity of water available for system uses by water managers and operators as they enter the high water use season (for water supply, water quality maintenance in the Delta, and upstream habitat requirements). The trend of average additional water in storage in May, as shown in Figure 25-9 would be reduced by 0.25 percent for the ELT Q5 scenario and by 4.1 percent for the LLT Q5 scenario. As climate change and sea level rise effects increase, the ability of the proposed Project to improve flexibility would be somewhat diminished. The potential range of effect would range from a 1.8 percent increase to a 9.0 percent decrease. The amount of additional water available in storage in Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, and the proposed Sites Reservoir would improve water and fisheries managers' ability to respond to various uncertainties and challenges, including climate change and sea level rise.

   For the proposed Project action alternatives, Sites Reservoir storage conditions would decrease consistent with the trend observed in existing SWP and CVP storage across the ELT Q5 and LLT Q5 climate and sea level scenarios. These trends are similar; however, not as large as the trends seen for the No Project/No Action Alternative. The distinct difference in these trends in total storage between the proposed Project action alternatives and the No Project/No Action Alternative is that the No Project/No Action Alternative results show a substantial loss in systemwide storage due to climate change and sea level rise. The proposed Project action alternatives show improved storage, when compared to the No Project/No Action Alternative. As climate change and sea level rise effects increase, the gain in storage in comparison to the No Project/No Action Alternative (without climate change and sea level rise) would be lost. The results over the ELT Q5 and LLT Q5 trend show that the proposed Project action alternatives could mitigate the loss in storage associated with the ELT Q5 scenario and, depending on the alternative, much of the loss in storage associated with the LLT Q5 scenario. The proposed Project action alternatives could not mitigate for the loss in storage in the LLT Q2 scenario. Also, the ability of the proposed Project action alternatives to accomplish the proposed Project's primary objectives would depend primarily on the ability of the action alternative to store and manage additional flows not otherwise available in the No Project/No Action Alternative. Under all climate and sea level conditions, including Current, there would be improvements in operations of these reservoirs with the proposed Project action alternatives, when compared to the No Project/No Action Alternative under the same climate and sea level condition. It is assumed that reduction in these extreme operations (operating at dead pool conditions) would improve compliance with minimum flow criteria and Delta salinities standards, and would help to meet allocated diversion volumes and water rights priorities, as well as operating agreement requirements.

   Finally, system flexibility (water in storage) is an excellent indicator of the viability and sustainability of the SWP and CVP water management systems. The ability of the systems to accomplish most of their purposes, including water supply, instream flows, temperature and habitat maintenance, Delta water quality, hydropower generation, and recreation, depend upon water in storage. Therefore, it is likely that if water in storage is improved by implementation of the proposed Project, then the long-term viability and sustainability of California's water management system would be improved as well.

The ability of the proposed Project to provide benefits (i.e., meet Project objectives) is measured by metrics chosen to represent the three main proposed Project water benefits. These benefits are fish survival (indicated by the coldwater pools at existing reservoirs), water supply reliability (indicated by Delta deliveries to SWP and CVP contractors), and improved water quality (indicated by the X2 position). These metrics are described below in items 3 through 5.

3. Cold water pool improvements at the existing reservoirs, as indicated by additional end-of-September storage at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake, would be sensitive to climate change and sea level rise (Figure 25-10). The trend of Alternative C additional water in storage at existing reservoirs would be reduced by 13.2 percent and 16.8 percent for the ELT Q5 and LLT Q5 scenarios, respectively. The potential range of effect on the coldwater pool improvement does not contain the trend. For most metrics, Q5 falls within the Q2 to Q4 range. In this case, the coldwater pool improvement would be 3.2 percent to 41.0 percent for Q4 and Q2, respectively. For the primary Project objective of increasing survival of anadromous fish populations, the highest priority would be to maintain improved storage conditions through the Dry years and summer months (July through September season). The improvement in storage conditions during these periods would retain cooler water (i.e., a coldwater pool improvement) and allow for more water releases for improving temperature conditions in the river reaches downstream of these reservoirs. As indicated by the improvement in the beginning (end-of-May storage) and ending (end-of-September storage) of the coldwater pool maintenance period, there would be a potential improvement in temperature conditions downstream of Trinity Lake, Shasta Lake, Lake Oroville and Folsom Lake with the proposed Project action alternatives, when compared to the No Project/No Action Alternative under the same climate and sea level scenario. This was found to be the case under the Current scenario evaluated in the Draft Feasibility Report and in the detailed evaluation of the Draft EIR/EIS. Consistent with the intent of the proposed Project action alternatives operations, the most substantial relative improvement in storage would be at Shasta Lake.

   Habitat suitability for anadromous fish populations is dependent upon both temperature and flow conditions. The expected improvement in storage conditions during the Dry years and summer months (July through September season) for cooler water (i.e., a coldwater pool improvement) and more water with the proposed Project action alternatives would result in temperature and flow improvements through increases in reservoir releases during Dry years and summer months (July through September season). These results indicate that proposed Project action alternatives would continue to improve conditions for fish survival with climate change.

4. Water supply reliability improvements, as indicated by exports from the Banks and Tracy pumping plants, would be minimally sensitive to climate change and sea level rise (Figure 25-11). Between Current, ELT Q5, and LLT Q5 climate and sea level scenarios, for all proposed Project action alternatives, long-term average annual total exports from the Banks Pumping Plant and Jones Pumping Plant would increase, when compared to the No Project/No Action Alternative. There are variations in these changes across climate scenarios as the changing conditions for Delta exports vary. This variation was described for the No Project/No Action Alternative. The values vary more in the LLT Q2 and Q4 results. Across all climate and sea level scenarios, below median and Dry year (lower quartile) averages show additional exports are sustained in drier year types due to the proposed

Project action alternatives. The absolute and relative magnitude of improvement increasing as the effect of climate change and sea level rise increases.

The relative increase in annual total exports under below median and Dry year average conditions is an indicator of the economic impact of the primary Project objective of improving water supply reliability for urban uses. The economic value of a given increment of water for urban use would increase as the "without project supply condition" deteriorates with climate change and sea level rise. The results of the sensitivity analysis indicate that the increment of water provided by the proposed Project action alternatives could increase even as overall system supply decreases. The primary Project objective of water supply reliability also includes agricultural and environmental uses (such as the replacement of wildlife refuge water supplies). The economic value of each of these supplies would be increased by storing and exporting these supplies through the Delta and making them available to the south-of-the-Delta water resources system. The results of the absolute and relative trends, when compared to the No Project/No Action Alternative, for below median and Dry year pumping at Banks Pumping Plant and Jones Pumping Plant indicate that the proposed Project action alternatives would continue to perform well (i.e., reliability improvements are sustained when comparing without climate change against with climate change) for the primary Project objective of increasing water supply reliability and indicate a trend of increased economic value of the exports as climate change and sea level rise occurs.

5. Water quality improvements, as indicated by the X2 position during July through September, would be minimally sensitive to climate change and sea level rise (Figure 25-12). The sensitivity analysis indicates that the trend of the X2 position would diminish by 0.1 percent in the ELT Q5 scenario and increase by 0.1 percent in the LLT Q5 scenario, when compared to the Current scenario. Between Current, ELT Q5, and LLT Q5 climate and sea level scenarios, the X2 position (and Old River at Rock Slough salinity conditions) would be improved during April through December. An improvement is indicated by a westward movement (i.e., reduction) in the X2 position (distance from the Golden Gate Bridge in kilometers) or a reduction in electrical conductivity (EC). The No Project/No Action Alternative results indicate that the degree of impact to the X2 position would vary according to Delta outflow conditions, and that the X2 position would move further eastward (i.e., it would increase) under all climate and sea level scenarios, when compared to the Current scenario.

   The improvement shown in the ELT Q5 and LLT Q5 scenarios, when comparing the proposed Project action alternatives and the No Project/No Action Alternative at a specific climate and sea level condition, would result from the operation of the proposed Project for supplemental Delta outflows to improve water quality conditions for urban intakes and environmental benefit in the Delta. These releases would occur in the summer (July through September) and fall (October through December). The effectiveness of improving Delta water quality conditions with supplemental releases from the proposed Project would decrease with sea level rise. Water quality would still be improved with the proposed Project, but to a lesser degree. Under ELT Q5 and LLT Q4 scenario conditions, the releases would be as effective as, or more effective than, under the Current scenario; however, under LLT Q5 and LLT Q2, the effectiveness of releases would be further diminished. For this reason, the Ecosystem Enhancement Storage Account (EESA) Action 5 (Delta outflow for Delta Smelt Habitat Improvement) was removed from the climate change sensitivity analysis. This EESA water is instead used in this sensitivity analysis to further enhance the increase coldwater pool actions at the existing reservoirs. Consequently, the water quality improvement provided by the proposed Project is less than in the detailed analysis, which includes the ecosystem water quality action.

The results of the X2 position and the Old River at Rock Slough salinity results indicate that in summer and fall (July through December), there would be a potential benefit of operating the proposed Project action alternatives for the primary Project objective of improving drinking water quality and environmental water quality in the Delta. Water quality improvements would still be achievable even in climate change and sea level rise scenarios where the improvement would require relatively more water than in the Current scenario.

6. The sustainability of system reservoirs would be sensitive to climate change and sea level rise, as indicated by the trend increase of dead storage occurrences associated with the No Project/No Action Alternative. The proposed Project would have the ability to provide improved system sustainability, as indicated by reductions in occurrences of dead storage at system reservoirs; however, this ability would be sensitive to climate change and sea level rise. Dead storage occurrences would increase from 28 to 69 to 123 for the No Project/No Action Alternative under the Current, ELT Q5, and LLT Q5 scenarios, respectively. With Alternative C, the occurrences would be reduced to 9, 35, and 111, respectively. Both the No Project/No Action Alternative and Alternative C expected occurrences of dead storage are shown in Figure 25-13. The proposed Project effect of mitigating occurrences of dead storage would be reduced as the trend of climate change and sea level rise continues, with reductions of 67.8 percent, 49.3 percent, and 9.8 percent for the Current, ELT Q5, and LLT Q5 scenarios, respectively. The frequency of dead pool conditions would increase under ELT Q5 and LLT Q5 climate and sea level scenarios.

NODOS Effects with Climate Change and Sea Level Rise

The NODOS Project climate change and sea level rise sensitivity analysis compares some metrics associated with some environmental resources. As a sensitivity analysis, the evaluation is not as comprehensive or precise as the detailed evaluation of effects in the environmental resource chapters of this EIR/EIS (i.e., Chapters 6 through 31). The evaluations of proposed Project effects within the environmental resource chapters are based upon Current climate conditions.

The following discussion provides a general understanding of how environmental resources and effects associated with the proposed Project action alternatives may be altered with climate change. Each of the environmental resource categories are described with consideration of the anticipated general climate change effects to the resource, the potential for changed proposed Project effects with climate change, as compared to without climate change (i.e., as presented in the environmental resource chapters), and potential resiliency improvements that may be provided by proposed Project implementation. For this discussion, resilience for a resource is a potential improvement of the capacity for that resource to return to prior conditions after anticipated climate change and sea level rise effects.

Generally, the relative degree of environmental effects would be greater under the Current climate scenario because the SWP and CVP systems are already subject to significant environmental effects with the No Project/No Action Alternative in the climate change and sea level rise scenarios. If a significant effect were identified for the Current scenario, the effect would likely be relatively less significant in the sensitivity analysis scenario. As previously noted, effects to resources associated with the detailed evaluation and Current climate are evaluated using more comprehensive and detailed analysis and modeling. These more detailed evaluations and descriptions of proposed Project effects are found in the individual resources chapters. These more comprehensive analyses were not included as part of the climate change and sea level rise sensitivity analysis. Consequently, more precise determinations of effects associated with the sensitivity analysis are not available.

Surface Water Resources (Chapter 6)

Climate change and sea level rise are expected to affect surface water resources due to the anticipated increased air, water, and soil temperatures; altered runoff; increased frequency and severity of floods and droughts; and Delta salinity intrusion. Most of these effects were evaluated in the NODOS Project climate change sensitivity analysis in this chapter. The sensitivity analysis results indicate that most metrics of surface water resources, including reservoir storage, streamflow, and deliveries, would trend negatively as climate change and sea level rise effects increase in the future. However, with implementation of Alternatives A, B, and C, water supply reliability would be maintained or increased, when compared to the No Project/No Action Alternative. The NODOS Project formulations were developed to add resiliency to the CVP, SWP, and Central Valley water systems. As noted, these systems have an identified need for flexibility (i.e., water in storage) that would be demonstrably enhanced by implementation of the proposed Project. In addition, the proposed Project’s ability to meet objectives that require additional water, including fish survival, water supply reliability, water quality, and flexible generation hydropower, appears resilient to climate change and sea level rise effects. Having more water in storage, both in the proposed Sites Reservoir and in existing reservoirs, would allow water system operators and managers to more easily adapt to a number of future uncertainties, including climate change.

Surface Water Quality (Chapter 7)

Climate change and sea level rise are expected to affect surface water quality due to the anticipated increased water temperatures, altered runoff, increased frequency and severity of floods and droughts, and increased Delta salinity. As noted previously, salinity in the western and central Delta is expected to increase due to both sea level rise and changes in runoff, especially during summer/fall months and drier year type conditions. As in the detailed Current climate analysis comparison of proposed Project effects, the X2 position would generally increase during the winter/spring period when the proposed Project would divert, and the X2 position would improve (i.e., decrease) during summer/fall, reflecting the Delta water quality proposed Project objective improvements. According to the sensitivity analysis, changes to the X2 position with climate change would be similar to those with Current climate. Improvements to the X2 position supported by the proposed Project water quality objective operations would, however, become relatively less effective with climate change and sea level rise. As noted in the Surface Water Resources discussion presented above, the proposed Project action alternatives would be a helpful adaptive asset and provide resilience because water system operators and managers would have more water in storage to manage Delta water quality, among other proposed Project and existing system objectives.

Fluvial Geomorphology and Riparian Habitat (Chapter 8)

Climate change and sea level rise may change our rivers geomorphic characteristics and associated riparian habitat. Changes could occur as a result of the anticipated increased frequency and severity of high flow events and erosion, and changes in runoff timing. In addition, future reservoir operations would be maintained at relatively lower levels to respond to increased demand. These operations would allow a greater percentage of flood flows to be managed by existing reservoirs, thereby reducing geomorphic function and riparian succession below those facilities. The total direction and magnitude of these effects associated with climate change and sea level rise are uncertain. However, the adaptive capability and resilience of the system, as described above, would be improved with proposed Project implementation.

Relatively fuller reservoirs (such as associated with proposed Project implementation) may improve resiliency to climate change and sea level rise for geomorphic functions and riparian success.

Flood Control and Management (Chapter 9)

Climate change and sea level rise are anticipated to affect flood management. Water storage levels in existing reservoirs with climate change and sea level rise are expected to trend down. This result is shown in the sensitivity analysis No Project/No Action scenario. This effect could provide some improvement in flood management capability by providing more space in reservoirs for flood events. However, expected increases in the frequency and severity of high flow events would diminish flood management capability. The total magnitude and direction of effects on flood management is uncertain, and therefore, speculative. As noted in Chapter 9 Flood Control and Management, there would be some flood management benefit for the areas immediately downstream of the proposed Project dams that are prone to flooding. The adaptive capability related to flood management is less certain. As noted above, water system operators and managers would have more water to manage with proposed Project implementation than without. The expected additional water in storage could potentially provide operators and flood and water managers additional system resources to shift additional flood management protection to existing reservoirs, thus providing some resilience. This type of operation was not included in the proposed Project action alternatives formulations. Although this type of adaptive operation would be possible and would provide some resilience for flood management, this type of flood management operational change is speculative.

Groundwater Resources (Chapter 10)

Groundwater resources are likely to be affected by climate change and sea level rise. Groundwater use is expected to increase as surface water availability is affected by increasing temperatures, as runoff shifts, and due to Delta salinity intrusion that would require additional water quality dedicated releases from reservoirs. Comparative effects of the proposed Project would likely be similar with current conditions, when compared to climate change and sea level rise conditions. Some resilience of groundwater resources may be provided by proposed Project benefits because the water system (i.e., surface and groundwater) would be improved by proposed Project reliability benefits and improved surface water storage conditions. For example, a more reliable surface water system would reduce dependence upon the groundwater system. Consequently, the adaptive capability and resilience of the surface water system would improve the resiliency of the groundwater resources that are expected to lose resilience with climate change and sea level rise.

Groundwater Quality (Chapter 11)

Climate change and sea level rise are expected to affect groundwater quality due to the anticipated changes in runoff, increased soil temperature, and Delta salinity intrusion. Specific climate change and sea level rise effects, as well as potential changes to identified proposed Project impacts to groundwater quality within the three study areas, are uncertain.

Aquatic Biological Resources (Chapter 12)

Climate change and sea level rise are expected to affect aquatic biological resources due to the anticipated increased air and water temperatures, altered runoff and erosion, Delta salinity intrusion, and increased acidification of ocean waters from increased CO_2. The ability of water system operators to maintain stream temperatures that support salmonids would likely be increasingly challenged as the coldwater pools at existing reservoirs are compromised due to other increasing system needs. Increased air temperatures are expected to lead to increased water temperatures in streams and reservoirs. The climate change and sea level rise sensitivity analysis indicates a trend of decreased water in storage for the No Project/No Action Alternative. As climate change effects increase over time, more water is expected to be required to meet Delta salinity standards, which would decrease the amount of water available for all other purposes, including instream fishery needs such as coldwater pool management and stream temperature maintenance.

As noted previously, the proposed Project alternative operations with climate change were modified (when compared to the proposed Project alternatives operations with current climate) to emphasize coldwater pool management over the delta smelt habitat supplemental flows. Some Project-related water quality improvements would persist (as noted above). The proposed Project would provide significant adaptive capability for water and fishery managers that face uncertain future conditions, including climate change and sea level rise. The fish survival actions that improve the coldwater pools at existing reservoirs and provides supplemental temperature flows downstream would provide some resilience to increased water temperatures that are expected with climate change and sea level rise. Improved water in storage would improve water system operators' ability to support system objectives, including maintaining and improving anadromous fish habitat. The benefits associated with fish survival, with the exception of supplemental flows for delta smelt, appear to be sustainable with the climate change and sea level rise trend.

The NODOS Investigation has made recommendations to support an adaptive approach to the fishery benefits provided by the proposed Project. Conceptually, the fishery benefits would be supported by a proposed Project EESA, as described in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives. More practically, a portion of proposed Project resources (i.e., storage and conveyance) would be committed to providing eight water-related actions to improve anadromous fish habitat at and downstream of existing CVP and SWP reservoirs and in the Delta. The relative priorities of ecosystem actions supported by the EESA may change over time. Climate change and sea level rise effects may warrant some adaptation of the EESA. Modifications could be made with the approval of member agencies of a proposed governing board. This adaptive capability would support the resilience of the proposed Project and its benefits.

Botanical Resources (Chapter 13)

Climate change and sea level rise are expected to affect botanical resources due to the anticipated increased air and water temperatures, altered runoff and erosion, increased frequency and severity of flood and drought events, and salinity intrusion in the Delta. These effects could result in changes in vegetation species abundance (including invasive species), habitat quality, species range, and the spread of pests. The relative effect of climate change and sea level rise upon the identified proposed Project impacts to botanical resources is uncertain.

Terrestrial Biological Resources (Chapter 14)

Climate change and sea level rise are expected to affect terrestrial biological resources due to the anticipated higher temperatures, altered runoff and erosion, increased frequency and severity of flood and drought events, and Delta salinity intrusion. These effects are expected to contribute to decreased wildlife species abundance and habitat quality. However, some of these effects could improve conditions for certain species. For example, the anticipated increased frequency and severity of flood events and associated erosion with climate change would likely increase the quantity and quality of bank swallow nesting habitat.

The climate change sensitivity analysis indicates a general decrease in storage at existing reservoirs with the No Project/No Action Alternative. The analysis also indicates an increase in storage with proposed Project implementation, when compared to the No Project/No Action Alternative. This Project-related increase in storage would likely benefit bald eagles because long-term monitoring data from Shasta Reservoir indicate that bald eagle production increases as reservoir surface water elevation increases. The relative effect of climate change and sea level rise upon the identified proposed Project impacts to terrestrial biological resources is uncertain.

Wetlands and Other Waters of the U.S. (Chapter 15)

Climate change and sea level rise are expected to affect wetlands and other waters of the U.S. Because wetlands and waters of the U.S. are a subset of surface water resources, the effects described for surface water resources would also apply to this resource. The effects include increased air, water, and soil temperatures; altered runoff; increased frequency and severity of floods and droughts; and Delta salinity intrusion. In addition, decreased species abundance and habitat quality, the spread of pests, and increased fire risk would affect wetlands. The proposed Project would provide improvements and adaptive capability to the water resources systems of the State, including the CVP and SWP and their respective facilities and associated watersheds, including improved storage conditions. Improved storage may provide some resilience to the effects of climate change and sea level rise upon wetlands and waters of the U.S. Relatively fuller reservoirs would more effectively support downstream wetlands and waters of the U.S. that are dependent upon either deliveries or streamflow. The relative effect of climate change and sea level rise upon the identified proposed Project impacts to wetlands and other waters of the U.S. is uncertain.

Geology, Minerals, Soils, and Paleontology (Chapter 16)

Climate change and sea level rise could affect geology, minerals, soils, and paleontology due to the anticipated increased soil temperature, altered runoff, increased frequency and severity of flood and drought events, increased Delta salinity intrusion, and changes in rates of erosion. The relative effect of climate change and sea level rise upon identified proposed Project impacts to these resources is uncertain.

Faults and Seismicity (Chapter 17)

Faults and seismicity are not expected to be affected by climate change and sea level rise. However, if there is an effect, the relative effect of climate change and sea level rise upon identified proposed Project impacts to this resource is uncertain.

Cultural Resources (Chapter 18)

Climate change and sea level rise are expected to affect cultural resources due to the anticipated increased soil temperatures, altered runoff and erosion, increased frequency and severity of flood and drought events, Delta salinity intrusion, and increased fire risk. The relative effect of climate change and sea level rise upon identified proposed Project impacts to cultural resources is uncertain.

Indian Trust Assets (Chapter 19)

The nature of Indian Trust Assets indicates a potential connection to other resource areas including land use, surface water, minerals, and terrestrial and aquatic biological resources. However, as noted in Chapter 19, there are no ITAs within the vicinity of the proposed Project study areas.

Land Use (Chapter 20)

Land use is expected to be affected by climate change and sea level rise due to the anticipated increased air and soil temperature, altered runoff, Delta salinity intrusion, and increased fire risk. The relative effect of climate change and sea level rise upon identified proposed Project impacts to land use is uncertain.

Recreation Resources (Chapter 21)

Climate change and sea level rise are expected to affect recreation resources due to the anticipated increased temperatures, altered runoff, increased frequency and severity of flood and drought events, and Delta salinity intrusion. These effects could result in changes in species abundance, habitat quality, pest populations, and fire risk. Proposed Project implementation would result in increased surface water level fluctuations at San Luis Reservoir. The relative effect of climate change and sea level rise upon identified proposed Project impacts to San Luis Reservoir is uncertain.

Generally, recreation opportunities would be diminished when reservoir water storage levels are low. Implementation of the proposed Project action alternatives is expected to improve storage conditions in the reservoirs north of the Delta, including Trinity, Shasta, Oroville, and Folsom. The higher reservoir levels associated with proposed Project implementation would provide recreation benefits at those reservoirs. With climate change and sea level rise, the trend of Alternative C additional water in storage at existing reservoirs would be reduced, but would still be an improvement, when compared to the No Project/No Action Alternative.

Socioeconomics (Chapter 22)

Climate change and sea level rise are expected to affect socioeconomics due to the anticipated increased temperatures, altered runoff, increased frequency and severity of flood and drought events, Delta salinity intrusion, spread of pests, and increased fire risk. Specifically, climate change and sea level rise effects to the CVP and SWP water systems could have various negative effects to socioeconomics, including an increase in the price and availability of water, increasing crop prices as well. The relative effect of climate change and sea level rise upon identified proposed Project impacts to socioeconomics is uncertain. From a proposed Project perspective, the array of benefits appears to be sustainable with climate change and sea level rise (refer to Figures 25-10 through 25-12). The unit value of the benefits would likely be greater with the effects of climate change and sea level rise, assuming a typical supply and demand response (i.e., as supply is diminished by climate change and sea level rise effects, a shortage would result in higher water prices or value). Because the proposed Project benefits associated with Project objectives appear sustainable and the unit values would likely be greater, some resilience or positive socioeconomic effects appear likely with climate change and sea level rise as well.

Environmental Justice (Chapter 23)

Climate change and sea level rise are expected to affect the general population. Consequently, similar effects are anticipated with minorities and low-income populations (i.e., environmental justice populations) as well due to the anticipated increased temperatures, increased severity and frequency of flood and drought events, Delta salinity intrusion, changes in species range, and distribution, and increased fire risk. The relative effect of climate change and sea level rise upon identified proposed Project impacts to environmental justice populations is uncertain.

Air Quality (Chapter 24)

Climate change and sea level rise are expected to affect air quality due to the anticipated increased air temperatures, increased frequency and severity of floods, increased fire risk, and ocean acidification. The relative effect of climate change and sea level rise upon identified proposed Project impacts to air quality is uncertain.

Climate Change and Greenhouse Gas Emissions (Chapter 25)

Proposed Project operations would be similar with and without climate change and sea level rise. The effects upon total GHG emissions associated with the proposed Project and pumping specifically would be compensated by the GHG emission improvements related to the renewable integration operation of the Project, as described in the GHG emissions portion of this chapter.

Navigation, Transportation, and Traffic (Chapter 26)

Climate change and sea level rise are expected to affect navigation, transportation, and traffic due to the anticipated increased frequency and severity of floods. The relative effect of climate change and sea level rise upon identified proposed Project impacts to navigation, transportation, and traffic is uncertain.

Noise (Chapter 27)

Noise is not expected to be affected by climate change and sea level rise. However, if there is an effect, the relative effect of climate change and sea level rise upon identified proposed Project impacts to this resource is uncertain.

Public Health and Environmental Hazards (Chapter 28)

Climate change and sea level rise are expected to affect public health and environmental hazards due to the anticipated increased temperatures, increased frequency and severity of floods and droughts, Delta salinity intrusion, spread of pests, and increased fire risk. The relative effect of climate change and sea level rise upon identified proposed Project effects to public health and environmental hazards is uncertain.

Public Services and Utilities (Chapter 29)

Climate change and sea level rise is expected to potentially affect public services and utilities due to anticipated increased temperature, increased frequency and severity of flood and drought events, spread of pests, and increased fire risk. The relative effect of climate change and sea level rise upon identified proposed Project effects to public service and utilities is uncertain.

Visual Resources (Chapter 30)

Climate change and sea level rise are expected to affect visual resources due to the anticipated increased air and water temperatures, increased severity and frequency of flood and drought events, changes in vegetation and wildlife species distribution, and increased fire risk. The relative effect of climate change and sea level rise upon identified proposed Project effects to visual resources is uncertain.

Power Production and Energy (Chapter 31)

Climate change and sea level rise are expected to affect power production and energy due to the anticipated increased temperatures, altered runoff, and increased frequency and severity of flood and drought events. Some of these climate change and sea level rise effects would increase or decrease hydropower production; some would increase or decrease energy needs associated with the CVP and SWP systems. The proposed Project is intended to provide a specific kind of adaptive capability for power production and energy. Consistent with hydropower project objective, the proposed Project would provide hydropower facilities to support integration of renewable energy sources. The relative effect of climate change and sea level rise upon identified proposed Project impacts to power production and energy is uncertain.

26. Navigation, Transportation, and Traffic

26.1 Introduction

This chapter describes the existing navigation, transportation, and traffic conditions for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. The navigation section discusses the physical characteristics of major waterways in the three study areas, with emphasis on the waterways located in Glenn and Colusa counties. The transportation and traffic section focuses on the existing vehicle, rail, and air traffic facilities that are expected to be used during Project construction and operation or are located near the Project facility sites.

The regulatory setting for navigation, transportation, and traffic is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant impacts, where appropriate.

26.2 Environmental Setting/Affected Environment

26.2.1 Methodology

26.2.1.1 Navigation

Navigable waters for the purposes of this analysis have been defined using both the federal and State codes:

- Navigable waters of the United States are those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A determination of navigability, once made, applies laterally over the entire surface of the waterbody, and is not extinguished by later actions or events which impede or destroy navigable capacity (33 CFR Part 329).
- Navigable waters means waters which come under the jurisdiction of the United States Corps of Engineers and any other waters within the state with the exception of those privately owned (California Harbor and Navigation Code, Chapter 1).

Major waterways within the Extended, Secondary, and Primary study areas were identified using maps, boating guides from the California Department of Boating and Waterways, and marine highway corridor guides from the U.S. Department of Transportation.

26.2.1.2 Transportation and Traffic

Roadway Condition

Pavement condition was determined by driving the roads that are the main access routes to Project facilities within Glenn and Colusa counties. The pavement condition categories and criteria for each category are provided in Table 26-1.

Table 26-1
Pavement Condition Categories and Criteria

Pavement Condition	Criteria
Good	Fully paved with very few cracks or potholes that result in desirable driving conditions
Fair	Fully paved with some cracks or potholes that result less-than-desirable driving conditions
Poor	Un-paved or paved with significant cracks and potholes that need to be avoided while driving and result in undesirable driving conditions

Source: MTC, 1986.

Roadway Classification

Major roadways within the Extended, Secondary, and Primary study areas were identified using Google maps. For the Primary study area, roadway classifications were determined using County general plans. As an example, the roadway classifications for Glenn County are presented in Table 26-2.

Table 26-2
Roadway Classifications for Glenn County

Roadway Classification	Description
Minor Collector	Carries traffic from residential subdivisions/settlements, farms, logging operations, and other local area trip generators to higher classification roads.
Collector	Primarily intra-county travel serving smaller communities and countywide trip generators, such as consolidated schools, freeway interchanges, major shipping terminals, major recreational facilities, and concentrations of commercial/industrial activity.

Source: Glenn County, 1993.

Roadway Level of Service

Both Glenn County and Colusa County use the Level of Service criteria, as defined by the 2000 Highway Capacity Manual (HCM), to assess the performance of its street and highway system and the capacity of roadways. Level of Service is a qualitative assessment of the quantitative effects of such factors as traffic volume, roadways geometrics, speed, delay, and maneuverability on roadway and intersection operations. Roadway traffic flow characteristics for different Levels of Service are described in Table 26-3.

Table 26-3
General Level of Service Criteria for Roadways

Level of Service	V/C	Traffic Flow Characteristics
A	0.00 – 0.60	Free flow; insignificant delays
B	0.61 – 0.70	Stable operation; minimal delays
C	0.71 – 0.80	Stable operation; acceptable delays
D	0.81 – 0.90	Approaching unstable flow; queues develop rapidly but no excessive delays
E	0.91 – 1.00	Unstable operation; significant delays
F	> 1.00	Forced flow; jammed conditions

Note:
V/C = traffic volume (demand) / roadway capacity ratio

Source: Transportation Research Board, 2010.

Traffic Operations and Capacity

Average Daily Traffic (ADT) volumes were estimated for representative segments of the roadways that would be used to access the site of the proposed pump installation at the Red Bluff Pumping Plant (a Secondary Study Area Project facility). A four percent growth factor was applied to the most recent ADT counts available from Tehama County and the California Department of Transportation (Caltrans), and was determined from historical traffic data.

ADT volumes for 2010 for Glenn County roads were estimated based on a three percent growth factor applied to the most recent ADT counts available from Glenn County and Caltrans. A three percent growth factor was determined from historical data in the Glenn County General Plan (Glenn County, 1993).

ADT volumes for 2010 for Colusa County roads were estimated based on a two percent growth factor applied to the most recent ADT counts available from Colusa County and Caltrans. A two percent growth factor was determined from historical data in the Colusa County General Plan (Colusa County, 1989).

An update to the Glenn County General Plan (1993) began in 2006, but has since been put on hold and an estimate for completion of that update is not available. The Colusa County General Plan was updated in July 2012. For planning-level analysis, Caltrans identifies Level of Service D as the acceptable mobility criteria. The Glenn County and Colusa County general plans both identify Level of Service C as the acceptable mobility criteria (Glenn County, 1993 and Colusa County, 2012). These criteria were used for the quantitative analysis for roadways within the Primary Study Area. A description of roadway operations for each Level of Service and the associated criteria for Caltrans roadways are presented in Table 26-4. A description of roadway operations for each Level of Service and the associated criteria for Glenn and Colusa County roadways are presented in Table 26-5.

Table 26-4
Caltrans Average Daily Traffic Level Of Service Criteria

Level of Service	Two-Lane Highway	Four-Lane Freeway
A	Undefined	Undefined
B	< 3,300	< 22,400
C	< 7,100	< 32,300
D	< 13,100	< 42,500
E	< 24,900	< 49,700
F	24,900	49,700

Source: Transportation Research Board, 2010.

The Caltrans average daily traffic Level of Service criteria are based on two- and four-lane highway daily service volumes as defined by the HCM. The terrain and traffic patterns assumed for these criteria are consistent with those observed in the Primary Study Area. The HCM does not provide average daily traffic Level of Service criteria for interstate freeways. The four-lane highway Level of Service criteria are considered appropriate for I-5 within the Primary Study Area. Some roadways to the Project facility sites may not have vehicle count information available. For these facilities, Level of Service operational analysis has not been conducted.

Table 26-5
Glenn and Colusa County Average Daily Traffic Level Of Service Criteria

Level of Service	Minor Collector (2-lane)	Collector (2-lane)
A	< 1,000	< 1,300
B	< 3,000	< 3,900
C	< 5,500	< 7,500
D	< 8,750	< 12,600
E	< 11,200	< 16,900
F	11,200	16,900

Source: Fehr & Peers, 2009.

26.2.2 Extended Study Area

26.2.2.1 Navigation

The 39 counties that are included within the Extended Study Area have many navigable waterways. Marine traffic within the Extended Study Area varies from commerce to recreation. Marine traffic congestion varies from waterway to waterway and by study area, but generally, there is expected to be more commercial traffic (e.g., in the shipping lanes near the ports) during working hours Monday through Friday, and there is expected to be more recreational traffic during weekends and holidays.

Marine facilities represent substantial transportation capacity within the Extended Study Area. Navigable coastal waters parallel the entire I-5 corridor, including numerous deep and safe rivers, bays, and ports and serving as extensions of the surface transportation system, particularly for freight and goods movement. Commercial ports, ferries, and bridges exist within the Extended Study Area and include facilities that are part of the Marine Highway Program overseen by the U.S. Department of Transportation Maritime Division.

Two designated Marine Highway (M-) corridors lie within the Extended Study Area: the M-5 corridor and the M-580 corridor. The M-5 corridor includes the Pacific Ocean coastal waters, connecting commercial navigation channels, ports, and harbors from San Diego to the U.S.-Canada border north of Seattle, Washington. The corridor spans Washington, Oregon, and California along the West Coast. It connects to the M-84 corridor at Astoria, Oregon, and the M-580 corridor at Oakland, California. The M-580 corridor includes the San Joaquin River, Sacramento River, and connecting commercial navigation channels, ports, and harbors in Central California from Sacramento to Oakland (USDOT, 2010).

Typical marine traffic within the Extended Study area is described geographically in Table 26-6.

Neither San Luis Reservoir, nor the Wildlife Refuges, within the Extended Study Area, is considered to be a navigable waterway.

Table 26-6
Navigable Waters in the Counties that Comprise the Extended Study Area

Geographic Area	Description of Typical Navigation	Major Waterways	Counties
Shasta Lake	Houseboats and smaller recreational watercraft, consisting of kayaks, canoes, personal sailing crafts, jet-skis, and small motorized boats for fishing and water skiing. Ferry service to the Shasta Caverns on the McCloud arm of the Lake.	Pit River, McCloud River, Sacramento River, Squaw Creek	Shasta
Upper Central Valley (Sacramento Valley)	The majority of the Sacramento Valley waterways are limited to small recreational watercraft and sport fishing by flows and waterway depths. The Lower Sacramento River carries marine traffic through the Sacramento Deep Water Ship Channel.	Sacramento River, Bear River, Feather River, Yuba River	Butte, Colusa, Glenn, Placer, Plumas, Sutter, Tehama, Yolo
Lower Central Valley (San Joaquin Valley)	The majority of the San Joaquin Valley waterways are limited to small recreational watercraft and sport fishing by flows and waterway depths. The Lower San Joaquin River carries marine traffic and through the Port of Stockton.	San Joaquin River, Stanislaus River, Kings River, Merced River, Kern River, Kaweah River	Fresno, Kern, Kings, Madera, Merced, San Joaquin, Stanislaus, Tulare
Sacramento-San Joaquin Bay-Delta	Commercial navigation channels and ports are prevalent within the Bay-Delta. There is a high volume of recreational traffic within this area, consisting of motorized marine craft for fishing, skiing, and boating.	Sacramento-San Joaquin Delta, American River, Folsom Lake, Sacramento River, Napa River, Napa-Sonoma Marsh, Suisun Bay, San Pablo Bay	Alameda, Contra Costa, Sacramento, Solano, Napa
Gold Country	The majority of these waterways are limited to small recreational watercraft and sport fishing by flows, structures (e.g., dams), and waterway depths.	Calaveras River, Stanislaus River, Tuolumne River, Lake Tahoe, American River, Folsom Lake, Cosumnes River, Mokelumne River	Calaveras, El Dorado, Nevada, Tuolumne
Central Coast	The majority of these waterways are limited to small recreational watercraft and sport fishing by flows, structures (e.g., dams), and waterway depths.	Pajaro River, San Lorenzo River, Santa Ynez River, Santa Maria River, Lake Cachuma	Monterey, San Benito, San Luis Obispo, Santa Barbara, Santa Clara, Santa Cruz
South Coast/Inland Empire	These waterways are primarily seasonal, and in some instances, channelized by concrete. The Colorado River is the largest and most widely trafficked of the waterways. Traffic is generally recreational.	Ventura River, Los Angeles River, Santa Clara River, San Gabriel River, Santa Ana River, San Diego River, Tijuana River, Colorado River	Los Angeles, Orange, San Diego, San Bernardino, Ventura
Salton Sea	Recreational watercraft only.	Salton Sea, New River, Whitewater River, Alamo River	Imperial, Riverside

Source: USDOT, 2010; maps.google.com, 2013.

26.2.2.2 Transportation and Traffic

The Extended Study Area includes many freeways, highways, and local roadways. For each of the 39 counties that comprise the Extended Study Area, Table 26-7 lists the major roadways (i.e., interstate freeways [I], U.S. highways [U.S.], and State Routes [SRs]). Traffic congestion in these areas can vary considerably depending on the location, season, and time of day. Typical baseline conditions are congestion during commute hours on weekdays in urban settings, and congestion on weekends and off-peak hours on weekdays if these roads serve recreational facilities or recreational areas.

Table 26-7
Major Roadways in the Extended Study Area

County	Major Roadways
Alameda	I-80, I-580, I-680, I-880, and I-980, and numerous SRs
Butte	SR 32, SR 70, SR 99, SR 149, SR 162, and SR 191
Calaveras	SR 4, SR 12, SR 26, and SR 49
Colusa	I-5, SR 16, SR 20 and SR 45
Contra Costa	I-80, I-680, SR 4, SR 24 and SR 242

26.2.3 Secondary Study Area

26.2.3.1 Navigation

Similar to the Extended Study Area, marine traffic congestion varies across the waterways and study area, but there is generally more commercial traffic (e.g., in the shipping lanes near the ports) during working hours Monday through Friday and more recreational traffic during weekends and holidays. There are 22 counties included in the Secondary Study Area. Fourteen of the 22 counties are also located in the Extended Study Area. Table 26-8 expands on the information provided in Table 26-6 by including the additional Secondary Study Area counties.

Table 26-8
Navigable Waters in the Counties that Comprise the Secondary Study Area

Geographic Area	Description of Typical Navigation	Major Waterways	Counties
Upper Central Valley (Sacramento Valley)	The majority of the Sacramento Valley waterways are limited to small recreational watercraft and sport fishing by flows and waterway depths. The lower Sacramento River carries marine traffic through the Sacramento Deep Water Ship Channel.	Sacramento River, Bear River, Feather River, Yuba River	Yuba
Sacramento-San Joaquin Bay-Delta	Commercial navigation channels and ports are prevalent within the Bay-Delta. There is a high volume of recreational traffic within this area, consisting of motorized marine craft for fishing, skiing, and boating.	Sacramento-San Joaquin Delta, American River, Sacramento River, Napa River, Napa-Sonoma Marsh, San Francisco Bay, Suisun Bay, San Pablo Bay	Sonoma, Marin, San Francisco, San Mateo
North Coast	Generally recreational motorized and non-motorized marine craft for fishing, skiing, and boating.	Klamath River downstream of the Trinity River, Trinity River, Smith River, Mad River, Eel River, Russian River, Navarro River	Del Norte, Humboldt, Trinity

Source: USDOT, 2010; maps.google.com, 2013.

26.2.3.2 Transportation and Traffic

For each of the 22 counties included in the Secondary Study Area, Table 26-9 lists the major roadways. Fourteen of the 22 counties in the Secondary Study Area are also located within the Extended Study Area (Table 26-7), and are not duplicated in Table 26-9. Similar to the Extended Study Area, traffic congestion in these areas can vary considerably depending on the location, season, and time of day. Typical baseline conditions are the same as those described for the Extended Study Area.

Table 26-9
Major Roadways in the Secondary Study Area

County	Major Roadways
Del Norte	I-101 and I-199
Humboldt	U.S. 101, SR 299
Marin	U.S. 101, SR 1, and SR 37
San Francisco	I-80, I-280, U.S. 101, SR 1, and SR 35
San Mateo	U.S. 101, I-280, I-380, SR 1, SR 82, SR 84, and SR 92
Sonoma	U.S. 101, SR 1, SR 12, SR 116, SR 121, and SR 128
Trinity	SR 3, SR 36, and SR 299
Yuba	SR 20, SR 65, and SR 70

Notes:

I = Interstate Freeway
SR = State Route
U.S. = U.S. Highway

Source: maps.google.com, 2013.

Three roadways in Tehama County were identified as primary access roads to the site of the proposed pump installation at the Red Bluff Pumping Plant. The roadways are listed in Table 26-10, including a summary of their observed characteristics.

Table 26-10
Characteristics of Roadways in Tehama County that are Main Access Routes to the Proposed Pump Installation Site at the Red Bluff Pumping Plant[a]

Roadway	Number of Lanes	Roadway Condition	Comments
I-5	4	Good[b]	Divided
Antelope Boulevard	4	Good	Has turning lanes
South Main Street	4	Good	Has turning lanes
Diamond Avenue	2	Good	

[a]The expected access route to the proposed pump installation site is as follows: from I-5 southbound, travel south on Diamond Avenue in Red Bluff. From I-5 northbound, travel west on Antelope Boulevard, south on South Main Street, and then south on Diamond Avenue in Red Bluff.

[b]Good roadway condition is defined as fully paved with very few cracks or potholes that result in desirable driving conditions.

Note:

I = Interstate Freeway

ADTs on the selected representative road segments are presented in Table 26-11.

Table 26-11
ADT for Selected Roads in Tehama County

Roadway	Segment	Year	ADT	Calculated 2010 ADT*
I-5	Glenn County Line to SR 36	2010	38,000	38,000
Diamond Avenue	South Main Street to end of road	2007	5,344	6,012

*Calculated volumes are based on four percent average annual growth rate (City of Red Bluff, 2011).

Notes:

ADT = Average Daily Traffic
I = Interstate Freeway
SR = State Route

Source: City of Red Bluff, 2011; Caltrans, 2009.

26.2.4 Primary Study Area

26.2.4.1 Navigation

The major waterway that flows through the Primary Study Area is the Sacramento River, which is regulated by Shasta Dam and is navigable year round. The river is 327 miles long and is considered a navigable river from its mouth to Keswick Dam, a distance of 301 miles.

The State of California, as covered by the California Constitution, allows for public access to waterways, further empowered by the public trust doctrine. Marine traffic within the Primary Study Area (which is located at the Delevan Pipeline Intake/Discharge Facilities) is recreational, and is limited to motorized and non-motorized watercraft for the purposes of fishing and boating.

Peak flows in the Sacramento River generally occur in the late winter months in Wet years and peak in July in the Dry years due to Shasta Dam releases. Flows during the recreation season (Memorial Day to Labor Day) do not vary a great deal across water year types. The river is navigable throughout the recreation season in all water year types, with flows at Bend Bridge and Red Bluff Diversion Dam ranging from approximately 6,000 cfs to 13,000 cfs.

26.2.4.2 Transportation and Traffic

Roadway Traffic Levels and Condition

The Glenn County roadways within the Primary Study Area are considered minor collectors, except Canal Road, which is considered a collector. All Colusa County roadways are considered minor collectors.

Table 26-12 describes the routes that are expected to be used to access Project facility sites during Project construction, operation, and maintenance. These routes include existing roads and new permanent roads to be constructed as part of the Project. Figure 3-1 in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives shows the locations of these roads relative to the Project facilities.

Table 26-12
Expected Roadway Access Routes to Project Facilities

Facility #	Project Feature	Access Route
1a	Sites Reservoir Inundation Area (northern area)	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and continue straight on North Road (new permanent)
1b	Sites Reservoir Inundation Area (central area)	• From I-5, travel west on Maxwell Sites Road
1c	Sites Reservoir Inundation Area (southern area)	• From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), and turn right on Huffmaster Road • From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), and turn right on Lurline Road (new permanent, detour during construction)
2a	Sites Dam	• From I-5, travel west on Maxwell Sites Road
2b	Golden Gate Dam	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on Eastside Road (new permanent), and turn right on new permanent O&M road • From I-5, travel west on Maxwell Sites Road, turn right on Eastside Road, and turn left on new permanent O&M road
2c	Saddle Dams	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, continue straight on North Road (new permanent) for Saddle Dams 7, 8, and 9, or turn left from North Road onto Saddle Dam Road (new permanent) for Saddle Dams 1, 2, 3, 4, and 5, or turn left from North Road onto new permanent O&M road for Saddle Dam 6, or turn left from County Road 69 onto Eastside Road (new permanent) and turn right on new permanent O&M road for the Golden Gate Saddle Dam • From I-5, travel west on Maxwell Sites Road, turn right on Eastside Road and turn left on new permanent O&M road
3a 4a	Saddle Dam Recreation Area Saddle Dam Road	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, continue straight on North Road (new permanent), and turn left on Saddle Dam Road (new permanent)
3b 4b	Lurline Headwaters Recreation Area Lurline Road	• From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), and turn right on Lurline Road (new permanent, detour during construction)

Table 26-12
Expected Roadway Access Routes to Project Facilities

Facility #	Project Feature	Access Route
3c	Antelope Island Recreation Area	• From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), turn right on Huffmaster Road, and turn left on new temporary construction road • From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), turn right on Lurline Road (new permanent, detour during construction), turn right on Huffmaster Road, and turn left on new temporary construction road
3d 4c	Stone Corral Recreation Area Stone Corral Road	• From I-5, travel west on Maxwell Sites Road, turn right on Eastside Road (new permanent), turn left on Stone Corral Road (new permanent), and turn left on Stone Corral Recreation Area Road (new permanent)
3e 4d	Peninsula Hills Recreation Area Peninsula Road	• From I-5, travel west on Maxwell Sites Road to Sites Lodoga Road, and turn right on Peninsula Road (new permanent campground spur road) • From I-5, travel west on Maxwell Sites Road, turn right on Eastside Road (new permanent), turn left on Stone Corral Road (new permanent), across the South Bridge (new permanent) onto Sites Lodoga Road, and turn right on Peninsula Road (new permanent campground spur road)
4e	South Bridge	• From I-5, travel west on Maxwell Sites Road, and turn right on Peterson Road to reach central footings (this route is only available if the bridge is constructed before Sites Dam, which will block access on Maxwell Sites Road) • From I-5, travel west on Maxwell Sites Road and continue straight on Sites Lodoga Road to reach the western approach/footings • From I-5, travel west on Maxwell Sites Road, turn right on Eastside Road (new permanent), and turn left on Stone Corral Road to reach the eastern approach/footings
4f	Com Road	• From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), and turn right on Lurline Road (new permanent, detour during construction), and turn right on Com Road (new permanent)
4g 5 6	Eastside Road Sites Pumping/Generating Plant Field Office Maintenance Yard	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on Eastside Road (new permanent) • From I-5, travel west on Maxwell Sites Road and turn right on Eastside Road (new permanent)
4h	Sulphur Gap Road	• From I-5, travel west on Maxwell Sites Road, and turn left on Sulphur Gap Road (new permanent)

Table 26-12
Expected Roadway Access Routes to Project Facilities

Facility #	Project Feature	Access Route
4i	North Road	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, continue straight on North Road (new permanent) • From I-5, travel west on Maxwell Sites Road, and turn right on Eastside Road (new permanent) and follow to North Road
7 8	Holthouse Reservoir Complex Holthouse Reservoir Electrical Switchyard	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on Eastside Road (new permanent), turn left on access road on south side of Funks Reservoir • From I-5, travel west on Maxwell Sites Road and turn right on Eastside Road (new permanent), turn right on access road on south side of Funks Reservoir
9 10	Sites Electrical Switchyard Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on Eastside Road (new permanent), and turn left on new permanent O&M road • From I-5, travel west on Maxwell Sites Road, turn right on Eastside Road (new permanent), turn right on new permanent O&M road
11	Sites Reservoir Inlet/Outlet Structure	• From I-5, travel west on Maxwell Sites Road, turn left onto Sulphur Gap Road, to Lurline Road, to Huffmaster Road, to Peterson Road
12	GCID Canal Facilities Modifications Headgate Modifications Railroad Siphon Modifications	• From I-5, travel east on SR 32 and turn left on Canal Road • From I-5 northbound, exit County Road 53, immediately turn left onto SR 99, and proceed 1.1 miles north to the intersection with the GCID Canal. Turn right at GCID Canal; the railroad siphon is approximately 200 feet east of SR 99
13 14 15 16 17	GCID Canal Connection to the TRR TRR TRR Pumping/Generating Plant TRR Electrical Switchyard GCID Canal Connection to the TRR	• From I-5, travel west on Delevan Road, and turn left on McDermott Road or turn left on Noel Evan Road
18 19 20	TRR Pipeline TRR Pipeline Road Delevan Pipeline Electrical Switchyard	• From I-5, travel west on Delevan Road, turn left on McDermott Road, turn right on temporary construction access road
21a 22a	Delevan Pipeline (western portion) Delevan Transmission Line (western portion)	• From I-5, travel west on Delevan Road, then turn left on Sutton Road, McDermott Road, or County Road D

Table 26-12
Expected Roadway Access Routes to Project Facilities

Facility #	Project Feature	Access Route
23 24 21b 22b	Delevan Pipeline Intake Facilities Delevan Pipeline Discharge Facility Delevan Pipeline (eastern portion) Delevan Transmission Line (eastern end)	• From I-5, travel east on Maxwell Road, and turn left on SR 45 • From I-5, travel east on SR 162, and turn right on SR 45
21c 22c	Delevan Pipeline (central portion) Delevan Transmission Line (central portion)	• From I-5, travel east on Maxwell Road, and turn left on Four Mile Road or Two Mile Road • From I-5, travel east on Delevan Road, and turn right on Four Mile Road or Two Mile Road
21d	Delevan Pipeline (far western portion)	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on Eastside Road (new permanent) • From I-5, travel west on Maxwell Sites Road, and turn right on Eastside Road (new permanent)
25	Borrow Areas (Generally Within the Reservoir Inundation Area or Adjacent on Logan Ridge)	• From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on Eastside Road (new permanent) • From I-5, travel west on Maxwell Sites Road, turn left on right on Eastside Road (new permanent) • From I-5, travel west on Maxwell Sites Road, turn left on Sulphur Gap Road (new permanent), turn right on Lurline Road (new permanent, detour during construction), turn right on Huffmaster Road, and travel straight on Peterson Road • From I-5, travel west on Maxwell Sites Road

Notes:
I = Interstate Freeway
O&M = Operations and maintenance
SR = State Route

Glenn County

Ten roadways in Glenn County were identified as primary access roads to Project facility sites. The roadways and a summary of their observed characteristics are listed in Table 26-13.

Table 26-13
Characteristics of Roadways in Glenn County that are Main Access Routes to Project Facilities

Roadway	Project Facility # Accessed by Roadway[a]	Number of Lanes	Roadway Condition[b]	Comments
I-5	All Project facilities	4	Good	Divided Interstate
SR 32	12	2	Fair to Good	Through Orland, it is two paved lanes with a center lane and on-street parking in places; two paved lanes east of town with some visible cracks
County Road 68	1a, 2b, 2c, 3a, 4g, 4i, 5, 6, 7, 8, 9,	2	Poor to Good	Shoulders partially paved; some visible cracks

Table 26-13
Characteristics of Roadways in Glenn County that are Main Access Routes to Project Facilities

Roadway	Project Facility # Accessed by Roadway[a]	Number of Lanes	Roadway Condition[b]	Comments
	10, 21d, 25			
County Road 69	1a, 2b, 2c, 3a, 4g, 4i, 5, 6, 7, 8, 9, 10, 21d, 25	2	Fair to Good	
County Road D	1a, 2b, 2c, 3a, 4g, 4i, 5, 6, 7, 8, 9, 10, 21a, 21d, 22a, 25	2	Fair to Good	No shoulder at some locations
Canal Road	12	2	Good	No shoulders

[a]Refer to Table 26-12 for the Project facility name associated with each Project facility number.

[b]Roadway Condition: Good = Fully paved with very few cracks or potholes that result in desirable driving conditions.
Fair = Fully paved with some cracks or potholes that result less-than-desirable driving conditions.
Poor = Un-paved or paved with significant cracks and potholes that need to be avoided while driving and result in undesirable driving conditions.

Notes:

I = Interstate Freeway
SR = State Route

ADTs on selected representative road segments in Glenn County are presented in Table 26-14. Figure 3-1 in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives shows the locations of these roads relative to the Glenn County portion of the Project facility sites.

Table 26-14
2010 ADT for Selected Roads in Glenn County

Roadway	Segment	Year	ADT	Calculated 2010 ADT	2010 Level of Service[a]
I-5	Glenn/Colusa County Line to County Road 68	2008	25,000	26,523	C
I-5	County Road 16 to SR 32 E	2008	25,000	26,523	C
SR 32	I-5 to SR 45	2010	10,800	10,800	D
County Road 68	County Road F to I-5	2009	186	192	A
County Road 68	I-5 to County Line/Norman Road	2007	212	232	A

Colusa County

Fourteen roadways in Colusa County were identified as primary access roads to Project facility sites. The roadways and a summary of their observed characteristics are listed in Table 26-15. Figure 3-1 in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives shows the locations of these roads relative to the Colusa County portion of the Project facility sites.

The proposed Sites Reservoir would be located approximately 10 miles west of the town of Maxwell. Maxwell Sites Road would provide east-to-west access through that Project site. This road experiences higher traffic volumes than other local roadways in the area, particularly on weekends. Travelers use this road to access East Park Reservoir, the southwest portion of the Mendocino National Forest, and the communities of Stonyford and Lodoga (Calfed Bay-Delta Program, 2000).

Table 26-15
Characteristics of Roadways in Colusa County that are Main Access Routes to Project Facilities

Roadway	Project Facility # Accessed by Roadway[a]	Number of Lanes	Roadway Condition[b]	Comments
I-5	All Project facilities	4	Good	Divided interstate highway.
SR 45 (Colusa County only)	16, 17, 21b, 22b	2	Fair to Good	25 mph to 55 mph posted speed limit; unpaved shoulders at some locations.
SR 162	16, 17, 21b, 22b	2	Fair to Good	Through Willows, it is four paved lanes with a center lane; two paved lanes east of town with some visible cracks (some sealed, some not sealed)
Maxwell Sites Road	1b, 1c, 2a, 2b, 3b, 3c, 3d, 3e, 4b, 4c, 4d, 4e, 4f, 4g, 4h, 4i, 5, 6, 7, 8, 9, 10, 11, 21b, 21c, 22b, 22c, 23, 24, 25	2	Fair to Good	Narrow shoulders east of Maxwell. Unpaved or no shoulders west of Mills Orchard; 35 mph posted speed limit.
Huffmaster Road	1c, 3c, 11, 25	1½	Poor to Fair	From Maxwell Sites Road intersection south 0.2 mile, the road is cracked, potholed pavement; gravel road south of that point.
Sites Lodoga Road	3e, 4e	2	Poor to Good	Shoulders sometimes absent; 25 mph posted speed limit east of Lodoga Stonyford Road.
Delevan Road	13, 14, 15, 16, 17, 18, 19, 20, 21a, 21c, 22a, 22c	2	Good and Poor to Fair	Paved shoulders are narrow near the canal, and east of Old Hwy 99. Some areas are depressed; some potholes, cracking, and patching. New pavement west of I-5 to McDermott Road. Dirt and below grade west of McDermott Road (possibly being prepared for paving).
Noel Evan Road	13, 14, 15, 16, 17	1	Poor	A gravel canal road.
Sutton Road	21a, 22a	1½ to 2	Poor and Fair to Good	North of Delevan Road: gravel 1½-lane road (poor condition); south of Delevan Road: paved two-lane road with no shoulders (fair to good condition)
Four Mile Road	21c, 22c	2	Poor to Fair	Dirt and gravel road south of Delevan Road and north of Maxwell Road.

Table 26-15
Characteristics of Roadways in Colusa County that are Main Access Routes to Project Facilities

Roadway	Project Facility # Accessed by Roadway[a]	Number of Lanes	Roadway Condition[b]	Comments
Two Mile Road	21c, 22c	2	Poor to Fair	Dirt and gravel road south of Delevan Road and north of Maxwell Road.
Maxwell Road	21b, 21c, 22b, 22c, 23, 24	2	Poor to Good	Narrow shoulders; 35 mph posted speed limit.
McDermott Road	13, 14, 15, 16, 17, 21a, 22a	2	Fair to Good	Narrow or no shoulder. Some patching, some cracking. New pavement north of Delevan Road. Gravel north of Dirks Road.
Peterson Road	4e, 11, 25	2	Poor	Unpaved; dirt and gravel road wide enough for two cars.

[a]Refer to Table 26-12 for the Project facility name associated with each Project facility number.

[b]Roadway Condition: Good = Fully paved with very few cracks or potholes that result in desirable driving conditions.
Fair = Fully paved with some cracks or potholes that result less-than-desirable driving conditions.
Poor = Un-paved or paved with significant cracks and potholes that need to be avoided while driving and result in undesirable driving conditions.

Notes:

I = Interstate Freeway
mph = miles per hour
SR = State Route

ADTs on the selected representative road segments are presented in Table 26-16.

Table 26-16
2010 ADT for Selected Roads in Colusa County

Roadway	Segment	Year	Daily Traffic Volumes	Calculated 2010 ADT	2010 Level of Service[a]
I-5	SR 20 to Maxwell Colusa Road	2008	24,700	25,698	C
I-5	Delevan Road to Glenn/Colusa County Line	2008	25,000	26,010	C
SR 45	Maxwell Colusa Road to County Road P29	2008	2,100	2,185	B
SR 45	County Road P29 to Glenn/Colusa County Line	2008	2,300	2,393	B
SR 162	County Road D to SR 45	2010	8,800	8,800	D
Maxwell Sites Road	I-5 to Sutton Road	2000	1,486	1,812	B
Maxwell Sites Road	GCID Canal to Sites Lodoga Road	2000	618	754	A
Huffmaster Road	Beginning of road to end of road	N/A	N/A	N/A	N/A
Sites Lodoga Road	Maxwell Sites Road to Leesville Lodoga Road	2000	360	439	A

Transit System

Glenn County

The Glenn Transit Service is the public transit operator for Glenn County, administered by the Glenn County Department of Public Works. It offers four types of public transportation services (Nelson/Nyygard, 2008):

- **Glenn Ride** is the only general fixed-route inter-city transit service in the county, connecting Willows, Artois, Orland, and Hamilton City, as well as Chico in Butte County. Seven trips are provided during the weekdays and three trips are provided on Saturday. No service is provided on Sundays.
- **Glenn Transport (Dial-a-Ride)** is available to senior residents who meet particular eligibility requirements and are unable to use the Glenn Ride bus system. Services are restricted to within a 1.5-mile radius of the City Halls of Orland and Willows, the Leisure Mobile Home Park, the Willows-Glenn Mobile Home Park, and the Huggins/Cannell Drives area. The service operates from 7:30 a.m. to 6:00 p.m. on weekdays and from 9:00 a.m. to 4:00 p.m. on Saturdays.
- **Volunteer Medical Transport** provides transportation service to medical appointments for Glenn County residents who are unable to use Glenn Ride and do not have a personal mode of transportation. Volunteers use their personal vehicles to transport the patients.
- **CalWORKs "Ride to Work"** offers a van service to eligible CalWORKs workers referred by Glenn County Human Resource Agency. Transportation is provided to and from work opportunities.

Colusa County

Nine vehicles comprise the Colusa County Transit services. The services include:

- Five routes operated on a fixed route and schedule. Pick-ups are arranged on a dial-a-ride basis, with door-to-door service available for ADA passengers.
- Out-of-county medical transportation service provided to Chico, Davis, Lincoln, Marysville, Oroville, Roseville, Sacramento, Willows, Woodland, and Yuba City.
- Trips to/from Yuba City provided on Fridays (bus departs Colusa at 9:30 a.m. and departs Yuba City at 1:30 p.m.).
- Charter trips can be arranged using the available fleet if it does not interfere with regularly scheduled service.

Rail Traffic

Railway Facilities and Operations

The West Valley Line of the California Northern Railroad (CFNR) is located east of the town of Sites, and operates between Davis and Tehama, California. The major commodities carried by CFNR include tomato products, olives, rice, cheese, frozen foods, beer, wine, and wheat, as well as stone, petroleum products, and chemicals. The CFNR does not provide passenger service.

Air Traffic

Air Facilities and Operations

The airfield nearest to the town of Sites is Moller Airport located approximately eight miles to the east, outside of Maxwell, California. There are eight single engine aircraft based at Moller Airport. Other nearby airports include Colusa County Airport, Gunnersfield Ranch Airport, Antelope Valley Ranch Airport, and Willows-Glenn County Airport.

26.3 Environmental Impacts/Environmental Consequences

26.3.1 Regulatory Setting

Navigable waterways and transportation/traffic are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

26.3.1.1 Federal Plans, Policies, and Regulations

- National Environmental Policy Act (NEPA) of 1969
- Rivers and Harbors Act of 1899, Section 10

26.3.1.2 State Plans, Policies, and Regulations

- California Environmental Quality Act (CEQA) of 1970
- California Department of Transportation (Caltrans) regulatory authority over the California State highway system

26.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

26.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* does not include significance criteria for navigation, and suggests the following evaluation criteria for transportation and traffic:

Would the Project:

- Conflict with an applicable plan, ordinance, or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit?
- Conflict with an applicable congestion management program, including, but not limited to, level of service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways?
- Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?
- Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?
- Result in inadequate emergency access?
- Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Conflict with navigation along navigable waterways.
- Conflict with an applicable plan, ordinance, or policy establishing measures of effectiveness for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit.
- Conflict with an applicable congestion management program, including, but not limited to, Level of Service standards and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways.

- Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment).
- Result in inadequate emergency access.
- Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities.

Within the Primary Study Area, Level of Service D was considered the significance threshold for Caltrans roadways and Level of Service C was considered the significance threshold for Glenn and Colusa County roadways.

26.3.3 Impact Assessment Assumptions and Methodology

26.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to navigation, transportation, and traffic:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.

26.3.3.2 Methodology

Navigation

When considering Project construction impacts on the navigability of the Sacramento River, a review was conducted of the construction activities and equipment that would be required to construct the Delevan

Pipeline Intake Facilities and the Delevan Pipeline Discharge Facility. Data regarding the number and types of equipment that would be required to construct, operate, and maintain Project facilities were developed by Project engineers.

When considering Project operation impacts on the navigability of the Sacramento River, the proposed diversion and release amounts and velocities were considered.

Transportation

Most transportation impacts are not measured quantitatively, but rather relatively. For the analysis of these impacts, the No Project/No Action Alternative and the action alternatives were compared to Existing Conditions, and impacts were determined based on the criteria defined in Section 26.3.2. Traffic operations impacts were measured quantitatively. Project construction-, operations-, and maintenance-related vehicle trips were added to existing roadways volumes, using data regarding the number and types of equipment and vehicles that would be required to construct, operate, and maintain Project facilities (data were developed by Project engineers).

The roadway volume to capacity ratio was then calculated and the associated Level of Service was determined. The Level of Service from the No Project/No Action Alternative and the action alternatives was then compared to Existing Conditions, and impacts were determined based on the defined criteria (Section 26.3.2) and mobility thresholds, as defined by the transportation facilities' governing agency (Section 26.2.1.2).

For analysis purposes, the peak construction period for each Project facility within each alternative was assumed to overlap. Although the overlap of certain construction phases may not be feasible, this approach accounts for unforeseen schedule changes and provides a conservative analysis. Of the Project construction-related trips, construction worker trips would comprise the majority. Construction workers were assumed to commute to construction sites from regional population centers, including Maxwell, Willows, Orland, Williams, Colusa, and from other northern California counties when specialty trades or skillsets are not available regionally. The number of construction workers required during peak construction of Project facilities varies by alternative, resulting in different trip distributions for each alternative.

To determine impacts to traffic on the local roads, the estimated visitation to Sites Reservoir and its Recreation Areas (developed by Project Economists) was used to estimate the potential distribution of recreation traffic on local roads. The traffic estimate considered a May to September recreation season (with fewer recreationists traveling there October to April – a 70/30 percent split) and a March to November recreation season (with fewer recreationists traveling there December to February – a 95/5 percent split). The traffic estimate also considered more recreation traffic Friday through Sunday than during other week days, as well as 2.6 persons per vehicle.

26.3.4 Topics Eliminated from Further Analytical Consideration

26.3.4.1 Navigation

San Luis Reservoir is not a navigable waterway, so it is not addressed in the analysis for the Extended Study Area. In addition, none of the creeks, bypasses, and reservoirs that are included in the Secondary Study Area are navigable waterways, so they are not addressed in this analysis.

The navigation discussion for the Primary Study Area focuses on the Delevan Pipeline Intake Facilities (Alternatives A and C) and the Delevan Pipeline Discharge Facility (Alternative B) because they are the only proposed facilities that could result in impacts to navigation. The other Project facilities that are proposed within the Primary Study Area are, therefore, not addressed in this analysis.

26.3.4.2 Transportation and Traffic

None of the identified airports (Moller Airport, Colusa County Airport, Gunnersfield Ranch Airport, Antelope Valley Ranch Airport, and Willows-Glenn County Airport) are located near the Project facility sites; therefore, Project construction and operation would not affect air traffic patterns. For this reason, air traffic patterns are not discussed in this analysis.

The transportation and traffic discussion for the Secondary Study Area focuses on the pump installation at the Red Bluff Pumping Plant because this is the only location within that study area where construction and maintenance activities would occur that could result in impacts to transportation and traffic. Operational changes within the waterways of the Secondary Study Area would not affect traffic or transportation, and are, therefore, not addressed in this analysis.

26.3.5 Impacts Associated with the No Project/No Action Alternative

26.3.5.1 Navigation

Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, Trinity River, Klamath River downstream of the Trinity River, Sacramento River, Feather River, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and Pump Installation at the Red Bluff Pumping Plant

Impact Nav-1: Conflict with Navigation along Navigable Waterways

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to navigation has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on navigation when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to cause increased use of navigable waterways throughout the State, both for commerce and recreational purposes. Navigation impacts that could potentially occur as a result of the increased population would be managed by USDOT for issues related to interstate marine traffic, and local navigation issues would be managed at the local level in accordance with those agencies' regulations. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions

Projects considered within the No Project/No Action Alternative are not located within the Primary Study Area and **would, therefore, not have a substantial adverse effect** on navigation within that study area, when compared to Existing Conditions. In addition, if the No Project/No Action Alternative is implemented, no new Project-related construction would occur within any of the three study areas. Therefore, **there would not be a substantial adverse effect** on navigation in existing waterways within the Extended, Secondary, or Primary study areas, when compared to Existing Conditions**.**

26.3.5.2 Transportation and Traffic

Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, and Pump Installation at the Red Bluff Pumping Plant

Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation

If the No Project/No Action Alternative is implemented, Project-related construction would not occur and the Project would not be completed. In addition, other projects and programs included in the No Project/No Action Alternative would occur as planned, but would not result in a conflict with plans, ordinances, or policies regarding the transportation systems within the three study areas that has not already been addressed in environmental documents that have been prepared, pursuant to CEQA and NEPA, addressing those projects. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions

Population growth that is expected to occur in California throughout the period of Project analysis is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to result in increased traffic levels, which have been anticipated in local general plans and regional transportation plans and policies. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Trans-2: Conflict with an Applicable Congestion Management Program, Including, but not Limited to, Level of Service Standards and Travel Demand Measures, or Other Standards Established by the County Congestion Management Agency for Designated Roads or Highways

Refer to the **Impact Trans-1** discussion. For those same reasons, implementation of the No Project/No Action Alternative would not conflict with congestion management programs, Level of Service standards, travel demand measures, or other transportation standards within the Extended, Secondary, or Primary study areas. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions

Impact Trans-3: Substantially Increase Hazards Due to a Design Feature or Incompatible Uses

Refer to the **Impact Trans-1** discussion. For those same reasons, implementation of the No Project/No Action Alternative would not affect existing roadway hazards, such as curved alignments or dangerous intersections that may exist within the Extended, Secondary, or Primary study areas. In addition, there would be no potential conflicts between vehicles and farm equipment on roads within the Extended, Secondary, or Primary study areas. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions

Impact Trans-4: Result in Inadequate Emergency Access

Refer to the **Impact Trans-1** discussion. For those same reasons, implementation of the No Project/No Action Alternative would not affect existing emergency access to and from properties located within the Extended, Secondary, or Primary study areas. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Trans-5: Conflict with Adopted Policies, Plans, or Programs Regarding Public Transit, Bicycle, or Pedestrian Facilities, or Otherwise Decrease the Performance or Safety of Such Facilities

Refer to the **Impact Trans-1** discussion. For those same reasons, implementation of the No Project/No Action Alternative would not conflict with adopted public transit, bicycle, or pedestrian facility policies, plans, or programs that are currently in effect within the Extended, Secondary, or Primary study areas. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions**.**

26.3.6 Impacts Associated with Alternative A

26.3.6.1 Navigation

Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, and Wildlife Refuge Water Use

Impact Nav-1: Conflict with Navigation along Navigable Waterways

Because there would be no direct Project construction or maintenance occurring in the Extended Study Area, there would be no interruption of marine traffic on the navigable waterways within that study area. Implementation of Alternative A would result in increased water supply reliability to agricultural, municipal, and industrial water users, and the provision of an alternate Level 4 wildlife refuge water supply. These operational changes would not result in interruption of marine traffic on the navigable waterways within the Extended Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity River, Klamath River downstream of the Trinity River, Sacramento River, Feather River, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and Pump Installation at the Red Bluff Pumping Plant

Impact Nav-1: Conflict with Navigation along Navigable Waterways

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant on the Sacramento River. This construction activity would not affect the navigational channel of the Sacramento River, and therefore, is not expected to result in interruption of marine traffic along that portion of the Sacramento River. The only direct Project-related maintenance activity that would occur is the removal and disposal of sediment from the existing GCID Canal Intake and the Red Bluff Pumping Plant. This activity is expected to occur within the footprint of the Project facilities, and is not expected to affect the navigational channel of the Sacramento River. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of Alternative A would result in operational changes to the navigable waterways included in the Secondary Study Area. However, these operational changes would fall within the historical range of operation of these waterbodies, resulting in **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Delevan Pipeline Intake Facilities

Impact Nav-1: Conflict with Navigation along Navigable Waterways

The cofferdam that would be installed to dewater the Project facility's construction site would extend into the river approximately 40 feet from the river bank, compared to a low-flow river channel width of 240 feet. The navigational channel of the Sacramento River would, therefore, be narrowed during the construction of the Delevan Pipeline Intake Facilities, but would not substantially affect the navigability of the Sacramento River at that location. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The existing Maxwell ID Pumping Plant, located immediately upstream of the proposed Delevan Pipeline Intake location, is located in a narrow section of the river and consequently acts as a local flow control point (Reclamation, 2012). Therefore, following construction, the Delevan Pipeline Intake Facilities would not alter the flow of the river. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Alternative A operations are not expected to alter the navigable channel of the Sacramento River. Operation of the proposed Delevan Pipeline Intake Facilities is expected to follow flow regime criteria that are set forth by the resource agencies, and as such, would maintain sufficient flow to not adversely affect marine traffic. In addition, at low flow of 6,000 cfs in the river, the proposed fish screen would extend approximately 40 feet into the 240-feet-wide river channel, which would allow for recreational boat traffic to pass the fish screen structure. Therefore, there would be a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

26.3.6.2 Transportation and Traffic

Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation

Because there would be no direct Project construction- or maintenance-related vehicle trips occurring in the Extended Study Area, there would be no conflict with plans, ordinances, or policies regarding the transportation systems within the Extended Study Area. Implementation of Alternative A would result in slight operational changes to San Luis Reservoir, increased water supply reliability to agricultural, municipal, and industrial water users, and the provision of an alternate Level 4 wildlife refuge water supply. These operational changes would not be expected to result in changes to traffic levels. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-2: Conflict with an Applicable Congestion Management Program, Including, but not Limited to, Level of Service Standards and Travel Demand Measures, or Other Standards Established by the County Congestion Management Agency for Designated Roads or Highways

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no conflict with congestion management program standards or measures within the Extended Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-3: Substantially Increase Hazards Due to a Design Feature or Incompatible Uses

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no increase in hazards due to a design feature or incompatible use within the Extended Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-4: Result in Inadequate Emergency Access

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no change in emergency access. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-5: Conflict with Adopted Policies, Plans, or Programs Regarding Public Transit, Bicycle, or Pedestrian Facilities, or Otherwise Decrease the Performance or Safety of Such Facilities

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Pump Installation at the Red Bluff Pumping Plant

Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant. The only direct Project-related maintenance activity that would occur is the removal of sediment from the existing canal intakes. Neither of these Project-related activities in the Secondary Study Area is expected to result in conflicts with transportation circulation system plans, ordinances, or policies due to the low number of vehicle trips associated with these activities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-2: Conflict with an Applicable Congestion Management Program, Including, but not Limited to, Level of Service Standards and Travel Demand Measures, or Other Standards Established by the County Congestion Management Agency for Designated Roads or Highways

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no conflict with congestion management program standards or measures within the Secondary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-3: Substantially Increase Hazards Due to a Design Feature or Incompatible Uses

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no increase in hazards due to a design feature or incompatible use within the Secondary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-4: Result in Inadequate Emergency Access

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no change in emergency access. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-5: Conflict with Adopted Policies, Plans, or Programs Regarding Public Transit, Bicycle, or Pedestrian Facilities, or Otherwise Decrease the Performance or Safety of Such Facilities

Refer to the **Impact Trans-1** discussion. For those same reasons, there would be no conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Within the Primary Study Area, Project construction-related vehicle trips would occur on numerous roadways for the duration of the Project construction period. The Level of Service for the roadways leading to the proposed Project facilities prior to and during construction is presented in Table 26-17.

Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation

All roadways would continue to operate at an acceptable Level of Service during Project construction. Traffic levels on roadways would increase during Project construction, particularly before construction activities start and after they end each day, and would result in an increase in traffic congestion. The Level of Service on County Road 68 between County Road F and I-5, County Road 69 between I-5 and County Road F, County Road D between the Glenn/Colusa County Line and County Road 57, Maxwell Sites Road between the GCID Canal and Sites Lodoga Road, and Delevan Road between Four Mile Road and the GCID Canal would change from Level of Service A to Level of Service B. This increase in vehicle traffic and congestion would result in a **less-than-significant impact** because the Level of Service criteria for County roadways would not be exceeded, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation- and maintenance-related traffic would use the same roads that were used for Project construction but would require 60 total vehicles trips per day throughout the Primary Study Area, which would not impact the roadway Level of Service. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative, due to the low number of vehicle trips associated with Project operation and maintenance.

During Project operation, recreational traffic would use I-5, County Road 68, County Road D, County Road 69, Maxwell Sites Road, Huffmaster Road, and new Project roads to access Sites Reservoir and its Recreation Areas. Recreational traffic levels on roads leading to these Project facilities are expected to increase from existing levels because recreationists are likely to want to visit the new reservoir to see what it offers. The expected increase in traffic on these roads could cause an associated temporary or even permanent reduction in recreation traffic on roads leading to other regional reservoirs (i.e., those located in the Secondary Study Area).

Table 26-17
2010 and Alternative A Construction Level Of Service

Roadway	Segment	Calculated 2010 ADT	2010 Level of Service*	ADT with Peak Construction Trips	Peak Construction Level of Service
Glenn County Roadways					
I-5	Glenn/Colusa County Line to County Road 68	26,523	C	27,938	C
I-5	County Road 16 to SR 32 E	26,523	C	27,432	C
SR 32	I-5 to SR 45	10,800	D	10,868	D
County Road 68	County Road F to I-5	192	A	1,409	B
County Road 68	I-5 to County Line/Norman Road	232	A	300	A
County Road 69	I-5 to County Road F	20	A	1,237	B
County Road D	Glenn/Colusa County Line to County Road 57	402	A	1,599	B
Canal Road	SR 32 to end of road	1,740	B	2,094	B
Colusa County Roadways					
I-5	SR 20 to Maxwell Colusa Road	25,698	C	26,607	C
I-5	Delevan Road to Glenn/Colusa County Line	26,010	C	27,409	C
SR 45	Maxwell Colusa Road to County Road P29	2,185	B	2,471	B
SR 45	County Road P29 to Glenn/Colusa County Line	2,393	B	2,679	B
SR 162	County Road D to SR 45	8,800	D	9,086	D
Maxwell Sites Road	I-5 to Sutton Road	1,812	B	2,961	B
Maxwell Sites Road	GCID Canal to Sites Lodoga Road	754	A	1,903	B
Huffmaster Road	Beginning of road to end of road	N/A	N/A	519	A

Table 26-17
2010 and Alternative A Construction Level Of Service

Roadway	Segment	Calculated 2010 ADT	2010 Level of Service*	ADT with Peak Construction Trips	Peak Construction Level of Service
Sites Lodoga Road	Maxwell Sites Road to Leesville Lodoga Road	439	A	868	A
Delevan Road	Four Mile Road to GCID Canal	500	A	1,016	B
Sutton Road	Maxwell Sites Road to Delevan Road	234	A	414	A
Excelsior Road/Four Mile Road	Maxwell Road to Delevan Road	51	A	231	A
Pole Line Road/Two Mile Road	Delevan Road to Maxwell Colusa Road	88	A	268	A
Maxwell Road	I-5 to SR 45	2,535	B	2,821	B
McDermott Road	Maxwell Sites Road to Lenahan Road	364	A	880	A

*Refer to Tables 26-4 and 26-5 for the Level of Service criteria.

Notes:

ADT = Average Daily Traffic
I = Interstate Freeway
N/A = not available
SR = State Route

Source: Colusa County, 2011; Caltrans, 2009 and 2010.

Recreational traffic levels on roads leading to these Project facilities are expected to increase from existing levels because recreationists are likely to want to visit the new reservoir to see what it offers. The expected increase in traffic on these roads could cause an associated temporary reduction in recreation traffic on roads leading to other regional reservoirs (i.e., those located in the Secondary Study Area).

Recreation visitor days (RVDs) have been estimated by Project Economists for Alternative A at 360,975 per year[1] (Pavich, 2012). Maxwell Sites Road is expected to have traffic levels that would result in Level of Service D during the Friday through Sunday period during the recreation season (either the March to November or May to September recreation season). I-5 would have Level of Service A or B. County Roads 68, 69, and D are expected to have traffic levels that would result in Level of Service E during the Friday through Sunday period of a March to November recreation season, or a Level of Service that is worse than F during the Friday through Sunday period of a May to September recreation season. This increase would result in a **significant impact** on the Level of Service of County roads listed above, and a **less-than-significant impact** on I-5's Level of Service, when compared to Existing Conditions and the No Project/No Action Alternative.

[1] An RVD is defined as a recreation visit by one person for part or all of one day.

Impact Trans-2: Conflict with an Applicable Congestion Management Program, Including, but not Limited to, Level of Service Standards and Travel Demand Measures, or Other Standards Established by the County Congestion Management Agency for Designated Roads or Highways

Within the Primary Study Area there are no Congestion Management Programs or County Congestion Management Agencies. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-3: Substantially Increase Hazards Due to a Design Feature or Incompatible Uses

All Project construction of roadways and bridges within the Primary Study Area would adhere to the appropriate city, county, and State design standards, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During construction, the use of construction equipment, such as oversize or overweight vehicles, on roadways near Project facility sites could result in unsafe conditions or damage to road surfaces. This would result in a **potentially significant impact** due to roadway hazards and damage associated with oversize and overweight loads, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation- and maintenance-related traffic would not cause damage to road surfaces or unsafe conditions. Therefore, there would be **no impact** during Project operations and maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-4: Result in Inadequate Emergency Access

During construction of all Project facilities, the temporary closure of lanes and various roadways would likely occur. Construction of Sites Reservoir and Sites Dam has the potential to cause short-term effects to emergency services access response times by eliminating a portion of Maxwell Sites Road and Sites Lodoga Road, which provide access to both sides of the reservoir. However, the South Bridge would be constructed and operating before the portions of these roads are demolished and removed. The new route that includes the South Bridge would be approximately two miles longer than the existing route. Access to the west side of the proposed Sites Reservoir from the east side during construction of the South Bridge would be via the existing Maxwell Sites and Sites Lodoga roads (i.e., no change from the existing route). Access to the southern portion of Sites Reservoir during the construction of the South Bridge would be via the existing Huffmaster Road (also no change from the existing route). Sulphur Gap Road would be constructed prior to the demolition and removal of the portion of Huffmaster Road that crosses the proposed Sites Reservoir footprint. This and other Project construction activities may affect emergency access to properties near Project construction sites. This would result in a **less-than-significant impact** during Project construction, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operations and maintenance, adequate emergency access would be maintained. Therefore, there would be **no impact** during Project operation and maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Trans-5: Conflict with Adopted Policies, Plans, or Programs Regarding Public Transit, Bicycle, or Pedestrian Facilities, or Otherwise Decrease the Performance or Safety of Such Facilities

Construction of Sites Reservoir and Sites Dam has the potential to cause short-term disruptions to public school bus service by eliminating a portion of Maxwell Sites Road and Sites Lodoga Road, which are part of a bus route for the Maxwell Unified School District. However, the South Bridge would be constructed and operating before the portions of these roads are demolished and removed. Bus service would then be provided via the South Bridge, which would be approximately two miles longer than the existing route. This would, therefore, result in a **less-than-significant** impact during Project construction and operations, when compared to Existing Conditions and the No Project/No Action Alternative. No other conflicts with policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities would occur with the Project.

During Project maintenance, no conflicts with policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities would occur. Therefore, there would be **no impact** during Project maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

26.3.7 Impacts Associated with Alternative B

26.3.7.1 Navigation

Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to navigable waterways (**Impact Nav-1**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

Delevan Pipeline Discharge Facility

Impact Nav-1: Conflict with Navigation along Navigable Waterways

The navigational channel of the Sacramento River would be narrowed slightly during the construction of the Delevan Pipeline Discharge Facility, but would not substantially affect the navigability of the Sacramento River at that location. The cofferdam that would be installed to dewater the Project facility's construction site would extend into the river approximately 5 to 10 feet from the river bank, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Alternative B operations are not expected to alter the navigable channel of the Sacramento River. Operation of the proposed Delevan Pipeline Discharge Facility is expected to follow criteria that are set forth by the resource agencies, and as such, releases would be such that they would not adversely affect marine traffic. In addition, the small size of this proposed facility would allow for recreational boat traffic to pass. Therefore, there would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

26.3.7.2 Transportation and Traffic

Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to circulation system performance (**Impact Trans-1**), congestion management programs (**Impact Trans-2**), design feature hazards or incompatible uses (**Impact Trans-3**), emergency access (**Impact Trans-4**), and adopted transportation policies, plans, or programs (**Impact Trans-5**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to transportation and traffic:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprints and construction disturbance areas of Sites Reservoir and Dams, the Road Relocations and South Bridge, and the Delevan Transmission Line would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities (that are included in Alternative A) would be replaced by the Delevan Pipeline Discharge Facility in Alternative B. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on congestion management programs (**Impact Trans-2**), design feature hazards or incompatible uses (**Impact Trans-3**), emergency access (**Impact Trans-4**), and adopted transportation policies, plans, or programs (**Impact Trans-5**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on congestion management programs (**Impact Trans-2**), design feature hazards or incompatible uses (**Impact Trans-3**), emergency access (**Impact Trans-4**), and adopted transportation policies, plans, or programs (**Impact Trans-5**) as described for Alternative A.

The changes to facility footprints and construction disturbance areas would, however, result in a different number of ADT with peak construction trips, with an associated change in Level of Service. The changes associated with implementation of Alternative B, as related to **Impact Trans-1**, are described below.

All Primary Study Area Project Facilities

Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation

When compared to Alternative A, Alternative B would not have construction trips along I-5, SR 162, SR 45, Canal Road, and Maxwell Road related to the Delevan Pipeline Intake Facilities, but would have construction trips along the same roads related to the Delevan Pipeline Discharge Facility. Alternative B would also result in an increase in construction trips along I-5, County Road 68, County Road D, County Road 69, Maxwell Sites Road, and Sites Lodoga Road related to the construction of the larger Sites Reservoir. In addition, the Road Relocations associated with this alternative would differ slightly from Alternative A and the Delevan Transmission Line would be shorter for Alternative B than for Alternative A. The roadway Level of Service for each Project facility prior to and during construction is presented in Table 26-18.

Table 26-18
2010 and Alternative B Construction Level Of Service

*Refer to Tables 26-4 and 26-5 for the Level of Service criteria.

Notes:

ADT = Average Daily Traffic
I = Interstate Freeway
SR = State Route

Source: Colusa County, 2011; Caltrans, 2009 and 2010.

All roadways would continue to operate at an acceptable Level of Service. Traffic levels on roadways would increase during Project construction, particularly before construction activities start and after they end each day, and would result in an increase in traffic congestion. The Level of Service on County Road 68 between County Road F and I-5, County Road 69 between I-5 and County Road F, County Road D between the Glenn/Colusa County Line and County Road 57, Maxwell Sites Road between I-5 and Sutton Road and between the GCID Canal and Sites Lodoga Road, Sites Lodoga Road between Maxwell Sites Road and Leesville Lodoga Road, and Delevan Road between Four Mile Road and the GCID Canal would change Level of Service, but would still meet the County roadway criteria of Level of Service C or better. Therefore, this increase in Project construction-related vehicle traffic and congestion would result in a **less-than-significant impact** because Level of Service criteria would not be exceeded, when compared to Existing Conditions and the No Project/No Action Alternative.

Traffic levels associated with Project operations and maintenance would increase, when compared to Existing Conditions and the No Project/No Action Alternative. Project operation- and maintenance-related traffic would use the same roads that were used for Project construction but would require 60 total vehicles trips per day throughout the Primary Study Area, which would not impact the roadway Level of Service. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative, due to the low number of vehicle trips associated with Project operations and maintenance.

RVDs have been estimated by Project Economists for Alternative B at 358,049 per year (Pavich, 2012). Maxwell Sites Road is expected to have traffic levels that would result in Level of Service D during the Friday through Sunday period during the recreation season (either the March to November or May to September recreation season). I-5 would have Level of Service A or B. County Roads 68, 69, and D are expected to have traffic levels that would result in Level of Service E during the Friday through Sunday period of a March to November recreation season, or a Level of Service that is worse than F during the Friday through Sunday period of a May to September recreation season. This increase would result in a **significant impact** on the Level of Service of County roads listed above, and a **less-than-significant impact** on I-5's Level of Service, when compared to Existing Conditions and the No Project/No Action Alternative.

26.3.8 Impacts Associated with Alternative C

26.3.8.1 Navigation

Extended, Secondary, and Primary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to navigable waterways (**Impact Nav-1**), would be the same as described for Alternative A for the Extended, Secondary, and Primary study areas.

26.3.8.2 Transportation and Traffic

Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to circulation system performance (**Impact Trans-1**), congestion management programs (**Impact Trans-2**), design feature hazards or incompatible uses (**Impact Trans-3**), emergency access (**Impact Trans-4**), and adopted transportation policies, plans, or programs (**Impact Trans-5**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to transportation and traffic:

- Recreation Areas
- Sites Pumping/Generating Plant

- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to transportation and traffic as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to transportation and traffic as described for Alternative B.

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

However, these differences in the size of the facility footprint, alignment, or construction disturbance area (between Alternative C and Alternatives A and B) would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on congestion management programs (**Impact Trans-2**), design feature hazards or incompatible uses (**Impact Trans-3**), emergency access (**Impact Trans-4**), and adopted transportation policies, plans, or programs (**Impact Trans-5**) as described for Alternative A.

The changes to facility footprints and construction disturbance areas would, however, result in a different number of ADT with peak construction trips, with an associated change in Level of Service. The changes associated with implementation of Alternative C, as related to **Impact Trans-1**, are described below.

All Primary Study Area Project Facilities

Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation

When compared to Alternative A there would be an increase in construction trips along I-5, County Road 68, County Road D, County Road 69, Maxwell Sites Road, and Sites Lodoga Road due to a larger Sites Reservoir with Alternative C than with Alternative A. When compared to Alternative B, there would be an increase in construction trips related to the larger Delevan Pipeline Intake Facilities (which are not included in Alternative B) and the Delevan Transmission Line (which is a shorter transmission line in Alternative B). The roadway Level of Service for each facility prior to and during construction is presented in Table 26-19.

All roadways would continue to operate at an acceptable Level of Service. Traffic levels on roadways would increase during Project construction, particularly before construction activities start and after they end each day, and would result in an increase in traffic congestion. The Level of Service on County Road 68 between County Road F and I-5, County Road 69 between I-5 and County Road F, County Road D between the Glenn/Colusa County Line and County Road 57, Maxwell Sites Road between I-5 and Sutton Road and between the GCID Canal and Sites Lodoga Road, Sites Lodoga Road between Maxwell Sites Road and Leesville Lodoga Road, and Delevan Road between Four Mile Road and the GCID Canal would change Level of Service, but would still meet the County roadway criteria of Level of Service C or better. This increase in vehicle traffic and congestion would result in a **less-than-significant impact** because Level of Service criteria would not be exceeded, when compared to Existing Conditions and the No Project/No Action Alternative.

Traffic levels associated with Project operations and maintenance would increase, when compared to Existing Conditions and the No Project/No Action Alternative. Project operation- and maintenance-related traffic would use the same roads that were used for Project construction but would require 60 total vehicles trips per day throughout the Primary Study Area, which would not impact the roadway Level of Service. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative, due to the low number of vehicle trips associated with Project operations and maintenance.

RVDs have been estimated by Project Economists for Alternative C at 373,659 per year (Pavich, 2012). Maxwell Sites Road is expected to have traffic levels that would result in Level of Service D during the Friday through Sunday period during the recreation season (either the March to November or May to September recreation season). I-5 would have Level of Service A or B. County Roads 68, 69, and D are expected to have traffic levels that would result in Level of Service E during the Friday through Sunday period of a March to November recreation season, or a Level of Service that is worse than F during the Friday through Sunday period of a May to September recreation season. This increase would result in a **significant impact** on the Level of Service of County roads listed above, and a **less-than-significant impact** on I-5's Level of Service, when compared to Existing Conditions and the No Project/No Action Alternative.

26.4 Mitigation Measures

26.4.1 Navigation

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

26.4.2 Transportation and Traffic

Mitigation measures are provided below and summarized in Table 26-20 for the impacts that have been identified as significant or potentially significant.

Table 26-20
Summary of Mitigation Measures for
NODOS Project Impacts to Traffic

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation	Sites Reservoir Inundation Area and Recreation Areas (operation – recreation traffic)	Significant	Mitigation Measure Trans-1: Prepare and Implement a Project Operation Traffic Control Plan	Less than Significant
Impact Trans-3: Substantially Increase Hazards Due to Design Feature or Incompatible Uses	All Project facilities (construction)	Potentially Significant	Mitigation Measure Trans-3: Prepare and Implement a Project Construction Traffic Control Plan	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Trans-1: Prepare and Implement a Project Operation Traffic Control Plan

DWR and Reclamation shall prepare and implement an Operation Traffic Control Plan for the Project. Consultation with Glenn and Colusa counties shall occur to determine what those agencies would require to manage the traffic congestion that is expected to occur as a result of recreationists traveling to Sites Reservoir and its Recreation Areas. It is possible that the Counties may want to wait to do any road improvements until a recreation season (or more) has passed, so that actual recreation visitation and associated traffic congestion on local roadways could be monitored.

Consultation and coordination with Caltrans shall also occur to manage traffic at onramps and offramps from I-5 that would connect to the County roads leading to Sites Reservoir and its Recreation Areas.

Consultation with local fire and sheriff departments shall occur to obtain input regarding maintaining adequate emergency response times and access to properties along the roads that comprise the routes to Sites Reservoir and its Recreation Areas.

The Operation Traffic Control Plan may include, but not be limited to, ideas such as:

- Widening the existing County roads that comprise the primary route to Sites Reservoir and its Recreation Areas, and maintaining such roads
- Signalizing or signage at intersections along the primary route to Sites Reservoir and its Recreation Areas
- Developing alternate routes to Sites Reservoir that would intersect at Maxwell Sites Road and signalizing that intersection
- Providing bus service to Sites Reservoir and its Recreation Areas and providing a Park and Ride Lot at the bus pickup location
- Provisions for maintaining emergency vehicle access (detailed measures to be developed in coordination with the local sheriff and fire departments)
- Provisions to reduce potential school bus delays that may occur as a result of Project recreation visitation traffic (detailed measures to be developed in coordination with the local school district and sheriff departments)
- Directional roadway signage to Sites Reservoir and its Recreation Areas

The Operation Traffic Control Plan shall be prepared in coordination with, and approved by, affected agencies, such as Caltrans, Glenn County, Colusa County, and Maxwell Unified School District.

Mitigation Measure Trans-3: Prepare and Implement a Project Construction Traffic Control Plan

DWR and Reclamation shall prepare and implement a Construction Traffic Control Plan for the Project. The Construction Traffic Control Plan shall include, but would not be limited to, the following measures that are intended to manage:

- Construction-related traffic
- Temporary and/or permanent bus reroutes
- Pavement repairs before and after construction
- Measures to reduce emergency vehicle delay and maintain emergency vehicle access (detailed measures to be developed in coordination with the local sheriff and fire departments)
- Measures to accommodate potential school bus reroutes and reduce potential school bus delays (detailed measures to be developed in coordination with the school district and sheriff departments)
- Construction site parking
- Construction signage

The Construction Traffic Control Plan shall be prepared in coordination with, and approved by, affected agencies, such as Caltrans, Glenn County, Colusa County, and Maxwell Unified School District.

Implementation of **Mitigation Measures Trans-1** and **Trans-3** would reduce the level of significance of Project impacts to transportation and traffic to **less than significant**.

27. Noise

27.1 Introduction

This chapter describes the noise setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for noise is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Effects of Project noise on wildlife are discussed in Chapter 14 Terrestrial Biological Resources, and the effects of groundborne vibration on fish are discussed in Chapter 12 Aquatic Biological Resources. Mitigation measures are provided for identified significant impacts, where appropriate.

27.2 Affected Environment

27.2.1 Introduction

Noise is defined as unwanted sound. Levels of sound are measured and expressed in decibels (dB). Airborne sound is a rapid fluctuation of air pressure above and below atmospheric pressure. Methods used to measure or quantify sound levels depend on the source, the receiver, and the reason for measurement.

The most common metric is the overall A-weighted sound level measurement, which measures sound in a manner similar to the way a person perceives or hears sound, thus achieving a strong correlation for evaluating acceptable and unacceptable sound levels. A-weighted measurement has been adopted by regulatory agencies worldwide. These sound levels are expressed as dBA.

A-weighted sound levels are typically measured or presented as L_{eq}, which is defined as the average sound level on an equal energy basis for a stated period of time. The L_{eq} is commonly used to measure steady state sound or noise that is usually dominant. The relative A-weighted noise levels of common sounds measured in the environment and industry for various qualitative sound levels are provided in Table 27-1.

Table 27-1
Typical Sound Levels Measured in the Environment and Industry

Noise Source at a Given Distance	A-Weighted Sound Level in Decibels (dBA)	Qualitative Description
Carrier Deck Jet Operation	140	
	130	Pain threshold
Jet Takeoff (200 feet)	120	
Auto Horn (3 feet)	110	Maximum vocal effort
Jet Takeoff (1,000 feet) Shout (0.5 feet)	100	

Table 27-1
Typical Sound Levels Measured in the Environment and Industry

Noise Source at a Given Distance	A-Weighted Sound Level in Decibels (dBA)	Qualitative Description
New York Subway Station Heavy Truck (50 feet)	90	Very annoying Hearing damage (8-hour, continuous exposure)
Pneumatic Drill (50 feet)	80	Annoying
Freight Train (50 feet) Freeway Traffic (50 feet)	70 to 80	
	70	Intrusive (Telephone use difficult)
Air Conditioning Unit (20 feet)	60	
Light Auto Traffic (50 feet)	50	Quiet
Living Room, Bedroom	40	
Library, Soft Whisper (5 feet)	30	Very quiet
Broadcasting/Recording Studio	20	
	10	Just audible

Source: New York Department of Environmental Conservation. 2001.

Statistical methods are used to capture the dynamics of a changing acoustical environment. These measurements are typically denoted by L_{xx}, where $_{xx}$ represents the percent of time a sound level is exceeded. The L_{90} represents the noise level that is exceeded during 90 percent of the measurement period. Similarly, the L_{10} represents the noise level exceeded for 10 percent of the measurement period. Another sound level expression is L_{max}, which is the maximum sound pressure level over a defined period.

Another metric used in determining the effect of environmental noise is the difference in response that people have to daytime and nighttime noise levels. During the evening and at night, exterior background noises are generally lower than daytime levels. However, most household noise also decreases at night and exterior noise becomes more noticeable. Furthermore, most people sleep at night and are more sensitive to intrusive noises at that time. To account for human sensitivity to evening and nighttime noise levels, the Daytime-Nighttime Noise Level (DNL) (also abbreviated as L_{dn}) and the Community Noise Equivalent Level (CNEL) for California were developed. The DNL is a noise metric that accounts for the greater annoyance of noise during the nighttime hours (10:00 p.m. to 7:00 a.m.). The CNEL is a noise index that accounts for the greater annoyance of noise during the evening hours (7:00 p.m. to 10:00 p.m.) and nighttime hours.

DNL values are calculated by averaging hourly L_{eq} sound levels for a 24-hour period and applying a weighting factor to the nighttime L_{eq} values. CNEL values are calculated similarly, except that a weighting factor is also added to evening L_{eq} values. The weighting factors, which reflect the increased sensitivity to noise during evening and nighttime hours, are added to each hourly L_{eq} sound level before the 24-hour DNL or CNEL is calculated. For the purposes of assessing noise, the 24-hour day is divided into three time periods, with the following weightings:

- Daytime hours: 7:00 a.m. to 7:00 p.m. (12 hours) – Weighting factor of 0 dBA
- Evening hours (for CNEL only) 7:00 p.m. to 10:00 p.m. (3 hours) – Weighting factor of 5 dBA
- Nighttime hours (for both CNEL and DNL) 10:00 p.m. to 7:00 a.m. (9 hours) – Weighting factor of 10 dBA

The adjusted time period noise levels are then averaged (on an energy basis) to compute the overall DNL or CNEL value. For a continuous noise source, the DNL value is easily computed by adding 6.4 dBA to the overall 24-hour noise level (L_{eq}). For example, if the expected continuous noise level from a noise source is 60.0 dBA, the resulting DNL from the source would be 66.4 dBA. Similarly, the CNEL for a continuous noise source is computed by adding 6.7 dBA to the overall 24-hour L_{eq}. Given the small differences, the two are often used interchangeably.

The effects of noise on people can be listed in three general categories:

- Subjective effects of annoyance, nuisance, dissatisfaction
- Interference with activities, such as speech, sleep, learning
- Physiological effects, such as startling and hearing loss

In most cases, environmental noise effects are limited to the first two categories - creating an annoyance or interference with activities. No completely satisfactory way exists to measure the subjective effects of noise or to measure the corresponding reactions of annoyance and dissatisfaction. This lack of a common standard is primarily due to the wide variation in individual thresholds of annoyance and habituation to noise. Therefore, an important way of determining a person's subjective reaction to a new noise is to compare it to the existing or "ambient" environment to which that person has adapted. In general, the more the level or the tonal (frequency) variations of a noise exceed the previously existing ambient noise level or tonal quality, the less acceptable the new noise is, as perceived by the exposed individual.

The general human response to changes in noise levels that are similar in frequency content (for example, comparing increases in continuous [L_{eq}] traffic noise levels) are summarized as follows:

- A 3 dB change in sound level is considered a barely noticeable difference
- A 5 dB change in sound level is typically noticeable
- A 10 dB change is considered to be a doubling in loudness

27.2.2 Extended Study Area

The Extended Study Area consists of the Central Valley Project and the State Water Project service areas located in northern and southern California. Noise levels in these areas can vary considerably, depending on the location, season, and time of day. Noise levels in noisy urban settings can be as high as 75 dBA during the day. In extremely isolated outdoor locations with no wind, wildlife, or running water, noise levels may be less than 20 dBA. Typical noise levels in rural settings are approximately 40 dBA during the day and 30 dBA during the night. In wilderness areas, ambient noise levels are on the order of 20 dBA (USEPA, 1971). In rural areas with low population density, the LD_n likely varies between 35 to 40 dBA (Miller, 2002). Noise levels in recreational settings, such as San Luis Reservoir, can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).

Noise-sensitive land uses generally are defined as locations where people reside or where the presence of unwanted sound could adversely affect the designated use of the land. Noise-sensitive land uses located in the Extended Study Area include residences, hospitals, places of worship, libraries, and schools, as well as nature and wildlife preserves and parks.

27.2.3 Secondary Study Area

The Secondary Study Area consists of existing facilities in 22 counties in northern California that may be affected by Project operation. Descriptions of the ambient noise levels in these counties are provided below; however, because noise is a local phenomenon that is influenced by discrete activities, noise levels at the existing facilities not proposed for modification are not discussed in this section. Similar to the Extended Study Area, noise-sensitive land uses located in the Secondary Study Area include residences, hospitals, places of worship, libraries, and schools, as well as nature and wildlife preserves and parks.

27.2.3.1 Alameda

Transportation noise in Alameda County includes vehicle, aircraft, and train traffic. Major roadways in the County include Interstates 80, 580, 680, 880, and 980, and numerous State Routes. Railroad activity occurs along two railroad lines of the Union Pacific Railroad and also along the Bay Area Rapid Transit (BART) system. There are three public airports within Alameda County: Oakland International Airport, Hayward Executive Airport, and Livermore Municipal Airport. Other sources of noise in the county include stationary noise sources associated with industrial and commercial uses (Alameda County, 1985; Alameda County, 2000; Alameda County, 2009).

27.2.3.2 Butte

Transportation noise in Butte County includes vehicle, aircraft, and train traffic. Major roadways in the county include State Routes 32, 70, 99, 149, 162, and 191. Railroad activity occurs along two railroad lines of the Union Pacific Railroad. One line is aligned parallel to the west side of State Route 99. The other line is generally parallel to the east and west sides of the Feather River. There are four public airports within Butte County: Chico Municipal, Oroville Municipal, Paradise Skypark, and Ranchero.

Non-transportation noise sources in the county include noise from commercial, industrial, and public facilities. Significant stationary noise sources in unincorporated Butte County are the Neal Road Recycling and Waste Facility, solid waste transfer stations, aggregate mining operations, general service commercial and light industrial uses, recreational uses, and parks and school playing fields (Butte County, 2009). Noise levels in recreational settings, such as Lake Oroville and the Thermalito Complex, can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).

27.2.3.3 Colusa

Ambient noise levels in portions of Colusa County are defined primarily by traffic on major roadways, including, but not limited to, Interstate 5 and State Routes 16 and 20. Agricultural activities, as well as aircraft from the Colusa County Airport, also contribute to the noise environment. In addition, there are numerous stationary noise sources (e.g., quarry operations, lumber mills, industrial facilities) dispersed throughout the county (Colusa County, 2012).

27.2.3.4 Contra Costa

The primary source of noise in Contra Costa County is from transportation, which includes vehicle, aircraft and train traffic. Vehicular traffic along freeways (e.g., Interstates 80 and 680 and State Routes 24 and 4), and major arterials (e.g., Willow Pass Road and Ygnacio Valley Road) are the primary sources of vehicular traffic noise. Rail operations produce noise along the Atchison Topeka and Santa Fe and Southern Pacific railroad corridors. Passbys from the Bay Area Rapid Transit system also contribute to noise from train traffic. Aircraft from Buchanan Field, near Concord, is the primary source of aircraft noise. Other sources of aircraft noise are local airports and military helicopter activity. Motorized boats along the San Joaquin River also contribute noise.

Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, and heavy equipment use. Industrial plants, such as oil refineries and materials processing plants, contribute noise as do operations at the Camp Parks Reserve Forces Training Area (Contra Costa County, 2005).

27.2.3.5 Del Norte

Ambient noise levels in portions of Del Norte County are defined primarily by traffic on major roadways, including, but not limited to, Interstates 101 and 199. Aircraft from the Jack McNamara Field contribute to the noise environment. There are also numerous stationary noise sources dispersed throughout the county (Del Norte County, 2003).

27.2.3.6 El Dorado

Ambient noise levels in portions of El Dorado County are defined primarily by traffic on major roadways, including, but not limited, to U.S. 50 and State Routes 49, 193, and 89. Aircraft from the Cameron Airpark Airport, Placerville Airport, Georgetown Airport, Lake Tahoe Airport, and Sacramento Mather Airport contribute to the noise environment. There are also numerous stationary noise sources (e.g., quarry operations, lumber mills, industrial facilities) dispersed throughout the county (El Dorado County, 2003). Noise levels in recreational settings, such as Folsom Lake, can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).

27.2.3.7 Glenn

Ambient noise levels in portions of Glenn County are defined primarily by traffic on major roadways, including, but not limited to, Interstate 5 and State Route 162. Aircraft from the Willow-Glenn County Airport also contribute to the noise environment. In addition, there are numerous stationary noise sources throughout the county (Glenn County, 1993).

27.2.3.8 Humboldt

Ambient noise levels in portions of Humboldt County are defined primarily by traffic on major roadways, including, but not limited to, U.S. 101, and State Routes 36, 255, and 299. Train traffic from the Northwestern Pacific Railroad and aircraft from the Rohnerville, Dinsmore, Murray Field, and City of Eureka airports also contribute to the noise environment. In addition, there are numerous stationary noise sources throughout the county (Humboldt County, 2008).

27.2.3.9 Marin

Vehicle traffic is the primary source of noise in Marin County, with the highest noise levels occurring along major highways (U.S. 101 and State Routes 1 and 37) and major county roads (including Sir Francis Drake Boulevard, Petaluma Point Reyes Road, Lucas Valley Road, and Novato Boulevard). Other significant local noise sources include aircraft from Rafael Airport, Gnoss Field, and the Richardson Bay Helipad, trains, mining activity, and construction (Marin County, 2007).

27.2.3.10 Placer

Ambient noise levels in portions of Placer County are defined primarily by traffic on major roadways, including, but not limited to, Interstate 80 and State Routes 20, 28, 49, 65, 89, and 193. Aircraft from the Lincoln Regional Airport, Auburn Airport, and Truckee-Tahoe Airport also contribute to the noise environment. In addition, there are numerous stationary noise sources throughout the county. Noise levels in recreational settings such as Folsom Lake can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).

27.2.3.11 Sacramento

The primary source of noise in Sacramento County is from transportation, which includes vehicle, aircraft, and train traffic. There are five freeways in the county (Interstates 5 and 80, State Routes 99 and 160, and U.S. 50) that all converge near downtown Sacramento, seven public airports, and multiple heavy and light rail lines. There are also numerous arterial roadways and highways that have two to eight lanes that generate noise. Motorized boats along the Sacramento River also contribute noise.

Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, heavy equipment use, and outdoor sporting event facilities (Sacramento County, 2010). Noise levels in recreational settings such as Folsom Lake can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).

27.2.3.12 San Francisco

Noise sources in San Francisco County include personal and public transportation vehicles (including rail, bus, and cable car), aircraft from the San Francisco International Airport, commercial and industrial activities, construction, heating and cooling equipment, landscape maintenance, heavy equipment use, and outdoor events (City and County of San Francisco, 1996).

27.2.3.13 San Mateo

Transportation noise in San Mateo includes vehicle and aircraft traffic. Major roadways in the county include U.S. 101, Interstates 280 and 380, and State Routes 1, 82, 84 and 92. Aircraft from the San Francisco International Airport and two general aviation airports (Half Moon Bay and San Carlos) contribute to the noise environment.

Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, heavy equipment use, and outdoor sporting event facilities (San Mateo County, 1986).

27.2.3.14 Santa Clara

Transportation noise in Santa Clara County includes vehicle and aircraft traffic. Major roadways in the county include U.S. 101, Interstate 880, and several State Routes. Aircraft from the San Jose International Airport, Moffett Field, and three general aviation airports also contribute to the noise environment.

Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, heavy equipment use, and outdoor sporting event facilities (Santa Clara County, 1994).

27.2.3.15 Shasta

Transportation noise in Shasta County includes vehicle, aircraft, and train traffic. Major roadways in the county include State Routes 44, 89, 273 and 299, and Interstate 5. The principal railroad activity in the county occurs along the Union Pacific Railroad main line track that is aligned north/south. In addition to vehicle and train traffic, aircraft from the Redding Municipal Airport, Shingletown Airport, and Fall River Mills Airport contribute to the noise environment.

Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, heavy equipment use, and outdoor sporting event facilities (Shasta County, 2004). Noise levels in recreational settings, such as Shasta and Whiskeytown lakes, can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).

27.2.3.1 Solano

Bisecting the county from north to south, Interstate 80 is the dominant noise source in Solano County, with State Routes 12 and 113 also contributing transportation noise. In addition to freeway noise, the county's ambient noise levels include local traffic on city streets, commercial and industrial uses, active recreation areas of parks and outdoor play areas, railroad operations, and aircraft overflights. Motorized boats along the Sacramento River also contribute noise (Solano County, 2008).

27.2.3.2 Sonoma

Transportation noise in Sonoma County includes vehicle, aircraft, and train traffic. Major roadways in the county include State Routes 1, 12, 116, 121, and 128, U.S. 101, and county roads. The principal railroad activity occurs along the Northwest Pacific Railroad. It parallels U.S. 101 the entire length of the county. In addition to vehicle and train traffic, aircraft from the Charles M. Schulz Airport contribute to the noise environment.

Non-transportation noise sources in the county include agriculture (primarily wineries and cattle ranching), industrial and heavy commercial activities, the Infineon International Raceway, geothermal power plants at the Geysers, solid waste landfills and transfer stations, concerts, and other outdoor events (Sonoma County, 2008).

27.2.3.3 Sutter

The dominant sources of noise in Sutter County are related to transportation and include automobile and truck traffic, aircraft, and trains. State Routes 20, 70, 99 and 113 are major sources of traffic noise. Sutter County Airport is the only publicly owned and operated airport in the county. Noise from aircraft traffic at Sacramento International Airport, located approximately one mile south of the southern Sutter County's border, also influences Sutter County's noise environment. In addition, two rail lines are active in the county: the Southern Pacific Transportation Company and Union Pacific Railroad.

Stationary sources of noise in the county include natural gas extraction facilities, construction sites, mining activities, agricultural activities, and commercial and industrial facilities (Sutter County, 1996).

27.2.3.4 Tehama

The major noise sources in Tehama County consist of highway and local traffic on county roads, as well as commercial and industrial uses, airports, and railroad operations. Major roadways in the county include Interstate 5 and State Routes 32, 36, 89, and 99. The only active railroad operation within Tehama County is the Union Pacific Railroad. There are two public airports within Tehama County: Corning Municipal Airport and Red Bluff Municipal Airport (Tehama County, 2009). Existing sources of noise at/near the location of the existing Red Bluff Pumping Plant include roadway traffic and stationary noise sources, such as mechanical equipment at the Red Bluff Pumping Plant, the existing Red Bluff Diversion Dam, and the T-C Canal Intake, as well as noise from activities on the Sacramento River.

27.2.3.5 Trinity

Transportation noise in Trinity County includes vehicle, aircraft, and train traffic. Major roadways in the county include State Routes 3, 36, and 299, and county roads. The principal railroad activity in the county occurs along the Northwest Pacific Railroad. It parallels Highway 101 the entire length of the county. Aircraft from the Weaverville, Ruth, Hyampom, Hayfork and Trinity Center airports contribute to the noise environment.

Noise levels in recreational settings, such as Trinity and Lewiston lakes, can range from 55 to 65 dBA during the day, dropping to 50 to 60 dBA at night (Miller, 2002).Non-transportation noise sources in the county include stationary sources, such as the Weaverville landfill/transfer station, the Trinity River lumber mill, concrete/aggregate plants, and other industrial facilities (Trinity County, 2003).

27.2.3.6 Yolo

Noise sources in eastern Yolo County and West Sacramento include transportation and non-transportation activities. Traffic noise occurs along the corridors of Interstates 5 and 80, and State Route 84. Rail operations from freight and passenger traffic, and aircraft from the Sacramento International Airport and Bourges-Clarksburg Airport, contribute to the noise environment. Motorized boats along the Sacramento River also contribute noise. Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, and heavy equipment use (Yolo County, 2009).

27.2.3.7 Yuba

The dominant sources of noise in Yuba County are from transportation, which includes vehicle, train, and aircraft traffic. Major roadways in the county include State Routes 20, 65 and 70. Two major railroad lines, Southern Pacific and Union Pacific, contribute rail traffic noise. Aircraft from the Yuba County Airport and Beale Air Force Base contribute to the noise environment.

Non-transportation noise sources in the county include agricultural operations, commercial and industrial activities, parks and school playing fields, heating and cooling equipment, landscape maintenance, natural gas compression stations, and heavy equipment use (Yuba County, 1996).

27.2.4 Primary Study Area

Existing noise levels are described at each of the proposed Project facility locations. Ambient noise levels are estimated based on existing land uses. Noise-sensitive land uses are described by Project feature. Noise-sensitive land uses include residences, hospitals, places of worship, libraries, and schools, as well as nature and wildlife preserves and parks.

27.2.4.1 Sites Reservoir Inundation Area and Sites Reservoir Dams, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Recreation Areas, and Road Relocations and South Bridge

The majority of the footprint of the proposed Sites Reservoir, its proposed dams, pumping/generating plant, tunnel to the inlet/outlet structure, the inlet/outlet structure, electrical switchyard, field office maintenance yard, recreation areas, bridge, and roads would be located within Colusa County in what is currently a rural and sparsely populated area. Within the vicinity of these Project features, there are several residences and one paved road (Maxwell Sites Road, which, as it continues west, becomes Sites Lodoga Road). Ambient noise levels in this area are expected to be low due to the few roads and the sparse population. The primary noise source is traffic noise and noise associated with ranching operations.

The northernmost portion of the proposed Sites Reservoir would be located within Glenn County. No developed road access exists in this area. Road 69 dead-ends three miles west of the existing T-C Canal, which is located to the east of the proposed reservoir site. Noise sources along/near Road 69 include a few rural residences and agricultural operations. Ambient noise levels in this area are expected to be low due to the general lack of roads and residences in the area, and the limited accessibility of the area.

27.2.4.2 Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The existing Funks Reservoir is located within Colusa County. There is no public access to the reservoir; the T-C Canal levee road that provides access to the reservoir has locked gates to provide access to only authorized personnel. Similar to Sites Reservoir, Funks Reservoir is located in an area that is expected to have low ambient noise levels. No noise-sensitive receptors are located within a one-mile buffer around the proposed Funks Reservoir Dredging area. Primary noise sources at the reservoir include wildlife that visit the site, as well as human and vehicle noise when the reservoir is visited by authorized personnel.

The Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard are proposed to be located adjacent to and on the east side of the existing Funks Reservoir. The area is currently undeveloped open space that is not accessible to the public. This area is expected to have low ambient noise levels. No noise-sensitive receptors are located within a one-mile buffer around the Hothouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard. Primary noise sources in this area include wildlife that visit the site, agricultural operations, and human and vehicle noise from authorized personnel using the portion of the T-C Canal levee road that is nearby.

27.2.4.3 Terminal Regulating Reservoir (includes the Terminal Regulating Reservoir to Funks Creek Pipeline and Outlet), Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Terminal Regulating Reservoir Pipeline, and Terminal Regulating Reservoir Pipeline Road

The proposed TRR, its connection to the GCID Canal, the pumping plant and electrical switchyard, two pipelines, and maintenance road would be located within Colusa County. Similar to Sites Reservoir, the TRR and associated facilities would be located in an area that is expected to have low ambient noise levels. There are a few residences within a 0.5-mile radius of the proposed TRR location. The nearest residences are located northeast of and adjacent to the TRR. This area is agricultural, so the primary noise source is agricultural equipment that currently operates at the TRR site and in all directions around the site. Due to the proposed TRR's location near existing local roads (Delevan, Mc Dermott, and Lenahan roads), traffic noise also contributes to the ambient noise setting.

27.2.4.4 Glenn-Colusa Irrigation District Canal Facilities Modifications

The GCID Canal Facilities Modifications would be located in Glenn County. The proposed headgate and canal lining sites would be located approximately five miles northwest of Hamilton City within the existing GCID Canal. Existing land uses in the area, in all directions surrounding the GCID Canal facilities, include agriculture (row crops and orchards), a few rural residences, and undeveloped open space. This area is expected to have low ambient noise levels; noise sources include vehicle traffic and equipment associated with farming operations. The nearest residence is located approximately 680 feet west of the proposed headgate structure.

The site of the proposed railroad siphon replacement is at the GCID Canal at the southeast edge of the City of Willows. Existing land uses in the area include residential to the south and west, commercial to the west, light industrial and undeveloped open space to the north, and agricultural to the east. This area is expected to have low ambient noise levels; noise sources include vehicle traffic and equipment associated with farming operations. The nearest residence is located approximately 100 feet southwest of the proposed railroad siphon replacement location.

27.2.4.5 Delevan Pipeline, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line

The proposed Delevan Pipeline, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line would be located within agricultural fields and orchards in Colusa County. Similar to Sites Reservoir, the Delevan Pipeline, Electrical Switchyard, and Transmission line would be located in an area that is expected to have low ambient noise levels. However, intermittent noise sources include crop dusters and/or helicopters, the use of propane cannons to reduce bird depredation, and gun shots during hunting season. There are various residences adjacent to and within a 0.5-mile radius of the proposed Delevan Pipeline and Delevan Transmission Line locations. The nearest residence to the proposed Delevan Pipeline Electrical Switchyard location is approximately 1.7 miles to the east.

27.2.4.6 Delevan Pipeline Intake/Discharge Facilities

The proposed Delevan Pipeline Intake/Discharge Facilities would be located at the eastern terminus of the proposed Delevan Pipeline at the Sacramento River. The footprint of the intake/discharge facilities proposed for Alternatives A and C is larger than the discharge-only facilities proposed for Alternative B; however, their location is the same. The existing noise sources in this area include agricultural operations associated with the orchards that are located at the site, vehicle traffic noise from SR 45, noise from boat traffic and humans on the Sacramento River, and the noise that is generated from the existing Maxwell Irrigation District pumps that are located adjacent to and north of the proposed intake/discharge facilities location. There are two residences within a one-mile buffer of the proposed Delevan Pipeline Intake/Discharge Facilities.

27.2.4.7 Project Buffer

The Project Buffer would surround all of the Primary Study Area Project facilities, except for the Delevan Pipeline and Transmission Line, TRR Pipeline and Road, Delevan Pipeline Electrical Switchyard, TRR to Funks Creek Pipeline, and portions of the roads. The existing noise sources and proximity of noise-sensitive receptors within a given area of the Project Buffer would, therefore, be the same as those described for the Project facilities that the Project Buffer surrounds.

27.3 Environmental Impact/Environmental Consequences

27.3.1 Regulatory Setting

Noise associated with projects are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These policies are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

27.3.1.1 Federal Plans, Policies, and Regulations

- Federal guidance for environmental noise and regulations for specific sources (for example, aircraft or federally funded highways) by the Federal Energy Regulatory Commission, Federal Transit Administration (FTA), Federal Railroad Administration, Federal Highway Administration (FHWA), Federal Aviation Administration, U.S. Environmental Protection Agency, and the U.S. Department of Housing and Urban Development

A summary of various federal noise guidelines is presented in Table 27-2. As an example, the Federal Railroad Administration (FRA) and Federal Transit Administration (FTA) guidelines are presented on a sliding scale. Therefore, if the existing noise exposure at a sensitive receptor is 50 dBA, an effect would occur if an increase of 5 dBA is predicted.

Table 27-2
Summary of Federal Guidelines/Regulations for Residential Exterior Noise

Agency	L_{eq}[e] (dBA)	DNL[f] (dBA)
Federal Energy Regulatory Commission	**49**	55
Federal Highway Administration	67	67
Federal Aviation Administration	**59**	65
Federal Railroad Administration and Federal Transportation Administration[a,b]	Sliding scale	Sliding scale
U.S. Environmental Protection Agency[c]	**49**	55
U.S. Department of Housing and Urban Development[d]	**59**	65

[a]FRA 1998.
[b]FTA 2006.
[c]EPA 1974.
[d]24 CFR Part 51B.
[e]The average sound level on an equal energy basis for a stated period of time. The L_{eq} is commonly used to measure steady state sound or noise that is usually dominant.
[f]The Daytime/Nighttime Noise Level (DNL) was developed to account for human sensitivity to evening and nighttime noise levels. The DNL is a noise metric that accounts for greater annoyance of noise during the nighttime hours (10:00 p.m. to 7:00 a.m.).

Notes:
Bold numbers indicate calculated equivalent standard. Because the Federal Highway Administration regulates peak hour noise level, the DNL is assumed equivalent to the peak noise hour.
dBA = decibel A-weighted sound level; the sound pressure level in decibels as measured on a sound level meter using the A-weighted filter network.

27.3.1.2 State Plans, Policies, and Regulations

- California Noise Control Act of 1973 (California Health and Safety Code Sections 46000-46080)
- DWR Specification 05-16 (Section 01570 Environmental Protection)[1]

[1] DWR Specification 05-16, Section 01570 Environmental Protection describes the requirements for conservation and protection of environmental resources at construction work sites, Part 1.07(B)(3) addresses the threshold for establishing noise impacts to wildlife and the recommended mitigation for such potential impacts.

- California Administrative Code Title 4
- California Government Code §65302(f)

27.3.1.3 Regional and Local Plans, Policies, and Regulations

- Tehama County General Plan
- Glenn County General Plan
- Colusa County General Plan

27.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for noise:

Would the Project:

- Result in exposure of persons to or generation of noise levels in excess of standards established in the local General Plan or noise ordinance, or applicable standards of other agencies?
- Result in exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?
- Result in a substantial permanent increase in ambient noise levels in the Project vicinity above levels existing without the Project?
- Result in a substantial temporary or periodic increase in ambient noise levels in the Project vicinity above levels existing without the Project?
- Expose people residing or working in the Project area to excessive noise levels (for a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport).?
- Expose people residing or working in the Project area to excessive noise levels (for a project within the vicinity of a private airstrip)?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Expose persons to or generation of noise levels in excess of standards established in the local General Plans, or applicable standards of other agencies.
- Expose persons to or generation of excessive groundborne vibration or groundborne noise levels.
- Result in a substantial permanent increase in ambient noise levels in the Project vicinity above levels existing without the Project.
- Result in a substantial temporary or periodic increase in ambient noise levels in the Project vicinity above levels existing without the Project.

- Expose people residing or working in the Project area to excessive noise levels (for a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport).
- Expose people residing or working in the Project area to excessive noise levels (for a project within the vicinity of a private airstrip).

27.3.3 Impact Assessment Assumptions and Methodology

27.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to noise levels:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.
- All residences located outside of proposed Project facility footprints, but within the Project Buffer, would be acquired, vacated, and demolished, as necessary, prior to the start of Project construction.
- Project construction activities and the transportation/delivery of construction vehicles, equipment, and materials are anticipated to occur between the hours of 6:00 a.m. and 7:00 p.m. on Mondays through Fridays. Nighttime and weekend construction and transportation/delivery of construction vehicles, equipment, and materials are not planned, but may occur on an as-needed basis. Nighttime construction would not be conducted within 1,000 feet of occupied residences between 10:00 p.m. and 7:00 a.m. Project construction haul times in residential communities would be limited to 7:00 a.m. to 10:00 p.m., and air brake restrictions would be applied in residential communities.

- Construction of Project facilities would require a substantial number of workers traveling to construction sites during the construction period (refer to Chapter 26 Navigation, Transportation, and Traffic). Truck traffic associated with the transport of construction materials, borrow and spoil materials, and concrete would also increase the number of heavy vehicles on roadways in the vicinity of the work sites during construction. Construction would increase the number of construction vehicles on the roadways adjacent to the construction activities. Passenger vehicles transporting workers would add to existing volumes and associated noise levels along the major transportation roadways in the vicinity of Project facilities. Truck traffic would be distributed throughout the day. Construction would also require other noise- and vibration-generating activities such as clearing and grubbing, demolition of existing structures, excavation, drilling, and blasting.
- Project implementation would involve the long-term operation of noise-generating stationary equipment, including pumping plants, mechanical cleaning mechanisms on fish screens, and emergency generators.

27.3.3.2 Methodology

<u>Construction</u>

The area of influence for the evaluation of the impact of Project construction activities on ambient noise levels is defined as a 0.5-mile radius around the noise source. At a 0.5-mile radius around the noise source, there would be a 34-dBA noise reduction compared to a reference distance of 50 feet. It is important to note that other attenuating mechanisms, such as atmospheric or ground effects, may increase the amount of attenuation further, resulting in even lower noise levels. For construction equipment with typical reference noise levels of 80 and 90 dBA at 50 feet, this attenuation would result in noise levels from the equipment being reduced to 46 to 56 dBA at the 0.5-mile distance, respectively. Although these noise levels may still be noticeable at this distance, they would typically fall within the range of the Tehama, Colusa, and Glenn County General Plan requirements for steady operations.

Construction noise impacts were evaluated by estimating noise levels from various construction activities. Table 27-3 lists equipment noise levels from Table 1 of the FHWA Roadway Construction Noise Model User's Guide (FHWA, 2006). All listed noise levels are maximum A-weighted sound pressure levels (L_{max}) at a reference distance of 50 feet. The acoustical usage factor is the fraction of time each piece of construction equipment is operating at full power (i.e., its loudest condition) during a construction operation. The model calculates the total noise level at the receptor by logarithmically summing noise levels from each piece of equipment in use and accounting for the reduction of noise over distance caused by geometric divergence[2]. At farther distances, additional attenuation (e.g., ground effects and atmospheric attenuation) can be substantial, but the model does not account for this additional attenuation. Therefore, the model output should be considered conservatively high.

[2] Geometric divergence is the primary mechanism of noise reduction close to a noise source.

Table 27-3
Construction Equipment Noise Levels

Equipment Description	Acoustical Usage Factor (Percent)	Noise Control Specification Lmax at 50 feet (dBA)	Actual Measured Lmax at 50 feet (dBA)	Actual Data Samples (Count)
All Other Equipment >5 hp	50	85	N/A	0
Auger Drill Rig	20	85	84	36
Backhoe	40	80	78	372
Bar Bender	20	80	N/A	0
Blasting	NA	94	N/A	0
Boring Jack Power Unit	50	80	83	1
Chain Saw	20	85	84	46
Clam Shovel (dropping)	20	93	87	4
Compactor (ground)	20	80	83	57
Compressor (air)	40	80	78	18
Concrete Batch Plant	15	83	N/A	0
Concrete Mixer Truck	40	85	79	40
Concrete Pump Truck	20	82	81	30
Concrete Saw	20	90	90	55
Crane	16	85	81	405
Dozer	40	85	82	55
Drill Rig Truck	20	84	79	22

dBA = A-weighted decibel
hp = horsepower
kVA = kilovolt-amperes
L_{max} = maximum sound pressure level
N/A = not available

Source: FHWA, 2006.

Table 27-3 indicates that the loudest equipment generally emits noise in the range of 80 to 90 dBA at 50 feet. Noise at any specific receptor is dominated by the closest and loudest equipment. The types and numbers of construction equipment near any specific receptor location would vary over time. The construction noise estimate was based on assumptions of multiple pieces of loud equipment operating close together near the edge of the construction site. This is believed to be a conservative, yet realistic, scenario. Additional assumptions include the following:

- One piece of equipment generating a reference noise level of 85 dBA (at a 50-foot distance with a 40 percent usage factor) located at the edge of the construction site
- Two pieces of equipment each generating reference noise levels of 85 dBA located 50 feet farther away on the construction site
- Two more pieces of equipment each generating reference noise levels of 85 dBA located 100 feet farther away on the construction site

Table 27-4 provides construction equipment noise levels at various distances, as calculated using the preceding assumptions. This extrapolation is considered conservative because it considers only geometric spreading and does not account for absorption from atmospheric particles, physical topography, or vegetation.

Table 27-4
Construction Equipment Noise Levels versus Distance

Distance from the Construction Site Boundary (feet)	L_{eq} Noise Level (dBA)
50	83
100	79
200	74
400	69
800	63
1,600	58
3,200	52
6,400	46

Notes:
dBA = A-weighted decibel
L_{eq} = equivalent sound pressure level

Source: Data developed using FHWA Roadway Construction Noise Model.

In the absence of a Tehama, Glenn, or Colusa County noise standard for construction activities, DWR's Specification 05-16 was interpreted. Section 01570 of DWR Specification 05-16 indicates that noise levels that exceed 60 dBA in areas where the ambient noise level is less than 60 dBA[3] require temporary sound walls. Therefore, 60 dBA was interpreted as the noise level in which mitigation would be required due to a significant impact.

Vibration generated by construction equipment typically spreads through the ground and diminishes in magnitude with increases in distance. Although effects of ground vibration may be imperceptible at low levels, they may result in detectable vibrations and slight damage to nearby structures at moderate and high levels, respectively. At the highest levels of vibration, damage to structures is primarily architectural (e.g., loosening and cracking of plaster or stucco coatings) and rarely results in structural damage. There is significant potential for impact from construction activities, such as blasting, pile-driving, vibratory compaction, demolition, and drilling or excavation, that occur in proximity to vibration-sensitive structures (FTA, 2006). Vibratory impacts from construction activities were evaluated by examining the presence and extent of these activities and their proximity to vibration-sensitive structures.

Operations and Maintenance

Noise impacts from operation and maintenance of Project facilities were evaluated by comparing the noise levels generated by the Project facility equipment to noise standards that were set by the counties, and by comparing projected noise levels to projected ambient noise levels.

27.3.4 Topics Eliminated from Further Analytical Consideration

Within the Extended and Secondary study areas, no Project-related activities would expose people residing or working in the vicinity of the Project facilities to excessive aircraft-generated noise levels

[3] This noise level is applicable to the Primary Study Area.

because of the distance of existing public airports or private airstrips to the Project facilities. Therefore, potential impacts related to aircraft-generated noise (**Impact Noise-5** and **Impact Noise-6**) are not discussed further for these two study areas. Within the Primary Study Area, a public airport is located near the site of proposed modifications to the GCID Canal railroad siphon (**Impact Noise-5**). Potential impacts related to aircraft-generated noise are discussed for that Project facility only. Because a private airstrip is not located near Project facilities within the Primary Study Area, **Impact Noise-6** is not discussed further.

Although Project construction, operation, and maintenance activities would generate noise, there are no noise-sensitive receptors located within a 0.5-mile radius of the following Project facilities or their associated construction disturbance areas: Sites Reservoir Inundation Area, Sites Dams, Recreation Areas, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, and Delevan Pipeline Electrical Switchyard. These facilities are, therefore, not evaluated.

27.3.5 Impacts Associated with the No Project/No Action Alternative

27.3.5.1 Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential to exceed established standards has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on noise levels, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to cause increases in existing ambient noise levels. Noise impacts that would occur as a result of the increased population would be managed at the local level (e.g., cities and counties) in accordance with those agencies' regulations. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

In addition, projects considered within the No Project/No Action Alternative are not located within the Primary Study Area, and therefore, **there would not be a substantial adverse effect** on ambient noise levels within that study area, when compared to Existing Conditions.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Refer to the **Impact Noise-1** discussion. The discussion also applies to groundborne vibration and noise levels.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion regarding the projects that are included in the No Project/No Action Alternative not being located in the Primary Study Area. The discussion also applies to ambient noise levels.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion regarding the projects that are included in the No Project/No Action Alternative not being located in the Primary Study Area. The discussion also applies to ambient noise levels.

Impact Noise-5: Expose People Residing or Working in the Project Area to Excessive Noise Levels (for a Project Located within an Airport Land Use Plan or, Where Such a Plan Has Not Been Adopted, within Two Miles of a Public Airport OR Public Use Airport)

Refer to the **Impact Noise-1** discussion regarding the projects that are included in the No Project/No Action Alternative not being located in the Primary Study Area. The discussion also applies to excessive noise levels.

Impact Noise-6: Expose People Residing or Working in the Project Area to Excessive Noise Levels (for a Project within the Vicinity of a Private Airstrip)

Refer to the **Impact Noise-1** discussion regarding the projects that are included in the No Project/No Action Alternative not being located in the Primary Study Area. The discussion also applies to excessive noise levels.

27.3.6 Impacts Associated with Alternative A

27.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

There would be no direct Project-related construction or maintenance occurring in the Extended Study Area; therefore, no exceedance of established standards would occur and there would be **no impact** on noise levels from construction or maintenance activities in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of San Luis Reservoir would be altered to accommodate Project operation, which would result in more frequent and larger surface water elevation fluctuations at the reservoir than currently occurs there. In addition, Project operation would result in increased water supply reliability to agricultural, municipal, and industrial users, and the wildlife refuges in the Extended Study Area. These operations would not be expected to change existing noise levels. Therefore, there would be **no impact** on noise levels from operations in the Extended Study Area, when compared to both Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Because there would be no direct Project-related construction or maintenance occurring in the Extended Study Area, there would be **no impact** on existing groundborne vibration or noise levels from construction or maintenance activities in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion. The discussion also applies to ambient noise levels.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion. The discussion also applies to ambient noise levels.

27.3.6.2 Secondary Study Area – Alternative A

<u>Construction, Operation, and Maintenance Impacts</u>

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Project operation would affect the flow regime or surface water elevations of many of the facilities in the Secondary Study Area (listed above). However, changes in flow regime or surface water elevations would not be expected to change existing noise levels. Therefore, there would be **no impact** on noise levels from Project operations in the Secondary Study Area, as compared to both Existing Conditions and the No Project Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Refer to the **Impact Noise-1** discussion. The discussion also applies to groundborne vibration and noise levels.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion. The discussion also applies to ambient noise levels.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion. The discussion also applies to ambient noise levels.

Pump Installation at the Red Bluff Pumping Plant

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant. Glenn County exempts construction site sounds between 7:00 a.m. and 7:00 p.m. If construction activities occur outside of the exemption period, they would be conducted in compliance with applicable noise standards. Therefore, construction activities associated with the installation of an additional pump would have a **less-than-significant impact** on noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Pump operation would also generate noise. However, the pumping plant already has several pumps operating and the addition of one pump would not be expected to generate noise that could be distinguished from existing noise levels. Therefore, operation of an additional pump at the Red Bluff Pumping Plant would have a **less-than-significant impact** on noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the removal of sediment from the existing GCID Canal and Red Bluff Pumping Plant intakes, located in Glenn and Tehama counties, respectively. Project-related operational changes at these facilities could result in increased sedimentation at the intakes and consequently require increased rates of sediment removal. Sediment removal activities, which would involve the use of heavy machinery and equipment (such as bulldozers, excavators, dump trucks, and gradalls[4]), would generate noise. It is expected that maintenance activities would occur during the day, between the hours that Glenn County exempts construction site sounds. If maintenance activities occur outside of the exemption period, they would be conducted in compliance with applicable noise standards. Therefore, maintenance activities associated with the removal of sediment from the existing GCID Canal and Red Bluff Pumping Plant intakes would have a **less-than-significant impact** on noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

The installation of an additional pump into an existing bay at the Red Bluff Pumping Plant may generate groundborne vibration and noise. However, these activities would occur during the daytime and would be temporary. Therefore, construction activities at this facility would result in a **less-than-significant** impact at the nearest noise-sensitive receptors, when compared to Existing Conditions and the No Project/No Action Alternative.

[4] Gradalls are hydraulic wheel-mounted backhoes often used with wide buckets for dressing earth slopes.

Pump operation would also generate noise and may generate groundborne vibration. However, the pumping plant already has several pumps operating and the addition of one pump would not be expected to generate noise or vibration that could be distinguished from existing levels. Therefore, operation of an additional pump at the Red Bluff Pumping Plant would have a **less-than-significant impact** on groundborne noise and vibration levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities associated with sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant) could also result in groundborne vibration or groundborne noise levels. However, these activities would occur during the daytime and would be temporary. Therefore, maintenance activities would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a substantial permanent increase in ambient noise levels in the Project vicinity above Levels Existing without the Project

There are several residences within a 0.5-mile radius of the GCID Canal Intake facilities. There are three residences located on the opposite side of the river from the Red Bluff Pumping Plant, less than one mile from the Project construction site. In addition, the Sacramento River Discovery Center is located approximately 0.25 mile from the pumping plant.

Construction activities related to installation of an additional pump at the Red Bluff Pumping Plant facility would generate noise that would be temporary, not permanent. Therefore, noise levels from construction would have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Operation of the additional pump at the Red Bluff Pumping Plant would result in a permanent increase in ambient noise levels. However, the pumping plant already has several pumps operating and the addition of one pump would not be expected to generate noise that could be distinguished from existing levels. Therefore, operation of an additional pump at the Red Bluff Pumping Plant would have a **less-than-significant impact** on noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities at the GCID Canal and the Red Bluff Pumping Plant would increase the ambient noise levels at those facilities when the maintenance activities are occurring. Because maintenance activities would be required throughout the life of the Project, and those activities would generate noise, that noise is considered a long-term impact. Because the noise emitted from maintenance activities would be intermittent, i.e., lasting only as long as the activity occurred, the maintenance activities would not result in a permanent increase in noise levels. Therefore, Project maintenance activities would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary OR Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Refer to the **Impact Noise-1** discussion**.** The discussion also applies to ambient noise levels.

27.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Modeling results presented in Table 27-3 indicate that noise-sensitive receptors would be subjected to noise levels from construction ranging from 83 dBA at 50 feet from the construction site boundary to

52 dBA at 3,200 feet. At 0.5 mile (the boundary for the area of influence for noise impacts), construction noise would attenuate to approximately 55 dBA. Noise levels resulting from construction and operation activities could disturb adjacent uses if noise-sensitive receptors are located within this range of distances.

The sources of noise associated with construction, operation, and maintenance of the Road Relocations and South Bridge, GCID Canal Facilities Modifications, TRR and associated facilities, Delevan Pipeline and Transmission Line, Delevan Pipeline Intake Facilities, and Project Buffer, as well as distances from those facilities to the nearest noise-sensitive receptors located within a 0.5-mile radius, are described below.

Road Relocations and South Bridge

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Glenn County and Colusa County do not have a noise ordinance. Glenn County exempts construction site sounds between 7:00 a.m. and 7:00 p.m. Noise emitted from construction activities associated with the road relocations and the new South Bridge would exceed DWR's Specification 05-16. Therefore, construction activities would have a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The Colusa County Code restricts noise generated from any developed use to a DNL of 60 dB or less as measured at the nearest residential zoned property. In addition, developed uses must not exceed a median hourly noise level of 50 dBA in daytime and 45 dBA in the nighttime. Project operation would result in a continuation of travel on the existing roads (resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative) and also travel on the new and/or relocated Project roads and the new bridge. Travel on new and/or relocated roads would introduce vehicle noise to areas that do not currently experience traffic noise. Traffic noise levels, although they would increase from Existing Conditions in those areas, are not expected to exceed established standards, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance of the roads and bridge would occur periodically, and would result in travel on the existing, new, and relocated roads and the new bridge. Maintenance activities on the roads and bridge would also generate noise. Maintenance activities associated with the road relocations and the new South Bridge would need to comply with applicable noise standards. By meeting the noise standards, construction activities would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Project construction ground disturbing activities, such as grading, may generate localized groundborne vibration and noise. Any Project construction groundborne vibration and noise would occur during daytime hours, and would be temporary. No construction activities with the potential for significant impact would occur. Therefore, road and bridge construction would result in a **less-than-significant impact** related to groundborne vibration and noise, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation (i.e., travel on the roads and bridge) would not result in groundborne vibration and noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Typical road and bridge maintenance activities (such as chip sealing, patching, asphalt overlays, repair of guardrails, embankment and/or abutment repair, clearing debris, and safety/maintenance inspections) are not expected to cause groundborne vibration and noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction activities, including associated construction traffic, would be temporary, and therefore, would cause no permanent increase in ambient noise levels in the vicinity of these Project features, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation and maintenance, the introduction of vehicles onto new roads, relocated existing roads, and the South Bridge would result in a permanent increase in ambient noise levels from vehicle traffic. This would result in a **less-than-significant impact** on the ambient noise levels of those roadways, when compared to Existing Conditions and the No Project/No Action Alternative because there would be no noise-sensitive receptors located within a 0.5-mile radius.

Project operation would result in a continuation of travel on the existing roads (resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative) and also travel on the new and/or relocated Project roads and the new bridge. Travel on new and/or relocated roads would introduce vehicle noise to areas that do not currently experience traffic noise. Traffic noise levels, although they would permanently increase from Existing Conditions in those areas, are not expected to be substantial, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Road and bridge maintenance activities would occur periodically, and would result in travel on the existing, new, and relocated roads and the new bridge. Maintenance activities on the roads and bridge would also generate noise. Maintenance activities would be long-term, but would result in intermittent (not permanent) increases in noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction activities associated with the existing, relocated, and new roads and the South Bridge would be temporary, emitting noise levels of 83 dBA at 50 feet from the construction site boundary to approximately 55 dBA at 0.5 mile (the boundary for the area of influence of noise impacts), resulting in an increase in ambient noise levels in the areas around the roads and bridge.

There are three residences located near to the affected roads: one residence located approximately 0.6 mile east of Sulphur Gap Road, one residence located approximately 0.75 mile east of Sulphur Gap Road, and one residence located approximately 600 feet south of County Road 69/North Road, to the west of the T-C Canal. The first two residences mentioned are beyond the noise impact boundary of 0.5 mile. The residence located south of County Road 69/North Road would experience noise levels of approximately 66 dBA when Project construction work to that road was occurring nearest to the residence. Applying this construction-related noise level to DWR's Specification 05-16 60-dBA limit for requiring sound walls, would result in a **significant impact** on ambient noise levels at that location, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation would result in a continuation of travel on the existing roads and also travel on the new and/or relocated roads and the new bridge. Travel on new and/or relocated roads would introduce vehicle noise to areas that do not currently experience traffic noise. These expected long-term travel patterns would not result in substantial temporary or periodic noise increases, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Road and bridge maintenance activities would occur periodically, and would result in travel on existing, new, and relocated roads and the new bridge. Maintenance activities on the roads and bridge would also generate noise. Maintenance activities would be long-term, and would result in a temporary and periodic increase in noise that would not be substantial, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Glenn County exempts construction site sounds between 7:00 a.m. and 7:00 p.m. Construction activities that occur outside of the exemption period would comply with applicable noise standards. Due to the County's daytime construction exemption, construction activities would have a **less than-significant-impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation and maintenance activities at the headgate, canal lining, and railroad siphon locations and their associated noise levels are not expected to increase from existing levels because the same noise-generating activities that currently occur along the GCID Canal would continue, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

The temporary bypass channel would be constructed using a combination of excavation, earth embankment, and sheetpile walls to isolate the construction site from the canal. These construction activities are considered to have a potential for impact when occurring in proximity to vibration-sensitive structures. There are several existing residences within 0.25 mile of the proposed headgate and canal lining location, and several more within a 0.5-mile radius of those Project facilities. The railroad siphon that would be replaced would be located adjacent to several neighborhoods in the City of Willows. Therefore, construction activities would result in **potentially significant impact** on groundborne vibration and noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation and maintenance activities at the headgate, canal lining, and railroad siphon locations are not expected to cause groundborne vibration or noise that would differ from existing levels because the same noise-generating activities that currently occur along the GCID Canal would continue, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Project construction activities at these locations would not permanently increase ambient noise levels there, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation and maintenance activities at these locations and their associated noise levels are not expected to increase substantially from existing levels because the same noise-generating activities that currently occur along the GCID Canal would continue, resulting in a **less-than-significant impact** on ambient noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Required maintenance activities would be very similar to current maintenance; however, dredging of the Intake Channel would now occur periodically throughout the year instead of every three years. The intake and fish screen facility would operate year-round and would be very similar to existing operations. Therefore, operation and maintenance activities would result in a **less-than-significant impact** on ambient noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Project construction activities associated with the proposed GCID Canal Facilities Modifications would be temporary, generating noise levels of approximately 78 to 83 dBA at 50 feet (approximately 61 dBA at 0.25 mile). This would result in a **potentially significant impact** on ambient noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of the GCID Canal Facilities Modifications would be a long-term impact, not a temporary or periodic increase in noise levels. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance of the GCID Canal Facilities Modifications would be a long-term impact that would result in a temporary and periodic increase in noise levels that would not be substantial. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-5: Expose People Residing or Working in the Project Area to Excessive Noise Levels (for a Project Located within an Airport Land Use Plan or, Where Such a Plan Has Not Been Adopted, within Two Miles of a Public Airport or Public Use Airport)

The Willows-Glenn County Airport is located approximately 1.3 miles from the railroad siphon that would be replaced during the GCID Canal Facilities modifications. However, Project construction workers and operations/maintenance personnel would be provided OSHA-approved hearing protection, if necessary. Therefore, exposure to airport-associated noise levels would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Colusa County does not have a noise ordinance. However, noise emitted from construction activities associated with the TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, and TRR Pipeline Road would exceed DWR's Specification 05-16. Therefore, construction activities would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The operation of the proposed TRR and its associated facilities would result in operation of noise-generating stationary equipment, including a pumping plant and emergency generators. This operational noise would be a change from the noise that is currently generated at the site from its existing agricultural practices. Vendor-specific noise information is not currently available for the equipment needed to operate the TRR. However, it is possible that the generated noise levels would exceed established standards, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities associated with sediment removal and disposal at the TRR and the pump operation could result in an increase in ambient noise levels. However, these activities are expected to result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Construction activities (e.g., transport of materials to the Project site, clearing and grading the construction work space, staging of construction materials, dewatering, and excavation and embankment construction) associated with the construction of the TRR and its associated facilities may generate groundborne vibration and noise. These construction activities would result in a **potentially significant impact,** when occurring in proximity to the nearest residence, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance activities associated with sediment removal and disposal and the Project's pump operation could also result in groundborne vibration or groundborne noise levels. However, these activities would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction activities associated with the TRR and its associated facilities would result in temporary impacts, not permanent impacts, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The long-term operation and maintenance of the proposed TRR and its associated facilities would result in operation of noise-generating stationary equipment, including a pumping plant and emergency generators. This would be a change from the noise that is currently generated at the site from its existing agricultural practices. Vendor-specific noise information is not currently available for operation and maintenance equipment. However, it is possible that the noise levels that would be generated would result in a **potentially significant impact** on ambient noise levels at the nearest noise-sensitive receptor (a residence), when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

The construction of the TRR and its associated facilities would require excavation, transport, stockpiling, and grading. Construction equipment would generate noise levels between 80 and 85 dBA at a 50-foot distance (i.e., the nearest noise-sensitive receptor). This would result in a temporary **significant impact** on ambient noise levels during Project construction, particularly when working within the northeast corner of the TRR, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of the proposed TRR and its associated facilities would be a long-term impact, not a temporary or periodic increase in noise levels. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance of the proposed TRR and its associated facilities would be a long-term impact that would result in a temporary and periodic increase in noise levels that would not be substantial. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline and Delevan Transmission Line

The Delevan Transmission Line would parallel and overlap with the construction disturbance area of the Delevan Pipeline from the Delevan Pipeline Intake Facilities to the TRR. The transmission line and pipeline would then diverge as their alignments would continue west of the TRR to other Project facilities. There are no noise-sensitive receptors located within a 0.5-mile radius of the divergence area. This impact analysis, therefore, focuses on the segments of the Delevan Pipeline and Transmission Line that are located between the Delevan Pipeline Intake Facilities and the TRR. There are approximately 49 residences located within the construction disturbance area of the Delevan Pipeline and Transmission Line. The nearest residence that was identified for the TRR is also located within these facilities' construction disturbance area.

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Colusa County does not have a noise ordinance. Noise emitted from construction activities associated with the Delevan Pipeline and Delevan Transmission Line would exceed DWR's Specification 05-16. Therefore, Delevan Pipeline and Delevan Transmission Line construction activities would have a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The long-term operation of the proposed Delevan Pipeline would generate only minimal noise at the aboveground blow-off structures and air valve structures, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. Maintenance of the proposed pipeline would consist of periodic inspections and maintenance as needed, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The long-term operation and maintenance of the proposed Delevan Transmission Line would result in noise generated from two sources: the transmission line would emit a “hum”, and periodic maintenance trips to the individual transmission line towers by inspection vehicles would emit vehicle noise. These noise sources would not be expected to exceed applicable noise standards and would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Construction activities (e.g., ground disturbing activities, including excavation and movement of heavy construction equipment) associated with the installation of the pipeline may generate groundborne vibration and noise. These construction activities would result in a **potentially significant impact**, when in proximity to noise-sensitive receptors (residences), when compared to Existing Conditions and the No Project/No Action Alternative.

Construction activities associated with installation of the proposed transmission line (clearing, grading, delivering construction materials at the staging areas, excavating tower footings, erecting the towers, and stringing the conductor) are not expected to generate groundborne vibration or noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of the pipeline and transmission line would require no ground disturbing activities and would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction of the Delevan Pipeline would require dewatering, as well as trenching of soils and alluvial material down to the design depth. Construction of the Delevan Transmission Line would require the construction of a temporary access road along the alignment and soil excavation for tower footings. Construction equipment would generate noise levels between 80 and 85 dBA at a 50-foot distance. However, these activities would be temporary, not permanent, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The long-term operation of the proposed Delevan Pipeline would generate minimal noise at the above-ground blow-off structures and air valve structures, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The long-term operation of the proposed Delevan Transmission Line would result in noise generated from two sources: the transmission line would emit a “hum”, and periodic maintenance trips to the individual transmission line towers by inspection vehicles would emit vehicle noise. These noise sources would not cause a substantial permanent increase in ambient noise levels, and would, therefore, result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance of the proposed pipeline and transmission line would generate noise from vehicles and equipment on a periodic and temporary basis, not permanently. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction activities associated with the Delevan Pipeline and Transmission Line would result in temporary increases in noise, emitting noise levels of between 80 and 85 dBA at a 50-foot distance, which would attenuate to approximately 55 dBA at 0.5 mile. This would result in a **significant impact** on the residences located within the construction disturbance area of the pipeline and transmission line, when compared to Existing Conditions and the No Project/No Action Alternative.

Operations activities would be a long-term impact, not a temporary or periodic increase in noise levels. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would be a long-term impact that would result in a temporary and periodic increase in noise levels that would not be substantial. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Colusa County does not have a noise ordinance. However, noise emitted from construction activities associated with the Delevan Pipeline Intake Facilities would exceed DWR's Specification 05-16. Therefore, construction activities would have a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance activities would involve the long-term operation of noise-generating stationary equipment, including the pumping plant, mechanical cleaning mechanisms on fish screens, and emergency generators. Noise is currently generated near the site from the existing adjacent Maxwell Irrigation District Pumping Plant. Vendor-specific noise information is not currently available for the equipment needed to operate this Project facility. However, it is possible that the generated noise levels would exceed established standards, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Construction of the Delevan Pipeline Intake Facilities would require the use of a vibratory pile driver to install a cofferdam. Because the nearest residence is located approximately 0.3 mile away from the intake facility footprint, groundborne vibration or groundborne noise levels are not expected to be excessive, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of the Delevan Pipeline Intake Facilities would not involve the use of equipment that would emit groundborne vibration or noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction of the proposed Delevan Pipeline Intake Facilities would result in temporary impacts, not permanent impacts on noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation would involve the long-term operation of noise-generating stationary equipment, including the pumping plant, mechanical cleaning mechanisms on fish screens, and emergency generators. Noise is currently generated near the site from the existing adjacent Maxwell Irrigation District Pumping Plant. Vendor-specific noise information is not currently available for the equipment needed to operate this Project facility. However, ambient noise levels are expected to increase, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would generate noise from vehicles and equipment on a periodic and temporary basis, not permanently. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

The construction of the Delevan Pipeline Intake Facilities would require installation of a cofferdam within the Sacramento River; dewatering, clearing and grading the construction workspace; excavating soils and alluvium from the forebay, afterbay, and pumping plant sites; construction of the levee, pump house, pump bays, forebay structure, and fish screens; and filling and re-grading, where needed. Modeling results presented in Table 27-4 indicate that noise-sensitive receptors would be subjected to noise levels from construction of approximately 58 dBA at 0.3 mile. Therefore, noise levels from construction would have **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operations activities would be a long-term impact, not a temporary or periodic increase in noise levels. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would be a long-term impact that would result in a temporary and periodic increase in noise levels that would not be substantial. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Within the Project Buffer, a fence would be constructed, several existing structures would be demolished, and a fuelbreak would be created. Glenn County and Colusa County do not have a noise ordinance. Glenn County exempts construction site sounds between 7:00 a.m. and 7:00 p.m. Noise generated from fence construction is not expected to exceed DWR’s Specification 05-16; however, noise emitted from demolition activities and fuelbreak discing may. Therefore, construction activities would have a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance activities, including fence and fuelbreak maintenance, would generate noise (particularly fuelbreak work), resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Construction of a fence, demolition of structures, and creation of a fuelbreak within the Project Buffer would not generate groundborne vibration or groundborne noise. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, operation and maintenance activities (including fence and fuelbreak maintenance) would not generate groundborne vibration or groundborne noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction and demolition activities would result in temporary impacts, not permanent impacts, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operations activities would be long-term, resulting in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would be long-term, and would not result in a permanent increase in ambient noise levels, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction and demolition activities would result in temporary noise impacts, resulting in a **less-than-significant impact** at noise-sensitive receptors, when compared to Existing Conditions and the No Project/No Action Alternative.

Operations activities would be a long-term impact, not a temporary or periodic increase in noise levels. This would result in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would be a long-term impact that would result in a temporary and periodic increase in noise levels. Noise levels associated with fence maintenance would not be substantial, resulting in **a less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative. However, fuelbreak maintenance would result in a **potentially significant impact** to ambient noise levels, when compared to Existing Conditions and the No Project/No Action Alternative.

27.3.7 Impacts Associated with Alternative B

27.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to excessive noise levels (**Impact Noise-1**), excessive groundborne vibration or noise levels (**Impact Noise-2**), permanent increases in ambient noise levels (**Impact Noise-3**), and temporary or periodic increases in ambient noise levels (**Impact Noise-4**), would be the same as described for Alternative A for the Extended and Secondary study areas.

27.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to noise:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

Alternative B includes the construction of a 1.81-MAF reservoir. The increased reservoir size necessitates the addition of two saddle dams and the movement of various associated Project features. However, similar to Alternative A, there are no noise-sensitive receptors located within a 0.5-mile radius of these facilities.

The Alternative B Delevan Transmission Line would differ from Alternative A. Alternative B includes no transmission line alignment between the Sacramento River and the WAPA or PG&E transmission lines. The transmission line would be approximately three miles long, from the proposed Sites Electrical Switchyard to the WAPA or PG&E transmission line, which are located west of the TRR. However, similar to Alternative A, there are no noise-sensitive receptors located within a 0.5-mile radius of this construction disturbance area.

The Alternative B Road Relocations and South Bridge would differ slightly from those described for Alternative A. The lengths of the saddle dam access roads included in Alternative A would be reduced in Alternative B because the dams would be larger and would be located closer to the main roads. In addition, an extension of an access road would be constructed for Alternative B to provide access from Saddle Dam 3 to saddle dams 1 and 2. However, there are no noise-sensitive receptors located within a 0.5-mile radius of these portions of the road relocations. Construction activities along the Road 69 segment of the North Road in the vicinity of a residence would have the same impact on excessive noise levels (**Impact Noise-1**), excessive groundborne vibration or noise levels (**Impact Noise-2**), permanent increases in ambient noise levels (**Impact Noise-3**), and temporary or periodic increases in ambient noise levels (**Impact Noise-4**) as described for Alternative A.

The size of the Alternative B Project Buffer would differ from that of Alternative A because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives. However, the boundary of the Project Buffer would be the same for Alternatives A and B and would be the same distance from noise-sensitive receptors as described for Alternative A. In addition, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. The Project Buffer would, therefore, have the same impact on excessive noise levels (**Impact Noise-1**), excessive groundborne vibration or noise levels (**Impact Noise-2**), permanent increases in ambient noise levels (**Impact Noise-3**), and temporary or periodic increases in ambient noise levels (**Impact Noise-4**) as described for Alternative A.

Alternative B would replace the Delevan Pipeline Intake Facilities with the Delevan Pipeline Discharge Facility. The Delevan Pipeline would be operated as a release-only pipeline, so the associated Delevan Pipeline Discharge Facility would, therefore, not include a fish screen or any of the facilities needed for the pumping and generating operations that were described for Alternative A. The construction, operation, and maintenance impacts on noise levels from this facility are discussed below.

Delevan Pipeline Discharge Facility

The proposed Delevan Pipeline Discharge Facility would be smaller than the Delevan Pipeline Intake Facilities included in Alternative A. The proposed Discharge Facility would also have fewer Project features, which would result in a shorter construction time frame for this facility, when compared to the facility included in Alternative A.

Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards

Construction of the Delevan Pipeline Discharge Facility would require installation of a cofferdam within the Sacramento River; dewatering, clearing, and grading the construction workspace; excavation of the bank and backfilling the area for the spillway, channel, and valve house; construction of the setback level and slurry walls, valve house, channel, and spillway; and placing rip rap rock slope protection along the river bank.

Colusa County does not have a noise ordinance. However, noise emitted from construction activities associated with the Delevan Pipeline Discharge Facility would exceed DWR's Specification 05-16. Therefore, construction activities would have a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative

Operation and maintenance activities would involve the long-term operation of noise-generating stationary equipment. Noise is currently generated near the site from the existing adjacent Maxwell Irrigation District Pumping Plant. Vendor-specific noise information is not currently available for the equipment needed to operate this Project facility. However, it is possible that the generated noise levels would exceed established standards, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels

Construction of the Delevan Pipeline Discharge Facility would require the use of a vibratory pile driver to install a cofferdam. Because the nearest residence is located approximately 0.3 mile away from the facility footprint, groundborne vibration or groundborne noise levels are not expected to be excessive, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of the Delevan Pipeline Discharge Facility would not involve the use of equipment that would emit groundborne vibration or noise, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

Construction equipment would generate noise that would be temporary, not permanent. Therefore, noise levels from Project construction would have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative

Project operation would involve the long-term operation of noise-generating stationary equipment. Noise is currently generated near the site from the existing adjacent Maxwell Irrigation District Pumping Plant. Vendor-specific noise information is not currently available for the equipment needed to operate this Project facility. However, ambient noise levels are expected to increase, resulting in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would generate noise from vehicles and equipment on a periodic and temporary basis, not permanently. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity above Levels Existing without the Project

The nearest residence is located approximately 0.3 mile northwest of the Delevan Pipeline Discharge Facility footprint.

The construction of the Delevan Pipeline Discharge Facility would require installation of a cofferdam within the Sacramento River; dewatering, clearing and grading the construction workspace; excavating soils; construction of the levee; and filling and re-grading, where needed. Modeling results presented in Table 27-4 indicate that noise-sensitive receptors would be subjected to noise levels from construction of approximately 58 dBA at 0.3 mile. Therefore, noise levels from construction would have **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operations activities would be a long-term impact, not a temporary or periodic increase in noise levels. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would be a long-term impact that would result in a temporary and periodic increase in noise levels that would not be substantial. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

27.3.8 Impacts Associated with Alternative C

27.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to excessive noise levels (**Impact Noise-1**), excessive groundborne vibration or noise levels (**Impact Noise-2**), permanent increases in ambient noise levels (**Impact Noise-3**), and temporary or periodic increases in ambient noise levels (**Impact Noise-4**), would be the same as described for Alternative A for the Extended and Secondary study areas.

27.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to noise:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would be located the same distance from noise-sensitive receptors as described for Alternative A. They would, therefore, result in the same construction, operation, and maintenance impacts to noise as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Sites Reservoir Dams is the same as described for Alternative B. Therefore, there are no noise-sensitive receptors located within a 0.5-mile radius of these proposed facilities. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to land use as described for Alternative B.

The Alternative C design of the Road Relocations, South Bridge, TRR Pipeline Road, and the Electrical Distribution Lines is the same as described for Alternative B. Therefore, they would be located the same distance from noise-sensitive receptors as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to noise as described for Alternative B.

The boundary of the Project Buffer would be the same for all alternatives, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact have the same impact on excessive noise levels (**Impact Noise-1**), excessive groundborne vibration or noise levels (**Impact Noise-2**), permanent increases in ambient noise levels (**Impact Noise-3**), and temporary or periodic increases in ambient noise levels (**Impact Noise-4**) as described for Alternative A.

27.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 27-5 for the impacts that have been identified as significant or potentially significant.

Table 27-5
Summary of Mitigation Measures for
Potential NODOS Project Impacts to Noise

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Noise-1: Expose Persons to or Generation of Noise Levels in Excess of Established Standards	Road Relocations and South Bridge, TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline, Delevan Transmission Line, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility (construction)	Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant

Table 27-5
Summary of Mitigation Measures for
Potential NODOS Project Impacts to Noise

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
	Project Buffer (construction)	Potentially Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant
	TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Intake Facilities, Project Buffer, Delevan Pipeline Discharge Facility (operation)	Potentially Significant	Mitigation Measure Noise-1b: Design Facilities to Incorporate Noise Mitigation	Less than Significant
	Delevan Pipeline Intake Facilities, Project Buffer, Delevan Pipeline Discharge Facility (maintenance)	Potentially Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant
Impact Noise-2: Expose Persons to or Generation of Excessive Groundborne Vibration or Groundborne Noise Levels	GCID Canal Facilities Modifications, TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline, (construction)	Potentially Significant	Mitigation Measure Noise-2: Develop and Implement a Vibration Monitoring Plan	Less than Significant

Table 27-5
Summary of Mitigation Measures for
Potential NODOS Project Impacts to Noise

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Noise-3: Result in a Substantial Permanent Increase in Ambient Noise Levels in the Project Vicinity Above Levels Existing without the Project	TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility (operation)	Potentially Significant	Mitigation Measure Noise-1b: Design Facilities to Incorporate Noise Mitigation	Less than Significant
	TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, (maintenance)	Potentially Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant
Impact Noise-4: Result in a Substantial Temporary or Periodic Increase in Ambient Noise Levels in the Project Vicinity Above Levels Existing without the Project	Road Relocations and South Bridge, TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline, Delevan Transmission Line, (construction)	Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant
	GCID Canal Facilities Modifications, (construction)	Potentially Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant
	Project Buffer (maintenance)	Potentially Significant	Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant

LOS = Level of Significance

Mitigation Measure Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels

DWR and Reclamation shall include in both the construction and maintenance contracts the specifications indicating the requirements listed below. DWR's and Reclamation's intent is that all Project construction noise-related impacts at noise-sensitive receptor property boundary lines be minimized or eliminated completely to the extent feasible, and/or that construction noise levels at noise-sensitive receptor property boundary lines not exceed 60 dBA. The construction contractor may propose other methods to sufficiently reduce construction noise levels if it can be demonstrated that those methods are implementable and suitable for the particular location and situation:

- **Local requirements.** Project construction and maintenance activities shall follow local requirements to the extent possible.
- **Portable barriers.** Portable barriers shall be used to shield noise from compressors and other small stationary equipment used during Project construction and/or maintenance if the construction or maintenance activity occurs near a residence.
- **Equipment.** Quiet equipment (for example, equipment that incorporates noise-control elements into the design; compressors can be quiet models) shall be used during Project construction and/or maintenance whenever possible. Preventive maintenance on equipment, including practicable methods and devices to control, prevent, and minimize noise, shall be performed on a regular basis. To the extent feasible, portable and stationary equipment shall be located, stored, and maintained as far as possible from nearby residents.
- **Exhaust.** Equipment exhaust stacks and vents shall be directed away from residential buildings.
- **Truck traffic routing.** Project construction and/or maintenance truck traffic shall be routed away from noise-sensitive areas where feasible. Truck companies that would transport Project construction equipment and/or materials shall be informed that air braking along haul routes where there are residences shall be prohibited.
- **Construction activity scheduling.** To the extent feasible, Project construction activities shall be scheduled so that the activities that are the noisiest occur when ambient noise is also at its peak.
- **Residential notification.** DWR and Reclamation shall notify residents near the Project facility site(s) of the timeframe for Project construction and maintenance activities. In addition, DWR and Reclamation shall notify residents near the Project facility site(s) if nighttime Project construction and/or transportation/delivery of construction vehicles, equipment, or materials is necessary. Such notification would occur prior to such activities occurring.
- **Addressing noise complaints.** If complaints from residents that are located near Project facility locations are received due to nighttime Project construction activities, the construction contractor shall monitor construction noise levels at the property line of the affected residence(s). If the construction noise exceeds the applicable noise standard, the responsible construction activity shall cease until feasible measures are implemented to reduce nighttime noise levels.

Mitigation Measure Noise-1b: Design Facilities to Incorporate Noise Mitigation

During Project design, all facilities shall be designed to incorporate noise-reducing features to comply with applicable noise regulations and/or guidelines. Noise-reducing features could include, but are not limited to, acoustically rated wall, ceiling, and door assemblies, and silenced building ventilation; and acoustical treatments on above-ground piping and valving.

Mitigation Measure Noise-2: Develop and Implement a Vibration Monitoring Plan

During Project design, a vibration monitoring plan shall be prepared for construction activities that would require pile driving or excavation. The plan shall be implemented during Project construction to ensure that no vibration-related damage is caused by Project-related construction activities.

Implementation of **Mitigation Measures Noise-1a, Noise-1b,** and **Noise-2** would reduce the level of significance of Project impacts to noise to **less than significant**.

28. Public Health and Environmental Hazards

28.1 Introduction

This chapter describes hazardous materials and other environmental hazards, such as wildland fires and mosquito/vector-borne illnesses that present risks to human health or the environment within the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Other hazards, such as flooding, dam failure, and issues related to public services (e.g., fire protection, law enforcement, emergency services), are addressed in other chapters in this DEIR/EIS.

The regulatory setting for public health and environmental hazards is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

28.2 Environmental Setting/Affected Environment

28.2.1 Extended Study Area

28.2.1.1 Hazardous Materials

Hazardous materials are defined in Section 66260.10, Title 22, of the California Code of Regulations as:

> A substance or combination of substances which, because of its quantity, concentration, or physical, chemical, or infectious characteristics, may either (1) cause, or significantly contribute to, an increase in mortality or an increase in serious, irreversible, or incapacitating reversible, illness; or (2) pose a substantial present or potential hazard to human health or environment when improperly treated, stored, transported, or disposed of or otherwise managed.

In addition, California Health and Safety Code Section 25501 defines a hazardous material as follows:

> Any material that, because of its quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment. “Hazardous materials” include, but are not limited to, hazardous substances, hazardous waste, and any material which a handler or the administering agency has a reasonable basis for believing that it would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or environment.

“Hazardous wastes” are defined in the California Health and Safety Code Section 25141(b) as wastes that:

> …because of their quantity, concentration, or physical, chemical, or infectious characteristics, [may either] cause, or significantly contribute to an increase in mortality or an increase in serious illness [or] pose a substantial present or potential hazard to

human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed.

Hazardous materials contamination throughout the Extended Study Area has resulted from a variety of activities. These activities include the following influences:

- Agriculture operations that include the storage and application of pesticides, herbicides, and fertilizers, and production activities in farming operations
- Urban land uses that generate, store, or transport hazardous materials in the industrial, commercial, and residential setting on both land and water
- Historic mining operations

Potential sources of hazardous material and waste that may exist in the agricultural, urban, and historic mining areas throughout the Extended Study Area may be present in a variety of common contexts, including:

- Petroleum hydrocarbons
- Landfills or solid waste disposals sites
- Volatile organic carbons
- Wastewater and wastewater treatment plants
- Herbicide, insecticides, fungicides, and other pesticides
- Contaminated aggregate (such as mercury-contaminated)
- Underground storage tanks
- Stormwater runoff structures
- Utility poles
- Abandoned mines

Superfund is the name given to the national environmental program that was established to address abandoned hazardous waste sites. It is also the name of the fund established by the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as amended. This law was enacted because of the discovery of toxic waste dumps. California has 94 Superfund sites; there are designated Superfund sites in 26 of the counties included in the Extended Study Area. DTSC oversees the State Superfund sites and also administers the USEPA Brownfields Program. It strives to clean up and redevelop potentially contaminated lands, making it easier for such lands to become functioning parts of their communities. California has 67 Brownfields sites statewide; there are designated Brownfields sites in 11 of the counties included in the Extended Study Area. Refer to Appendix 28A for a list of Superfund and Brownfields sites throughout California (USEPA, 2013).

In addition to the hazardous material contamination issues noted above (agriculture and mining), the following are also areas of concern: quarries, railroads, and private water wells and septic systems.

28.2.1.2 Wildland Fires

Wildland fires pose a hazard to rural and urban development, infrastructure, and natural resources. Numerous factors, such as topography, vegetation characteristics, fuel load, and climate contribute to the degree of fire hazard throughout the State. Based on a review of the California Department of Forestry and Fire Protection's (CAL FIRE) statewide map of fire hazard severity zones, the CVP and SWP service areas within the Extended Study Area include lands designated with a fire hazard severity ranging from moderate to very high. In general, the service areas located in the lower foothills that surround the Central Valley include lands designated as moderate risk; the service areas located in the San Francisco Bay area and in the adjacent East Bay and coastal counties include lands designated as high risk; and the service areas located in Shasta County, in southern California, and in the higher elevations of Tehama County and the eastside counties include lands designated as very high risk for wildland fire (CAL FIRE, 2007a). All of these areas also include identified communities at risk from wildlfire. Communities at risk from wildfire are those located within 1.5 miles of areas of high or very high risk for wildland fire (CAL FIRE, 2001).

28.2.1.3 Mosquitoes, Other Vectors, and Nuisance Problems

Mosquitoes

Several species of mosquitoes are common in California. Each species has a season when it is most active. Depending on the California region, some species may be active during most or all of the year. Each mosquito species has a range of preferred hosts, and most species feed on more than one type of host. Mosquitoes have blood meal hosts that range from reptiles, amphibians, mammals, birds, to humans. Protein from a host’s blood is used by the female mosquito to produce eggs.

Mosquitoes carry diseases that afflict humans. They also transmit several diseases and parasites that dogs, birds, and horses are susceptible to. These diseases include protozoan diseases, such as malaria and dog heartworm, and viruses such as West Nile virus and Eastern equine encephalitis[1] (AMCA, 2013).

Mosquito breeding habitat is briefly characterized below to aid in understanding how mosquito-borne diseases are spread. According to a white paper written by the Society of Wetland Scientist (SWS, 2009), female mosquitoes can be classified into two general groups based on their egg-laying and hatching behavior, namely, the floodwater habitat mosquitoes or the permanent aquatic habitat mosquitoes.

Floodwater mosquito eggs are deposited on moist substrate and do not hatch until subsequently inundated. They include mosquitoes in the genera *Aedes*, *Anopheles*, and *Ochlerotatus* that are primarily daytime mosquitoes. These mosquitoes can be significant vectors for diseases.

Permanent aquatic habitat female mosquitoes lay eggs on stagnant warm water surfaces, which hatch after three to five days. Mosquitoes in the genera *Culex*, *Culisteta*, and *Orthopodomyia* are included in this group. Many species in this group are active at dusk and can feed on both humans and livestock. Conditions conducive to permanent aquatic habitat are shallow stagnant ponds with emergent vegetation, standing rain puddles, and poorly drained or flooded agricultural fields.

The mosquito species that are found within the counties that comprise the Extended Study Area are listed in Table 28-1.

Other Vectors and Nuisance Problems

Stinging Insects

Stringing insects, such as bees, yellowjackets, paper wasps, and stinging ants (all found within the Extended Study Area), can cause injury to humans ranging from sharp temporary pain to anaphylaxis shock leading to death. Stinging insects can be divided into social (those that live in colonies) and non-social (Mussen, 2011a). Non-social stinging insects are individual insects that tend to avoid human contact by fleeing. Social stinging insects include the western yellowjacket (*Vespula pennsylvanica*), the

---

[1] Dengue and yellow fever are also mosquito-vectored diseases; however, they have not been reported in California. Yellow fever occurs only in tropical areas of Africa and the Americas (AMCA, 2013).

German yellowjacket (*Vespula germanica*), the prairie yellowjacket (*Vespula atropilosa*), the European honey bee (*Apis mellifera*), and fire ants (*Solenopsis* spp.). The red imported fire ant (*Solenopsis invicta)* is particularly aggressive and can cause injury and damage to humans, crops, and livestock. Generally, social stinging insects are not aggressive to humans unless perceived as a threat to their nest and foraging activities (Mussen, 2011a and 2011b). In addition, stinging insects are attracted to food sources such as trash receptacles, outdoor cooking areas, and picnic areas.

European honey bees are used by beekeepers in California for honey production and crop pollination although they are non-native to the Americas. Several different subspecies of the European honey bee now exist throughout the United States. The Africanized honey bee[2] has been in California since 1994 (LACWVCD, 2011). Africanized honey bees have colonized in the Extended Study Area in Kings, Madera, San Luis Obispo, Santa Barbara, and Tulare counties.

Yellowjackets and paper wasps are beneficial insects. Yellowjackets and the European paper wasp are often confused, but have distinct differences. Most of the time, yellowjackets are not aggressive and will not harm humans if they stay out of their way. European paper wasps are more easily provoked than other wasps, and will more readily sting when someone nears their nest. In the summer months, foraging yellowjackets may become a nuisance in parks, campgrounds, and other areas. Paper wasps may become a nuisance when they build a nest on or near homes (SYMVCD, 2011).

Stinging ants are non-native but were found in California in 1997. Since then, they have rapidly spread throughout central and southern California and because of their potential for substantial injury and damage to humans, crops, and livestock, several southern California counties (Riverside, Orange, Los Angeles, and San Diego) have established quarantines to confine further spreading (Jetter et al., 2002).

Ticks, Liver Flukes, and Conenose Bugs

Ticks are small insect-like creatures most often found in naturally vegetated areas. They feed by attaching to animals and humans, sticking their mouthparts into the skin, and sucking blood for up to several days. Ticks can be vectors for disease, particularly Lyme disease. Ticks have four life cycle stages: egg, larva, nymph, and adult. Only the nymph and adult ticks can transmit the bacteria that eventually cause Lyme and other diseases (Lane, 2008).

There are 47 species of ticks in California, but only six species are known to commonly bite humans (Lane, 2008). Although the western black-legged tick (*Ixodes pacificus*) is the only species that carries the bacteria which cause Lyme disease, other diseases can be transmitted by the other human-biting ticks. For example, Rocky Mountain spotted fever can be transmitted by the American dog tick (*Dermacentor variabilis)* and the Rocky Mountain wood tick (*Dermacentor andersoni).* Bacteria causing Colorado tick fever and Tularemia can be transmitted by the Pacific Coast tick (*Dermacentor occidentalis*) (Lane, 1990).

[2] The Africanized honey bee is a cross-breed of the African honey bee and the European honey bee.

[a]These counties are located in both the Secondary and Extended study areas.
[b]These two counties are located in all three study areas (Primary, Secondary, and Extended).
Source: MVCAC, 2003.

Liver flukes and conenose bugs exist throughout the Extended Study Area. Liver flukes infect mammals (both humans and animals) when the human/animal drinks contaminated water or ingests raw watercress or other aquatic plants that are contaminated with immature parasite larvae. The immature larval flukes migrate through the intestinal wall, the abdominal cavity, and the liver tissue into the bile ducts where they develop into mature adult flukes. The adult flukes lay eggs, which are passed out in the infected human/animal feces. The eggs hatch in fresh water and infect a snail host by penetrating its shell. The eggs develop within the snail and attach to aquatic plants, and the cycle continues (CDC, 2010).

Conenose bugs are also known as kissing bugs. They are a bloodsucking parasite of a wide variety of domestic and wild animals and humans. In California, these bugs are most prevalent in the foothill areas surrounding the Central Valley and in the foothills and desert areas of southern California. The only important species in California is the western bloodsucking conenose (*Triatoma protracta*). It lives in the nests of wood rats, but also flies into homes. The bites are not painful, but can produce an allergic reaction. Typically, bites occur at night while victims are sleeping (Greenberg and Klotz, 2002).

Rodents and Flies

Other vectors transmitting disease in the Extended Study Area include rodents and flies. Hantavirus Cardiopulmonary Syndrome Disease (HCSD) is a potentially fatal disease caused by the Sin Nombre virus, which can be carried by wild rodents. In California, only wild deer mice (*Peromyscus* spp.) carry the Sin Nombre virus. Because these deer mice are present throughout California, the California Department of Public Health routinely tests rodents for the presence of the virus. During 2011, although the virus was present in eight percent of the rodents tested (primarily in San Diego County), no cases of HCSD were reported (CDPH, 2012).

Plague is a bacterial disease caused by the bacterium *Yersinia pestis* and is transmitted by wild rodents. Humans can contract the disease if bitten by the fleas of an infected rodent, or through direct contact with a sick rodent. In California, the most common carriers of plague are ground squirrels, chipmunks, woodrats, and mice. The California Department of Public Health routinely tests rodents for the presence of antibodies to *Yersinia pestis*. During 2012, seven ground squirrels and 28 chipmunks tested positive for the antibodies. No human cases of plague were reported (CDPH, 2013).

Nuisance flies are insects that are annoying or can spread disease. All nuisance flies are of the Order Diptera and are found throughout California. Common nuisance flies include midges, house, deer, and horse flies. Flies become a problem when they congregate on dead animals, feces, or garbage, and then transfer pathogens to humans and animals (CDPH, 2010).

Rattlesnakes

The rattlesnake is California's only native venomous snake. California rattlesnake species include the western rattlesnake (*Crotalus oreganus*) found throughout California (with the exception of the desert), and the following species found in southern California: western diamondback (*Crotalus atrox*), sidewinder (*Crotalus cerastes*), speckled rattlesnake (*Crotalus mitchellii*), red diamond rattlesnake (*Crotalus ruber*), Mojave rattlesnake (*Crotalus scutulatus*), and the Panamint rattlesnake (*Crotalus stephensi*) (CDFG, 2012). In California, rattlesnakes are found from sea level to the inland prairies and desert areas and to the mountains at elevations of more than 10,000 feet (CDFW, 2013).

Most rattlesnakes forage for prey in or near brushy or tall grass areas, rock outcrops, rodent burrows, around and under surface objects, and sometimes in the open. Adults eat live prey, primarily rodents; the young take mostly lizards and young rodents (Salmon, et al., 2004). Rattlesnakes are generally not aggressive, but will strike when threatened or deliberately provoked. Most snake bites occur on the hands, ankles, or feet when a rattlesnake is handled or accidentally touched by someone walking or climbing. Rattlesnakes cause serious injury to humans on rare occasions. In the United States, out of the approximately 800 rattlesnake bites reported annually, one to two are fatal. Most bites occur between the months of April and October (CDFW, 2013).

Poison Oak

Poison oak (Toxicodendron diversilobum), which can take the form of a shrub or climbing vine, is widespread in California and grows in a variety habitats. Direct contact with the oil from poison oak leaves or stems can cause an allergic skin reaction (dermatitis) in humans that typically lasts for 10 days. An allergic reaction can also occur through indirect contact with the plant, such as by touching contaminated clothing or pets. Poison oak is considered to be the most hazardous plant in California due to the number of working hours lost as a result of the dermatitis it causes (DiTomaso and Lanini, 2009).

Giardia and Swimmer's Itch

The vectors that transmit Giardia and Swimmer's Itch occur throughout the Extended Study Area. Giardia (also known as beaver fever, backpacker disease, and Giardiasis) is caused by the microscopic parasite *Giardia lamblia* and is considered to be one of the most common sources of waterborne illness. The parasite lives in the intestines of warm-blooded animals and is transmitted from host to host when it is ingested. The parasite attaches itself to the host's intestine and causes gastrointestinal symptoms that can last from two weeks to two months. *Giardia* is typically passed to humans when they drink surface water that is contaminated by grazing cattle or game animals (Hairston, No Date).

Swimmer's itch (also called cercarial dermatitis) is a rash that is caused by an allergic reaction to certain parasites (cercaria[3]) that infect some birds and mammals. The parasites are released from infected snails into fresh and salt water (including lakes, ponds, and oceans). If the parasite comes into contact with a swimmer, it burrows into the skin, causing an allergic reaction and rash. Swimmer's itch occurs more frequently during the summer months (CDC, 2012).

Appendix 28B describes vectors found within California and nuisance problems associated with them.

28.2.2 Secondary Study Area

28.2.2.1 Hazardous Materials

The Secondary Study Area also covers a large and diverse geographical area, and the causes of concern are similar to that described for the Extended Study Area. In addition, the hazardous material contamination issues noted in the Extended Study Area also relate to the Secondary Study Area and are discussed in detail below.

Dredging, Mining, and Mercury

Mercury contamination from the inorganic mercury used in historic gold mines represents a potential risk to human health and the environment. Inorganic mercury is converted by microorganisms in soil and sediments (in air or water) to organic methylmercury, which is a neurotoxin that attacks the central nervous system and causes numerous developmental and other problems. Methylmercury then bioaccumulates[4] in

[3] The free-swimming parasitic larva of a trematode worm.

[4] The gradual build-up of toxins in an organism at levels higher than those that occur in the surrounding environment.

the food chain. High levels of methylmercury contamination in fish, amphibians, and invertebrates downstream of the hydraulic mines are a consequence of historic mercury use (USGS, 2000).

Mercury was a key element in the California Gold Rush because of its role in separating precious metals, such as gold and silver, from contaminants. The extensive panning activity along California's streams soon exhausted the readily available gold and led to the development of hydraulic mining. Hard rock mining and dredging was also initiated during this period. A significant step in all of these procedures involved the use of large quantities of mercury (UCD, 2010).

To enhance gold recovery from hydraulic mining, hundreds of pounds of liquid mercury were added to riffles and troughs in a typical sluice. The high density of mercury allowed gold and gold-mercury amalgam to sink while sand and gravel passed over the mercury and through the sluice. Large volumes of turbulent water flowing through the sluice caused many of the finer gold and mercury particles to wash through and out of the sluice before they could settle in the mercury-laden riffles. A modification known as an undercurrent reduced this loss. The finer grained particles were diverted to the undercurrent, where gold was amalgamated on mercury-lined copper plates. Most of the mercury remained on the copper plates; however, some was lost to the flowing slurry and was transported to downstream environments (USGS, 2000).

Loss of mercury in the mining process resulted in highly contaminated sediments at mine sites. Elevated mercury concentrations in present-day mine waters and sediments indicate that hundreds to thousands of pounds of mercury remain at each of the many sites affected by hydraulic mining (USGS, 2000).

Hydraulic mines were operated on a large scale from the 1850s to the 1880s in the northern Sierra Nevada region. In 1884, the Sawyer Decision prohibited discharge of mining debris in the Sierra Nevada region, but not in the Klamath-Trinity Mountains where hydraulic mining continued until the 1950s. Underground mining of placer deposits and of hard rock gold-quartz vein deposits produced most of California's gold from the mid-1880s to the early 1900s. Dredging of gold-bearing sediments in the Sierra Nevada foothills has been an important source of gold since the early 1900s (USGS, 2000).

The American, Bear, Yuba, and Feather River watersheds each have been affected by hydraulic mining. In the northwestern Sierra Nevada, the highest average levels of mercury bioaccumulation occur in the Bear River and South Yuba River watersheds (USGS, 2000).

Acid mine drainage is also an issue within the Secondary Study Area. In particular, the Iron Mountain Mine Superfund site in Shasta County continues to cause environmental concern. The Iron Mountain Mine operated within the Spring Creek watershed from the 1860s to the 1960s. The mine extracted iron, silver, gold, copper, zinc, and pyrite. This historic mining activity at the mine fractured the mountain, exposing minerals in the mountain to surface water, rain water, and oxygen. When pyrite is exposed to moisture and oxygen, sulfuric acid forms. The sulfuric acid flows through the mountain and leaches out copper, cadmium, zinc, and other heavy metals. Much of this acidic mine drainage ultimately is channeled into the Spring Creek Reservoir by creeks surrounding the mine. Reclamation periodically releases the stored acid mine drainage into Keswick Reservoir. Planned releases are timed to coincide with the presence of diluting releases of water from Shasta Dam. On occasion, uncontrolled spills and excessive waste releases have occurred when Spring Creek Reservoir reached capacity. Without sufficient dilution, this results in the release of harmful quantities of heavy metals into the Sacramento River. Since 1940, high levels of contamination in the Sacramento River have caused numerous fish kills. The low pH level and the heavy metal contamination from the mine have caused the virtual elimination of aquatic life in sections of Slickrock Creek, Boulder Creek, and Spring Creek. The continuous release of metals from the mine has contributed to a steady decline in the fisheries population in the Sacramento River (USEPA, 2011).

Quarrying

Quarrying can substantially modify the routing of groundwater recharge, causing water quality degradation. Commonly, the first impact of quarrying is to remove the overlying vegetation and soil. In temperate areas, removing vegetation and soil reduces evapotranspiration and increases the effective rainfall. Unless measures are taken to control runoff and sedimentation, deterioration of groundwater is likely (USGS, 2001).

Engineering activities associated with quarrying can directly change the course of surface water. Sinkholes created by quarrying can intercept surface water flow. Groundwater pumping from quarries changes gaining streams (volume is contributed to by groundwater) to losing streams (volume decreases as it flows downstream), and can drain other nearby surface water features such as ponds and wetlands. Similarly, blasting can modify groundwater flow, which ultimately can modify surface water flow. Discharging quarry water into nearby streams can increase flood recurrence intervals (USGS, 2001).

The risk of groundwater pollution may increase if the direction of groundwater flow is modified. New source areas of recharge may be introduced, and those sources may contain contaminated water. This situation can arise because of groundwater pumping, or can occur if old choked passages are flushed and become operational again (USGS, 2001).

Railroads

Although rail transport is generally considered a safe form of shipment, there are various possibilities for accidents and breakdowns to occur. Trains are heavy, unable to deviate from the track, and require a great distance to stop. Accidents include derailments, head-on collisions with other trains, collisions with road vehicles, and hazardous material spills into waterways. Any train derailment that results in a release or threatened release of contaminants is considered a major hazardous material spill (NTSB, 2010).

Some historic railroad operations involved the use of chemicals that may have resulted in contamination. The most commonly reported contamination along rail lines includes metals, pesticides[5] (such as lead arsenate), and constituents of oil or fuel (petroleum products). These chemicals have been associated with normal railroad operations and are likely to be found anywhere along the line. An example is arsenic (up to ten times natural background levels) may be present in the soil along a right-of-way from old railroad ties dipped in an arsenic solution, arsenic weed-control sprays, and arsenic-laced slag used as railroad bed fill. Lubricating oil and diesel that dripped from the trains are likely sources of the petroleum product found along the lines. Other sources of contaminants associated with historic railroad operation may include coal ash from engines, creosote from ties, and polynuclear aromatic hydrocarbons (“PAHs”) from the diesel exhaust (CMDEP, 2011).

Agriculture

Agriculture is a major land use in the Secondary Study Area, and a wide variety of crops are grown year-round. Long-term use of agricultural chemicals, including pesticides, herbicides, fertilizers, and crop-specific additives can lead to toxic buildup of residues in the soil (DWR, 2010).

[5] The application of pesticides consistent with their labeling is excluded from the definition of a “release” under M.G.L. Chapter 21E.

Water Wells and Septic Systems

Communities in rural areas may rely on septic systems and water wells. Failure of septic systems can result in pollution of the soil and groundwater (Marin County, 2005). Abandoned, unsecured, or damaged underground water wells or piping systems can serve as a potential conduit for soil and groundwater contamination (DWR, 2010).

28.2.2.2 Wildland Fires

Similar to that described for the Extended Study Area, wildland fires within the Secondary Study Area also pose a hazard to rural and urban development, infrastructure, and natural resources. Based on a review of CAL FIRE's statewide map of fire hazard severity zones, the lands surrounding the waterbodies included within the Secondary Study Area are designated with a fire hazard severity ranging from moderate to very high. The lands surrounding Trinity Lake, Trinity River, Klamath River, Whiskeytown Lake, Lewiston Lake, Spring Creek, Clear Creek, Shasta Lake, and Keswick Reservoir are designated as very high risk for wildland fire (CAL FIRE, 2007a).

The lands surrounding the Sacramento River downstream of Shasta Dam, the Sutter Bypass, and the Yolo Bypass are largely unzoned for fire hazard, with intermittent areas designated as moderate risk for wildland fire. The lands surrounding Lake Oroville are designated as very high risk, and the lands surrounding the Feather River downstream of Oroville Dam are designated as high risk near the dam, and as moderate risk for the rest of the river. The lands surrounding Folsom Lake are designated as moderate risk for wildland fire, and the American River downstream of Folsom Dam is largely unzoned for fire hazard, with intermittent areas designated as moderate risk for wildland fire (CAL FIRE, 2007a).

The lands surrounding the Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay are mostly unzoned for fire hazard, with intermittent areas designated as moderate or high risk for wildland fire (CAL FIRE, 2007a).

All of these waterbodies are surrounded intermittently by identified communities at risk from wildlfire. Numerous identified communities at risk from wildfire are located in the vicinity of Trinity Lake, Shasta Lake, and Lake Oroville (CAL FIRE, 2001).

28.2.2.3 Mosquitoes, Other Vectors, and Nuisance Problems

Because much of the Secondary Study Area is included within the Extended Study Area, the mosquito, other vectors, and nuisance problem concerns for the Extended Study Area are also applicable to the Secondary Study Area. The mosquito species that are found within the counties that comprise the Secondary Study Area are listed in Table 28-2.

Table 28-2
Distribution of Mosquitoes in Counties that Comprise the Secondary Study Area

	Mosquito Species																													
	Aedes		Ochlerotatus										Anopheles					Culex									Culiseta			Others

Note:
See Table 28-1 for 14 additional counties that are located within the Secondary Study Area.
Source: MVCAC, 2003.

28.2.3 Primary Study Area

28.2.3.1 Hazardous Materials

Hazardous material contamination issues noted in the Extended and Secondary study areas may also apply to the Primary Study Area, depending upon proximity. There are no designated Superfund or Brownfields sites located within the Primary Study Area. Hazardous material contamination issues specific to the Primary Study area are discussed below.

Environmental Contamination Assessment Methodology

Assessing environmental contamination within a property can be accomplished through the Phase I Environmental Site Assessment process. Phase I Environmental Site Assessments are performed in conformance with the scope and limitations of the American Society for Testing and Materials (ASTM) E1527-05 standard practice and the requirements set forth in Title 40, Part 312 of the Code of Federal Regulations (CFR).

The purpose of a Phase I Environmental Site Assessment, as specified by ASTM E1527-05 standard practice is to identify “recognized environmental conditions”. This standard defines the term “recognized environmental conditions” as:

> “…the presence or likely presence of any hazardous substances or petroleum products on a property under conditions that indicate an existing release, a past release, or material threat of a release of any hazardous substances or petroleum products into structures on the property or into the ground, groundwater, or surface water of the property. The term includes hazardous substances or petroleum products even under conditions in compliance with laws…The term is not intended to include de minimis conditions that generally do not present a material risk of harm to public health or the environment and that generally would not be the subject of an enforcement action if brought to the attention of appropriate government agencies” (ASTM, 2005).

The Phase I Environmental Site Assessment process includes information obtained from the following activities: a site reconnaissance, historical review of land use, review of land title records, consultation with local environmental health officials, contact with the land owners, review of available maps and records, and review of federal and State environmental databases (ASTM, 2005).

A review of federal and State databases can be accomplished through an environmental database search. BBL Environmental Information was contracted to conduct a database search for the Primary Study Area. The resulting report identified reported sources of hazardous materials contamination existing within the footprints of Project features.

Only the database portion of the Phase I process was conducted for this DEIR/EIS. A full Phase I Environmental Site Assessment would be conducted prior to property acquisition and would be presumed to be valid for 180 days. After that period, it should not be used without a current investigation of conditions likely to affect recognized environmental conditions on the property, which may have changed materially since the assessment was first conducted (ASTM, 2005).

Database Search Methodology

A record search determines if any reported sources of hazardous materials contamination exists within an approximate minimum search distance (ASTM, 2005). An extensive list of federal, State, and local regulatory agencies' published databases was reviewed; a complete listing of the records is included in Appendix 28C.

A standard ASTM record search uses a one-mile radial search from the center of a property, but because of the large size and irregular shape of the Primary Study Area, modified search patterns were performed.

To ensure complete coverage of the locations of all of the proposed Primary Study Area Project facilities, the record search was divided into two separate reports: the Sites Reservoir Environmental Record Search Report and the Funks Reservoir/Delevan Pipeline Environmental Record Search Report[6] (Appendix 28C). All Primary Study Area Project facilities were included in the database record searches, with the exception of the GCID Canal Facilities Modifications.

Database Search Results

The sites identified in the record search reports as having known environmental concerns are discussed below and identified by their respective Environmental Record Search Report map ID number. All other sites with operating permits are included only in the full record search reports (Appendix 28C).

Sites Reservoir and Related Project Facilities

Sixteen records were identified in the Sites Reservoir Report (Appendix 28C), representing 15 separate sites. Ten sites have operating permits. The remaining five sites have environmental concerns and are mentioned below.

Four sites were identified from the Mineral Industry Location System (MILS), a database maintained by the U.S. Bureau of Mines. The MILS covers over 200,000 mineral occurrences, deposits, mines, and processing plants in the U.S. The information is used to support government agencies that have land use planning responsibilities. These agencies look to the Bureau of Mines both for mineral resource assessments and for help identifying and remediating inactive and abandoned mine hazards.

- Map ID 2: An unnamed location and operation, but identified chromium as a commodity. The closest Project facility is the proposed South Bridge west approach road on the west side of the proposed Sites Reservoir. The site is located outside of the proposed Project Buffer.
- Map ID 4: Sandstone Company Quarry, a surface operation producing sand and gravel. The closest Project facility is the proposed Com Road on the eastern border of the proposed Sites Reservoir. The site is located outside of the road right-of-way.
- Map ID 6: McGilvray Quarry, a surface operation producing sand and gravel that is closed. The quarry is located on the eastern border of the proposed Sites Reservoir, between Maxwell Sites Road, the proposed Sulphur Gap Road, and the proposed Com Road. The site is located outside of the road right-of-way.
- Map ID 7: Talbot, an underground operation producing stone. The closest Project facility is the proposed Saddle Dam 6 on the northern border of the proposed Sites Reservoir. This site is located within the proposed Project Buffer.

[6] Some overlap may occur between the two reports.

One site was identified from the Emergency Response Notification System (ERNS), a national computer database used to store information on unauthorized releases of oil and hazardous substances. There were two incidences where unauthorized releases of oil and hazardous substances occurred at this site.

- Map ID 8: Delevan Compressor Station, located at 5001 Delevan Road in Maxwell, California. On June 24, 2007, 250 gallons of turbine oil were released from a gas turbine onto a concrete structure because of equipment failure. On May 2, 2005, 220 gallons of turbine oil were released into a secondary containment area because of a broken hydraulic pipe. Cleanup was completed. The western end of the proposed Delevan Pipeline and the Terminal Regulating Reservoir (TRR) facilities are located in proximity to this identified site.

Funks Reservoir and Related Project Facilities

Fifty records were identified in the Funks Reservoir and Delevan Pipeline Report (Appendix 28C), representing 46 separate sites. Thirty-six sites are identified as having operating permits. The remaining 10 sites have known environmental concerns, but only three are located within the search boundaries. These three sites are discussed below and identified by their Environmental Record Search Report map ID number.

The following sites were identified from MILS and ERNS, respectively:

- Map ID 2: Compton Landing, an unnamed operation in Colusa, California, lists its commodity as natural gas. The closest Project facilities are the proposed Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility at the eastern end of the proposed Delevan Pipeline.
- Map ID 21: An unnamed site at McDermott and Delevan roads in Delevan, California. A spill of 20 percent aqua ammonia (unknown quantity) occurred into an irrigation canal from an overturned truck. The spill date is unknown. The closest Project facilities are the western portion of the proposed Delevan Pipeline and the TRR facilities.

The site mentioned below was listed in the Toxic Releases database. The California RWQCBs or local Department of Health Services tracks toxic releases to the environment. These lists are known as Unauthorized Releases, Spills, Leaks, Investigations, and Cleanups (SLIC), Non-Tank Releases, Toxics List or similar, depending on the local agency.

- Map ID 16: JR Simplot Soil Builders, located on old Highway 99 at Lenahan Road in Maxwell, California. No additional information regarding type of incident was available. Status is inactive. The nearest Project facility is the proposed Delevan Pipeline.

Numerous permitted Underground Storage Tanks (USTs) were identified in the two record search reports. Three USTs were found within the footprint of the proposed Sites Reservoir. Not all UST locations are known. In addition, there is the possibility of unidentified USTs because of the remote location and history of agricultural activity in the area.

The town of Sites is located within the proposed footprint of Sites Reservoir. Existing residences, outbuildings, and roads are associated with the town. No site reconnaissance was conducted for this analysis to assess the potential hazardous material concerns related to these structures; therefore, further investigation is recommended prior to property acquisition. Hazardous material concerns within the Primary Study Area that were not identified through the BBL record search include septic systems, water wells, a railroad, a quarry, and agricultural activity. The potential hazards associated with these issues are discussed in Section 28.2.2.1.

Hazardous material concerns within the Primary Study Area not documented in the BBL reports include historic salt mining and oil wells. Salt mining occurred in the Antelope Valley beginning in the 1860s and continued until 1900. In addition, oil was discovered in the spring of 1865 in Colusa County. Several test wells were drilled in the area, but did not prove profitable.

Arsenic is also a hazardous material concern not identified in the BBL reports. High arsenic levels have been found in areas located within the Primary Study Area. Salt Lake, which is located within the northeastern portion of the Sites Reservoir footprint (inundation area), has high arsenic levels. Funks Creek and Stone Corral Creek have levels of arsenic that exceed the California Public Health Goal, but meet the USEPA arsenic rule. Water samples from the T-C Canal and GCID Canal intakes, the Colusa Basin Drain, and from the Sacramento River near Moulton Weir exceed the human toxicity criteria for arsenic.

28.2.3.2 Wildland Fires

Wildland fires within the Primary Study Area pose a hazard to rural development, infrastructure, and natural resources. The lands surrounding the proposed TRR Pipeline, TRR and associated facilities, Delevan Pipeline Electrical Switchyard, Delevan Pipeline, and Delevan Pipeline Intake/Discharge facilities, which are intensively managed agricultural lands, are unzoned for fire hazard. The lands surrounding the locations of the proposed GCID Canal Facilities Modifications are also unzoned for fire hazard. The remaining proposed Project facilities within the Primary Study Area are surrounded by lands designated as moderate risk for wildland fire (CAL FIRE, 2007b).

The identified community at risk for wildfire that is located closest to the defined Primary Study Area is the town of Lodoga (CAL FIRE, 2001).

28.2.3.3 Mosquitoes and Other Vectors

Mosquitoes

Mosquito species found in Glenn and Colusa counties are listed in Table 28-3.

Table 28-3
Distribution of Mosquitoes in Counties that Comprise the Primary Study Area

	Mosquito Species																		
	Aedes	Ochlerotatus						Anopheles			Culex							Culiseta	
County	vexans	dorsalis	Increpitus	melanimon	nigromaculis	sierrensis	sticticus	franciscanus	freeborni	punctipennis	apicalis	boharti	erythrothorax	pipiens/quinque	stigmatosoma	tarsalis	thriambus	incidens	inornata
Colusa	x	x	x	x	x	x	x	x	x	x			x	x	x	x		x	x
Glenn	x			x	x	x		x	x		x	x	x	x	x	x	x	x	x

Source: MVCAC, 2003.

Appendix 28B describes these mosquito species, their season of activity, preferred host, and habitat, as well as several mosquito-borne diseases.

Other Vectors and Nuisance Problems

Stinging Insects, Ticks, Liver Flukes, Conenose Bugs, Rodents, Rattlesnakes, Flies, Poison Oak, Giardia, and Swimmer's Itch

The western yellowjacket and the German yellowjacket, as well as the European honeybee, inhabit Glenn and Colusa counties. Stinging ants are also a concern in Glenn and Colusa counties, particularly the red imported fire ant.

The Pacific Coast tick, the American dog tick, and the western black-legged tick inhabit Glenn and Colusa counties (Cavier Jr., 2004; Kiely, 2004). Ticks were incidentally observed during Project field surveys.

As indicated previously, in California, only wild deer mice carry the Sin Nombre virus. Deer mice are present in Glenn and Colusa counties, but of the rodents tested in the fall and winter of 2011, there were no cases of the Sin Nombre virus antibodies present (CDPH, 2012). Deer mice were captured during Project field surveys in annual grassland, oak woodland, riparian, and chaparral habitat.

The California ground squirrel, which as indicated previously can carry plague, was observed during Project field surveys throughout the Primary Study Area in annual grassland and oak woodland habitat.

Western rattlesnakes were also frequently observed during Project field surveys in annual grassland and oak woodland habitats.

All nuisance flies are found throughout California. The olive fruit fly is common in areas where olive trees are abundant, such as in the orchards in Glenn and Colusa counties. Although these flies are not known to transmit disease, they can damage the olive fruit and make it unusable for commercial olive oil and olive production (CDPH, 2010).

Poison oak was observed in the Primary Study area during Project field surveys, typically associated with oak woodland and riparian habitat.

Giardia occurs within Glenn and Colusa counties. During Project field surveys, a beaver dam was observed along Funks Creek immediately downstream of the existing Funks Reservoir. Liver flukes, conenose bugs, and the parasites that cause Swimmer's Itch also occur within Glenn and Colusa counties. Appendix 28B describes these vectors and the nuisance problems associated with them.

28.3 Environmental Impacts/Environmental Consequences

28.3.1 Regulatory Setting

Hazardous materials and other environmental hazards are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this DEIR/EIS.

28.3.1.1 Federal Plans, Policies, and Regulations

- Clean Water Act
- Comprehensive Environmental Response, Compensation, and Liability Act of 1980, as Amended
- Federal Insecticide, Fungicide, and Rodenticide Act of 1996
- Safe Drinking Water Act (Underground Injection Control) of 1974, as Amended
- Hazardous Materials Transportation Act of 1975
- Resource Conservation and Recovery Act of 1976, as Amended

- Toxic Substances Control Act of 1976

28.3.1.2 State Plans, Policies, and Regulations

- California Safe Drinking Water Act
- California Hazardous Substances Account Act of 1999
- California Land Reuse and Revitalization Act of 2004
- California Underground Storage Tank Program
- Aboveground Petroleum Storage Act of 2007
- Toxic Injection Well Control Act of 1985
- Safe Drinking Water and Toxics Enforcement Act
- California Hazardous Waste Control Act
- California Integrated Waste Management Board Solid Waste Program
- Hazardous Materials Release Response Plans and Inventory
- State Board Resolution Number 92-49, Policies and Procedures for Investigation and Cleanup and Abatement of Discharges
- Mosquito Abatement Act of 1915
- California Health and Safety Code: Division 3, Chapter 1, Article 4, Sections 2040, 2041, 2060-2065 (Mosquito and Vector Control District Law)
- California Government Code: Title 3, Division 2, Part 2, Chapter 8, Article 3, Section 25842.5
- California Mosquito-Borne Virus Surveillance and Response Plan

28.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

28.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for hazards and hazardous materials:

Would the Project:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 0.25 mile of an existing or proposed school?

- Be located on a site, which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5, and as a result, would it create a significant hazard to the public or the environment?
- Result in a safety hazard for people residing or working in the Project area (for a project located within an airport land use plan, or where such a plan has not been adopted, within two miles of a public airport or public use airport)?
- Result in a safety hazard for people residing or working in the Project area (for a project within the vicinity of a private airstrip)?
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?
- Expose people or structures to a significant risk of loss, injury, or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Create a significant public or environmental hazard from the routine transport, use, or disposal of hazardous materials.
- Create a significant public or environment hazard from the release of hazardous materials into the environment.
- Effects from hazardous emissions or hazardous materials, substances, or waste within 0.25 mile of an existing or proposed school.
- Create a significant hazard to the public or the environment from the Project being located on a listed hazardous materials site.
- Effects on adopted emergency response plan or emergency evacuation plan implementation.
- Expose people or structures to a significant risk of loss, injury, or death from wildland fires.
- Create a safety hazard for people residing or working in the Project area (if located within an airport land use plan, or within two miles of a public airport or public use airport if no plan has been adopted).
- Create a safety hazard for people residing or working in the Project area (if located within the vicinity of a private airstrip).

In addition to addressing the impacts listed above, this chapter also evaluates the public health hazards from mosquitoes, other vectors, and nuisance problems. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Expose people to an increased risk of mosquito-borne or other vector-borne illnesses, or increased exposure to nuisance problems.

28.3.3 Impact Assessment Assumptions and Methodology

28.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to public health and environmental hazards:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational activities would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.

28.3.3.2 Methodology

<u>Hazardous Materials and Wildland Fires</u>

Identification of existing hazardous material contamination at Project facility locations was conducted by reviewing a list of federal, State, and local regulatory agencies' published databases and comparing that information to the Project's footprint.

A review of Fire Hazard Severity Zones (CAL FIRE, 2001, 2007a, and 2007b) was conducted to determine wildland fire safety hazards.

A review of County Zoning Maps (Glenn County, 2006 and Colusa County, 2011) was conducted to determine airport zones within the Primary Study Area.

Mosquitoes, Other Vectors, and Nuisance Problems

The evaluation of potential impacts to the public's health from the possible exposure to mosquitoes or other vectors and their associated ailments, as well as to nuisance problems due to implementation of the Project, was a multi-step process and included the following:

- Determining the types of vector habitats that would be created from the Project facilities
- Determining at which Project facilities the public would have access to those vector habitats, or to habitats that support nuisance species
- Assessing whether the public's exposure to such vector or nuisance species habitats would result in a significant impact

28.3.4 Topics Eliminated from Further Analytical Consideration

Within the Extended and Secondary study areas, no Project-related activities would expose people residing or working in the vicinity of the Project facilities to an aircraft safety hazard because of the distance of existing public airports or private airstrips to the Project facilities. Therefore, potential impacts related to aircraft safety hazards (**Impact Pub Health-7** and **Impact Pub Health-8**) are not discussed further for these two study areas.

Within the Primary Study Area, a public airport is located near the proposed modifications to the GCID Canal Facilities. Potential impacts related to aircraft safety hazards (**Impact Pub Health-7**) are discussed for that Project facility only. There are no private airstrips in the vicinity of the Primary Study Area facilities. Therefore, potential impacts related to private airstrip safety hazards (**Impact Pub Health-8**) are not discussed further for this study area.

28.3.5 Impacts Associated with the No Project/No Action Alternative

28.3.5.1 Hazardous Materials and Wildland Fires

Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Pub Health-1: Create a Significant Public or Environmental Hazard from the Routine Transport, Use, or Disposal of Hazardous Materials

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts due to hazardous materials has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** related to the transport, use, or disposal of hazardous materials, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to increase the potential for hazardous materials spills/accidents as urban growth moves out into the undeveloped vegetated areas of the state. These impacts that could occur as a result of the increased population would be managed at the local level (e.g., cities and counties) in accordance with those agencies' regulations. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions

In addition, projects considered within the No Project/No Action Alternative are not located within the Primary Study Area and therefore **would not have a substantial adverse effect** related to the transport, use, or disposal of hazardous materials, when compared to Existing Conditions.

Impact Pub Health-2: Create a Significant Public or Environmental Hazard from the Release of Hazardous Materials into the Environment

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to the release of hazardous materials into the environment.

Impact Pub Health-3: Effects from Hazardous Emissions or Hazardous Materials, Substances, or Wastes within 0.25 Mile of an Existing or Proposed School

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to hazardous emissions, materials, substances, or wastes in the vicinity of a school.

Impact Pub Health-4: Create a Significant Hazard to the Public or the Environment from the Project being Located on a Listed Hazardous Materials Site

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to Projects being located on a listed hazardous materials site.

Impact Pub Health-5: Effects on Adopted Emergency Response Plan or Emergency Evacuation Plan Implementation

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to effects on emergency response or evacuation plan implementation.

Impact Pub Health-6: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Wildland Fires

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to wildland fire risk.

28.3.5.2 Mosquitoes, Other Vectors, and Nuisance Problems

Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts from mosquitoes, other vectors, and nuisance problems has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** from mosquito or vector populations, habitat, and the spread of mosquito- or vector-borne illnesses, or an exposure to nuisance problems, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population and its associated additional residential, commercial, and industrial development could be expected to cause more standing water and other conditions considered favorable to mosquitoes and other vectors, and could create habitat that supports nuisance species.

There are currently many areas within the Extended, Secondary, and Primary study areas where favorable conditions exist for mosquitoes and other vectors. The 1915 Mosquito Abatement Act allowed for communities to form Mosquito and Vector Control Districts, and the subsequent passage of the Mosquito and Vector Control District Law provided the authority to county agencies to implement surveillance and abatement programs to control mosquito and other vector populations. Thus, many counties within the three study areas have extensive mosquito and vector control programs in place. If the No Project/No Action Alternative is implemented, **there would not be a substantial adverse effect** from mosquito or vector populations, habitat, the spread of mosquito- or vector-borne illnesses, or an exposure to nuisance problems when compared to Existing Conditions, because these mosquito and vector control programs are expected to remain in place.

It is possible, however, that private landowners within the three study areas could ignore existing control practices and create conditions (such as stagnant stock ponds) that may cause an increase in mosquito or other vector populations. This increase, in turn, may create new demands on existing mosquito and vector control program resources. In such cases, the local county agencies have the authority to leverage fines on the non-compliant landowners to recover costs of abatement programs on a case-by-case basis (CDPH, 2005). Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

In addition, projects included in the No Project/No Action Alternative are not located within the Primary Study Area and therefore **would not have a substantial adverse effect** to/from mosquitoes or vector populations, habitat, and the spread of mosquito- or vector-borne illnesses, or from increased exposure to nuisance problems, when compared to Existing Conditions.

28.3.6 Impacts Associated with Alternative A

28.3.6.1 Hazardous Materials and Wildland Fires

Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Pub Health-1: Create a Significant Public or Environmental Hazard from the Routine Transport, Use, or Disposal of Hazardous Materials

Because there would be no direct Project-related construction or maintenance occurring in the Extended Study Area, there would be no direct or indirect impacts on public health related to hazardous materials in the Extended Study Area. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Although there are no direct Project-related construction or maintenance activities that would occur in the Extended Study Area, there would be operational activities. Project operations would result in increased water fluctuations at San Luis Reservoir, increased water supply reliability to agriculture, municipal, and industrial users, and an alternate water supply for wildlife refuge use. The increased water level fluctuations at San Luis Reservoir would be within the historic range of the reservoir's fluctuations, and the wildlife refuges would receive water from the Project only as an alternate source. These changes would not be associated with or have an effect on hazardous waste transport, use, or disposal. Similarly, the expected small increase in municipal and industrial water supply reliability would not be expected to affect hazardous waste transport, use, or disposal. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

It is possible that increased agricultural water supply reliability, associated with proposed Project operations, would have the potential to change cropping patterns, such as from annual crops to orchards. This change in cropping patterns could result in differing amounts and types of pesticides used. However, modeling results show that the potential effects of increased water supply reliability would be small, and would not occur on a large enough scale that would be expected to have a substantial effect on pesticide use patterns for agriculture. These Project operations are not expected to create a hazard, resulting in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Pub Health-2: Create a Significant Public or Environmental Hazard from the Release of Hazardous Materials into the Environment

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to the release of hazardous materials into the environment.

Impact Pub Health-3: Effects from Hazardous Emissions or Hazardous Materials, Substances, or Wastes within 0.25 Mile of an Existing or Proposed School during Project Construction, Operation, or Maintenance

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to hazardous emissions, materials, substances, or wastes in the vicinity of a school.

Impact Pub Health-4: Create a Significant Hazard to the Public or the Environment from the Project being Located on a Listed Hazardous Materials Site

No Project-related construction would occur in the Extended Study Area. Consequently, no listed hazardous materials sites would be affected. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Pub Health-5: Effects on Adopted Emergency Response Plan or Emergency Evacuation Plan Implementation

There would be no direct Project-related construction or maintenance occurring in the Extended Study Area. Operation at San Luis Reservoir would be modified to accommodate the proposed Project operation, which would result in more frequent and larger surface water elevation fluctuations at the reservoir than currently occurs there. The ability of emergency responders to respond to future emergencies or evacuations is not expected to change from existing conditions as a result of those changes in operations. Increased water supply reliability to agricultural, municipal, and industrial users, as well as an alternate supply of wildlife refuge water, would have no effect on emergency response or evacuation plans. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Pub Health-6: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Wildland Fires

Operations at San Luis Reservoir would be modified with implementation of Alternative A, but would not be expected to change any existing wildland fire risk to people and structures at the reservoir. Similarly, increased water supply reliability to agricultural, municipal, and industrial users, as well as an alternate supply of wildlife refuge water, would not change existing wildland fire risk. Operational changes within the Extended Study Area would, therefore, result in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Pub Health-1: Create a Significant Public or Environmental Hazard from the Routine Transport, Use, or Disposal of Hazardous Materials

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant. The installation of the pump and its associated operation and maintenance, as well as the maintenance activities at the canal intakes, would require the use of limited quantities of hazardous materials, such as fuels, oils, grease, and lubricants. Maintenance and repair of the equipment would be completed at the facility site, or the equipment would be transported to nearby facilities.

The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the removal of sediment from the existing canal intakes. Sediment removal has the potential to accidentally release hazardous materials.

The use, storage, handling, or disposal of hazardous materials could result in hazardous releases from equipment or through other means during construction, operation, or maintenance, thereby exposing workers to hazardous materials. There could also be accidental releases of hazardous materials that would contaminate soil or degrade water quality. The potential release of hazardous materials during construction, operation, or maintenance activities would be a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation could affect the flow regime of all of the streams, or the storage conditions of all of the reservoirs, included in the Secondary Study Area. However, the primary hazardous material issue of concern in this study area is the acid mine runoff from the Iron Mountain Mine Superfund site in the Spring Creek watershed. Historical gold mining and associated mercury contamination in the environment are also hazardous material concerns in this area, as well as in the other watersheds within the Secondary Study Area. Project operational modeling indicates no change in Spring Creek Reservoir water levels or releases, or in Spring Creek dilution flows. Because no Project construction would occur in this area, no Project-related soil or sediment disturbance would occur. As a result, the existing risk of soil and sediment contamination would not change from what currently occurs, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Pub Health-2: Create a Significant Public or Environmental Hazard from the Release of Hazardous Materials into the Environment

Refer to the **Impact Pub Health-1** discussion. The discussion also applies to the release of hazardous materials into the environment.

Impact Pub Health-3: Effects from Hazardous Emissions or Hazardous Materials, Substances, or Wastes within 0.25 Mile of an Existing or Proposed School

No Project construction, operation, or maintenance activities would occur within 0.25 mile of a school site in the Secondary Study Area, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Pub Health-4: Create a Significant Hazard to the Public or the Environment from the Project being Located on a Listed Hazardous Materials Site

No Project construction, operation, or maintenance activities would occur on a site in the Secondary Study Area that is included on any list of hazardous materials sites, including the list compiled pursuant to Government Code Section 65962.5. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Pub Health-5: Effects on Adopted Emergency Response Plan or Emergency Evacuation Plan Implementation

Operational changes in the flow regime or storage conditions of the waterbodies included in the Secondary Study Area would not significantly impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan. There would, therefore, be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Installation of the pump at the Red Bluff Pumping Plant would require few vehicles and equipment, and its construction period would be short; therefore, it is not expected to significantly affect emergency response or evacuation procedures in that area. Similarly, its regular and routine maintenance activities are also expected to require few vehicles and take a short time to complete. This would result in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Pub Health-6: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Wildland Fires

Operational changes in the flow regime or storage conditions of the waterbodies included in the Secondary Study Area would not be expected to expose people or structures to wildland fires, and would, therefore, have **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Pump installation and its associated operation and maintenance at the Red Bluff Pumping Plant would not be expected to expose people or structures to risks associated with wildland fires because the pump would be installed in an existing developed plant, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Pub Health-1: Create a Significant Public or Environmental Hazard from the Routine Transport, Use, or Disposal of Hazardous Materials

Project construction activities at all Primary Study Area Project facility sites have the potential to accidentally release hazardous materials during implementation of Alternative A.

In addition, Project maintenance activities would require the use of hazardous materials, such as fuels, oils, grease, and lubricants. Maintenance and repair of the equipment would be completed at the project facility site, or the equipment would be transported to nearby facilities.

The use, storage, handling, or disposal of hazardous materials could result in hazardous releases from equipment or through other means during Project construction and/or maintenance activities, thereby exposing workers to hazardous materials. There could also be accidental releases of hazardous materials that would contaminate soil or degrade water quality. The potential release of hazardous materials during construction, operation, or maintenance activities would be a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Pub Health-2: Create a Significant Public or Environmental Hazard from the Release of Hazardous Materials into the Environment

Refer to the Impact **Pub Health-1** discussion. The discussion also applies to the release of hazardous materials into the environment.

Impact Pub Health-3: Effects from Hazardous Emissions or Hazardous Materials, Substances, or Wastes within 0.25 Mile of an Existing or Proposed School

No Project construction, operation, or maintenance activities would occur within 0.25 mile of a school site, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Pub Health-4: Create a Significant Hazard to the Public or the Environment from the Project being Located on a Listed Hazardous Materials Site

The results of the agency database review indicate that no Project construction, operation, or maintenance activities would occur on a site that is included on any list of hazardous materials sites, including the list compiled pursuant to Government Code Section 65962.5.

It is possible that not all septic tanks, water wells, underground storage tanks, or other underground storage devices or conveyance systems have been identified on the published databases. These systems are considered as potential conduits for groundwater contamination. It is also possible that not all hazardous spills within the Primary Study Area were reported.

Although there would be no impact due to Project facilities being located on a listed hazardous materials site, there is the potential for Project facilities to be located near unlisted septic tanks, water wells, other underground storage devices, or unreported hazardous spills. Therefore, there would be a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Pub Health-5: Effects on Adopted Emergency Response Plan or Emergency Evacuation Plan Implementation

Project construction equipment and materials would be transported on local roads to access the proposed Project facilities, with many over-sized Project vehicles traveling on the roads. This may result in a reduction in travel speeds on those roads throughout the Project construction period. In addition, some road closures and detours would be necessary during the Project construction period. This would result in a **potentially significant impact** on emergency and/or evacuation response if an emergency occurred in the vicinity of a Project facility during the Project construction period, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation is expected to increase traffic on local roads leading to the proposed recreation areas at the proposed Sites Reservoir. Sites Reservoir is expected to generate 360,975 Recreation Visitor Days (RVDs[7]) per year during the operation of Sites Reservoir. Therefore, the expected increased traffic on Maxwell Sites Road and County Roads 68, 69, and D during Project operation (primarily Fridays through Sundays during the recreation season[8]) would result in a **significant impact** on emergency and/or

[7] An RVD is defined as a recreation visit by one person for part or all of one day.

[8] The recreation season is typically defined as Memorial Day through Labor Day.

evacuation response at/near existing residences in the vicinity of Sites Reservoir during that time, when compared to Existing Conditions and the No Project/No Action Alternative.

Adding a recreation destination (Sites Reservoir) to the area is expected to increase the number of people in that area during the recreation season. An increase in the number of people in that area has the potential to increase the need for emergency and/or evacuation response, resulting in a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative, although it is acknowledged that Colusa and/or Glenn County may be able to request mutual aid from other jurisdictions, including nearby cities, counties, the California OES, and ultimately, the Federal Emergency Management Agency (FEMA) if a catastrophic event occurred.

In addition, operation and maintenance of all Project facilities would increase traffic on local roads to the individual Project facilities when regular and routine tasks are scheduled to be performed. However, these activities are expected to be performed by a few trained individuals with few vehicles and equipment, resulting in a **less-than-significant impact** on emergency and evacuation response in the areas near Project facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Pub Health-6: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Wildland Fires

The vegetation within the Primary Study Area creates an existing risk of fire hazard from natural hazards, such as lightning strikes, or from human activities that occur there. Project construction, operation, and maintenance activities within the Primary Study Area would increase the potential exposure of people, structures, infrastructure, and other resources to a significant risk of loss, injury, or death from fire.

Most of the proposed Project facilities would be constructed in rural undeveloped areas that have trees, grasses, and shrubs. Project construction activities would likely occur during the summer and fall months, which are generally considered a time of high fire hazard in northern California.

Construction workers traveling to the Project facility sites and construction materials being transported to the construction sites would increase the risk of fire hazard along their travel route. Operation of vehicles throughout the area, particularly when vegetation adjacent to roads is dry, can increase the fire potential from accidental combustion (e.g., sparks), hot metal (e.g., tail pipes, motors), or traffic accidents.

Project construction activities at individual Project facility locations would increase the risk of fire hazard at those locations due to the presence of construction and worker vehicles and equipment (i.e., combustion engines), the presence of fuels, lubricants, and other flammable substances at the Project facility sites, and the presence of construction workers at the Project sites, if they smoke when there.

Vegetation clearing that would be required as part of Project construction, both at Project facility sites and within Project disturbance areas, would reduce the overall fuel loading in those areas, thereby reducing the long-term fire hazard. In addition, filling Sites Reservoir, TRR, and Holthouse Reservoir with water would reduce the long-term fire hazard at those locations. However, the presence of the construction vehicles and equipment operating in those areas when the facilities are being constructed would increase the fire hazard risk at the facility sites. Project implementation could also result in additional water supplies being available in the Primary Study Area, which could assist in future firefighting responses.

Operation and maintenance activities at Project facilities would occur on a regular basis, and would require the use of vehicles and equipment (also combustion engines) that would increase the risk of fire hazard at those locations when those activities are being performed.

Visitors to the proposed recreation areas at the proposed Sites Reservoir would also increase the risk of fire hazard in those areas. Potential fire sources include campsites, campfires, vehicles, and watercraft.

Therefore, the existing fire hazard risk would be increased during Project construction, operation, and maintenance periods, resulting in a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Pub Health-7: Create a Safety Hazard for People Residing or Working in the Project Area (if Located within an Airport Land Use Plan or within Two Miles of a Public Airport or Public Use Airport if no Plan has been Adopted)

A review of County Zoning Maps (Glenn County, 2006 and Colusa County, 2011) indicated that Project facilities would not be located within designated airport zones. The closest airport to a Project facility is the Willow-Glenn County Airport, located approximately 0.9 mile west of the GCID Canal Railroad Siphon. No Project construction, operation, or maintenance activities would occur within or near a public airport; therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

28.3.6.2 Mosquitoes, Other Vectors, and Nuisance Problems

Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use and Municipal and Industrial Water Use

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

Alternative A does not include any construction or subsequent maintenance of Project-related facilities within the Extended Study Area, so there would be **no impact** from increased exposure to nuisance problems, or to/from existing mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses within the Extended Study Area from those activities, when compared to Existing Conditions and the No Project/No Action Alternative.

The operation of Alternative A would result in increased water supply reliability to agricultural, municipal, and industrial uses. However, Alternative A would result in approximately 19,000 fewer acres in agricultural land use, when compared to Existing Conditions, and 2,000 more acres in agricultural land use, when compared to the No Project/No Action Alternative (refer to Chapter 22 Socioeconomics Table 22-27). These changes in agricultural acreage are expected to result in little to no change in exposure to nuisance problems, or in mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses within the Extended Study Area, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Wildlife Refuge Water Use

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

Operational modeling indicates that the amount of Level 4 wildlife refuge water supply would be the same every year with or without the Project. Project operations would provide an alternate source of Level 4 wildlife refuge water in some years, but would not increase its reliability. Therefore, the provision of an alternate source of Level 4 wildlife refuge water supply would have **no impact** on exposure to nuisance problems, or to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses, when compared to Existing Conditions and the No Project/No Action Alternative.

San Luis Reservoir

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

San Luis Reservoir currently experiences severe water level fluctuations. Operational modeling for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates that operation of the Project would cause San Luis Reservoir water levels to continue to fluctuate, but the fluctuations could be more severe. Water fluctuations within the reservoir can create an environment conducive to mosquito habitat and subsequent mosquito population growth. The Merced County Mosquito Abatement District has established existing mosquito abatement controls for the county. In addition, land uses surrounding the reservoir, including adjacent Pacheco State Park, have an established ecosystem which supports mosquito predators, such as frogs, bats, and birds. In addition to mosquito abatement, other vector controls are in place due to the public recreational use of Pacheco State Park and San Luis Reservoir. Water fluctuations at the reservoir would not be expected to increase exposure to nuisance species. Therefore, the impact resulting from Project operation at this reservoir in the Extended Study Area is considered **less than significant,** when compared to Existing Conditions and the No Project/No Action Alternative.

Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

Installation of an additional pump into an empty bay within the existing Red Bluff Pumping Plant (a developed site) would not affect exposure to nuisance problems or mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses at that location, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of the pump and maintenance of the canal's intakes would occur as part of the operation and maintenance routine that occurs at those facilities, resulting in no change in exposure to nuisance problems, and no change to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses from what currently occurs. Therefore, **no impact** would occur as a result of the operation and maintenance of the additional pump, when compared to Existing Conditions and the No Project/No Action Alternative.

No direct Project-related construction or maintenance activity would occur within the Secondary Study Area at the other locations listed above. Therefore, there would be no change in exposure to nuisance problems, and no change to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses at the locations listed above from Project-related construction or maintenance activities, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation could affect the flow regime of all of the above-listed streams and/or the storage conditions of all of the above-listed reservoirs that are located in the Secondary Study Area. River flows and reservoir water level fluctuations resulting from Alternative A are expected to be within the historic range of operations, resulting in no change in exposure to nuisance problems, and no change to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

All Primary Study Area Project Facilities

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

Construction sites are generally flat and have the potential to create ponding areas after a rainstorm. Large ponding areas that do not completely dry after three to five days are conducive to mosquito breeding and can contribute to mosquito population growth. In addition, to satisfy NPDES stormwater permit requirements, some construction contractors create drainage ditches and subsequent retention ponds at Project construction sites to prevent stormwater runoff from entering nearby waterbodies. These ponds also have the potential for becoming mosquito breeding grounds, resulting in a **potentially significant impact** at all Project facility construction sites, when compared to Existing Conditions and the No Project/No Action Alternative.

The construction and filling of the three proposed reservoirs (Sites, Holthouse, and the TRR), plus the forebay and afterbay that would be constructed at the Delevan Pipeline Intake Facilities, would create an increase in total surface water area and reservoir shoreline. Increased surface water area would create habitat suitable for mosquito egg deposition. Increased shoreline also would result in favorable mosquito habitat for floodwater mosquitoes, particularly if water levels are expected to fluctuate greatly, as is the case with the Project facilities. Impacts to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses at the new reservoirs would result in a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Although surface water fluctuations occur at the existing Funks Reservoir, operation of the proposed expanded reservoir (i.e., Holthouse Reservoir) would result in more varied surface water fluctuations. These fluctuations in water levels can create favorable conditions for floodwater mosquito habitat increasing the potential for mosquito growth. However, there are established mosquito controls in place to abate mosquito growth at Funks Reservoir that would continue to be implemented during Project operation. Therefore, impacts to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses at Holthouse Reservoir would result in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Site Reservoir is intended for water storage as well as for recreational use. Recreational use would be facilitated by the establishment of up to five recreation areas with hiking trails, picnic areas, camping areas, a swimming area, and boat ramps. Because these recreation areas would be open to the public, mosquito abatement is a priority to decrease the risk of spreading disease. Although existing mosquito abatement controls are in use in Colusa County, the maintenance and operational activities due to the establishment of the Sites Reservoir and associated recreation areas may result in increased impacts to/from mosquito or vector populations, habitat, controls, or the spread of mosquito- or vector-borne illnesses. This would result in a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

In addition to impacts to/from mosquitoes at Sites Reservoir and the recreation areas, impacts from rodents, flies, bees, yellowjackets, and stinging ants, as well as Giardia and Swimmer's Itch may be expected. The recreation areas are proposed to include picnic areas, camping areas, swimming beaches, boat ramps, wildlife viewing vistas, and hiking trails. In many of these areas, food would be eaten, which would attract foraging bees, yellowjackets, stinging ants, flies, and rodents. Over time, these species may develop nests and reproduce within the recreation areas. Recreationists using the swimming areas could potentially be exposed to Giardia, Swimmer's Itch, or liver flukes. Impacts from rodents, flies, bees, yellowjackets, and stinging ants, as well as Giardia and Swimmer's Itch, would require controls to abate health and nuisance problems, and are considered **potentially significant,** when compared to Existing Conditions and the No Project/No Action Alternative.

The location of the proposed Sites Reservoir supports small areas of forested woodlands and large areas of grassland, which provide suitable habitat for rattlesnakes, ticks, conenose bugs and poison oak. These areas would likely be part of the trail system within the recreation areas, exposing recreationists to the potential for being bitten by rattlesnakes, being exposed to poison oak, being bitten by conenose bugs, and being bitten by ticks and potentially contracting Lyme disease or Rocky Mountain spotted fever. This increased risk would result in a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

28.3.7 Impacts Associated with Alternative B

28.3.7.1 Hazardous Materials and Wildland Fires

<u>Extended and Secondary Study Areas – Alternative B</u>

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to the transport, use, or disposal of hazardous materials (**Impact Pub Health-1**), release of hazardous materials into the environment (**Impact Pub Health-2**), hazardous emissions, materials, substances, or wastes in the vicinity of a school (**Impact Pub Health-3**), projects being located on a listed hazardous materials site (**Impact Pub Health-4**), effects on emergency response or evacuation plan implementation (**Impact Pub Health-5**), and wildland fire risk (**Impact Pub Health-6**) would be the same as described for Alternative A for the Extended and Secondary study areas.

<u>Primary Study Area – Alternative B</u>

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public and environmental hazards:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The remaining Primary Study Area Project facilities have different designs for Alternative B than for Alternative A: The Alternative B Sites Reservoir would be larger than the Alternative A reservoir and would consequently alter the size and location of the dams; the road relocations associated with Alternative B differ from those for Alternative A, mostly due to changes to the saddle dam access roads; the Alternative B design for the Delevan Transmission Line would be much shorter than the Alternative A design; the Alternative B Delevan Pipeline Discharge Facility would replace the Alternative A Delevan Pipeline Intake Facilities; and the area included in the Project Buffer would change because the size of some of the facilities surrounded by the Project Buffer would change. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on the transport, use, or disposal of hazardous materials (**Impact Pub Health-1**), release of hazardous materials into the environment (**Impact Pub Health-2**), hazardous emissions, materials, substances, or wastes in the vicinity of a school (**Impact Pub Health-3**), Projects being located on a listed hazardous materials site (**Impact Pub Health-4**), effects on emergency response or evacuation plan implementation (**Impact Pub Health-5**), wildland fire risk (**Impact Pub Health-6**), and aircraft safety hazards (**Impact Pub Health-7**) as described for Alternative A.

28.3.7.2 Mosquitoes, Other Vectors, and Nuisance Problems

<u>Extended and Secondary Study Areas – Alternative B</u>

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to increased risk of exposure to mosquito- or vector-borne illnesses or to nuisance problems (**Impact Pub Health-9**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public health from mosquitoes, other vectors, and nuisance problems:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprint or construction disturbance area of Sites Reservoir Dams, the Road Relocations and South Bridge, and the Delevan Transmission Line would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility. However, these differences in the size of the footprint or alignment of the construction disturbance area would require the same type of construction, operation, and maintenance activities as was described for Alternative A. They would, therefore, have the same impact to public health from the potential exposure to mosquito or vector populations, habitat, and the spread of mosquito- or vector-borne illnesses, and to exposure to nuisance problems (**Impact Pub Health-9**), within the Primary Study Area as described for Alternative A, with the exclusion of the potential impacts associated with the Delevan Pipeline Intake Facility forebay and afterbay that are included in Alternative A, but not Alternative B. Because Alternative B would not have a forebay and afterbay at that location, potential impacts to mosquito or vector populations, habitat, and the spread of mosquito- or vector-borne illnesses at that location would be less for Alternative B than described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact to increased risk of exposure to mosquito- or vector-borne illnesses or to nuisance problems (**Impact Pub Health-9**) as described for Alternative A.

The differences associated with the larger Alternative B Sites Reservoir and its impacts to public health from mosquitoes, other vectors, and nuisance problems are described below.

Sites Reservoir Inundation Area

Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems

The establishment of the larger capacity Sites Reservoir associated with Alternative B would create more shoreline and increased water surface area, both of which contribute to favorable habitat for mosquitoes and several vectors. These changes would require slightly more mosquito and/or vector abatement resources than for Alternative A, and the operational and maintenance impacts are considered **potentially significant** (i.e., the same as described for Alternative A), when compared to Existing Conditions and the No Project/No Action Alternative.

28.3.8 Impacts Associated with Alternative C

28.3.8.1 Hazardous Materials and Wildland Fires

Extended, Secondary, and Primary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to the transport, use, or disposal of hazardous materials (**Impact Pub Health-1**), release of hazardous materials into the environment (**Impact Pub Health-2**), hazardous emissions, materials, substances, or wastes in the vicinity of a school (**Impact Pub Health-3**), Projects being located on a listed hazardous materials site (**Impact Pub Health-4**), effects on emergency response or evacuation plan implementation (**Impact Pub Health-5**), and wildland fire risk (**Impact Pub Health-6**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public and environmental hazards:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard

- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as the Alternative A design. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public and environmental hazards as described for Alternative A.

The Alternative C design for the Sites Reservoir Inundation Area and Dams and Road Relocations and South Bridge are the same as the Alternative B design. These facilities would require the same construction, operation, and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public and environmental hazards as described for Alternative B.

The boundary of the Project Buffer is the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the construction, operation, and maintenance impacts to public and environmental hazards that were described for Alternative A.

28.3.8.2 Mosquitoes, Other Vectors, and Nuisance Problems

Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to increased risk of exposure to mosquito- or vector-borne illnesses or to nuisance problems (**Impact Pub Health-9**), would be the same as described for Alternative A for the Extended and Secondary study areas.

Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public health from mosquitoes, other vectors, and nuisance problems:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR

- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public health from mosquitoes, other vectors, and nuisance problems as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public health from mosquitoes, other vectors, and nuisance problems as described for Alternative B.

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the construction, operation, and maintenance impacts to public health from mosquitoes, other vectors, and nuisance problems that were described for Alternative A.

28.4 Mitigation Measures

28.4.1 Hazardous Materials and Wildland Fires

Mitigation measures are provided below and summarized in Table 28-4 for the impacts that have been identified as significant or potentially significant.

Table 28-4
Summary of Mitigation Measures for
NODOS Project Impacts to Public Health from Hazardous Materials and Wildland Fires

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Pub Health-1: Create a Significant Public or Environmental Hazard from the Routine Transport, Use, or Disposal of Hazardous Materials	All Project facility sites (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant
Impact Pub Health-2: Create a Significant Public or Environmental Hazard from the Release of Hazardous Materials into the Environment	All Project facility sites (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant

Table 28-4
Summary of Mitigation Measures for
NODOS Project Impacts to Public Health from Hazardous Materials and Wildland Fires

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Pub Health-4: Create a Significant Hazard to the Public or the Environment from the Project being Located on a Listed Hazardous Materials Site	All Project facility sites (construction,)	Potentially Significant	Mitigation Measure GW Qual-1b: Implement DWR and County Standards for the Proper Abandonment of Wells, Boreholes, and Septic Systems	Less than Significant
			Mitigation Measure Pub Health-4: Dispose of Hazardous Waste Discovered during Project Construction Pursuant to CERCLA Requirements	Less than Significant
Impact Pub Health-5: Effects on Adopted Emergency Response Plan or Emergency Evacuation Plan Implementation	All Project facility sites (construction, operation, and maintenance)	Potentially Significant and Significant	Mitigation Measure Trans-1: Prepare and Implement a Project Operation Traffic Control Plan	Less than Significant
			Mitigation Measure Trans-3: Prepare and Implement a Project Construction Traffic Control Plan	Less than Significant
Impact Pub Health-6: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Wildland Fires	All Project facility sites (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure Pub Health-6: Develop and Implement a Project Fire Prevention and Suppression Plan and Consult with Fire Protection Agencies	Less than Significant

Notes:
BMPs = Best Management Practices
LOS = Level of Significance

Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan

DWR and Reclamation shall prepare and implement a SWPPP that emphasizes proper hazardous materials storage and handling procedures; shall outline spill containment, cleanup, and reporting procedures; and shall limit refueling and other hazardous activities to designated upland areas. Signs prohibiting refueling shall be posted in sensitive areas. Equipment shall be inspected prior to use each day to ensure that hydraulic hoses are tight and in good condition. Other appropriate BMPs, such as use of concrete washout basins and proper waste management, combined with visual observation and water sample collection and analysis, shall be used to prevent discharge of drilling mud and other chemicals associated with construction activities and into receiving waters. Details of these BMPs are described in Section WM-4 of the Construction Site Best Management Practices Manual (Caltrans, 2003).

Mitigation Measure GW Qual-1b: Implement DWR and County Standards for the Proper Abandonment of Wells, Boreholes, and Septic Systems

According to DWR's Water Well Standards (DWR, 2012), a well that is no longer useful (including exploration and test holes) must be destroyed to assure that the existing groundwater quality and proposed Project water quality is protected and preserved for further use, and to eliminate any potential physical hazard. Destruction of a well shall consist of the complete filling of the well in accordance with the procedures described in DWR Water Well Standards Section 23. Permits for well destruction shall also be obtained from the appropriate County agency (Glenn or Colusa).

Any current or historic oil and gas wells detected within the Project facility footprints shall be addressed. Any well types that would be inundated shall be properly sealed and abandoned according to policies and procedures laid out in the California Code of Regulations Title 14 from the Department of Conservation. These wells shall be sealed to ensure that the existing groundwater quality is protected and preserved, and to eliminate any potential physical hazard. Permits for well destruction shall also be obtained from the appropriate County agency (Glenn or Colusa).

Any test holes, boreholes, other potential conduits to groundwater shall also be sealed and destroyed.

Existing septic systems, such as septic tanks, cesspools, and seepage pits, shall be identified and located. These septic systems shall then be properly abandoned and demolished, and, if necessary, removed and disposed of. Destruction of septic systems shall require:

- A licensed septic tank pumper to pump the septic tank. A copy of the receipt for this pumping shall be obtained.
- Abandonment of the tank in accordance with county ordinances, which may include methods such as:
  - Tank removed, then disposed of at a sanitary landfill
  - Tank top removed, tank crushed, then excavation filled with earthen materials to within 12 inches of native surface
  - Tank top removed, bottom perforated, then excavation filled with earthen materials to within 12 inches of native surface

Permits for abandonment and destruction shall also be obtained from the appropriate County (Glenn or Colusa) prior to work.

Mitigation Measure Pub Health-4: Dispose of Hazardous Waste Discovered during Project Construction Pursuant to CERCLA Requirements

If evidence of contaminated materials is encountered during Project construction, construction shall cease immediately and applicable requirements of the Comprehensive Environmental Release Compensation and Liability Act (CERCLA) and the CCR Title 22 regarding the disposal of waste shall be implemented.

Mitigation Measure Trans-1: Prepare and Implement a Project Operation Traffic Control Plan

DWR and Reclamation shall prepare and implement an Operation Traffic Control Plan for the Project. Consultation with Glenn and Colusa counties shall occur to determine what those agencies would require to manage the traffic congestion that is expected to occur as a result of recreationists traveling to Sites Reservoir and its Recreation Areas. It is possible that the Counties may want to wait to do any road improvements until a recreation season (or more) has passed, so that actual recreation visitation and associated traffic congestion on local roadways could be monitored.

Consultation and coordination with Caltrans shall also occur to manage traffic at onramps and offramps from I-5 that would connect to the County roads leading to Sites Reservoir and its Recreation Areas.

Consultation with local fire and sheriff departments shall occur to obtain input regarding maintaining adequate emergency response times and access to properties along the roads that comprise the routes to Sites Reservoir and its Recreation Areas.

The Operation Traffic Control Plan may include, but not be limited to, ideas such as:

- Widening the existing County roads that comprise the primary route to Sites Reservoir and its Recreation Areas, and maintaining such roads
- Signalizing or signage at intersections along the primary route to Sites Reservoir and its Recreation Areas
- Developing alternate routes to Sites Reservoir that would intersect at Maxwell Sites Road and signalizing that intersection
- Providing bus service to Sites Reservoir and its Recreation Areas and providing a Park and Ride Lot at the bus pickup location
- Provisions for maintaining emergency vehicle access (detailed measures to be developed in coordination with the local sheriff and fire departments)
- Provisions to reduce potential school bus delays that may occur as a result of Project recreation visitation traffic (detailed measures to be developed in coordination with the local school district and sheriff departments)
- Directional roadway signage to Sites Reservoir and its Recreation Areas

The Operation Traffic Control Plan shall be prepared in coordination with, and approved by, affected agencies, such as Caltrans, Glenn County, Colusa County, and Maxwell Unified School District.

Mitigation Measure Trans-3: Prepare and Implement a Project Construction Traffic Control Plan

DWR and Reclamation shall prepare and implement a Construction Traffic Control Plan for the Project. The Construction Traffic Control Plan shall include, but would not be limited to, the following measures that are intended to manage:

- Construction-related traffic
- Temporary and/or permanent bus reroutes
- Pavement repairs before and after construction
- Measures to reduce emergency vehicle delay and maintain emergency vehicle access (detailed measures to be developed in coordination with the local sheriff and fire departments)
- Measures to accommodate potential school bus reroutes and reduce potential school bus delays (detailed measures to be developed in coordination with the school district and sheriff departments)
- Construction site parking
- Construction signage

The Construction Traffic Control Plan shall be prepared in coordination with, and approved by, affected agencies, such as Caltrans, Glenn County, Colusa County, and Maxwell Unified School District.

Mitigation Measure Pub Health-6: Develop and Implement a Project Fire Prevention and Suppression Plan and Consult with Fire Protection Agencies

DWR and Reclamation shall include in the construction contract specifications the following requirements. Prior to the start of Project construction, the construction contractor shall coordinate with the fire protection agencies that would serve the Primary Study Area regarding their requirements for preventing and suppressing fires during Project construction, operations, and maintenance. This effort shall include the preparation and implementation of a Project Fire Prevention and Suppression Plan that shall provide requirements that the contractor(s) shall follow while constructing Project facilities. The Plan shall also provide requirements for operation and maintenance activities. The Plan shall include, but shall not be limited to, the following requirements:

- Equip all diesel and/or gasoline-operated engines (stationary and mobile) with spark arresters
- Provide fire-fighting equipment on each piece of heavy equipment and construction vehicle
- Clear equipment service areas, parking areas, and gas and oil storage areas of all flammable material
- Prohibit smoking at Project facility construction sites during fire season, except in barren areas or in an area cleared to mineral soil at least three feet in diameter (CPRC 4423.4). In areas closed to smoking, the permit administrator may approve special areas to be used for smoking. The Contractor shall assign designated smoking areas. Signs shall be posted at Project facility construction sites regarding smoking and fire rules in conspicuous places. Under no circumstances shall smoking be permitted during fire season while workers are operating light or heavy equipment, or walking or working in grass and woodlands.
- Confine welding activities to cleared areas having a minimum specified radius

- Furnish a full water tank truck with fire hose at Project facility sites
- Maintain minimum vegetation clearance distances
- Establish long-term fuel management requirements
- Notify the local fire protection agencies of any fires along roads or within or near the Project facility sites as soon as feasible, after initial control action is taken
- Provide an on-site fire patrol person who shall patrol all Project facility sites during Project construction for the purpose of preventing and detecting fires and taking suppression action where necessary
- Furnish an agreed upon communications system connecting each Project facility construction site with the local fire protection agencies

In addition, DWR and Reclamation shall include into the construction contract specifications the following requirement:

- Prepare a Project-specific Emergency Evacuation Plan that includes a Project-specific contingency plan for fires, and submit the Plan to the agency or agencies with jurisdiction before Project site activities commence.

Implementation of **Mitigation Measures SW Qual-1e, GW Qual-1b, Pub Health-4, Trans-1, Trans-3**, and **Pub Health-6** would reduce the level of significance of Project impacts from public and environmental hazards to **less than significant**.

28.4.2 Mosquitoes and Other Vectors

Mitigation measures are provided below and summarized in Table 28-5 for the impacts that have been identified as significant or potentially significant.

Table 28-5
Summary of Mitigation Measures for NODOS Project Impacts to Public Health from Mosquito or Vector Populations, Habitat, and the Spread of Mosquito- or Vector-Borne Illnesses

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Pub Health-9: Expose People to an Increased Risk of Mosquito-Borne or Other Vector-Borne Illnesses, or Increased Exposure to Nuisance Problems	All Project facility sites where ponding would occur (construction)	Potentially Significant	Mitigation Measure Pub Health-9a: Develop and Implement a Stormwater Pollution Prevention Plan	Less than Significant

Table 28-5
Summary of Mitigation Measures for NODOS Project Impacts to Public Health from Mosquito or Vector Populations, Habitat, and the Spread of Mosquito- or Vector-Borne Illnesses

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
	Sites Reservoir, Recreation Areas, Holthouse Reservoir, TRR, and the forebay and afterbay at the Delevan Pipeline Intake Facilities (operation and maintenance)	Potentially Significant	Mitigation Measure Pub Health-9b: Develop and Implement a Mosquito, Vector, and Other Nuisance Problems Control Plan	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Pub Health-9a: Develop and Implement a Stormwater Pollution Prevention Plan

The Project construction contractor shall develop and implement a Stormwater Pollution Prevention Plan that includes, but is not limited to, BMPs for minimizing on-site stormwater. In addition, the Plan shall include measures to minimize construction worker exposure to mosquitoes.

Mitigation Measure Pub Health-9b: Develop and Implement a Mosquito, Vector, and Other Nuisance Problems Control Plan

DWR and Reclamation shall prepare and implement a Mosquito, Vector, and Other Nuisance Problems Control Plan for the Project, in consultation with the Glenn County Mosquito and Vector Control District and the Colusa Mosquito Abatement District. This Plan shall include, but not limited to, the following:

- Conduct routine inspection and virus surveillance activities within the Sites Reservoir and its Recreation Areas, as well as the TRR and Holthouse reservoirs, and the forebay/afterbay at the Delevan Pipeline Intake Facility.
- Site managers shall eliminate unnecessary standing water in containers, old tires, or trash receptacles,
- Clean all rain gutters, storm drains, or similar features that could capture water.
- Minimize places where mosquitoes, ticks, rodents, or rattlesnakes may inhabit by removing heavy brush, trimming and pruning landscape shrubs, and mowing grass areas regularly.
- Install bird nesting boxes to encourage birds that feed on mosquitoes, midges and other vectors or nuisance species.
- Stock the reservoirs with fish that feed on mosquito larva and pupa.
- Provide printed materials at each recreation area that informs the recreationists (particularly recreationists using the Sites Reservoir and hikers using the trail system) to protect against mosquito, tick, stinging insect, flea, rattlesnake bites, poison oak, and to minimize exposure to Giardia and Swimmer's Itch. Such information shall include, but is not limited to, instructions to: (1) wear clothing that covers arms and legs and use a repellant that contains DEET; (2) never go barefoot or

wear sandals when walking through wild areas (wear hiking boots); (3) stick to well-used trails when hiking; (4) avoid tall grass, weeds, and heavy underbrush; (5) never step or put your hands where you cannot see, and avoid wandering around in the dark; (6) step on logs and rocks, never over them, and be especially careful when climbing rocks or gathering firewood; (7) check out stumps or logs before sitting down, and shake out sleeping bags before use; (8) never grab "sticks" or "branches" while swimming in lakes and rivers (rattlesnakes can swim); (9) never hike alone (always have someone with you who can assist in an emergency); (10) never handle a freshly killed snake (it can still inject venom); (11) teach children to respect snakes and to leave them alone; (12) avoid contact with wild rodents and their fleas, especially sick rodents; (13) minimize pet contact with rodents; (14) never camp near animal burrows; (15) never feed rodents; (16) store food and garbage in closed containers; and (17) explain how to identify poison oak and include a photo of poison oak leaves.

- Conduct routine inspections of all pipelines and other water conveyance structures for aboveground leaks that could create standing water. Repair all leaks in a timely manner.
- Provide covered trash receptacles within the recreation areas. Perform timely and frequent emptying of trash receptacles and cleanup of food spillage. Provide signs that encourage recreationists at these areas to cover and store food promptly after eating, and to properly dispose of food packaging and waste. Encourage recreationists to leave the areas as clean as possible to discourage foraging rodents, flies, and biting/stinging insects.
- Conduct routine inspections of property for stinging insect nests and remove them, if necessary, to avoid public health or nuisance issues.
- Promptly remove from property all dead animals, carnage, or animal feces.

Implementation of **Mitigation Measures Pub Health-9a** and **Pub Health-9b** would reduce the level of significance of Project impacts to public health from mosquitoes, other vectors, and nuisance problems to **less than significant**.

29. Public Services and Utilities

29.1 Introduction

This chapter describes the public services and utilities setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Public services include schools, hospitals/medical centers, and police and fire protection services. Utilities include water, wastewater, solid waste, natural gas, electricity, telephone, and cable providers.

The regulatory setting for public services and utilities is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

29.2 Environmental Setting/Affected Environment

29.2.1 Methodology

The identification of existing public services and utilities for the three study areas was performed by conducting a review of planning documents, consultation of websites, and by telephone and email communications with representatives of area agencies to identify and describe existing public services (schools, fire protection/emergency medical services, and law enforcement) and existing utilities (water, wastewater, drainage, energy, solid waste disposal) facilities and systems.

29.2.2 Extended and Secondary Study Areas

29.2.2.1 Public Services

Schools

The counties, cities, and communities in the Extended and Secondary study areas have both public (alternative, magnet, thematic, and charter) and private (religious and non-religious) schools. The public schools are under the jurisdiction of various public school districts.

Medical Care

There are many medical centers that serve the counties, cities and communities within the Extended and Secondary study areas. These hospitals/medical centers provide general medical and surgical care, emergency services, women's health, children's health, imaging services, and outpatient services (USA Hospitals, 2010).

Police Protection

The counties in the Extended and Secondary study areas are served by County Sheriff's departments/offices that are responsible for law enforcement services in the unincorporated areas of the counties. The County Sherriff departments typically administer the County Jails, function as the County

Coroner/Crime Lab, and act as the Office of Emergency Services (USA COPS, 2010). Law enforcement services are also provided by police departments within the individual cities (USA COPS, 2010), and also by the California Highway Patrol (CHP). The CHP is the primary law enforcement agency for state highways and roads. Its services include law enforcement, traffic control, accident investigation, and the management of hazardous materials spill incidents.

Fire Protection

Various fire departments and fire districts serve counties, cities, and communities in the Extended and Secondary study areas. Fire department/districts are staffed by paid workers, and volunteers in some instances.

29.2.2.2 Utilities

Water

Various municipal and agricultural water districts serve the counties, cities, and communities in the Extended and Secondary study areas from a variety of surface and groundwater sources. The water is conveyed through pipelines to water treatment systems operated by various water districts (special service districts or municipalities). The treated water is then distributed through a grid system that serves the incorporated areas and some of the rural neighborhoods adjoining the incorporated areas. Irrigation water is conveyed through canals operated by irrigation water districts to the agricultural lands where the water is applied.

Wastewater

Wastewater in the Extended and Secondary study areas is treated and returned to the environment using both on-site disposal and centralized disposal. The areas served by on-site systems are generally rural or agricultural. More populous areas have a wastewater treatment facility (centralized disposal) in which a series of underground pipelines convey wastewater from residences and businesses to a wastewater treatment plant for treatment before release to local waterways.

Solid Waste

Solid waste in the Extended and Secondary study areas is disposed of by individual public works departments and contracted private waste handling companies in the counties. Solid waste in these areas is transported to commercial Class I, II, and III landfills. Class I sites may accept hazardous and nonhazardous wastes; Class II sites may accept "designated" and nonhazardous wastes; and Class III sites may accept nonhazardous wastes. Examples of Class I landfills are Chem Waste Management-Kettleman in Kings County, and Safety-Kleen-Buttonwillow in Kern County. Examples of Class II landfills are Altamont Sanitary Landfill in Alameda County, Aqua Clear Farms Inc. in Solano County, and Ostrom Road Landfill in Yuba County. Examples of Class III landfills are Kiefer Landfill in Sacramento County, Red Bluff Landfill in Tehama County, Weaverville Landfill in Trinity County, and West Central Landfill in Shasta County.

Natural Gas

Natural gas is provided via a system of underground pipelines of varying diameters to residences and businesses throughout the Extended and Secondary study areas by PG&E, Southern California Gas (SoCalGas), San Diego Gas & Electric (SDG&E), Southwest Gas, and several smaller natural gas utilities (CPUC, 2010).

Electricity

Electricity is provided to the residences and businesses throughout the Extended and Secondary study areas by a combination of overhead and underground transmission and distribution lines. High voltage (> 230-kV) electricity is generated and transmitted throughout California (and also generated in other states, with some electricity being imported to California) and is stepped down in voltage for residential, commercial, and industrial land uses. Examples of providers include Pacific Gas and Electric Company (PG&E), San Diego Gas and Electric (SDG&E), municipal utilities, and San Francisco Public Utilities Commission (SFPUC).

Telephone

Telephone service (both land lines and cellular service) is provided by several companies in the Extended and Secondary study areas by a variety of providers such as AT&T, Comcast, Southern California Telephone Company, Sprint, Frontier Communications, Vonage, and Verizon.

Cable

Cable service for the television and internet is provided by a series of overhead and underground lines in the Extended and Secondary study areas. Service is provided by a variety of providers including AT&T, Comcast, and Time Warner Cable.

29.2.3 Primary Study Area

The Primary Study Area includes the areas where proposed Project facilities would be constructed. For data collection purposes, public services, facilities, and utilities are discussed at the County level (Glenn and Colusa counties). In addition, the existing communication tower on Logan Ridge (located on the southeast side of the proposed Sites Reservoir) is not a Project facility; however, its access would be affected by the Project, so a new road to access it is included in the Project, and it is discussed as part of the Primary Study Area.

29.2.3.1 Public Services

Schools

Glenn County

In 2009, there were 36 public schools within Glenn County, including 10 elementary/primary schools, two junior high/middle schools, five high schools, and 19 other types of schools (including continuation, community day, juvenile court, and special education) (Ed-Data, 2009). Additional educational opportunities are provided through the Butte-Glenn Community College District. Table 29-1 characterizes each public school in the County. Table 29-2 lists the school bus routes for each of the public school districts in the county.

Colusa County

In 2009, there were 22 public schools within Colusa County, including six elementary/primary schools, three junior high/middle schools, four high schools, and nine other types of schools (including alternative, juvenile court, opportunity, continuation, and special education) (Ed-Data, 2009). Table 29-3 characterizes each public school in the County. Table 29-4 lists the school bus routes for each of the public school districts in the county.

Medical Care

Glenn County

The Glenn Medical Center, located in Willows, provides medical care services in Glenn County. It provides general medical and surgical care, emergency services, outpatient chiropractic services, outpatient women's health center, outpatient sleep center, and imaging services. It is a 15-bed facility. It employs a total of 102 full-time facility personnel including registered nurses (RNs), licensed practical nurses (LPNs), and licensed vocational nurses (LVNs) (McMillan, 2010).

Colusa County

The Colusa Regional Medical Center, located in Colusa, provides medical care services in Colusa County. It provides general medical and surgical care, general intensive care, obstetrics, emergency services, specialized inpatient and outpatient care, and imaging services (AHA, 2010b). It is a 48-bed facility (AHA, 2010b). It employs 32 full and part-time registered nurses, 11 full and part-time licensed practical nurses, and 143 total full- and part-time other facility personnel (Athenais, 2010).

Police Protection

Glenn County

The Glenn County Sheriff's Department is located in Willows, California. It has 77 employees, of which 28 are sworn peace officers (Leath, 2010). It provides law enforcement services within the unincorporated areas of the County in addition to providing backup and dispatch services for the Willows and Orland police departments. The Sheriff also shares law enforcement responsibilities within the National Forest with the Mendocino National Forest. The department administers the County Jail, Dispatch, functions as the County Coroner, patrols waterways, and acts as the Director of Emergency Services (Glenn County, 2008).

Law enforcement emergency services are also provided by the Orland Police Department, the Willows Police Department (USACOPS, 2010), and the California Highway Patrol.

Colusa County

The Colusa County Sheriff's Office is located in Colusa, California. It has 75 employees, of which 32 are sworn peace officers (Dixon, 2010). It is responsible for law enforcement in the unincorporated areas of Colusa County (i.e., the entire County except for the incorporated cities of Williams and Colusa). The Sheriff's Office has the following departments: Patrol, Investigations, Coroner, Animal Control, Drug Abuse Resistance Education (D.A.R.E.) Program, Narcotics Task Force, Special Operations and Response Team (S.O.A.R), Jail, Civil, Dispatch, Records, and Office of Prevention Services (Colusa County Sheriff's Office, 2009).

The Sheriff's Office also uses volunteer organizations to augment their paid staff for Search and Rescue, Sheriff's Mounted Posse, Volunteer Citizen Service Unit, Aero Squadron, and the Sheriff's Explorer Program (Colusa County Sheriff's Office, 2009).

Municipal police departments serve the cities of Williams and Colusa (USACOPS, 2010). The city police forces work closely with the County Sheriff's Office because many police matters cross jurisdictional boundaries. The cities and County participate jointly in search and rescue efforts. The U.S. Forest Service District Ranger provides services for the Mendocino National Forest. CDFG's Law Enforcement Division protects California's natural resources and provides public safety in the areas within its jurisdiction (CDFW, 2013). Wardens from the USFWS provide similar law enforcement services on federal National Wildlife Refuges. The California Highway Patrol patrols state roads in the County (Colusa County, 1989).

Fire Protection

Glenn County

Glenn County has 12 fire departments operating in 13 fire protection districts. All are independent of the California Department of Forestry and Fire Protection (CAL FIRE). The only paid personnel (five) in Glenn County are in the City of Willows. The fire departments are: Willows, Orland, Elk Creek, Artois, Kanawha, Butte City, Hamilton City, Capay, Bayliss, Glenn/Codora, and Ord Bend. CAL FIRE provides services from west of the electrical transmission lines located west of I-5 to the Mendocino National Forest (Norcalscan.org, 2009a).

Colusa County

Fire protection services in Colusa County are provided by rural districts, city fire departments, CAL FIRE, and the U.S. Forest Service. There are mutual aid agreements between most of the agencies to ensure that adequate personnel and equipment can be provided when a fire occurs (Colusa County, 1989).

The Colusa Rural Fire District consolidated with Grand Island Fire District to form the Sacramento River Fire District. The Sacramento River Fire District provides fire protection services to the rural portions of Colusa County. The Sacramento River Fire District, as well as the fire districts that serve the towns in Colusa County, are dispatched by the Colusa County Sheriff's Department (Norcalscan.org, 2009b).

29.2.3.2 Utilities

Water

Glenn County

The eastern portion of the County overlies the Sacramento Valley Groundwater Basin, which contains abundant supplies of good quality groundwater to depths of 800 feet. Groundwater is the primary source of domestic water supply in the County, and is also used for irrigation in areas where surface water is not available (Glenn County, 1993a). There are 17 municipal wells serving Willows, Hamilton City, and Orland. These wells range in depth from an average of 250 to 500 feet. There are 46 industrial wells in the County; they have an average depth of 250 feet (Messina, 2010).

The Sacramento River is the primary source of surface irrigation water in Glenn County; approximately 30 percent of the agricultural irrigation supply comes from groundwater. Water from the river is diverted into the Glenn-Colusa Irrigation District (GCID) and Tehama-Colusa (T-C) canals. Approximately 99 percent of the County's total water supply from the Sacramento River and the GCID Canal is directed to agricultural uses. The breakdown of surface water and groundwater deliveries by land use are listed in Table 29-5.

Table 29-5
Glenn County Water Supply Statistics

Land Use	Applied Water (acre-feet)			Percent Surface Water	Percent Groundwater
	Surface	Ground	Total		
Agricultural	657,300	247,900	905,200	73	27
Municipal/Industrial	0	9,200	9,200	0	100
Total	657,300	257,100	914,400	72	28

Source: DWR, 2011.

The County has approximately 34 municipal water supply systems that serve approximately 89 percent of the County's residents. Table 29-6 lists the active water systems within Glenn County.

[a]Community Water Systems: Water systems that serve the same people year-round (e.g., in homes or businesses).

[b]Non-Transient Non-Community Water Systems: Water systems that serve the same people, but not year-round (e.g., schools that have their own water system).

[c]Transient Non-Community Water Systems: Water systems that do not consistently serve the same people (e.g., rest stops campgrounds, gas stations).

Note:

RV = Recreation Vehicle

Source: USEPA, 2010a.

Colusa County

Municipal and industrial water needs in Colusa County are primarily met by groundwater supply from an estimated 1,936 wells (DWR, no date). Supply is supplemented with approximately 27 percent surface water. Domestic water systems in Colusa County are supplied with groundwater from wells generally

100 to 500 feet deep. The County's water use is almost entirely agricultural. The breakdown of surface water and groundwater deliveries by land use are listed in Table 29-7.

Table 29-7
Colusa County Water Supply Statistics

Land Use	Applied Water (acre-feet)			Percent Surface Water	Percent Groundwater
	Surface	Ground	Total		
Agricultural	891,200	158,000	1,049,200	85	15
Municipal/Industrial	200	6,100	6,300	3	97
Total	891,400	164,100	1,055,500	84	16

Source: DWR, 2011.

The County has approximately 29 municipal water supply systems (USEPA, 2010b). Water is supplied to Colusa County from the T-C Canal, the GCID Canal, the Colusa Basin Drain, the Sacramento River, and groundwater. The T-C Canal provides irrigation water to lands west of the cities of Maxwell, Williams, and Arbuckle. Agricultural water districts in Colusa County include irrigation districts, water districts, County districts, reclamation districts, levee districts, drainage districts, mutual water companies, and national wildlife refuges (Colusa County, 1989). Table 29-8 lists the active water systems within Colusa County.

Table 29-8
Active Water Systems in Colusa County

Water System Name	Population Served	Primary Water Source Type	Water System ID
Community Water Systems[a]			
Arbuckle Public Utility District	2,100	Groundwater	CA0610001
Colusa County Service Area #1-Century Ranch	120	Surface water	CA0600012
Colusa County Service Area #2-Stonyford	200	Groundwater	CA0600005
Colusa County Water District #1-Grimes	500	Groundwater	CA0600008
Maxwell Public Utility District	850	Groundwater	CA0610003
Princeton Water District	356	Groundwater	CA0600013
Del Oro Water Company – Walnut Ranch	182	Groundwater	CA0600011
Non-Transient Non-Community Water Systems[b]			
ADM Rice, Inc.	30	Groundwater	CA0605004
SK Foods - Colusa Canning	31	Groundwater	CA0600061
Colusa Industrial Properties	350	Groundwater	CA0600065
Fouts Springs Youth Facility	120	Groundwater	CA0600041
Morning Star Packing Company-Williams	230	Groundwater	CA0605002
Sun Valley Rice Company	90	Groundwater	CA0605007
Transient Non-Community Water Systems[c]			
Arbuckle Golf Club	120	Groundwater	CA0600042
Caltrans-Maxwell Reststops	15,000	Groundwater	CA0600050
Colusa Landing	25	Groundwater	CA0600009
Grimes Boat and Landing	50	Groundwater	CA0600003
Kingdom Hall of Jehovah's Witness-Williams	100	Groundwater	CA0605005

Table 29-8
Active Water Systems in Colusa County

Water System Name	Population Served	Primary Water Source Type	Water System ID
Menf-Letts Lake Campground	100	Groundwater	CA0600056
Richmond Hunting Club-Arbuckle	63	Groundwater	CA0605009
Richmond Hunting Club-Maxwell	95	Groundwater	CA0605006
River Vista Farms	25	Groundwater	CA0600004
Squaw Creek Water System	25	Groundwater	CA0600072
Terhel Farms Trailer Park 01	25	Groundwater	CA0600027
Ward's Boat Landing	25	Groundwater	CA0600001
Wilbur Hot Springs	65	Groundwater	CA0600016
Wilderness Unlimited	25	Groundwater	CA0600032

Wastewater

Glenn County

In Glenn County, wastewater is treated and returned to the environment using primarily on-site disposal and centralized disposal. The areas served by on-site systems are generally rural or agricultural. The centralized disposal systems are comprised of three wastewater treatment facilities and collection systems serving most of the urbanized portions of Glenn County: Willows, Orland, and Hamilton City (Glenn County, 1993b). All other waste disposal occurs in individual septic systems, with the exception of Caltrans' I-5 rest stop, Glenn Milk Producers, and Holly Sugar, which use industrial wastewater treatment ponds.

Colusa County

In Colusa County, wastewater is treated and returned to the environment using primarily on-site disposal and centralized disposal. The areas served by onsite systems are generally rural or agricultural. Although most onsite systems serve an individual dwelling or commercial establishment, some serve groups of homes or businesses. The onsite systems consist of a septic tank and a leach field (Colusa County, 1989).

Five communities are served by centralized systems: Arbuckle, Colusa, Maxwell, Princeton, and Williams. Community systems consist of a network of collection lines, a treatment facility, and a disposal system (typically evaporation ponds that are discharged to a stream or drainage channel). The Arbuckle Public Utility District provides sewer service to Arbuckle residents using a system of clay pipes that convey wastewater to a treatment plant north of town. The City of Colusa operates a wastewater treatment plant and evaporation pond system in an agricultural area approximately 1.5 miles southwest of downtown. Maxwell's wastewater treatment plant is located approximately one mile south of town; it has a collection system of concrete, clay, and PVC pipes. Princeton also has a wastewater treatment system. The City of Williams operates a wastewater treatment plant on a 30-acre site north of town (Colusa County, 1989).

Solid Waste

Glenn County

Glenn County has one landfill, located near Artois. The permitted site area is 356.4 acres and the permitted disposal area is 83 acres. It is permitted to receive 200 tons of waste per day. The landfill has a design capacity of 2,400,000 cubic yards (cy) (CIWMB, 2010); total estimated capacity remaining as of June 8, 2010 was 348,223 cy (CIWMB, 2011a). It is a Class III facility, with an expected closure date of 2013. Glenn County has no plans to build a new landfill. A decision will be made by the County in the future regarding the selected method to manage waste disposal after its landfill closes. Glenn County is considering several options to constructing a landfill, including building a transfer station to transfer collected waste to landfills in other counties, using waste management companies that own or operate landfills in other counties, and adopting treatment technologies as an alternative to landfilling (Linhart, pers. comm., 2011).

The Glenn County Public Works Department owns and operates the landfill. Collection services are provided by Waste Management of California, Inc. Self-haul loads are also accepted. The landfill only accepts “in-County” loads (Varga, pers. comm. 2004).

In addition, in Glenn County, other active waste handling facilities include the Valley Gold Compost (composting operation for manure and green materials) (CIWMB, 2011b); Compost Solutions, Inc. (a composting operation that handles agricultural materials, green materials, and manure) (CIWMB, 2011c), and Caltrans Maintenance (a transfer and processing operation that handles metals, mixed municipal, tires, and wood waste) (CIWMB, 2011d).

Colusa County

There are four types of solid waste generated in Colusa County: residential, commercial, industrial, and natural resource byproducts[1] (Colusa County, 1989). Colusa County owns and operates the Stonyford Disposal Site, located on Lodoga Stonyford Road in Stonyford. The landfill is a 47-acre Class III facility that is permitted for up to 10 tons per day of non-hazardous waste. The mix of waste it receives includes agricultural, construction/demolition, mixed municipal, and tires. The landfill’s design capacity is 149,219 cy, and the total estimated capacity used was 93,536 cy with the remaining estimated capacity of 55,683 cy as of April 30, 2001 (CIWMB, 2011e). As of 2001, the landfill’s life expectancy was 63 years (closure date January 1, 2064). The landfill accepts only “in-County” loads.

Other active waste handling facilities in Colusa County include the Maxwell Transfer Station (transfer/processing of agricultural, construction/demolition, mixed municipal, and tire waste) (CIWMB, 2011f) and Premier Mushrooms (a composting operation for agricultural waste and manure) (CIWMB, 2011g). In addition, a solid waste disposal facility is planned to be located south of the City of Colusa (CIWMB, 2011h).

[1] Natural resource byproducts include rice stubble and straw, manure, gas well mud, cannery waste, and waste from prune dehydrators.

Two facilities outside of Colusa County provide additional landfill capacity. Approximately 55 tons per year of waste from the City of Colusa are shipped by compactor truck to Norcal Waste Systems Ostrom Road Landfill, Inc., located in Wheatland in Yuba County. In addition, the Maxwell Transfer Station sends 14,500 tons per year to the Anderson Landfill in Shasta County.

The Norcal Waste Systems Ostrom Landfill, Inc. is a 261-acre Class II facility, and can accept up to 3,000 tons of municipal solid waste per day. The facility has an expected closure date of December 31, 2066 (CIWMB, 2011i), with a total design capacity of 41,822,300 cy (CIWMB, 2002), and remaining capacity as of June 1, 2007 of 39,223,000 cy (CIWMB, 2011i).

The Anderson Landfill is a 246-acre Class III site with a design capacity of 16,353,000 cy (CIWMB, 2008). It has an expected closure date of January 1, 2055, and a total permitted capacity of 1,850 tons per day (CIWMB, 2011j). It is operated by Waste Management of California, Inc. Waste collection in Williams and in the unincorporated areas of the County is performed by Waste Management, Inc. The City of Colusa provides collection service in its jurisdiction (Colusa County, 2004).

Natural Gas

Glenn County

Natural gas is provided by PG&E in the more populated areas of Glenn County, and several propane companies serve the outlying areas of the County (Glenn County, 2010).

Colusa County

Natural Gas is provided by PG&E in the more populous areas of the County, and several propane companies serve the outlying areas in Colusa County (Colusa County, 2010). There is gas service to Maxwell, but none to the town of Sites or the proposed Sites Reservoir area. To the east of Funks Reservoir, aligned in a north/south orientation, PG&E operates two high-pressure arterial gas transmission lines that originate in Canada and serve most of northern and central California. These two lines are 42 and 36 inches in diameter, and have a right-of-way of 100 feet.

Electricity

Glenn County

Electricity is provided to the populated areas of Glenn County by PG&E (Glenn County, 2010).

Colusa County

PG&E provides electric service to Colusa County. Through the Project area in Colusa County, PG&E operates 12-kV distribution lines on rights-of-way that range from 10 to 30 feet wide. These lines serve the town of Sites and vicinity. Lines exist along the Maxwell Sites Road, and feed south in the general direction of Leesville via Huffmaster Road. In addition, the Western Area Power Administration operates two high-voltage transmission lines, aligned north/south and passing just east of Funks Reservoir. The 500-kV line occupies a 125-foot-wide right-of-way and is routed from the Olinda Substation to the Tracy Substation. The 230-kV line occupies a 160-foot-wide right-of-way, and is routed from Keswick to Elverta.

Telephone

Glenn County

In Glenn County, telephone service is provided by AT&T and Comcast (Glenn County, 2010).

Colusa County

In Colusa County, telephone service is provided by AT&T, Comcast, and Frontier Communications Solutions (Colusa County, 2010).

In the Project vicinity, telephone service is provided by Frontier Communications via buried lines in the town of Sites and in the valley. On Maxwell Sites Road, from the town of Maxwell, there is buried cable in the County road easement west to the town of Sites. In the town of Sites, there is a combination of buried and overhead cable on power poles serving the existing homes. West toward Lodoga there is a buried telephone cable in the County road for approximately one mile, and then on to private property for approximately one mile. Facilities also are located south on Huffmaster Road within the County right-of-way for 6.5 miles. Taps serve local ranches and a radio antenna site on PG&E poles.

Cable

Glenn County

Cable service in Glenn County is provided both individually and in tandem with telephone service by Comcast Cable and AT&T. Cable is available in most urban and urban-rural areas (Glenn County, 2010).

Colusa County

In Colusa County, cable TV service is provided individually by Comcast Cable, and is also provided in tandem with telephone service by Comcast Cable. Cable is available in most urban and urban-rural areas, but is not provided to the town of Sites, or nearby. Internet service is provided by a variety of DSL and cable internet service providers, including HughesNet Services, People PC Online, and in tandem with telephone service by Comcast and Frontier Communications Solutions (Colusa County, 2010).

29.3 Environmental Impacts/Environmental Consequences

29.3.1 Regulatory Setting

Public services and utilities are regulated at the federal, State, and local levels. Primary management occurs by local governments or local or regional special districts. Federal regulatory agency involvement is typically limited to review of a provider’s operation related to a specific area, such as the environment, public safety, waterways, and fisheries. Provided below is a list of the applicable public service/utility regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

29.1.1.1 Federal Plans, Policies, and Regulations

- Americans with Disabilities Act of 1990
- Critical Infrastructure Information Act of 2002
- National Fire Protection Association 1710 Standard

29.1.1.2 State Plans, Policies, and Regulations

- Health and Safety Code Sections 13000 et seq.
- Health and Safety Code Sections 13145 and 13146
- Health and Safety Code, Section 13801 et seq.
- California Government Education Code Section 17620

29.1.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

29.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for public services and utilities:

Would the Project:

- Result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any of the public services:
  - Fire protection?
  - Police protection?
  - Schools?
  - Parks?
  - Other public facilities?
- Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?
- Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?
- Require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?
- Have sufficient water supplies available to serve the Project from existing entitlements and resources, or are new or expanded entitlements needed?
- Result in a determination by the wastewater treatment provider which serves or may serve the Project that it has adequate capacity to serve the Project's projected demand in addition to the provider's existing commitments?
- Be served by a landfill with sufficient permitted capacity to accommodate the Project's solid waste disposal needs?
- Comply with federal, State, and local statutes and regulations related to solid waste?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- A substantial adverse physical impact associated with the provision of new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for the following public services: fire protection, police protection, schools, parks, and/or other public facilities, and disruptions to local or regional utility services.
-
- A decline in property tax or fee revenues that would lead to a substantial decrease in public services
- Exceed the wastewater treatment requirements of the applicable Regional Water Quality Control Board.
- The need for expansion of existing wastewater treatment, water treatment, stormwater, and/or landfill facilities.
- Require new or expanded water supply entitlements and resources.
- Non-compliance with federal, State, and local statutes and regulations related to solid waste.

29.3.3 Impact Assessment Assumptions and Methodology

29.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to public services and utilities:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.

29.3.3.2 Methodology

The evaluation of potential Project-related construction, operation, and maintenance impacts was performed by comparing the facilities and services that were identified in the Environmental Setting/Affected Environment discussion with proposed Project construction, operation, and maintenance activities to assess the potential for service disruptions.

The methodology used to calculate the annual Recreation Visitor Days (RVDs[2]) and changes in property taxes per year for Alternatives A, B, and C are described in Chapter 22 Socioeconomics.

29.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

29.3.5 Impacts Associated with the No Project/No Action Alternative

29.3.5.1 Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Sacramento River, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay,) Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Services-1: A Substantial Adverse Physical Impact Associated with the Provision of New or Physically Altered Governmental Facilities or the Need for New or Physically Altered Governmental Facilities (the Construction of which could cause Significant Environmental Impacts) in order to Maintain Acceptable Service Ratios, Response Times, or Other Performance Objectives for the Following Public Services: Fire Protection, Police Protection, Schools, Parks, and/or Other Public Facilities, and Disruptions to Local or Regional Utility Services

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential to result in impacts to local and regional public services and utilities has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on public services and utilities, when compared to Existing Conditions.

---

[2] An RVD is defined as a recreation visit by one person for part or all of one day.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to increase the demand for public services and utilities, as well as affect the existing levels of services that are currently provided. Public services and utilities are managed at the local level (e.g., cities and counties) in accordance with those agencies' regulations. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions

In addition, projects considered within the No Project/No Action Alternative are not located within the Primary Study Area, and therefore, **would not have a substantial adverse effect** on public services and utilities within that study area, when compared to Existing Conditions. Similarly, the Project would not be constructed if this alternative is implemented, so no temporary or permanent disruptions of or effects on public services and utilities would occur. Therefore, **there would not be a substantial adverse effect** on public services and utilities in any of the three study areas, when compared to Existing Conditions.

Impact Services-2: A Decline in Property Tax or Fee Revenues that Would Lead to a Substantial Decrease in Public Services

If the No Project/No Action Alternative is implemented, the fiscal condition of local governments in the Extended, Secondary and Primary study areas is expected to be similar to that described for Existing Conditions. Growth in population would be accompanied by a corresponding growth in tax revenues and government budgets. Therefore, **there would not be a substantial adverse effect** to public services as a result of property taxes or fee revenues, when compared to Existing Conditions.

Impact Services-3: Exceed the Wastewater Treatment Requirements of the Applicable Regional Water Quality Control Board

Refer to the **Impact Services-1** discussion. That discussion also applies to the exceedance of wastewater treatment requirements.

Impact Services-4: The Need for Expansion of Existing Wastewater Treatment, Water Treatment, Stormwater, and/or Landfill Facilities

Refer to the **Impact Services-1** discussion. That discussion also applies to the need for expansion of existing wastewater treatment, water treatment, stormwater, and/or landfill facilities.

Impact Services-5: Require New or Expanded Water Supply Entitlements and Resources

Refer to the **Impact Services-1** discussion. That discussion also applies to the need for new or expanded water supply entitlements and resources.

Impact Services-6: Non-Compliance with Federal, State, and Local Statutes and Regulations Related to Solid Waste

Refer to the **Impact Services-1** discussion. That discussion also applies to non-compliance with federal, State, and local statutes and regulations related to solid waste.

29.3.6 Impacts Associated with Alternative A

29.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir

Impact Services-1: A Substantial Adverse Physical Impact Associated with the Provision of New or Physically Altered Governmental Facilities or the Need for New or Physically Altered Governmental Facilities (the Construction of which could cause Significant Environmental Impacts) in order to Maintain Acceptable Service Ratios, Response Times, or Other Performance Objectives for the Following Public Services: Fire Protection, Police Protection, Schools, Parks, and/or Other Public Facilities, and Disruptions to Local or Regional Utility Services

There would be no direct Project-related construction or maintenance occurring within the CVP and SWP service areas of the Extended Study Area. Therefore, there would be no disruptions to utility services in the Extended Study Area, and there would not be a substantial adverse physical impact from new or physically altered governmental facilities (nor would Alternative A create demand for new or physically altered governmental facilities), resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of San Luis Reservoir would be altered to accommodate Project operation, which would result in more frequent and larger surface water elevation fluctuations at the reservoir than currently occur there. In addition, Project operation would result in increased water supply reliability to agricultural, municipal, and industrial users, and an alternate water supply source for the wildlife refuges in the Extended Study Area. These operations would not be expected to change the number of people living within the Extended Study Area (i.e., Alternative A would not induce population growth), and consequently are not expected to change the demand for public services or require new or physically altered governmental facilities. In addition, changes in reservoir operation would not be expected to disrupt utility services. Therefore, there would be **no impact** on public services and utilities from operations in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

The increased SWP/CVP exports associated with implementation of Alternative A could potentially result in increased storage at some of the export service area reservoirs within the Extended Study Area. Small increases in storage at these reservoirs could result in slightly increased recreation use at these reservoirs. These effects on recreation use in the Extended Study Area would be negligible and would not disrupt utilities or result in increased demand for public services that would require new or physically altered governmental facilities, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-2: A Decline in Property Tax or Fee Revenues that Would Lead to a Substantial Decrease in Public Services

Project construction, operation, and maintenance activities would affect the regional economic condition (including property taxes and other revenues) of the Extended Study Area through direct Project construction and maintenance expenditures in Glenn and Colusa counties, operation expenditures occurring throughout the Extended Study Area where SWP and CVP facilities are re-operated as a result of the Project, and where Project facilities would be operated. In addition, the removal of agricultural land from production at Project facility sites in Glenn and Colusa counties would affect revenues. The magnitude of the economic impacts and their associated effects on public services would be minor when compared to the regional economy of the Extended Study Area. Providing increased water supply reliability to agricultural, municipal, and industrial users, and an alternate water supply source for the wildlife refuges in the Extended Study Area would have no effect on property taxes or other revenues. Therefore, this would be **a less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-3: Exceed the Wastewater Treatment Requirements of the Applicable Regional Water Quality Control Board

Because no direct Project-related construction and/or maintenance work within the CVP and SWP service areas of the Extended Study Area is expected, there would be **no impact** on wastewater treatment agencies' abilities to meet wastewater treatment requirements.

The predicted changes in San Luis Reservoir operation, the increased reliability of water supply, and an alternate water supply for wildlife refuges, from implementing Alternative A, are not expected to affect the amount of wastewater that is currently generated or treated, nor would they affect the wastewater treatment requirements in the Extended Study Area. They would also not affect the abilities of wastewater treatment agencies in the Extended Study Area to meet existing wastewater treatment requirements because existing population growth rates throughout the Extended Study Area are not expected to change as a result of implementing Alternative A. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The potential increased recreation use at the export service area reservoirs within the Extended Study Area (refer to **Impact Services-1**) would be negligible and would not affect the amount of wastewater that is currently generated or treated, nor would it affect the wastewater treatment requirements in the Extended Study Area. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-4: The Need for Expansion of Existing Wastewater Treatment, Water Treatment, Stormwater, and/or Landfill Facilities

Because no direct Project-related construction and/or maintenance work within the CVP and SWP service areas of the Extended Study Area is expected, there would be **no impact** to utilities that manage wastewater treatment facilities, water treatment facilities, stormwater systems, and/or landfills, when compared to Existing Conditions and the No Project/No Action Alternative.

The predicted changes in San Luis Reservoir operation are not expected to change the public's recreation use at the reservoir, resulting in **no impact** to existing wastewater treatment, water treatment, stormwater, and/or landfill facilities in that area. Similarly, the increased reliability of agricultural and M&I water supply from implementing Alternative A is expected to result in **no impact** to wastewater treatment, water treatment, stormwater, or landfill facilities in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative, because existing population growth rates throughout the Extended Study Area are not expected to change as a result of implementing Alternative A.

Providing an alternate source of water supply to the wildlife refuges, as part of operation of Alternative A, is not relevant to existing wastewater treatment or landfill facility operations, and would, therefore, have

no impact on wastewater treatment or landfill facilities operations, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, the water deliveries to SWP and CVP contractors as a result of Alternative A operation would be within the historical range of existing operations and no additional construction of water conveyance or treatment facilities would be needed, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Most of the water contractors within the Extended Study Area have alternative water supplies (e.g., local surface water or groundwater). In the future, they may add recycling, conservation, and other improvements to their water systems to accommodate planned population growth and maintain reliability in their systems. Adding a surface water supply option (such as from Alternative A) may reduce the need for these additional alternative water supply options. Thus, increased water supply reliability may result in a reduction in the future need for construction and operation of additional water treatment and distribution facilities. Therefore, there would be a **less-than-significant impact** on the need to expand existing wastewater treatment, water treatment, stormwater, or landfill facilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-5: Require New or Expanded Water Supply Entitlements and Resources

When compared to Existing Conditions and the No Project/No Action Alternative, Project operation would result in a **potentially beneficial impact** by possibly reducing reliance on groundwater in the Extended Study Area in locations where water is provided by the CVP or SWP. With increased water supply reliability to CVP and SWP water contractors, shortages in deliveries may decrease if Alternative A is implemented.

In addition, the expected changes in San Luis Reservoir operation from implementing Alternative A, as well as providing an alternate water supply source for the wildlife refuges in the Extended Study Area, would not cause total deliveries to any contract to exceed existing contract quantities. San Luis Reservoir would be operated such that there would be more frequent and larger water level fluctuations than currently occurs as a result of the increases in deliveries associated with these contracts. Therefore, there would be **no impact** to water supply entitlements and resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-6: Non-Compliance with Federal, State, and Local Statutes and Regulations Related to Solid Waste

Because no direct Project construction, operation, and/or maintenance work within the CVP and SWP service areas of the Extended Study Area would occur with implementation of Alternative A, complying with federal, State, and local statutes and regulations pertaining to solid waste in the Extended Study Area would not be an issue. There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The expected changes in San Luis Reservoir operation, the increased reliability of water supply from implementing Alternative A, and providing an alternate source of wildlife refuge water supply in the Extended Study Area are not expected to affect solid waste facilities or transporters located in or serving the Extended Study Area. In addition, they would not restrict the facilities or transporters from complying with federal, State, and local solid waste regulations. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

29.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Sacramento River, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Services-1: A Substantial Adverse Physical Impact Associated with the Provision of New or Physically Altered Governmental Facilities or the Need for New or Physically Altered Governmental Facilities (the Construction of which could cause Significant Environmental Impacts) in order to Maintain Acceptable Service Ratios, Response Times, or Other Performance Objectives for the Following Public Services: Fire Protection, Police Protection, Schools, Parks, and/or Other Public Facilities, and Disruptions to Local or Regional Utility Services

No Project construction would occur within the Secondary Study Area at any of the above-listed facilities or areas, so there would not be a disruption to utility services or a substantial adverse physical impact from new or physically altered governmental facilities (nor would Alternative A create demand for new or physically altered governmental facilities), resulting in **no impact** on public services or utilities at or near those locations with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of Alternative A would result in operational changes to the CVP and SWP facilities (e.g., increased storage at reservoirs and altered flow regimes on rivers and in the bypasses) within the Secondary Study Area. These operational changes are not expected to disrupt local or regional utility providers, resulting in **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Operational modeling for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates that Alternative A would provide improved storage conditions in Trinity Lake, Shasta Lake, and other recreational areas in the Secondary Study Area. Improved storage conditions can result in increased recreation use, but these operational changes are not expected to increase recreation use to a level that would require new or physically altered governmental facilities in the Secondary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Altered flows and temperatures can result in an increased need for emergency response services to recreationists. However, the changes to the flow regime of the streams included in the Secondary Study Area would fall within the historic range of flows, and would not be expected to result in an increased need for emergency response at a level that would require new or physically altered governmental facilities. There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-2: A Decline in Property Tax or Fee Revenues that Would Lead to a Substantial Decrease in Public Services

No Project construction would occur within the Secondary Study Area at any of the above-listed facilities or areas, so no change in property taxes or other revenues are expected that would affect public services. Therefore, **no impact** on public services is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Integrated Project operation with existing SWP and CVP facilities may affect the O&M costs of public services and utilities for those facilities within the Secondary Study Area and could affect regional economic conditions. However, the magnitude of the economic impacts and their associated effects on public services would be minor. Therefore, this would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-3: Exceed the Wastewater Treatment Requirements of the Applicable Regional Water Quality Control Board

No Project construction would occur within the Secondary Study Area at any of the above-listed facilities or areas, so **no impact** on wastewater is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Alternative A would provide improved storage to Trinity Lake, Shasta Lake, and other recreational areas in the Secondary Study Area; however, the improved storage conditions are not expected to increase recreation use to a level that would affect the amount of wastewater that is currently generated or treated, nor would it affect the wastewater treatment requirements in the Secondary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-4: The Need for Expansion of Existing Wastewater Treatment, Water Treatment, Stormwater, and/or Landfill Facilities

No Project construction would occur within the Secondary Study Area at any of the above-listed facilities or areas, so **no impact** on wastewater treatment, water treatment, stormwater, or landfill facilities is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

The improved storage conditions at Secondary Study Area facilities that would be provided by Alternative A would not increase recreation use at the above-listed facilities to a level that would affect the amount of wastewater or refuse that is currently generated or treated/disposed of in the Secondary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Increased water supply reliability could potentially result in a reduction in the future need for construction and operation of additional water treatment and distribution facilities. There could be a shift from more costly options (including high cost recycling and desalination) to the less expensive option of maintaining and operating the existing water treatment and conveyance systems that are already in use. Therefore, there would be **a potentially beneficial impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-5: Require New or Expanded Water Supply Entitlements and Resources

Implementation of Alternative A would result in operational changes to the CVP and SWP facilities (e.g., increased storage at reservoirs and altered flow regimes on rivers and in the bypasses) within the

Secondary Study Area. These operational changes would not require new or expanded water supply entitlements/resources, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-6: Non-Compliance with Federal, State, and Local Statutes and Regulations Related to Solid Waste

Because no direct Project construction and/or maintenance work at the above-listed facilities in the Secondary Study Area would occur with implementation of Alternative A, complying with federal, State, and local statutes and regulations pertaining to solid waste in the Secondary Study Area would not be an issue. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative. Increased storage at CVP and SWP reservoirs and altered flow regimes on rivers and in the bypasses in the Secondary Study Area is not relevant to solid waste regulations, so there would be **no impact** on compliance with such regulations, when compared to Existing Conditions and the No Project/No Action Alternative.

Pump Installation at the Red Bluff Pumping Plant

Impact Services-1: A Substantial Adverse Physical Impact Associated with the Provision of New or Physically Altered Governmental Facilities or the Need for New or Physically Altered Governmental Facilities (the Construction of which could cause Significant Environmental Impacts) in order to Maintain Acceptable Service Ratios, Response Times, or Other Performance Objectives for the Following Public Services: Fire Protection, Police Protection, Schools, Parks, and/or Other Public Facilities, and Disruptions to Local or Regional Utility Services

The only direct Project-related construction that would occur in the Secondary Study Area is the installation of a pump into an existing bay at the Red Bluff Pumping Plant (RBPP). This pump would be installed at an existing plant, requiring few pieces of equipment, limited construction activities, and a short construction period. Therefore, the pump's installation would not disrupt local or regional utility services and would not result in a substantial adverse physical impact from new or physically altered governmental facilities (nor would Alternative A create demand for new or physically altered governmental facilities), resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative. The pump's operation, as part of the larger pumping plant's operation, would also result in **no impact** on public services and utilities.

The only direct Project-related maintenance activity that would occur with implementation of Alternative A is the maintenance of the pump and the continued removal of sediment from the existing T-C and GCID canal intakes as part of the pumping plant's maintenance activities. It is expected that contractors would transport and dispose of the sediment in accordance with all federal, State, and local regulations, in compliance with their contract specifications. These maintenance activities would not disrupt local or regional utility services and would not result in a substantial adverse physical impact from new or physically altered governmental facilities (nor would Alternative A create demand for new or physically altered governmental facilities), resulting in **no impact** on local public services and local/regional utilities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-2: A Decline in Property Tax or Fee Revenues that Would Lead to a Substantial Decrease in Public Services

The installation of the pump at the existing RBPP would have minimal, if any, effects on property taxes and other revenues within the Secondary Study Area. In addition, the pump's operation and maintenance, and continued sediment removal at the canal intakes, as part of the existing pumping plant's operation and maintenance, would not affect property taxes or revenues within the Secondary Study Area. Therefore, there would be **no impact** on public services, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-3: Exceed the Wastewater Treatment Requirements of the Applicable Regional Water Quality Control Board

The pump's installation, operation, and maintenance, and continued sediment removal at the canal intakes, would have no effect on the wastewater treatment requirements for the Secondary Study Area. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-4: The Need for Expansion of Existing Wastewater Treatment, Water Treatment, Stormwater, and/or Landfill Facilities

The pump would be installed at an existing pumping plant, requiring a limited number of pieces of equipment, limited construction activities, and short construction duration. Its installation, operation, and maintenance, and continued sediment removal at the canal intakes, would not require that any utility facilities be expanded. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-5: Require New or Expanded Water Supply Entitlements and Resources

The pump's installation, operation, and maintenance, and continued sediment removal at the canal intakes, would not require new or expanded water supply entitlements and resources. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-6: Non-Compliance with Federal, State, and Local Statutes and Regulations Related to Solid Waste

Complying with solid waste regulations is not related to the installation of a pump into an existing pumping plant, the maintenance of the pump and the two canal intakes, or the pump's operation. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

29.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Potential impacts to public services and utilities from construction, operation, and maintenance of the Project facilities are discussed below.

All Primary Study Area Project Facilities

Impact Services-1: A Substantial Adverse Physical Impact Associated with the Provision of New or Physically Altered Governmental Facilities or the Need for New or Physically Altered Governmental Facilities (the Construction of which could cause Significant Environmental Impacts) in order to Maintain Acceptable Service Ratios, Response Times, or Other Performance Objectives for the Following Public Services: Fire Protection, Police Protection, Schools, Parks, and/or Other Public Facilities, and Disruptions to Local or Regional Utility Services

Schools, Police Protection, Fire Protection, and/or Other Public Facilities

During construction of the Alternative A Sites Reservoir Inundation Area and Sites Dam, the existing western portion of Maxwell Sites Road and the portion of Sites Lodoga Road that currently crosses Antelope Valley (needed to develop Sites Reservoir) would be demolished and removed. However, the South Bridge would be constructed and operating before the portions of these roads were demolished and removed. The new route that would include the South Bridge would be approximately two miles longer than the existing route. The slightly longer route would have a minimal effect on bus services provided by the Maxwell Unified School District and on emergency service response times and therefore would not require new or physically altered government facilities, resulting in **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Access to the west side of the proposed Sites Reservoir (including to the town of Lodoga) from the east side during construction of the South Bridge would be via the existing Maxwell Sites and Sites Lodoga roads (i.e., no change from the existing route). Access to the southern portion of Sites Reservoir during the construction of South Bridge would be via the existing Huffmaster Road (also no change from the existing route). Sulphur Gap Road would be constructed prior to the demolition and removal of the portion of Huffmaster Road that crosses the proposed Sites Reservoir footprint to maintain access to residences near the southern portion of the reservoir footprint and to the town of Leesville. Scheduling the construction of the South Bridge and Sulphur Gap Road early in the Project construction period, thus maintaining access within and across Antelope Valley, would allow emergency service providers to maintain acceptable response times during Project construction. Consequently, there would be no need for new or physically altered governmental facilities to maintain response times, resulting in **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

During Project construction, traffic levels on local roads leading to all of the Project facilities would increase. This increased traffic could have an adverse effect on emergency service providers' ability to maintain acceptable response times during Project construction. However, construction traffic levels would not be expected disrupt emergency service response to the point that would require the construction of new facilities to maintain adequate response times, resulting in **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Construction of all of the Project facilities associated with implementation of Alternative A would require an estimated average workforce of 95 employees for the 10-year construction period. This temporary addition of people to the workforce is not expected to result in a substantial increase in demand for new or extended public services, or require additional schools. Similarly, Project operation and maintenance would require few permanent employees (35 employees), which would not be expected to result in a substantial increase in demand for public services or schools and therefore would not require new or altered governmental facilities. There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During construction, operation, and maintenance of Alternative A, adequate emergency access would be maintained to individual landowner properties located along routes to proposed Project facilities that are outside of the Sites Reservoir Inundation Area. Therefore, there would not be a need for new or altered government facilities, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of all of the Project facilities would result in the use of relatively few vehicles. This slight increase would not be expected to generate traffic levels that would interfere with emergency services. Consequently, there would not be a need for new or altered governmental facilities, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Because Sites Reservoir is expected to generate 360,975 RVDs per year during its operation, traffic is expected to increase on Maxwell Sites Road and County Roads 68, 69, and D during Project operation (primarily Fridays through Sundays during the recreation season) (refer to Chapter 26 Navigation, Transportation, and Traffic). This increase in traffic levels could adversely affect emergency response times. However, traffic levels would not be expected to disrupt emergency service response to the point that would require the construction of new facilities to maintain adequate response times, resulting in **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

The increased number of visitors to the area due to the development and presence of Sites Reservoir and the recreation opportunities that would be offered would likely increase the demand for fire protection, police protection, and emergency medical services. If demand were to increase substantially, existing government facilities may need to be expanded or new facilities may need to be constructed in order to maintain acceptable service ratios. However, the increased demand would be seasonal, and the emergency and law enforcement response to Sites Reservoir and associated Project facilities would be provided by numerous agencies and facilities. Depending on the location and type of service call, primary responsibility for response could fall under the jurisdiction of the Glenn or Colusa county sheriff's departments, municipal police departments, California Highway Patrol, U.S. Forest Service, CDFG, State Parks, CAL FIRE, city fire departments, volunteer fire departments or fire protection districts, or a combination thereof through mutual aid agreements. Given that the seasonal increase in service calls generated by the proposed Project would be spread among several agencies, the increased demand on public service providers is not expected to result in the need for new or altered governmental facilities to maintain adequate service ratios. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Local or Regional Utility Services

Construction of the Sites Reservoir Inundation Area and Sites Dam would eliminate the existing access to the communication tower array on Logan Ridge (southeast side of the proposed Sites Reservoir). However, an alternate new road (Com Road) would be constructed outside of the reservoir footprint to allow continued maintenance access to the communication tower and therefore would not result in a disruption to this utility. This would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project construction ground-disturbing activities, such as excavation and trenching, have the potential to directly interrupt electrical, cable, and gas utilities. Activities associated with the Delevan and TRR pipeline installation and the construction of the foundations for the South Bridge and high voltage Delevan Transmission Line towers also have the potential to interrupt utilities. Disruptions of utility services resulting from intentional de-energizing of lines, relocation or modification of existing utility infrastructure, or from unintentional damage to utility infrastructure during Project construction, operation, or maintenance activities would likely be localized because the majority of electrical, cable, and communication lines in the Primary Study Area serve the local population. Potential infrastructure damage is expected to be repaired soon after discovery and reporting of the damage. Thus, disruption to utility services is not expected to continue for extended periods of time, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. A disruption to existing utilities, if it occurred for an extended period of time, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Construction of the Sites Reservoir Inundation Area and the associated Road Relocations and South Bridge is expected to disrupt operation of utilities and eliminate existing access roads at those facility locations. Within the Sites Reservoir Inundation Area (which includes the location of the South Bridge) and along several of the roads that comprise the routes to Project facility sites, there are buried and overhead cables and electric distribution lines. All parcels within the Sites Reservoir Inundation Area footprint would be acquired for the Project and the structures within the Reservoir Inundation Area would be demolished. Existing aboveground utility equipment would be removed as part of development of the Sites Reservoir (and underground utility equipment would be left in place). Operation of those utilities within the Sites Reservoir Inundation Area would, therefore, not be disrupted, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The footprint of the proposed Holthouse Reservoir would conflict with existing WAPA high-voltage 500-kV and 230-kV transmission lines. This conflict would require the relocation of eight transmission towers, resulting in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The proposed TRR and Delevan pipelines would cross an identified PG&E natural gas pipeline, as well as an existing PG&E high-voltage 230-kV transmission line. These crossings would be accomplished with the bore and jack construction method to avoid disruption of the gas pipeline and the transmission line towers. The proposed Delevan Transmission Line would also cross the existing natural gas pipeline and 230-kV transmission line. These crossings would be accomplished by siting transmission line towers away from the existing utilities, and maintaining required minimum clearances between the two transmission lines by using towers approximately twelve feet higher than the existing transmission towers. Although a disruption is not expected, if construction activities were to cause a disruption to either of these utilities, the disruption would result in a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The Project Buffer would surround the Project facilities; within that buffer, during Project construction, all existing structures and utilities would be removed and a perimeter fence would be installed. Because the buffer lands between the Project facility footprints and the buffer boundary would be acquired for the Project prior to the removal of utilities, there would be **no impact** on existing utilities that are currently located within that buffer area, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, operation and maintenance activities (i.e., fence maintenance and periodic boundary fuel break construction and maintenance) that would occur on the buffer lands between the Project facility footprints and the Project Buffer boundary would have **no impact** on existing utilities (because they would have been removed during Project construction), when compared to Existing Conditions and the No Project/No Action Alternative.

During Project construction activities, if any existing and currently unidentified utilities are discovered and Alternative A facilities would conflict with those utilities, the conflict would result in a **significant impact** on the utility, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operations and maintenance would have a **less-than-significant impact** on utilities, when compared to Existing Conditions and the No Project/No Action Alternative, because once the Project utilities are installed, conflicts with existing utilities are not expected.

Impact Services-2: A Decline in Property Tax or Fee Revenues that Would Lead to a Substantial Decrease in Public Services

Project-related land acquisition required for implementation of Alternative A would result in a decrease in property tax receipts in the Primary Study Area. The annual property tax amount that would be removed from the Glenn County annual tax revenues would be $28,428, or approximately 0.033 percent, of the overall revenues for Glenn County. The annual property tax amount that would be removed from the Colusa County annual tax revenues due to the Project would be $252,366, or approximately 0.415 percent, of the overall revenues for Colusa County. These annual tax revenue losses are not expected to affect funding to the point where it would substantially decrease public services, resulting in a **less-than-significant impact** to public services, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-3: Exceed the Wastewater Treatment Requirements of the Applicable Regional Water Quality Control Board

Project construction, operations, and maintenance of the proposed facilities included in Alternative A would not generate wastewater that would exceed Regional Water Quality Control Board requirements. During Project construction, portable toilets would be located at Project facility sites and would be serviced by an appropriate provider, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operations and maintenance, minimal wastewater would be generated by the Project, with the majority generated at the Recreation Areas, and smaller amounts generated at the staffed Field Office Maintenance Yard, TRR Pumping/Generating Plant, and Delevan Pipeline Intake Facilities. The Recreation Areas would have vault toilets, and the two recreation areas that would provide potable water would have their own water treatment systems. The Field Office Maintenance Yard would have its own septic system, and the TRR Pumping/Generating Plant and Delevan Pipeline Intake Facilities would have portable toilets. These Project facilities would, therefore, have **no impact** on wastewater treatment agencies' abilities to meet wastewater treatment requirements, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-4: The Need for Expansion of Existing Wastewater Treatment, Water Treatment, Stormwater, and/or Landfill Facilities

During Project construction of the proposed facilities included in Alternative A, portable toilets would be provided at all proposed facility construction sites. Water would be provided by truck (or from the Sacramento River for in-river or near-river construction activities). No stormwater facilities exist at the Project facility locations. At most of the Project facility sites, minimal construction debris would be generated because the sites are currently undeveloped. In addition, excavated materials are expected to be re-used during Project construction to the extent feasible. Construction debris from the demolition of existing structures and fencing within the Sites Reservoir Inundation Area and from demolition of existing structures within the footprints of other proposed Project facilities would be transported and disposed of at suitable landfills, and recycling of wood, metal, and other materials would occur. Adequate landfill capacity exists in the Primary Study Area to accommodate the construction debris that would be generated. Therefore, expansion of existing wastewater treatment, water treatment, and landfill facilities would not be needed, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operations and maintenance, wastewater and solid waste would be generated at the Recreation Areas (vault toilets would be installed there) and the Field Office Maintenance Yard (which includes an on-site septic system). Wastewater would also be generated at the TRR Pumping Generating Plant and the Delevan Pipeline Intake Facilities (portable toilets would be provided). Water treatment that would be needed at the two recreation areas that would provide potable water would have their own water treatment systems. Stormwater management is included in the Project to minimize erosion. The need to provide wastewater and solid waste utility services during Project operations and maintenance would not necessitate the expansion of existing local or regional wastewater treatment and/or landfill facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-5: Require New or Expanded Water Supply Entitlements and Resources

During Project construction of proposed facilities included in Alternative A, water that is needed at Project facility sites would be provided by truck (or from the Sacramento River for in-river or near-river construction activities). No new or expanded water supply entitlements and resources would be necessary for Project construction, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The Project's operations **and** maintenance would require new or modified water rights, water supply, and operating agreements. The specific conditions of these rights and agreements are not known at this time. It is anticipated that these rights and agreements would be formulated to protect existing beneficial uses associated with existing water rights, and that the action to obtain new or modified water rights, water supply, and operating agreements would be evaluated pursuant to the State's water rights laws. Therefore, there would be **a less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Services-6: Non-Compliance with Federal, State, and Local Statutes and Regulations Related to Solid Waste

Complying with federal, State, and local statutes and regulations pertaining to solid waste is not expected to be an issue for the Project because construction contractors would be required to dispose of construction waste in accordance with federal, State, and local regulations, as a requirement of the Project construction contract specifications. In addition, adequate landfill capacity exists in the Primary Study Area to accommodate the construction debris that would be generated. Therefore, would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operations, including trash removal at recreation areas and debris removal from boat ramps, reservoirs, and dam embankments, would not adversely affect solid waste facilities or transporters located in or serving the Primary Study Area because adequate capacity exists in existing local landfills and waste would be delivered to the landfills using appropriate transporters. In addition, Project operations would not restrict the facilities or transporters from complying with federal, State, and local solid waste regulations. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

29.3.7 Impacts Associated with Alternative B

29.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**); property tax or fee revenues affecting public services (**Impact Services-2**); wastewater treatment requirements of the applicable Regional Water Quality Control Board (**Impact Services-3**); the need to expand existing wastewater treatment, water treatment, stormwater, and/or landfill facilities (**Impact Services-4**); water supply entitlements and resources (**Impact Services-5**); and compliance with federal, State, and local solid waste statutes and regulations (**Impact Services-6**); would be the same as described for Alternative A for the Extended and Secondary study areas.

29.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public services and utilities:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

Alternative B includes the construction of a 1.81-MAF reservoir. The increased reservoir size necessitates the addition of two saddle dams and the movement of various associated Project features. The Alternative B Delevan Transmission Line would differ from Alternative A. Alternative B includes no transmission line alignment between the Sacramento River and the WAPA/PG&E transmission line. The transmission line would be approximately three miles long, from the proposed Sites Electrical Switchyard to the WAPA/PG&E transmission line. The Alternative B Road Relocations and South Bridge would differ slightly from those included for Alternative A. The lengths of the saddle dam access roads included in Alternative A would be reduced in Alternative B because the dams would be larger and would be located closer to the main roads. In addition, an extension of an access road would be constructed for Alternative B to provide access from Saddle Dam 3 to saddle dams 1 and 2. Alternative B would replace the Delevan Pipeline Intake Facilities with the Delevan Pipeline Discharge Facility. The Delevan Pipeline would be operated as a release-only pipeline, so the associated Delevan Pipeline Discharge Facility would, therefore, not include a fish screen or any of the facilities needed for the pumping and generating operations that are included for Alternative A.

However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**); property tax or fee revenues affecting public services (**Impact Services-2**); wastewater treatment requirements of the applicable Regional Water Quality Control Board (**Impact Services-3**); the need to expand existing wastewater treatment, water treatment, stormwater, and/or landfill facilities (**Impact Services-4**); water supply entitlements and resources (**Impact Services-5**); and compliance with federal, State, and local solid waste statutes and regulations (**Impact Services-6**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**); property tax or fee revenues affecting public services (**Impact Services-2**); wastewater treatment requirements of the applicable Regional Water Quality Control Board (**Impact Services-3**); the need to expand existing wastewater treatment, water treatment, stormwater, and/or landfill facilities (**Impact Services-4**); water supply entitlements and resources (**Impact Services-5**); and compliance with federal, State, and local solid waste statutes and regulations (**Impact Services-6**) as described for Alternative A.

In addition to the changes in Project facility locations and sizes mentioned above, Alternative B would result in fewer RVDs at Sites Reservoir than for Alternative A (358,049 RVDs for Alternative B versus 360,975 RVDs for Alternative A). However, this difference in recreation use would have the same physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**) as described for Alternative A.

29.3.8 Impacts Associated with Alternative C

29.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**); property tax or fee revenues affecting public services (**Impact Services-2**); wastewater treatment requirements of the applicable Regional Water Quality Control Board (**Impact Services-3**); the need to expand existing wastewater treatment, water treatment, stormwater, and/or landfill facilities (**Impact Services-4**); water supply entitlements and resources (**Impact Services-5**); and compliance with federal, State, and local solid waste statutes and regulations (**Impact Services-6**); would be the same as described for Alternative A for the Extended and Secondary study areas.

29.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public services and utilities:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline

- Delevan Pipeline Electrical Switchyard

The Delevan Transmission Line and Delevan Pipeline Intake Facilities included in Alternative C are the same as those included in Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public services and utilities as described for Alternative A.

The Sites Reservoir Inundation Area and Dams and Road Relocations and South Bridge included in Alternative C are the same as included in Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to public services and utilities as described for Alternative B.

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**); property tax or fee revenues affecting public services (**Impact Services-2**); wastewater treatment requirements of the applicable Regional Water Quality Control Board (**Impact Services-3**); the need to expand existing wastewater treatment, water treatment, stormwater, and/or landfill facilities (**Impact Services-4**); water supply entitlements and resources (**Impact Services-5**); and compliance with federal, State, and local solid waste statutes and regulations (**Impact Services-6**) as described for Alternative A.

In addition to the comparisons of Project facilities mentioned above, Alternative C would result in more RVDs at Sites Reservoir than for Alternative A (373,659 RVDs for Alternative C versus 360,975 RVDs for Alternative A). However, this difference in recreation use would have the same physical impacts associated with new or physically altered governmental facilities or the need for new or physically altered governmental facilities (the construction of which could cause significant environmental impacts) in order to maintain acceptable service ratios, response times, or other performance objectives for public services and disruptions to local or regional utility services (**Impact Services-1**) as described for Alternative A.

29.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 29-9 for the impacts that have been identified as significant or potentially significant.

Table 29-9
Summary of Mitigation Measures for
NODOS Project Impacts to Public Services and Utilities

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Services-1: A Substantial Adverse Physical Impact Associated with the Provision of New or Physically Altered Governmental Facilities or the Need for New or Physically Altered Governmental Facilities (the Construction of which could cause Significant Environmental Impacts) in order to Maintain Acceptable Service Ratios, Response Times, or Other Performance Objectives for the Following Public Services: Fire Protection, Police Protection, Schools, Parks, and/or Other Public Facilities, and Disruptions to Local or Regional Utility Services				
Impact Services 1a: Damage to or Disruption of Existing Utility Services	All Project Facilities	Significant	Mitigation Measure Services-1a: Avoid Damage to or Disruption of Existing Utility Services	Less than Significant
Impact Services-1b: Project Facility Siting Impacts to Utilities				
500-kV and 230-kV Transmission Lines	Holthouse Reservoir (construction)	Significant	Mitigation Measure Services-1b: Perform Utility Relocation or Modification	Less than Significant
Gas Pipeline and 230-kV Transmission Line	Delevan Pipeline, TRR Pipeline, and Delevan Transmission Line(construction)	Significant	Mitigation Measure Services-1a: Avoid Damage to or Disruption of Existing Utility Services	Less than Significant
Impact Services 1c: Project Facility Conflicts with Currently Unidentified Utility Systems	All Project Facilities	Significant	Mitigation Measure Services-1a: Avoid Damage to or Disruption of Existing Utility Services	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Services-1a: Avoid Damage to or Disruption of Existing Utility Services

To minimize impacts to utility service providers by damage or disruption caused by the Project's construction, operation, and/or maintenance, DWR and Reclamation shall implement the following measures during Project construction to minimize impacts to existing utility infrastructure (whether it is currently identified or is discovered during Project construction):

- **Permits:** The Construction Contractor shall obtain utilities excavation or encroachment permits, as necessary, before initiating any work with potential to affect utilities.
- **Locating Line:** Utility locations shall be identified through field surveys and the use of the Underground Service Alert services. Any buried utility lines shall be clearly marked before initiation of any ground-disturbing construction activity.

- **Clearing Right-of-Way and Road Access:** If necessary, infrastructure shall be removed or reinforced in coordination with all potential service providers known to have, or potentially having, utility infrastructure in the vicinity of the Project facility.
- **Response Plan (Construction):** The Construction Contractor shall prepare a Response Plan to address potential accidental damage to utility infrastructure prior to the start of Project construction. The Response Plan shall identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and workers. The Response Plan shall be circulated to the potentially affected service system providers for review and approval prior to the start of the construction activities. Worker education training in response to such situations shall be conducted by the Contractor.
- **Response Plan (Operation and Maintenance):** DWR and Reclamation shall prepare a Response Plan to address potential accidental damage to utility infrastructure prior to the start of Project operation. The Response Plan shall identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and Project facility personnel. The Response Plan shall be circulated to the potentially affected service system providers for review and approval prior to the start of Project operation. Worker education training in response to such situations shall be conducted by DWR and Reclamation or such party that they designate.

Mitigation Measure Services-1b: Perform Utility Relocation or Modification

For each section of a utility line that would need to be relocated or modified as a result of Project construction and/or operation, DWR and Reclamation shall implement the following measures:

- **Permits:** The Construction Contractor shall obtain utilities excavation or encroachment permits, as necessary, before initiating any work with potential to affect utility lines.
- **Locating and Staking Line:** Locations for relocated utility lines shall be identified in coordination with affected service providers. As part of this effort, field surveys shall be conducted and the Underground Service Alert services shall be used to ensure that there are no conflicts with other existing utility lines. After the alignment of the line has been determined, a survey shall be conducted to map the route of the line. The results of the survey shall be plan and profile drawings, which shall be used to spot the poles and/or towers. After exact positions have been fixed, a stake shall be driven to indicate the center of the structure or pole.
- **Utilities Modification and Relocation Plan:** The Construction Contractor shall prepare a Utilities Modification and Relocation Plan prior to the start of Project construction. The Utilities Modification and Relocation Plan shall identify chain of command rules for notification of authorities and appropriate actions and responsibilities to ensure the safety of the public and workers and include a description of how utilities infrastructure shall be modified or relocated and identification of precise alignment where utility lines shall be relocated. The Utilities Modification and Relocation Plan shall be circulated to the potentially affected service system providers for review and approval prior to the start of the Project construction activities. Worker education training in response to such situations shall be conducted by the Construction Contractor.
- The Construction Contractor shall stage utility line modifications and relocations in a manner that minimizes interruption of service.

- The Construction Contractor shall follow local, State, and federal regulations regarding utilities and service systems location and construction to minimize potential disruption of services and damage to the utilities and service system infrastructure.

Implementation of **Mitigation Measure Services-1a** and **Services-1b** would reduce the level of significance of Project impacts to **less-than-significant**.

30. Visual Resources

30.1 Introduction

This chapter describes the visual resources setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Visual resources include the natural and artificial landscape features that contribute to perceived visual images and the aesthetic value of a view.

The regulatory setting for visual resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

30.2 Environmental Setting/Affected Environment

30.2.1 Introduction

Visual resources consist of the natural and artificial features that create the perceived visual character and sensitivity of a landscape. Several factors are considered when characterizing the existing visual resources of the study areas to help determine the degree to which those resources or landscapes may be affected by the Project. The principal existing visual factors considered in this analysis are defined below and include: Visual Quality, Viewer Types and Volumes, Viewer Exposure, and Visual Sensitivity.

Visual Quality is defined as the overall visual impression or attractiveness of an area as determined by the particular landscape characteristics, including landforms, rock forms, water features, and vegetation or land use patterns. The attributes of vividness (power or memorability of landscape components), intactness (integrity and freedom of landscape from encroaching elements), and unity (coherence and harmony of landscape as a whole) contribute to the overall visual quality of an area (FHWA, 1988).

For the purposes of this analysis, visual quality is defined according to three levels:

- **Low –** defined as visual resources that are indistinctive, and generally lacking in cohesiveness and natural or cultural visual resource amenities typical of the region
- **Moderate** – defined as visual resources typical or representative of the region's natural and/or cultural visual amenities
- **High** – defined as visual resources that are distinctive or exemplary of the region's natural or cultural scenic amenities

Viewer Types and Volumes of use pertain to the types (i.e., public viewers including recreationists and motorists) and amounts (i.e., number of recreationists or motorists) of use that various land uses receive. Land uses that derive value from the quality of their settings are considered potentially sensitive to changes in visual setting conditions. Land uses within the Project area that may be sensitive to change in visual conditions include designated scenic highways, designated scenic roads, and designated park, recreation and natural areas.

Viewer Exposure addresses the variables that affect viewing conditions from potentially sensitive areas. Viewer exposure considers the following factors:

- **Landscape visibility:** Whether the line of sight is open and panoramic to the Project facility sites or is restricted by terrain, vegetation, and/or structures.
- **Viewing distance:** The proximity of viewers to the Project. Viewing distances are described according to whether the Project activities would be viewed within the foreground (within 0.5 mile), middleground (0.5 to 2.0 miles), or background (beyond 2.0 miles) zone.
- **Viewing angle:** Whether the Project would be viewed from above (superior), below (inferior), or from a level (normal) line of sight. Viewing angle and extent of visibility considers the relative location of the Project facility to the viewer and whether visibility conditions are open, or are limited by intervening vegetation, terrain, or structures.
- **Number of viewers:** How many viewers would see the Project facilities.
- **Duration of view:** How long (days, hours, or minutes)] that viewers would see the Project facilities.

Visual Sensitivity is a combined measurement of the overall susceptibility of an area or viewer group to adverse visual or aesthetic impacts, given the combined factors of landscape visual quality, viewer types, and exposure conditions (FHWA, 1988).Visual sensitivity is reflected according to high, moderate, and low visual sensitivity ranges. The viewer groups for the Project can be classified as three types:

- **Residents:** Residents are considered to be a sensitive viewer group because of the Project’s long-term presence and the sensitivity with which people typically regard their places of residence. Residents are also considered to have frequent opportunities to experience the views from their homes, and view duration can be lengthy. Residents in the vicinity of Project facilities have views of varying landscapes and quality.
- **Recreationists:** Recreationists are considered to be a sensitive viewer group because they generally value and are more aware of the aesthetic quality of their surroundings than commuters or people at work. Their focus is usually on their surroundings while they are engaging in recreational activities. Individual views can be of an extended duration, although they may be limited in frequency. In addition, the recreation activity they are engaging in is usually enhanced by their surroundings. Recreation areas in the vicinity of the Primary Study Area include East Park Reservoir, the Delevan National Wildlife Refuge, and the Sacramento River and shoreline near the proposed Delevan Pipeline Intake Facilities. There are several State Recreation Areas and designated wildlife refuges within the Secondary and Extended study areas.
- **Motorists:** Motorists are considered to have lower sensitivity than residents and recreationists because views from the roadway are fleeting and short-term, are partially obstructed by the vehicle, and the drivers’ attention is primarily concentrated on maneuvering the vehicle on the roadway. It is acknowledged that scenic driving for pleasure is a valid recreational activity and the sensitivity of such viewers has not been ignored in this analysis. However, because of the short view time, the distraction that would occur from the actual driving activity and the obstructed views within vehicles, these travelers (drivers and passengers) are not considered highly sensitive viewers. The viewshed

from within vehicles sitting higher off the ground, such as commercial trucks, is greater than from passenger vehicles, but it is still of relatively short duration and can be partially obstructed by the vehicle itself. Portions of the Primary Study Area would be located within the viewshed of motorists on the I-5, Old Highway 99W, SR 45, Maxwell Sites Road, and several county roads.

30.2.2 Extended Study Area

The visual landscape for the Extended Study Area[1] is extremely varied; the area includes State and federal service areas providing water supply delivery to agricultural, industrial, and municipal water uses, and several wildlife refuges.

Availability, amount, and source of water supply for delivery by the CVP and SWP for the purpose of agricultural, industrial, and municipal water uses varies annually, and depends on several factors, including:

- Natural seasonal variability in weather and precipitation
- Ongoing implementation of agency programs and management plans, which cause a change (reduction or increase) in exports, allocation, or peak diversion rates

Due to this variability, it is complex to characterize a stable baseline visual resources environmental setting, or link an individual action to a change in visual resources, for the service areas within the Extended Study Area. Land uses in these areas vary considerably, depending on the location and include agricultural, municipal and industrial, commercial, open space, grazing, and timber production. Of these uses, agriculture dominates the Extended Study Area, therefore, much of the visual resources in the Extended Study are associated with active agricultural land and the conveyance systems that provide water service throughout the State, as well as the rural residences and towns, and the auxiliary structures associated with agricultural practice.

The Extended Study Area includes San Luis Reservoir, which is located approximately 170 miles southeast of the Primary Study Area in Merced County. San Luis Reservoir provides short-term offstream storage for water taken from the Sacramento-San Joaquin Delta, and is used to regulate distribution through the California Aqueduct. The reservoir is part of the San Luis Reservoir State Recreation Area, which provides recreational opportunities such as fishing, boating and camping to the public (Reclamation and CDPR, 2012). The existing visual environment of the areas surrounding San Luis Reservoir is hilly grassland interspersed with stands of oak trees and scrub habitat. San Luis Reservoir is drawn down annually, typically between March and the end of August. Because of the annual draw down, the aesthetic character of the reservoir is seasonal and depends primarily on annual precipitation; during Dry to Critical years, low water levels in the reservoir can expose wide areas of barren shoreline. During Normal to Wet years, higher water levels in the reservoir support riparian and upland vegetation, which is generally considered by recreationists to be a scenic vista of high aesthetic value. State Route (SR) 152 in Merced County is an officially designated State Scenic Highway that follows the northern shoreline of San Luis Reservoir for approximately 6 miles, offering extended views of the waterbody and its surroundings (Caltrans, 2012).

The Extended Study Area includes several other reservoirs operated within the SWP and CVP service areas and along the California Aqueduct. The most notable among them include the Tri-Dam Reservoir

[1] The Extended Study Area is defined as the portions of the CVP and SWP service areas that could be affected by Project operations, located within 39 counties

Complex (New Hogan, Comanche, and Pardee reservoirs), New Melones Reservoir, Don Pedro Reservoir, Lake McClure, Pyramid Lake, Castaic Lake, Silverwood Lake, and Lake Perris. These other reservoirs provide recreational opportunities to thousands of visitors each year. Because of the variability in annual precipitation, the existing visual quality of these reservoirs is seasonal and can range from moderate to high.

Level 4 wildlife refuge water supply delivery areas that could be affected by Project operations are located within the Extended Study Area. These delivery areas are described in Chapter 1 Introduction and shown in Figure 1-7 in Chapter 1 Introduction. The existing environmental settings of the wildlife refuges included in the Extended Study Area are of high visual quality, because they consist of vast undisturbed lands that include wetlands, grassland, and riparian areas with high biodiversity.

30.2.3 Secondary Study Area

The Secondary Study Area is defined as the CVP and SWP reservoirs, rivers, creeks, and associated floodplains that could be affected by Project operations, located in 22 counties (14 of the 22 counties are also located in the Extended Study Area). The individual waterbodies included in the Secondary Study Area are considered to be scenic resources of high visual quality, and are listed below:

- Trinity Lake
- Lewiston Lake
- Trinity River
- Klamath River (downstream of Trinity River)
- Whiskeytown Lake
- Spring Creek
- Shasta Lake
- Keswick Reservoir
- Clear Creek
- Sacramento River
- Lake Oroville
- Thermalito Complex (Diversion Pool, Forebay, Afterbay)
- Feather River
- Sutter Bypass
- Yolo Bypass
- Folsom Lake
- Lake Natoma
- American River
- Sacramento-San Joaquin Delta
- Suisun Bay
- San Pablo Bay
- San Francisco Bay

Several State Recreation Areas are located along the lakes, reservoirs, and rivers, and provide ample recreational opportunities and scenic views of open water and natural vegetation to recreationists, residents, and motorists. There are several State-designated scenic highways with views of the Secondary Study Area waterbodies (Caltrans, 2012).

The Sacramento River flows between the Cascade, Coast Range, and Sierra Nevada ranges through the Central Valley. Throughout the year, the volume of water in the Sacramento River varies greatly, accounting for some degree of visual change in the river. The Red Bluff Pumping Plant (RBPP) (Photo 26 on Figure 30-2Q), which is included in the Secondary Study Area, is located on the Sacramento River approximately two miles southeast of the City of Red Bluff, in Tehama County. The RBPP site's existing visual character is highly developed on the generally scenic Sacramento River. To the west of the RBPP, the area is characterized by suburban, industrial, and transitioning agricultural land uses. Across the Sacramento River to the east of the RBPP, the area is characterized by the open natural vegetation of the Red Bluff Recreation Area, beyond which lies agricultural and rural residential land uses. There are no State-designated highways in the viewshed of the RBPP.

30.2.4 Primary Study Area

30.2.4.1 Visual Environment

<u>Regional Landscape Description</u>

Glenn County

Glenn County's landscape consists of urban development in relatively flat land that is associated with small cities and towns (e.g., Orland, Willows, Hamilton City, and Artois), rural residences beyond the borders of the communities, undeveloped open space, agricultural land (crops and orchards), industrial and highway commercial land uses along the I-5 corridor, and recreation areas (Black Butte Reservoir, Sacramento River, wildlife areas, and wildlife refuges). Away from the town centers, fewer roadways exist, and public access to lands is limited.

The western portion of the county consists of hilly forested terrain and oak woodlands. In the lowlands, the landscape is characterized by grassland and woodland vegetation, with occasional wetlands, vernal pools, and riparian areas. The attributes of the landscape change over the course of a year in response to seasonal changes and weather. Vegetation, agricultural crops, and land use patterns vary according to the time of year and farming activities. For instance, the grasslands and cultivated areas of the county are a lush green in spring and early summer; as the hot weather continues, the grasslands turn a honey-brown hue, and the crops mature.

Water features in Glenn County include Black Butte Reservoir, which provides flood protection for local towns and agricultural lands. It is located on Stony Creek west of the City of Orland and the Sacramento River, which, in places, forms the county's eastern border with Butte County.

Although Glenn County contains numerous areas and viewsheds with relatively high scenic value, there are no officially designated scenic vista points. Scenic resources include the Sacramento River and streams, foothill and mountain areas, agricultural landscapes on the valley floor, the Sacramento National Wildlife Refuge, glimpses of wildlife, and a distant view of Mount Lassen. The Glenn County General Plan identifies twelve important biological resource areas in Glenn County that are of outstanding scenic value. Six of the areas (Llano Seco Unit of the Upper Butte Basin Wildlife Area, Oxbow Waterfowl Area, Oxbow Heron Rookery, Princeton Riparian Woodland, Sacramento River Wildlife Area, and Sacramento River Oxbow Preserve) are associated with the Sacramento River and are intended to protect the unique riparian forest, marsh, and floodplain bordering the Sacramento River. Two of the areas (St. Johns Mountain and Sheetiron Mountain) are within the Mendocino National Forest. The remaining areas are the Sacramento National Wildlife Refuge, Black Butte and Stony Gorge reservoirs, and Orland Buttes (Glenn County, 1993).

There are no eligible or State-designated scenic highways within Glenn County (Caltrans, 2012); however, SR 45 and SR 162 have been recommended for scenic highway status due to the presence of many unofficial scenic vistas of the features listed above. It has also been suggested that SR 32 and County Road 99W be considered for scenic highway status (Glenn County, 1993).

The visual quality of Glenn County is moderate to high due to the expansive open space provided by the Yolla Bolly, Middle Eel, and Snow Mountain designated wilderness areas in the west, aforementioned biological resource areas, large agricultural areas, and the undeveloped upland areas on the west. Existing sources of light and glare in the County include residential, agricultural, commercial and industrial development, vehicles traveling on roadways, and safety lighting on tall structures, such as transmission towers and cell towers.

Colusa County

Colusa County's landscape includes urban development in relatively flat terrain. Cities and small towns, such as Williams, Colusa, Arbuckle, Princeton, Stonyford, and Maxwell, exist along the major transportation corridors (I-5 and the state highways in the county). Land uses include the rural residences beyond the borders of the communities, undeveloped open space, agricultural land (crops and orchards), industrial and highway commercial land uses along the I-5 corridor, and recreation areas (several wildlife refuges and the Sacramento River). Away from the town centers, fewer roadways exist, and public access to lands is limited.

The western portion of the county is typified by the undulating hills of grassland and oak woodland terrain which transition to rugged Klamath and North Coast mountain ranges reaching elevations in excess of 7,000 feet above the valley floor. In the lowlands, the landscape is characterized by grassland, agricultural and rural landscapes, with occasional wetlands, vernal pools, and riparian areas. The agricultural landscape is dominated by crops (e.g. rice, almonds, vegetables, tomatoes, wheat, hay), rangeland livestock, and other ancillary facilities including outbuildings, tractors, irrigation, and drainage works. Vegetation, agricultural crops, and land use patterns vary according to the time of year and farming activities. For instance, the rangelands and cultivated areas of the county are a lush green in spring and early summer; as the hot weather continues, the grasslands turn a honey-brown hue, and the crops mature.

Although Colusa County contains numerous areas and viewsheds with relatively high scenic value, there are no officially designated scenic vista points in the County. Scenic resources and unofficial scenic vistas include features, such as the Sacramento River, Snow Mountain, Sutter Buttes, Mendocino National Forest, Colusa National Wildlife Refuge, Delevan National Wildlife Refuge, Sacramento National Wildlife Refuge, Willow Creek-Lurline Wildlife Management Area, North Central Valley Wildlife Management Area, Colusa Bypass Wildlife Area, Sacramento River Wildlife Area, Colusa-Sacramento State Recreation Area, as well as the vast agricultural lands located throughout the County (Colusa County, 2011).

There are no officially designated scenic highways or scenic corridors in Colusa County (Caltrans, 2012). However, there are two Eligible State Scenic Highway Corridors in Colusa County that have not yet been officially designated: SR 20 in the southwest between the county line and the junction of SR 20 and SR 16, and SR 16 between the county line and the aforementioned junction (Colusa County, 2011).

The general visual quality of Colusa County is moderate to high due to the expansive open space provided by the large agricultural areas, water features (including rivers, lakes, reservoirs, and wetlands), and the undeveloped upland areas on the west. Existing sources of light and glare include residential, agricultural, commercial and industrial development, vehicles traveling on roadways, water features, and safety lighting on tall structures, such as transmission towers and cell towers.

Project Viewshed

The visual sphere of influence (SOI) for the Project represents the area from which the Project has the potential to be visible. Beyond the SOI, a project's features would not be easily visible due to screening, or would be of such a small size in the background field of view that significant impacts to visual resources would not be expected. Depending on the location of the viewer, views toward the proposed Sites Reservoir could be blocked by intervening terrain, trees, shrubs, or other features in the viewer's immediate foreground. For this project, hills that would form the outer boundaries of the proposed reservoir are considered to also form the visual SOI for the Sites Reservoir. The SOI for the other Project facilities would vary because of the screening effects of minor variations in terrain, adjacent development, or vegetation, which would limit views of the facilities. The Project viewshed for the three alternatives was determined by mapping a one-mile buffer around Project facilities. This viewshed is considered sufficient given the topography of the study areas, the height and massing of Project facilities, and the number and location of sensitive receptors in the study areas. Additionally, the adopted General Plans of Glenn and Colusa counties each encourage the preservation of existing agricultural land uses and containment of growth and development to urban infill and revitalization within existing towns and cities (Colusa County, 2012; Glenn County, 1993).

Project Facility Footprints Landscape Description

Figures 30-1A to 30-1D show the locations of the proposed Project facilities and where landscape character photographs were taken when conducting Project site visits. They also show the direction that the camera was pointed when taking the photographs. Figures 30-2A to 30-2U are landscape character photos that are intended to aid the reader in understanding the nature of the area in which the Project would be constructed, operated, and maintained. Descriptions of the landscapes at and adjacent to the proposed Project facility footprints are provided below.

Sites Reservoir Inundation Area

The affected environment of the Sites Reservoir Inundation Area is the same for the two proposed reservoir sizes (and all three alternatives). The landscape of the proposed inundation area is characterized by moderate to low elevation and northwest-southeast trending ridgelines, and separated by valleys of varying steepness and width. Ridgelines surrounding the proposed reservoir rise to between approximately 500 and 1,200 feet above mean sea level. Overall, the visual quality of the proposed reservoir inundation area is considered high because the natural foothills landscape has been largely preserved and unaltered. Visual sensitivity is moderate to high because scenic views from the proposed inundation area can be extensive in duration and consist of a mixture of low-lying rangeland, active agricultural development and livestock in the foreground, hilly grasslands in the middleground, with occasional views of densely vegetated ridgelines and hillsides in the background to the west.

The rural town of Sites is located within the proposed reservoir inundation area (Figures 30-2B and 30-2C). The town consists of a concentrated grouping of 13 rural residences and peripheral structures including fences, sheds, garages, barns, silos, pump houses and water towers, flat agricultural land, and mature vegetation including native and ornamental trees. South of the town of Sites, the proposed inundation area consists predominantly of low-lying grassy rangeland interspersed with a few rural residences and peripheral structures, and oak trees. North of the town, the lowland transitions to hilly rangeland, with a few farmed parcels, rural residences, peripheral structures, and interspersed wetlands at lower elevations. In total, approximately 26 houses, 31 barns, 27 sheds, 4 shops, and 20 other peripheral structures are located within the proposed inundation area.

There are no State-designated scenic highways within or near the proposed Sites Reservoir Inundation Area (Caltrans, 2012). However, Maxwell Sites Road and Sites Lodoga Road, which traverse the proposed inundation area from southeast to northwest, have been recommended for scenic designation

(Colusa County, 1989). Viewers of the proposed reservoir inundation area are limited to residents and motorists who travel on those roadways.

Predominantly unpaved dirt roads provide access to residences and farming operations within the proposed inundation area. Automobiles traveling along the unpaved roads generate large plumes of dust visible from a distance of up to 1 mile. Existing sources of light and glare are associated with residences and peripheral structures, and the automobiles that use the roads. The proposed Sites Reservoir Inundation Area is shown in Figures 30-2A through 30-2C.

Sites Reservoir Dams

Sites Reservoir would require the construction of several dams; seven saddle dams are proposed for Alternative A and nine saddle dams are proposed for Alternatives B and C; Golden Gate Dam and Sites Dam are proposed for Alternatives A, B, and C. The dam locations for Alternatives A, B, and C are of high visual quality due to the presence of several distinctive rock outcroppings, and undisturbed and abundant vegetation. There are no State-designated scenic highways near or with views of the proposed dam locations (Caltrans, 2012), nor are there existing sources of light or glare. Viewers of the proposed dam locations are limited to motorists along the county roadways and are typically of short duration due to area terrain; therefore, visual sensitivity is low to moderate.

Golden Gate Dam would be constructed between two hillsides approximately two miles northeast of the town of Sites. The existing landscape consists of rolling grassland and vegetated rocky steppes, with several tree snags located in the lowland area. The proposed Golden Gate Dam location is shown in Figures 30-2D and 30-2E.

Sites Dam would be constructed between two steep hillsides approximately 0.3 mile east of the town of Sites upon a 0.25-mile-long section of the existing Maxwell Sites Road. The landscape of the north-facing right abutment location is densely vegetated with oak woodland and other native tree species. The landscape of the south-facing left abutment is predominantly rocky outcroppings and grassland, interspersed with a few oak trees. The proposed Sites Dam location is shown in Figures 30-2E and 30-2F.

Saddle dams would be located between hilltops along the northeastern boundary of the proposed reservoir. The existing landscape generally consists of gently rolling hills vegetated with non-native grasses. Figures 30-2F and 30-2G provide a representative view of the existing landscape at the proposed saddle dam locations.

Recreation Facilities

Up to five recreation areas are proposed for Alternatives A, B, and C. The recreation facility locations are of high visual quality with many scenic views of the open grassy lowlands, and surrounding rolling hills and oak woodlands. There are no State-designated scenic highways near or with views of the proposed recreation areas (Caltrans, 2012), nor are there existing sources of light or glare. Visual sensitivity is moderate because viewers of the recreation areas are limited to residents and users of the existing county roadways. These viewers have the opportunity for extended views of the recreation area locations from Huffmaster Road and Peterson Road. There are no public views of the proposed recreation facilities from outside of the proposed inundation area. The visual character of the individual proposed recreation areas is described below (Table 30-1), and photos of the Saddle Dam, Peninsula Hills, Stone Corral, Antelope Island, and Lurline Headwaters recreation areas are included as Figures 30-2A, 30-2H, 30-2I, 30-2J, and 30-2K.

Table 30-1
Visual Character of the Proposed Recreation Areas

Figure No.	Recreation Area	Location*	Size (acres)	Existing Visual Character
30-2H	Stone Corral	Central East	235	Hilly grasslands with scattered oak tree stands
30-2I, 30-2J	Peninsula Hills	Northwest	373	Hilly oak woodlands interspersed between open rolling grasslands
30-2J	Antelope Island	Southwest	49	Hilly oak woodlands
30-2K	Lurline Headwaters	Southeast	219	Low-lying open grasslands interspersed with areas of hilly oak woodlands to the west
30-2A	Saddle Dam	Northeast	329	Gently rolling open grasslands with interspersed seasonal wetland areas

*Relative to proposed Site Reservoir Inundation Area.

Road Relocations and South Bridge

The proposed Sites Reservoir would inundate several roads within Colusa County's jurisdiction, including portions of Maxwell Sites Road, Sites Lodoga Road, Huffmaster Road, and Peterson Road. Approximately 44 miles of new public access roads and approximately two miles of new private access roads would provide construction and maintenance access to Project facilities, as well as provide public access to proposed recreation areas. There are no State-designated scenic highways near or with views of the proposed road relocations and South Bridge (Caltrans, 2012). Views of the proposed road relocations and South Bridge alignment are of high visual quality due to the abundance of open grasslands in the foreground, transitioning to rolling hills and oak woodlands in the middle- and background. Visual sensitivity is low and views are brief because viewers of the road relocations and south bridge alignment are limited to motorists along existing roads. Existing sources of light and glare include vehicles using the existing system of roads.

The portions of Maxwell Sites and Sites Lodoga roads that would be inundated by the proposed reservoir would be replaced by the proposed South Bridge serviced by approach roads from the east and west. This route would also provide access to the proposed Stone Corral Recreation Area. The existing visual character of the proposed South Bridge location traversing west from the eastern access route is dominated by rolling grasslands through the central proposed inundation area to the western terminus of the bridge. A representative view of the proposed South Bridge alignment is provided in Figure 30-2K. The western South Bridge route transitions into oak woodland and winds through approximately 2.25 miles of moderately variable topography to rejoin the existing Sites Lodoga Road.

The proposed North Road and Saddle Dam Road (both new gravel roads) would provide access to northern portions of the reservoir, the saddle dams, and the Saddle Dam Recreation Area. North Road would be improved beginning at the intersection of the existing County Road 69 and the Tehama-Colusa Canal on the east, and would follow the route of County Road 69 through hilly grassland for approximately 4.6 miles to its western terminus. The new route would then be extended west for approximately 1.8 miles through rolling grasslands interspersed with small intermittent wetlands. Saddle Dam Road would be aligned north to south for approximately two miles through similar terrain if Alternative A is implemented, and three miles if Alternatives B or C are implemented. Two residences and four peripheral structures would be demolished that are located along the North Road access route and within the Project Buffer. Public views of the existing County Road 69 are limited due to varying topography. There are no existing public views of the new segment of the North Road or Saddle Dam Road locations.

The proposed Eastside Road would connect the proposed Stone Corral Road to County Road 69, providing access to the northern portion of the reservoir, Holthouse Reservoir Complex, Golden Gate Dam and appurtenant structures, and to properties northeast of the proposed reservoir. Eastside Road and Stone Corral Road would be aligned north to south along the grassy ridgelines between the proposed reservoir inundation area on the west and the existing upland agricultural areas on the east. The proposed Eastside Road location is visible from Maxwell Sites Road on the south and County Road 69 on the north.

Along the western side of the proposed reservoir, the proposed Peninsula Road would provide access from Sites Lodoga Road to the Peninsula Hills Recreation Area. Peninsula Road would generally traverse from east to west, winding sharply through hilly oak woodland and grassland.

The proposed Sulphur Gap Road would provide access to southern portions of the proposed reservoir, the proposed Lurline Headwaters Recreation Area, private property adjacent to the proposed Com Road (shown in Photo 33 on Figure 30-2U), and connect to Huffmaster Road. Sulphur Gap Road would traverse in a generally northeast-to-southwest direction beginning in the low-lying rangeland on the east, through hilly grassland and moderately steep oak woodland, and intersecting with Huffmaster Road in the grassy rangeland at the southern tip of the proposed reservoir inundation area.

Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

The Sites Inlet/Outlet Structure would consist of separate inlet and outlet structures connected by an approximately 0.8-mile tunnel. The inlet structure would be located on the ridgeline south of the proposed Golden Gate Dam, and the outlet structure would be located adjacent to, and would connect with, the existing Funks Reservoir. The electrical switchyard would be located north of the outlet structure. The tunnel, switchyard, and outlet structure would be located in an open hilly grassland area and rolling rangeland. The Field Office Maintenance Yard would be constructed on 18 acres southwest of and adjacent to the existing Funks Reservoir. One existing rural residence and two auxiliary structures are located in the footprint of the proposed outlet structure. Utilitarian features in the landscape include electrical distribution lines, poles, and fences. Views of the proposed facility locations are of high visual quality due to the presence of open hilly grasslands with limited development. Views from the area are obstructed by ridgelines, which focus views on the natural character of the hills in the foreground. Visual sensitivity is low because public views of this area are limited and brief due to varied topography. There are no State-designated scenic highways near or with views of the proposed intake/outlet structure and ancillary facilities (Caltrans, 2012). Existing sources of light and glare include the existing residence and vehicles using the existing Funks Reservoir maintenance roads. The existing visual character of the Outlet Structure and Pumping/Generating Plant locations is shown in Figure 30-2L. The existing visual character of the Field Office Maintenance Yard location is shown in Figure 30-2M.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would be located east of and adjacent to the existing Funks Reservoir, T-C Canal, and private service road in an area of gently rolling hills vegetated with non-native grasses and scrub on the west, transitioning to flat active agricultural land on the east. The existing Funks Reservoir water levels fluctuate annually and seasonally.

At full capacity, the approximately 230-acre reservoir is a water feature of high visual quality. During Dry years and late summer months, the water retreats to expose a barren shoreline of moderate visual quality. The area surrounding Funks Reservoir consists mainly of non-native grasses. The existing reservoir outfall to Funks Creek bisects the area and is lined with riparian trees and shrubs. The proposed Holthouse Reservoir location is traversed from north to south by parallel 500-kV and 230-kV WAPA electrical transmission lines on lattice towers. There are no State-designated scenic highways or vista points near, or with views of, the proposed Holthouse Reservoir Electrical Switchyard or the Holthouse Reservoir Complex facilities (Caltrans, 2012). Views of the proposed facility locations are of moderate to high visual quality due to the presence of a seasonal water feature amidst an area with scattered utility structures. Viewers of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard area are limited to operations and maintenance staff for the existing Funks Reservoir roads and facilities, and workers in the adjacent orchards and agricultural fields; therefore, although views can be of extended duration, visual sensitivity is low to moderate. Existing sources of light and glare include Funks Reservoir facilities, vehicles using the existing service roads, and nighttime safety lighting on transmission towers. Figure 30-2N provides a view of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard location from the existing Funks Reservoir near Funks Creek and the Funks Dam spillway. The existing Funks Reservoir is shown in Figure 30-2M.

Glenn-Colusa Irrigation District Canal Facilities Modifications

The Glenn-Colusa Irrigation District (GCID) Canal Facilities Modifications would include construction of a new headgate structure, concrete lining of the canal for 200 feet downstream of the new headgate structure, and replacement of a railroad siphon. The new headgate structure and canal lining would be completed within a portion of the GCID Canal that is bounded on the northeast by existing GCID maintenance facilities and orchards, and on the southwest by low density industrial development, agricultural fields, single-family rural residences, and constructed wetlands. The proposed GCID Canal Headgate Structure and Canal Lining location is shown in Figure 30-2O.

The railroad siphon replacement would be constructed at the intersection of the GCID Canal and the railway on the southeast boundary of the town of Willows. The visual setting of the area is characterized by predominantly residential and light industrial land uses to the north and west, and agricultural to the south and east. The location of the GCID Canal Railroad Siphon Replacement is shown in Figure 30-2P.

These two areas are of low to moderate visual quality due to the conspicuous presence of infrastructure and industrial development amidst the low-density residential and agricultural development typical of communities in the region. Visual sensitivity is moderate due to the large number of potentially sensitive viewers in the vicinity in conjunction with limited views and low to moderate visual quality.

The topography in both areas is generally flat. Views toward the east and west beyond the facilities are obstructed by orchards and urban development, which focus views on the utilitarian character of the canal upstream and downstream of the proposed improvements. There are no State-designated scenic highways or scenic vistas in the vicinity of the proposed improvements (Caltrans, 2012). Existing sources of light and glare include nearby residential and industrial development, vehicles on nearby roads, and the existing GCID facilities.

Terminal Regulating Reservoir, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

The TRR, Pumping/Generating Plant, and Electrical Switchyard would be located in an area of existing flat agricultural fields between McDermott Road on the east and the GCID Canal on the west. There are rural residences, farms, and auxiliary structures with views of the area. The 3.5-mile-long bidirectional TRR Pipeline and TRR Pipeline Road would be constructed between the TRR Pumping/Generating Plant southwest to the Holthouse Reservoir Spillway and Stilling Basin. The Delevan Pipeline Electrical Switchyard would be located where the existing PG&E transmission line crosses the proposed TRR Pipeline. The GCID Canal Connection to the TRR would connect the existing canal to the east side of the proposed reservoir. The TRR to Funks Creek Pipeline would connect the proposed reservoir to the existing creek to the south of the TRR location (Figure 30-2Q). Because of the minimal topographic variation within the agricultural region, views are fairly homogeneous in form, texture, and color. Foreground views are typically composed of large areas of flat agricultural land interspersed with farm roads, canals and associated infrastructure, tree clusters, electric distribution lines and poles, and occasional rural residences. The proposed facility locations are of moderate visual quality and sensitivity, because despite the homogeneity of views and the obvious imprint of humans upon the landscape, the area retains an open-space character due to the presence of agricultural crops, stands of native plants, and the minimal number of permanent structures. Views of the proposed facility location range from brief to extended, because the area is adjacent to several county roads used by motorists, existing rural residences, and agricultural fields.

Views from the proposed TRR location are of moderate visual quality and are relatively unobstructed. Looking northwest from the southeast corner of the proposed TRR facility location (Figure 30-2R), the 31-acre Colusa Generating Station is visible in the background approximately 2.5 miles away. There are public views of the facility location from adjacent residences, McDermott Road on the east, and Lenahan Road on the southeast. Utilitarian features in the middleground and background include electric distribution lines and poles, high-voltage lattice transmission structures, and fences. There are no State-designated scenic highways near or with views of the proposed TRR, pipeline alignment, and auxiliary facilities (Caltrans, 2012). Existing sources of light and glare include existing residences, the Colusa Generating Station, and vehicles traveling on the existing agricultural access roads.

Delevan Pipeline and Delevan Transmission Line

For all three alternatives, the proposed Delevan Transmission Line would be aligned east from the Sites Pumping/Generating Plant to the existing PG&E or WAPA transmission line. This segment of the Delevan Transmission Line would cross rolling rangeland transitioning into flat agricultural land. For Alternatives A and C, the Delevan Transmission Line would continue from the PG&E or WAPA transmission line for approximately 10 miles east to the proposed Delevan Pipeline Intake Facilities along the Sacramento River. For all three alternatives, the Delevan Pipeline would be aligned from the proposed Holthouse Spillway and Stilling Basin and parallel the TRR Pipeline east to the TRR Pumping/Generating Plant. The Delevan Pipeline would then parallel the Delevan Transmission Line route to the Sacramento River. The eastern segments of the transmission line and pipeline would traverse flat agricultural land interspersed with county roads, rural residences, farms, and industrial land uses; I-5, Old Highway 99W, SR 45, and railroad tracks. The proposed alignment would be located approximately 200 yards north of the boundary of the Delevan National Wildlife Refuge. The proposed pipeline and transmission line alignment is of moderate visual quality and sensitivity, due to the presence of primarily rural and agricultural land uses that are representative of the region. Several viewer types have views of the pipeline and transmission line alignment. Motorists traveling southbound on I-5, Old Highway 99W, SR 45, and county roads would have very brief views of the alignment, and motorists traveling westbound on Delevan Road and Lenahan Road would have views of moderate duration, and area residents and recreational users of the Delevan National Wildlife Refuge could have views of extended duration. There are no State-designated scenic highways near or with views of the proposed facilities (Caltrans, 2012). Existing sources of light and glare include vehicles on county roads, Old Highway 99W, SR 45, I-5, residences, and agricultural facilities. The alignment for the proposed Delevan Pipeline and Transmission Line facilities is shown in Figures 30-2S and 30-2T.

Delevan Pipeline Intake/Discharge Facilities

The Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility would be located on the western riverbank of the Sacramento River, downstream from the existing Maxwell Irrigation District Pumping Plant. The existing pumping plant is a large industrial facility that is of low visual quality. The surrounding visual setting is characterized by the Sacramento River and the associated riparian habitat along its levees. The Sacramento River and its generally undeveloped riverbanks are considered a scenic resource, and are of moderate to high visual quality because the river is lined by a variety of sandy shorelines, riparian vegetation, steep rocky riverbanks, and levees. There are no State-designated scenic highways near or with views of the proposed facility location and there are no existing sources of light or glare (Caltrans, 2012). Views of Sacramento River from the west are obstructed by the levee. Access to the Project facility location is restricted to Maxwell Irrigation District employees only, and views from the east are limited to recreationists and agricultural landowners. Therefore, visual sensitivity is low and views are generally brief. The proposed location of the Delevan Pipeline Intake/Discharge Facilities is shown in Figure 30-2U.

Project Buffer

The Project Buffer would surround all of the Primary Study Area Project facilities, except for the Delevan Pipeline and Transmission Line, TRR Pipeline and Road, Delevan Pipeline Electrical Switchyard, TRR to Funks Creek Pipeline, and portions of the other Project roads. The existing visual setting within a given area of the Project Buffer would, therefore, be the same as that described for the Project facilities that would be located within that area.

30.3 Environmental Impacts/Environmental Consequences

30.3.1 Regulatory Setting

Visual resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

30.3.1.1 Federal Plans, Policies, and Regulations

- National Scenic Byways Program

30.3.1.2 State Plans, Policies, and Regulations

- Delta Protection Act of 1992
- California Department of Transportation State Scenic Highway Program

30.3.1.3 Regional and Local Plans, Policies, and Regulations

- Tehama County General Plan
- Glenn County General Plan
- Colusa County General Plan

30.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the environmental thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for aesthetics:

Would the Project:

- Have a substantial adverse effect on a scenic vista?
- Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a State scenic highway?
- Substantially degrade the existing visual character or quality of the site and its surroundings?
- Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- A substantial adverse effect on a scenic vista.
- Substantial damage to scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a State scenic highway.
- Substantial degradation of the existing visual character or quality of the site and its surroundings.
- A new source of substantial light or glare which would adversely affect day or nighttime views in the area.

30.3.3 Impact Assessment Assumptions and Methodology

30.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to visual resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.

- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.
- Construction activities are anticipated to occur between the hours of 6:00 a.m. and 7:00 p.m. Monday through Friday. Nighttime and weekend construction are not planned, but may occur on an as-needed basis.

30.3.3.2 Methodology

The visual resources assessment is a multistep process, including:

- Defining baseline visual resources by:
  - Determining the visual environment of the Extended, Secondary, and Primary study areas
  - Characterizing the visual resources within the three study areas
  - Identifying viewer groups, viewpoints, exposures, sensitivities, and anticipated responses to those resources
- Describing the visual change that is expected from Project construction and operation
- Determining the degree of visual impact by considering:
  - The consistency of the visual changes from the Project with the Tehama, Glenn, and Colusa county general plans
  - The compatibility of the visual changes from the Project with the nearby landscape; whether the Project would substantially degrade the existing visual quality of the Project facility sites or their surrounding landscapes
  - The number of people who would have views of the proposed facilities, their typical sensitivity to landscape change, and the duration of their views
  - Whether a scenic vista, scenic highway, or a scenic resource would be affected
  - Whether Project facilities would introduce a new source of substantial light or glare which would adversely affect day or nighttime views in the area
- Developing mitigation for significant or potentially significant identified impacts on visual resources

The degree of visual impact depends on how perceptible the adverse change is. The perception of a visual impact is a function of the Project features, context, and viewing conditions (angle, distance, and typical viewing direction). The visual impact levels used in this analysis indicate the relative degree of change to the landscape that each alternative would create by considering visual sensitivity, visual contrast, project dominance, view impairment, and consistency with county General Plan policies.

Visual Sensitivity

The quality of the visual experience depends on the visual resources and the viewer response to those resources. When characterizing visual sensitivity, the following must be considered: the type of viewer group; the viewer exposure (their location, number of people in group, and duration and frequency of their view); and viewer profile (viewer activity, awareness, and values). For each of the viewer groups identified in the Project area, viewer exposure conditions were determined based on knowledge of the Project facility areas, review of aerial imagery, and site visits.

Visual Contrast

Visual contrast is a measure of the degree of change in line, form, color, and texture[2] that the Project would create, when compared to the Existing Conditions. Visual contrast ranges from “none” to “high”, and is defined as:

- *None* – The element contrast is not visible or perceived
- *Low* – The element contrast can be seen but does not attract attention
- *Moderate* – The element contrast begins to attract attention and dominate the characteristic landscape
- *High* – The element contrast attracts the viewer’s attention and cannot be overlooked

Project Dominance

Visual dominance is a measure of the Project feature’s perceived size relative to other visible landscape features in the viewshed. A Project facility’s dominance is determined by its relative location in the viewshed and the distance between the viewer and facility. The level of dominance can range from subordinate to dominant.

View Impairment

View impairment or blockage is a measure of the degree to which Project facilities would obstruct or block views to scenic resources due to the Project’s position and/or scale. Blockage of scenic resources or views can cause adverse impacts, especially in instances where scenic resources are essential to the use, value, or function of the land use.

Determination of Impact Significance

The determination of impact significance is based on combined factors of Visual Sensitivity and the Degree of Visual Change that the Project would cause. The relationship between these two overall factors in determining whether adverse visual impacts would be significant is shown in Table 30-2.

[2] The *form* of an object is its visual mass, bulk, or shape. *Line* is introduced by the edges of objects or parts of objects. The *color* of an object is both its value or reflective brightness (light, dark) and its hue (red, green). *Texture* is apparent surface coarseness (FHWA, 1988).

Table 30-2
Visual Impact Significance Summary

Visual Sensitivity	Visual Change: Low	Low to Moderate	Moderate	Moderate to High	High
Low	Less than Significant	Less than Significant	Less than Significant	Less than Significant	Less than Significant
Low to Moderate	Less than Significant	Less than Significant	Less than Significant	Less than Significant	Potentially Significant
Moderate	Less than Significant	Less than Significant	Less than Significant	Potentially Significant	Potentially Significant
Moderate to High	Less than Significant	Less than Significant	Potentially Significant	Potentially Significant	Significant
High	Less than Significant	Potentially Significant	Potentially Significant	Significant	Significant

Notes:

Less than Significant impacts are perceived as negative but are considered minor in the context of existing landscape characteristics, and view opportunity.

Potentially Significant impacts are perceived as negative and may exceed environmental thresholds depending on Project- and site-specific circumstances. Impacts may be reduced to less than significant with implementation of mitigation.

Significant impacts may or may not be reduced to less-than-significant levels with implementation of feasible mitigation, and could exceed environmental thresholds.

Adapted from Reclamation, CCWD, and WAPA, 2009.

30.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

30.3.5 Impacts Associated with the No Project/No Action Alternative

30.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, San Luis Reservoir, and Other Reservoirs

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to visual resources has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on visual resources, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to result in more municipal and industrial development throughout the three study areas, resulting in landscape changes to the study areas. The projects that are included in the No Project/No Action Alternative would already have been in place for most of the Project analysis period; as a result, the future population that chooses to relocate near the projects included in the No Project/No Action Alternative would not experience new visual resource impacts. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Historically, agricultural, municipal (including recreational water use at the reservoirs in the Extended Study Area), and industrial water use depends on several natural and human-induced variables. This trend is expected to occur into the future. The annual and seasonal variation in water use is typical and gradual, and is not expected to substantially impact visual resources. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Due to the commitments set forth in the Central Valley Project Improvement Act (CVPIA), water deliveries to the Wildlife Refuges are expected to remain as-is in most cases if the No Project/No Action Alternative is implemented. Therefore, **there would not be a substantial adverse effect**, and there may be a **potentially beneficial effect,** on overall visual resources within the wildlife refuges, when compared to Existing Conditions, because a stable water supply would support existing wetland habitat.

No new sources of light would be introduced in the Wildlife Refuges as a result of potential changes in wildlife refuge water usage. Increased water supply to the refuges would increase the potential for daytime glare from water surface areas. However, this potential increase would be marginal and not readily noticeable to recreationists using the refuges. Therefore, **there would not be a substantial adverse effect** on day or nighttime views in the area, when compared to Existing Conditions.

Project operational modeling for Existing Conditions at the San Luis Reservoir indicates that drawdown would vary less in summer months than observed historically due to the implementation of agency programs and management plans that would cause a reduction in exports, allocation, or peak diversion rates. Water levels for the No Project/No Action Alternative would be higher than for Existing Conditions due to recent drawdown reductions and would be less variable than recorded historically. Therefore, **there would not be a substantial adverse effect**, and there may be a **potentially beneficial effect,** on scenic vistas from the No Project/No Action Alternative, when compared to Existing Conditions, because the reservoir would, on average, maintain higher water levels, which would help to preserve or improve its high scenic quality.

No new sources of light would be introduced at San Luis Reservoir. A more stable water level in the reservoir may increase the potential for daytime glare from the water surface while reducing potential glare from exposed rock and barren shoreline during summer months. However, these changes would not be readily noticeable to recreationists using the San Luis Reservoir Recreation Area. Therefore, **there would not be substantial adverse effect** on daytime views in the area, when compared to Existing Conditions.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on scenic resources.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to sources of light or glare.

30.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for visual resources impacts has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on visual resources, when compared to Existing Conditions.

These Secondary Study Area waterbodies are operated pursuant to the same statutory regulations for both the No Project/No Action Alternative and Existing Conditions. In addition, the Secondary Study Area has historically experienced a wide range of reservoir storage levels and diversion rates, making it relatively complex to model future conditions.

Flows within the Sacramento River and through the Sacramento-San Joaquin Delta are highly regulated and are influenced by several factors: runoff from precipitation and snowmelt; natural variation; upstream water storage facilities; water diversions for agricultural, municipal, and industrial purposes; agricultural and municipal discharges; and a flood damage reduction system that includes levees, floodplains (the Yolo, Sutter, and Colusa bypasses), and weirs. Sacramento River and Delta flows vary substantially on a seasonal and annual basis. Seasonally, flows in the river may vary as a result of runoff from local tributaries and releases from the major water storage reservoirs, as well as diversions by agricultural, municipal, and other users. From year to year, river flows vary according to precipitation, the volume of carryover storage in reservoirs, and releases to downstream water users (SWRCB and CalEPA, 2010).

Although the above-listed reservoirs and rivers may experience marginal changes in reservoir storage levels and river flow rates as a result of implementation of projects and programs included in the No Project/No Action Alternative, they would not fall outside of the historical ranges of operation, and would, therefore, not visibly impact aesthetic resources. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Folsom Lake and Lake Natoma are the smallest of the upstream reservoirs in the Secondary Study Area. Significant urban development and population growth is predicted in the American River Basin through 2050 (DOF, 2007). Full urban contract deliveries to meet this need would cause a reduction in Folsom Lake storage levels if the No Project/No Action Alternative is implemented. Increased reservoir drawdown would have the potential to adversely impact visual resources at Folsom Lake by exposing wide portions of barren shoreline during the summer months and dry years. The No Project/No Action Alternative, therefore, **would have a potentially substantial adverse effect** on scenic vistas at Folsom Lake and Lake Natoma, when compared to Existing Conditions.

The Suisun, San Pablo, and San Francisco bays are large regional systems that do not respond dynamically to changes in flow due to the implementation of individual projects or management programs. No changes to visual resources are, therefore, expected if the No Project/No Action Alternative is implemented. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

SR 160 is a national and State-Designated Scenic Highway with extensive views along the Sacramento River and Sacramento-San Joaquin Delta (Caltrans, 2012). However, potential changes to flows in the Sacramento River and Delta if the No Project/No Action Alternative is implemented would not fall outside of historical operational ranges, and therefore, would not adversely impact visual resources. Except for the Sacramento River and Sacramento-San Joaquin Delta, there are no designated scenic highways in the vicinity of the reservoirs and rivers in the Secondary Study Area. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

No new sources of light would be introduced at the Secondary Study Area facilities if the No Project/No Action Alternative is implemented. Unstable and decreased water levels in the reservoirs may decrease the potential for daytime glare from water surface areas while increasing potential glare from exposed rock and barren shoreline during summer months. However, these changes would be gradual and would not be easily noticeable to recreationists visiting the recreation areas. Therefore, **there would not be a substantial adverse effect** on daytime views within the Secondary Study Area from implementation of the No Project/No Action Alternative, when compared to Existing Conditions.

30.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

The No Project/No Action Alternative assumes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to visual resources has been addressed in those environmental documents. Projects included in the No Project/No Action Alternative are not located within the Primary Study Area; therefore, **there would not be a substantial adverse effect** on visual resources in that study area, when compared to

Existing Conditions. In addition, the Project would not be constructed if this alternative is implemented; therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. In addition, projects considered within the No Project/No Action Alternative are not located within the viewshed of a State-designated scenic highway, and would, therefore, have **no impact** on scenic resources.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to sources of light or glare.

30.3.6 Impacts Associated with Alternative A

30.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, and Industrial Water Use

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There would be no direct Project-related construction or maintenance activities in the Extended Study Area; therefore, Alternative A would have **no impact** on visual resources in this area, when compared to Existing Conditions and the No Project/No Action Alternative. Proposed Project operational activities would result in improvement in surface water supply reliability for agricultural, municipal, and industrial users. It is improbable that improved water supply reliability would induce or change substantial agricultural land use changes or municipal and industrial water consumption patterns to the degree that would impact visual resources in the Extended Study Area. There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on scenic resources.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to sources of light or glare.

Wildlife Refuge Water Use

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

No direct Project-related construction or maintenance activities would occur in the Extended Study Area. The wildlife refuges that would receive Level 4 water supplies would receive the same amount of supply with implementation of Alternative A as with the No Project/No Action Alternative; however, the source of a portion of the supply would change.

Refer to the **Impact Vis-1** discussion for the No Project/No Action Alternative. There would be no adverse effect, resulting in **no impact** (and a **potentially beneficial effect**) from Alternative A, when compared to Existing Conditions.

When compared to the No Project/No Action Alternative, implementation of Alternative A would result in **no impact** because the wildlife refuge water use would remain the same.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on scenic resources.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to sources of light or glare.

San Luis Reservoir

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

No direct Project-related construction or maintenance activities would occur in the Extended Study Area. Direct Project-related operational effects at San Luis Reservoir would, however, result if Alternative A is implemented. San Luis Reservoir is a reregulating reservoir used to regulate distribution and meet delivery commitments to SWP and CVP contractors and is not intended for long-term storage. Drawdown of San Luis Reservoir is projected to increase with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative; however, projected levels would not be outside of the historical range. This would, therefore, be a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. State Designated Scenic Highway 152 follows the northern shore of San Luis Reservoir for approximately six miles. However, because projected reservoir water levels with implementation of Alternative A would remain within the historical range, there would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

No direct Project-related construction or maintenance activities would occur in the Extended Study Area, resulting in no new sources of artificial light. Project effects on San Luis Reservoir operation would not require the installation of new sources of artificial light. Decreased water levels in the reservoir would decrease the potential for glare from water surface areas and increase the potential for glare from the bare exposed shorelines. However, the potential change in water levels would be within the historical range, and would not be easily noticeable to recreationists. This would be considered a **less-than-significant** impact on day or nighttime views in the area, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Reservoirs

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

No direct Project-related construction or maintenance activities would occur in the Extended Study Area. All other reservoirs on the California Aqueduct are operated in a narrow range to reregulate the flows in the canals and to provide emergency storage if there is a failure in the conveyance system. These reservoirs are not operated in response to allocations or San Luis Reservoir operating conditions. There would, therefore, be **no impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on scenic resources.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to sources of light or glare.

30.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

No direct Project-related construction or maintenance activities would occur in the Secondary Study Area waterbodies listed above. Implementation of Alternative A would result in increased storage within the reservoirs of the Secondary Study Area, particularly in Critical and Dry years. Operationally, Alternative A would also result in a general increase and stabilization in flows within rivers and creeks within the Secondary Study Area. The overall increase in flows and storage, however, would not be outside of the historical range for the system, and would, therefore, not be visibly obvious to residents, recreationists, or motorists in the vicinity of these waterbodies. There would, therefore, be **no impact** (and **potentially beneficial effect)**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on scenic resources.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to effects on the existing visual character of a site and its surroundings.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. That discussion is also applicable to sources of light or glare.

Pump Installation at the Red Bluff Pumping Plant

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

The only direct Project-related construction that would occur in the Secondary Study Area is related to the installation of an additional pump at the RBPP. The existing visual character of the Sacramento River at the RBPP appears industrially developed. The construction of an additional pump within an existing concrete bay, followed by its operation and maintenance, would not substantially degrade the visual character of the area, nor impair the existing viewshed around the RBPP. Additionally, although the

Tehama County General Plan considers the Sacramento River to be a scenic resource, the pump installation and operation would be consistent with General Plan Policy OS-11.4 which states that "new development should be designed to be compatible with surrounding development in ways that contribute to the desired character of the surrounding area," (Tehama County, 2009).There would, therefore, be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the GCID Canal Intake and the Red Bluff Pumping Plant. The existing visual character would not be degraded by increasing the frequency and intensity of dredging at the RBPP nor are there any designated scenic vistas in the vicinity of the facility. The existing visual character at the GCID Canal Facilities is highly developed, and maintenance activities in and around the facility are common. Increasing the frequency or intensity of dredging at the GCID Canal Intake would not substantially degrade the existing visual quality of the site, nor adversely affect a scenic vista. Additionally, there are no Glenn County General Plan policies which would be relevant to the maintenance of the GCID Canal Intake. There would, therefore, be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-1** discussion. There are no State scenic highways within the vicinity of the RBPP or GCID Canal Intake; therefore, there would be no impact to scenic resources within a State scenic highway at these locations. In the greater Sacramento River region, there would be also be **no impact** (and **potentially beneficial effect**), when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. There would be **no impact** (and **potentially beneficial effect**), when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. In addition, pump installation at the RBPP would be consistent with Tehama County General Plan Policy OS-11.4a which states that "new development shall include provisions for the design of outdoor light fixtures to be directed/shielded downward and screened to avoid adverse night-time lighting spill-over effects on adjacent land uses and night-time sky glow conditions," (Tehama County, 2009). There would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

30.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County or Glenn County; therefore the proposed Sites Reservoir would be consistent with the Colusa County 2030 General Plan and the Glenn County General Plan (Colusa County, 2012; Glenn County, 1993). The existing Antelope Valley (Sites Reservoir Inundation Area) is of high visual quality due to its many panoramic landscapes of open, hilly grasslands and oak woodlands from existing roads and residences. Construction of Alternative A would require the demolition of all structures within the proposed inundation area, including houses, barns, sheds, shops, and others auxiliary structures. Additionally, vegetation removal activities would degrade existing scenic views of the valley floor. Although Project-related changes to the landscape could become less visible over time, there would be brief views of these modifications during construction by motorists on portions of Lurline Road and Huffmaster Road, which would provide detoured vehicle access between Maxwell and Lodoga during construction. During the construction of Sites Reservoir, the area is expected to be of moderate visual quality despite the removal of trees and other vegetation, the presence of construction equipment, and the potential for fugitive dust generation, because the remaining open grasslands would remain largely intact.

The initial filling of the reservoir would occur over several years, during which time the area would transition from open grasslands to deepening wetlands which may attract birds and other regional riparian species. During this time, the inundation area would be of moderate to high visual quality. The construction and initial filling of Sites Reservoir would be considered a temporary impact, and would, therefore, have a **less-than-significant impact** on scenic vistas within the site, when compared to Existing Conditions and the No Project/No Action Alternative.

Upon completion of the initial filling of the reservoir, the full Sites Reservoir would convey the aesthetic of a large natural lake during Normal to Wet years. The operational reservoir inundation area during this time would be unique and visually dominant due to largely uninterrupted views of the waterbody and surrounding vegetated hillsides. During Dry years and in some summer months, the reservoir water supply would be drawn down to meet Project purposes. During periods of substantial drawdown, the shores and reaches of the inundation area would be unvegetated. The area would be visible by motorists from the proposed South Bridge and relocated road system, and by recreationists at the proposed recreation areas located around the reservoir, resulting in moderate to high visual sensitivity. If Alternative A is implemented, visual change would be high because the Sites Reservoir Inundation Area would be of high visual contrast, when compared to Existing Conditions. During Normal to Wet years, the reservoir would, however, also be of high visual quality due to its distinctive nature and visibility to a greater number of motorists and recreationists, when compared to Existing Conditions. Scenic views of the upland areas would be maintained, and new scenic views across the expansive reservoir would be created. During Dry to Critical years and some late summer months, the existing visual character of the area would temporarily deteriorate to a low to moderate visual quality. If Dry to Critical conditions were to last for several years, there is the potential for substantial degradation of the existing visual quality. Therefore, when compared to Existing Conditions and the No Project/No Action Alternative, there would be a **potentially significant impact**.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

No State-designated scenic highways are aligned near or through the Sites Reservoir Inundation Area. When compared to Existing Conditions and the No Project/No Action Alternative, there would, therefore, be **no impact** from construction, operation, and maintenance of Alternative A.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. Colusa County 2030 General Plan Policy CC 1-15 requires that the rural landscape be preserved and enhanced as an important scenic feature of the County. In addition, Policy OSR 1-5 states that "new development should be designed and constructed to preserve open space features such as scenic corridors, wetlands, riparian vegetation, native vegetation, trees and natural resource areas where feasible and appropriate," (Colusa County, 2012). Glenn County General Plan Policy NRP-16 also requires that grazing land be retained in large contiguous areas of the foothills (Glenn County, 1993). The proposed Sites Reservoir would impact grazing land and many open space features, and therefore, would be inconsistent with General Plan policies of Colusa and Glenn counties. When compared to Existing Conditions and the No Project/No Action Alternative, there would be a **potentially significant impact**.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Construction of Sites Reservoir would create new temporary sources of reflective daytime and nighttime glare. Construction activities would include the removal of all human-made structures and trees from the proposed inundation area. Areas of exposed earth would create potential sources of daytime glare prior to the filling of the reservoir. Construction equipment and workers' vehicles could also be a temporary source of reflective daytime glare. Colusa County 2030 General Plan Policy OSR 1-14 requires that development "Reduce light and glare from artificial lighting within open space and agricultural areas to the extent that it does not adversely impact the County's rural character," (Colusa County, 2012). Additionally, Glenn County General Plan Policy NRP-86 requires projects to "avoid light and glare impacts when considering development," (Glenn County, 1993). Construction activities during early morning and evening hours could require the use of construction lighting at individual Project facility work sites in areas that previously had no source of artificial lighting. Therefore, conditions during construction may be inconsistent with the General Plans of Colusa and Glenn counties. However, no sensitive receptors (residents and recreationists) would have views of the construction sites, and motorists would have only brief views of some of the construction areas from Lurline Road and Huffmaster Road in the southern portion of the inundation area. In addition, construction activities would be temporary. Therefore, new sources of light or glare due to Project construction would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The permanent conversion of a vegetated landscape to a 1.27-MAF reservoir would introduce a substantial new potential source of daytime and nighttime glare in the area. In addition, new sources of light and glare would result from the introduction of recreational boat use in the reservoir. When compared to Existing Conditions and the No Project/No Action Alternative, due to the permanent new source of glare created by the reservoir, this impact is considered **potentially significant**.

Sites Reservoir Dams

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County; therefore, the proposed Sites Reservoir Dams would be consistent with the Colusa County 2030 General Plan and the Glenn County General Plan. Construction of the nine dams proposed as part of Alternative A would require the removal of vegetation and several large rock formations, which would degrade existing scenic views of the hilly grassland and rocky outcrops. These changes would be visible during construction; however, public views of the dam locations during construction would be partially obstructed by the terrain and limited to motorists along Eastside Road, which would not be included in the detour route for Maxwell Sites Road and Sites Lodoga Road. The construction of the dams would occur over several years, during which time the visual character is expected to be of low visual quality due to the presence of construction equipment and materials, and the removal of vegetation within the dam footprints. The dam construction would be considered a temporary impact, and would, therefore, result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The proposed dams would be constructed as earthfill embankment dams, and are designed to be constructed primarily of excavated on-site soil and rock. Although the dams would be large features, the use of largely on-site earthen materials for the proposed dams would generate low visual contrast for viewers while in operation and cause them to be visually subordinate to the proposed reservoir and its surroundings. Additionally, views of the proposed dams would be largely obstructed due to the area terrain and limited in duration to motorists on the relocated roads. The overall visual change would be low to moderate, and visual sensitivity would be low. Therefore, when compared to Existing Conditions and the No Project/No Action Alternative, construction and operation of the proposed dams would result in a **less-than-significant impact**.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to Sites Reservoir Dams.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. In addition, the proposed Sites Reservoir Dams would be consistent with Colusa County General Plan Policy OSR 1-5 as supported by the **Impact Vis-1** discussion. There are no Glenn County General Plan policies which would be relevant to the construction, operation, or maintenance of the Sites Reservoir Dams. Therefore, there would be **a less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

The construction of Golden Gate Dam, Sites Dam, and seven saddle dams would create new temporary and permanent sources of reflective daytime glare and nighttime lighting. Building materials used to construct the dams may have the potential to be reflective under natural and artificial light. Construction equipment and vehicles could also be a temporary source of reflective daytime glare.

Construction activities during early morning and evening hours would require the use of lighting at Project work sites for several years. In addition, operation and maintenance of the dams may require new sources of permanent safety lighting. Views of the proposed dams and their associated operations and maintenance activities would, however, be largely obstructed due to the area terrain and limited in duration to motorists on the relocated roads. The proposed dams would not require the installation of highly visible artificial lighting, and therefore, would be consistent with Colusa County General Plan Policy OSR 1-14 and Glenn County General Plan Policy NRP-86. Overall visual change would be moderate; however, because visual sensitivity would be low, the impact of new sources of light and glare is considered a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County or Glenn County; therefore, the proposed Recreation Areas would be consistent with the Colusa County 2030 General Plan and Glenn County General Plan. Construction of the proposed Recreation Areas would require grading and the removal of some vegetation for the construction of roads and facilities such as the restrooms, campsites, and picnic areas. However, construction would not be intensive because the natural character of the recreation areas would be generally maintained. These changes would be visible during construction; however, public views of the recreation area locations during construction would be partially obstructed by the terrain and limited to motorists along the proposed detour route. The construction of the recreation areas would occur over several years, during which time the visual character is expected to be of moderate visual quality due to the presence of construction equipment and materials within the proposed recreation areas footprints. Construction of the recreation areas would be considered a temporary impact, and would, therefore, have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of the proposed Recreation Areas would offer new recreation opportunities in scenic lakeside and island settings consistent with the Colusa County General Plan, and create viewing opportunities that do not currently exist. During Above Normal and Wet years, the aesthetic quality of the proposed Sites Reservoir and its surroundings would be high and result in a **beneficial effect** to scenic resources due to increased access to high quality views. During Dry to Critical years, drawdown of the reservoir could begin in early spring and continue through late summer. During this substantial reservoir drawdown, the shores along the proposed reservoir would be unvegetated, and temporarily degraded to a lower visual quality, but no change to the visual quality of the recreation areas would occur. Although the visual sensitivity of visiting recreationists would be moderate to high, the overall visual change would be low. Therefore, when compared to Existing Conditions and the No Project/No Action Alternative, this would result in a **less-than-significant impact**.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Recreation Areas.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. In addition, the proposed Recreation Areas would be consistent with Colusa County 2030 General Plan Policy CC 1-15 and Glenn County General Plan Policy NRP-16. Therefore, when compared to Existing Conditions and the No Project/No Action Alternative, this would result in a **less-than-significant impact**.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

The construction up to five Recreation Areas would create new temporary sources of reflective daytime and nighttime glare. Recreational facility structures, roadways, and roadway fixtures, such as safety barriers, have the potential to be reflective under natural and artificial light. Construction equipment and workers' vehicles could also be a temporary source of reflective daytime glare. Construction activities during early morning and evening hours would require the use of lighting. Construction lighting would be temporary, and therefore, would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. New sources of permanent nighttime lighting would be required for safety purposes in the recreational areas. In addition, new sources of light and glare would be introduced by operations and maintenance vehicles, recreationists' vehicles, boats, and campfires in the recreation areas. Therefore, operation of the proposed Recreation Areas has the potential to be inconsistent with Colusa County 2030 General Plan Policy OSR 1-14 and Glenn County General Plan Policy NRP-86. When compared to Existing Conditions and the No Project/No Action Alternative, this impact is considered **potentially significant.**

Road Relocations and South Bridge

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County or Glenn County; therefore, the proposed Road Relocations and South Bridge would be consistent with the Colusa County 2030 General Plan and Glenn County General Plan. Alternative A would require the construction of approximately 44 miles of new public access roads, and improvements to several existing paved and gravel roads. The construction of new roads and improvement of existing roads, and the maintenance of Project roads would temporarily degrade the scenic views from and visual character of the area due to the presence of construction equipment and workers, removal of vegetation, and generation of dust. During operation, views of the new roadways would generally be seen at a shallow viewing angle, and would appear similar to other county roads in the region, and therefore would be of low visual contrast. The road relocations would neither permanently block nor impair views of surrounding landscape, and would generally be visible only by motorists using these roads. Construction of the proposed relocated roads, road improvements, and the presence of the roads would not degrade any existing scenic vistas from or near the area. Visual sensitivity of motorists using the new roads would be low and the visual change would also be low, therefore, the proposed road relocations would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative

Construction of the bridge would occur over several years, during which time the visual character of the area would be temporarily degraded due to the presence of construction equipment, materials and workers, removal of vegetation, and generation of dust within the Project footprint. These changes would be visible during construction; however, public views of the bridge alignment during construction would be obstructed by the terrain. Operation and maintenance activities would include inspections and repairs, and would occur periodically throughout the life of the Project. They would typically be activities of short duration, requiring few vehicles, equipment, and personnel. Both bridge construction and its operation and maintenance would, therefore, have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative

Once operating, the South Bridge would be approximately 1.5 miles long and its deck would be 45 feet above the reservoir's maximum water surface elevation. The bridge would be visually dominant and create moderate to high visual contrast to viewers (relative to viewpoint) due to its form (height and massing), the introduction of a new line to the landscape, and a change in the landscape's texture and color from Existing Conditions. The South Bridge would also introduce urban infrastructure in an area that is largely characterized by its rural and undeveloped open space. This may cause it to be perceived as lacking harmony and cohesiveness within both the existing setting as well as alongside other Project facilities included in Alternative A. The South Bridge would be visible by recreationists from the proposed Stone Corral Recreation Area, who may have a high visual sensitivity to such infrastructure within a natural landscape. Introduction of the proposed South Bridge would create a significant visual change in a location with the potential for moderate to high visual sensitivity. This would, therefore, result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Road Relocations and South Bridge.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. Colusa County 2030 General Plan Policy CIRC 1-8 requires that transportation facilities are planned and designed to "avoid damage to the County's scenic and environmental resources, such as reductions in air quality and disruption of soils, topography, vegetative cover, and wildlife habitat," (Colusa County, 2012). Although new roads would be constructed to be aesthetically similar to existing County roads, the proposed Road Relocations and South Bridge would require permanent vegetation removal and would, therefore, be inconsistent with the Colusa County General Plan. In addition, North Road and Eastside Road would be constructed within Glenn County and would potentially be inconsistent with Glenn County General Plan Policy NRP-16, which involves retaining grazing land in large contiguous areas of the foothills (Glenn County, 1993). This would result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-4** discussion for the Site Reservoir Inundation Area construction impacts.

During operations, vehicles traveling on the South Bridge and relocated roads would create a new source of daytime glare and nighttime lighting in the area. In addition, guardrails and other roadway fixtures, such as retaining walls, safety barriers, light standards, and other structures, have the potential to be reflective under natural and artificial light. Therefore, operation of the proposed Road Relocations and South Bridge has the potential to be inconsistent with Colusa County 2030 General Plan Policy OSR 1-14 and Glenn County General Plan NRP-86. When compared to Existing Conditions and the No Project/No Action Alternative, this impact is considered **potentially significant**.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Holthouse Reservoir Complex, and Holthouse Reservoir Electrical Switchyard

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County; therefore, these proposed facilities would be consistent with the Colusa County 2030 General Plan. Construction of Alternative A would require the demolition of all structures within the footprint and buffer of the proposed facilities, including a shed and a barn. During construction, these facility locations would be concentrated in an area that would prohibit public access, and therefore, eliminate public views by motorists and residents. Residents located along Maxwell Sites Road, Delevan Road, Sutton Road, and McDermott Road would see a large number of construction vehicles driving within their viewsheds during the construction phase of these Project facilities; however, the vehicles and equipment used may be similar to those used in the transport of agricultural goods along the same roads. Construction of these facilities would not substantially affect a scenic vista, and would, therefore, result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative

During Project operations and maintenance, several of these facilities would be underground or underwater features (including the Site Reservoir Inlet/Outlet Structure and all tunnels and pipelines), and therefore, not visible. There would be limited views of the Holthouse Reservoir by motorists on Eastside Road; however viewers may perceive this water feature as having high visual quality. Motorists along Eastside Road would experience brief views of the Field Office Maintenance Yard and Sites Electrical Switchyard; however; these types of structures are characteristic of this agricultural region. Although the construction of a new reservoir complex and several new buildings would be a moderate visual change, the extent of visibility of these Project facilities is minimal; therefore, visual sensitivity is considered low. Operation of these facilities would not affect a scenic vista, resulting in a **less-than-significant impact** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Holthouse Reservoir Complex, and Holthouse Reservoir Electrical Switchyard.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. In addition, Colusa County 2030 General Plan Policy CC 1-16 requires "all new development to protect the scenic beauty of the County, incorporate high quality site design, architecture, and planning so as to enhance the overall quality of the built environment in the County's communities and create a visually interesting and aesthetically pleasing built environment that respects the rural nature of the County," (Colusa County, 2012). Therefore, construction and operation of the Field Office Maintenance Yard, Sites Electrical Switchyard, and Holthouse Reservoir Electrical Switchyard have the potential to be inconsistent with the General Plan. This would, therefore, result in a **potentially significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Construction of the Project facilities listed above would create new temporary sources of reflective daytime glare and nighttime lighting. Building materials used to construct the Sites Pumping/Generating Plant, Field Office Maintenance Yard, Sites Electrical Switchyard, and Holthouse Reservoir Electrical Switchyard may have the potential to be reflective under natural and artificial light. Construction equipment and vehicles could also be a temporary source of reflective daytime glare and nighttime light. Construction activities during early morning and evening hours would require the use of vehicle and perimeter lighting. However, construction lighting would be temporary, and would therefore, result in a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative

Operation and maintenance of the facilities would also require new sources of permanent access and safety lighting. Therefore, operation of the proposed facilities could potentially be inconsistent with General Plan Policy OSR 1-14. As discussed in **Impact Vis-1**, views of the facility locations would be largely obstructed due to terrain and lack of public access. Visual change in sources of light and glare would be high; however, because visual sensitivity would be low, the impact on day and nighttime views in the area is considered a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Pipeline Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County; therefore, the proposed TRR and its associated facilities listed above would be consistent with the Colusa County 2030 General Plan. During construction of the TRR and its associated facilities, views from adjacent residents and roads of scenic undeveloped hills to the west would have the potential to be temporarily impaired by construction equipment, vehicles, workers, and materials. Residents located along Maxwell Sites Road, Delevan Road, Sutton Road, and McDermott Road would see a large number of construction vehicles driving within their viewsheds during the construction phase of these Project facilities; however, some of the vehicles and equipment used may be similar to those used in the transport of agricultural goods along the same roads. Construction of the TRR and its associated facilities would be considered a temporary activity, and would, therefore, have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

The TRR and its associated facilities would be developed on the valley floor adjacent to the GCID Canal using a combination of excavation and embankment. The proposed reservoir embankments would be approximately six feet above the existing ground surface, which would make the TRR and its associated facilities, with the exception of the TRR Pipeline and TRR Pipeline Road, visually dominant in the landscape due to the minimal topographic variation and absence of large water features within this area, resulting in a moderate to high visual change. Views from adjacent residents and roads of scenic undeveloped hills to the west would have the limited potential to be obstructed during operations depending on their distance from the proposed facilities and viewing angle, resulting in moderate visual sensitivity. Operation and maintenance of these facilities would, therefore, result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the TRR and its associated facilities.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Construction of the TRR, its associated facilities, and the GCID Canal Connection to it would create temporary changes in the views of and from the Project area. Construction activities would introduce heavy equipment and associated vehicles, including cranes, scrapers, excavators, and graders, into the viewshed of residents and motorists near the Project work site. However, the proposed location for the TRR and its associated facilities is currently subject to the continual presence of tractors, trucks, and other equipment used in agriculture, although of differing types and intensity, so viewers may not be sensitive to the presence of construction equipment. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The proposed TRR and its associated facilities would cover approximately 200 acres of existing agricultural land, creating a moderate to high visual contrast, when compared to Existing Conditions. The new waterbody would be perceived as distinct to the area, which is characterized by agricultural fields, rural residences, and several small water storage facilities and water conveyance systems, due to its scale and designed height of approximately six feet above the existing ground level. The presence of the proposed TRR, its associated facilities (with the exception of the TRR Pipeline and TRR Pipeline Road), and the GCID Canal Connection and its operation and maintenance would, therefore, have the potential to degrade its moderate visual quality due to a substantial and distinct change from its existing use. The proposed TRR and its associated facilities (with the exception of the TRR Pipeline and TRR Pipeline Road) would also be inconsistent with Colusa County 2030 General Plan Policy OSR 1-12, which requires that visually intrusive development near scenic resources be limited in order to minimize visual impacts to the greatest extent feasible (Colusa County, 2012). This would, therefore, result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Construction of the TRR, its associated facilities, and the GCID Canal Connection would introduce new temporary sources of reflective daytime glare and nighttime lighting. Construction equipment and vehicles could be a temporary source of reflective daytime glare. In addition, materials that would be used to construct the TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Electrical Switchyard may have the potential to be reflective under natural and artificial light. Construction activities during early morning and evening hours would require the use of lighting. This impact on daytime and nighttime views is considered **potentially significant** due to the proximity of the nearby residences, when compared to Existing Conditions and the No Project/No Action Alternative.

Approximately 200 acres of agricultural land would be permanently converted to a regulating reservoir. This would expose area residents to a substantial new potential source of daytime and nighttime glare due to the reservoir's designed-embankment height of six feet. The reservoir would also create a potential source of glare to aircraft flying over the new reservoir, similar to what occurs when they pass over existing reservoirs. In addition, operation and maintenance of the facilities would require new sources of permanent access and safety lighting. Therefore, operation of the proposed TRR and its associated facilities has the potential to be inconsistent with General Plan Policy OSR 1-14. The visual change in sources of light and glare would be moderate to high, and visual sensitivity would be moderate to high due to the number of residents located in the vicinity of the proposed facilities. This impact is considered **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County; therefore the proposed Delevan Transmission Line would be consistent with the Colusa County 2030 General Plan. Construction of the Delevan Transmission Line would be moderately to highly visible by motorists and residents at approximately 30 residences within one mile of the proposed alignment due to lack of topography and mature vegetation along the alignment. Construction of the Transmission Line would create temporary changes in the views of and from the construction work site. Construction activities would introduce heavy equipment and associated vehicles into the viewshed of the proposed transmission line alignment. However, the area is currently subject to the continual presence of large agricultural equipment, although of differing types and intensity. Construction of the Delevan Transmission Line would, therefore, result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The proposed Transmission Line would not likely substantially impair views or visually dominate the viewshed due to the wide spacing and massing of the towers. In addition, views of the open agricultural land are fairly homogenous and several existing transmission lines already traverse the area. The Transmission Line would be aligned approximately 200 yards north of the northern boundary of the Delevan National Wildlife Refuge; however, public views both of and from the refuge on the north are obstructed by mature trees demarking the refuge boundary. The Transmission Line would terminate near the western bank of the Sacramento River, at the Delevan Pipeline Intake Facility. The Transmission Line would not be visible from the Sacramento River because views from the river to the west are blocked by the levee system and orchards. Operation and maintenance activities would consist of periodic inspections of the Transmission Line and towers by inspectors via truck, and repairs, as necessary. Transmission Line operation and maintenance activities would be visible by motorists and residents within one mile of the proposed alignment causing moderate to high sensitivity; however, due to the expected periodic timing and short duration at any given tower, this would be considered a low to moderate visual change. There would, therefore, be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Delevan Transmission Line.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion for the Delevan Transmission Line. There are several existing transmission lines and towers that traverse the flat agricultural land of Colusa County; therefore, a new transmission line would be compatible with the existing landscape, and would generate a low to moderate visual change. Visual sensitivity of residents and motorists would be moderate. Colusa County 2030 General Plan Policy CON 2-14 states that "Any proposed pipeline or transmission line within the county shall be aligned so that interference with agriculture is minimized," (Colusa County, 2012). The Delevan Transmission Line would be aligned above agricultural land, and its permanent impact would be limited to the transmission towers, which would not degrade a substantial portion of agricultural acreage. Therefore, the alignment of the proposed Delevan Transmission Line would be consistent with the Colusa County General Plan, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Construction of the Delevan Transmission Line would introduce new temporary sources of reflective daytime glare and nighttime lighting. Construction equipment and vehicles could be a temporary source of reflective daytime glare. Materials used to construct the transmission towers and line may have the potential to be reflective under natural and artificial light. Construction activities during early morning and evening hours would require the use of lighting. These activities and equipment would result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of the proposed Transmission Line may require permanent safety lighting. Therefore, operation of the proposed Delevan Transmission Line could potentially be inconsistent with General Plan Policy OSR 1-14. However, visual change in sources of light and glare would be low to moderate due to the spacing of the transmission towers and would depend on viewing angle and distance, and visual sensitivity would be moderate due to the number of residents and motorists in the vicinity of the proposed facilities. This would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

Refer to the **Impact Vis-1** discussion for construction impacts of the Delevan Transmission Line. The Delevan Pipeline would follow the same alignment and fall within the same construction disturbance area as the proposed Transmission Line from the Delevan Pipeline Intake Facilities to the TRR. From the

TRR to Holthouse Reservoir, the three-mile-long pipeline would diverge from the proposed Transmission Line alignment; however, the existing affected environment for both alignments between the TRR and the Holthouse Reservoir Complex is similar. Therefore, construction impacts would be similar.

Operation and maintenance of the Delevan Pipeline would not affect existing views of or from the Pipeline alignment because the pipeline would be installed underground. Above-ground structures associated with the Pipeline include blow-off structures, air valve structures, and outlet and energy dissipater structures. These installed structures would be spaced at intervals along the proposed Pipeline, and would be visually subordinate to the existing surrounding agricultural land uses. Operations and maintenance activities would consist of periodic inspections and repairs of the Pipeline and above-ground structures that would require the use of vehicles. These activities and the presence of the above-ground pipeline structures would not affect a scenic vista. Therefore, operations and maintenance of the Delevan Pipeline would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Delevan Pipeline.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Agricultural land and open space are considered to be a scenic area according to the Colusa County 2030 General Plan. The alignment of the proposed Delevan Pipeline through existing agricultural land uses may be inconsistent with General Plan Policy CON 2-14, which states that “Any proposed pipeline or transmission line within the county shall be aligned so that interference with agriculture is minimized” (Colusa County, 2012). Therefore, construction of the Delevan Pipeline would result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Refer to the **Impact Vis-1** discussion for operation and maintenance of the Delevan Pipeline. Following Project completion, the disturbed agricultural land used for temporary construction staging would be restored to pre-Project conditions, as feasible, which would be consistent with Colusa County General Plan policy. This would, therefore, result in a **less-than-significant impact** on the existing visual quality of the agricultural surroundings, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-4** discussion for construction impacts of the Delevan Transmission Line. The Pipeline would not require installation of structures that would permanently emit light or glare. Therefore, operation of the proposed Delevan Pipeline would be consistent with General Plan Policy OSR 1-14, and construction, operation, and maintenance of the Delevan Pipeline would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County; therefore the proposed Delevan Pipeline Intake Facilities would be consistent with the Colusa County 2030 General Plan. The Delevan Pipeline would terminate at the Sacramento River, adjacent to the existing Maxwell Irrigation District Pumping Plant (a large industrial facility that results in the area being of low to moderate visual quality). Construction of the proposed Delevan Pipeline Intake Facilities would introduce heavy equipment and vehicles, as well as construction workers, into the area.

Although much of the Sacramento River is generally considered to be a scenic vista, public views of the proposed Delevan Pipeline Intake Facilities during operation and maintenance would be obstructed on the west by the levee and privately owned orchards. On the east side of the river, public views would be obstructed by stands of mature trees and vegetation, beyond which is private agricultural development; in addition, public access to the east river bank is not legally permitted in the vicinity of the proposed facility location. Public views of the proposed facilities would be available from the river. The Delevan Pipeline Intake Facilities would result in a moderate visual change from the existing undeveloped riverbank. Despite the moderate to high visual quality of the area surrounding the existing pumping plant, the visual sensitivity would be low to moderate due to the lack of visibility of the facility location from land, the lack of public access in the vicinity of the proposed facilities, and the expected few viewers of the facilities from the river. This would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

Refer to the **Impact Vis-2** discussion for the Sites Reservoir Inundation Area. That discussion is also applicable to the Delevan Pipeline Intake Facilities.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Refer to the **Impact Vis-1** discussion. In addition, the proposed Delevan Pipeline Intake Facilities would be consistent with Colusa County 2030 General Plan Policy OSR 1-12 requiring that visual intrusive development near scenic resources be limited to minimize visual impacts. The facilities would be consistent with the policy due to the lack of public access in the vicinity of the proposed facilities, and the expected few viewers of the facilities from the river.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Refer to the **Impact Vis-1** discussion. Construction of the Delevan Pipeline Intake Facilities would introduce new temporary sources of reflective daytime glare and nighttime lighting. Construction equipment and vehicles could be a temporary source of reflective daytime glare. Materials used to construct the fish screen and pumping/generating plant may have the potential to be reflective under natural and artificial light. Construction activities during early morning and evening hours would require the use of lighting.

Operation and maintenance of the facilities may require new sources of permanent safety lighting. Therefore, operation of the proposed Delevan Pipeline Intake Facilities has the potential to be inconsistent with General Plan Policy OSR 1-14. The visual change in sources of light and glare would be moderate; however, viewer sensitivity would be low due to limited public views of the proposed facility location. Therefore, the impact on day and nighttime views in the area is considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista

There are no officially designated scenic vista points in Colusa County; therefore, the presence of the Project Buffer would be consistent with the Colusa County 2030 General Plan.

Construction of the Project Buffer would include demolition of existing structures, removal of vegetation to create a fuel break, and construction of a fence. The activities would require on-site equipment of varying sizes. The fence would consist of standard three-strand barbed wire fences with posts along the Project Buffer boundary where fences do not already exist. Equipment that would be used for structures and vegetation removal and installing fences to delineate between Project parcels and adjacent non-Project parcels are both typical for the Project's rural setting. These construction and demolition activities would be a temporary impact. Therefore, construction and demolition activities for the Project Buffer fence would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

No Project facilities are proposed to be located within the Project Buffer. The only Project operation and maintenance activities that would occur within the Project Buffer would be fence maintenance and periodic boundary fuel break construction and maintenance. In addition, public access would be prohibited. The fence would create a line across the landscape, but would be in character with existing fences in the area (i.e., having three-strand barbed wire strung on wooden posts). Although the visual sensitivity along the Project Buffer boundary ranges from low to high, the fence installation and periodic fuel break maintenance would be considered a low visual change. Therefore, the presence of the fence and the operation/maintenance activities that would occur within the Project Buffer would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-2: Substantial Damage to Scenic Resources, Including, but not Limited to, Trees, Rock Outcroppings, and Historic Buildings within a State Scenic Highway

No Project facilities would be located within a State Scenic Highway, so the Project Buffer and its associated fuel break maintenance activities and fence would also not be located within such a designated corridor, nor would it affect scenic resources within such a corridor. Therefore, construction, operation, and maintenance of the Project Buffer would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings

Construction of Alternative A would require the removal of vegetation to create a fuel break, the demolition of several structures that are located within the Project Buffer but outside of the associated Project facility footprints, and the installation of a fence. Structures include houses, barns, shops, and sheds adjacent to the proposed Sites Reservoir Inundation Area. These construction and demolition activities would introduce construction vehicles and workers into the landscape around each of the Project facilities. These activities would last only a short time, and while at each Project facility, it would not substantially degrade the visual character or quality of that area, resulting in a **less-than-significant impact**, when compared to Existing Conditions or the No Project/No Action Alternative.

The presence of the Project Buffer three-strand barbed wire fence and the periodic fuel break and fence maintenance that would occur within this area would not substantially degrade the visual character or quality of that area and would be consistent with General Plan policies of Colusa County and Glenn County, resulting in a **less-than-significant impact** during Project operation and maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Vis-4: A New Source of Substantial Light or Glare which would Adversely Affect Day or Nighttime Views in the Area

Removal of vegetation to create a fuel break, the demolition of several structures, and fence construction could introduce daytime glare in the landscape from Project construction vehicles and/or equipment. This source of potential glare would be mobile, as activities progress around the Project facilities, and is not expected to be in any given location for an extended period of time. If these activities were to occur at night, construction lighting would be used, which could affect nighttime views in the area. Because potential light and glare impacts would be in any given location for only a short period of time and many of the Project facilities would be located in areas that are not readily visible to residents (and may be visible to motorists for only short periods of time), this is considered a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The presence of the Project Buffer fence and the periodic fuel break and fence maintenance activities that would occur are not expected to emit glare during the daytime, and the fence would not be lit at night. Therefore, operation of the proposed Project Buffer would be consistent with the General Plan policies of Colusa County and Glenn County, and **no impact** would occur during Project operation and maintenance, when compared to Existing Conditions and the No Project/No Action Alternative.

30.3.7 Impacts Associated with Alternative B

30.3.7.1 Extended and Secondary Study Areas – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to scenic vistas (**Impact Vis-1**), scenic resources within a State Scenic Highway (**Impact Vis-2**), visual character or quality of a site and its surroundings (**Impact Vis-3**), and a new source of light or glare (**Impact Vis-4**) would be the same as described for Alternative A for the Extended and Secondary study areas.

30.3.7.2 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to visual resources:

- Recreation Areas
- Sites Pumping/Generating Plant

- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprints and construction disturbance areas of Sites Reservoir and Dams, the Road Relocations and South Bridge, and the Delevan Transmission Line would differ from Alternative A. If Alternative B is implemented, the Sites Reservoir Inundation Area would increase to a 1.81-MAF storage capacity. The boundary of the larger reservoir would range from less than 100 feet wider in some areas to several thousand feet larger in others, than that of the Alternative A reservoir, depending on the existing slope of the terrain. The 1.81-MAF reservoir proposed for Alternative B would necessitate the relocation and/or resizing of several Project features including the access roads, South Bridge, Golden Gate Dam, and Sites Dam, to accommodate an increased water elevation during Project operations. The larger reservoir would also require larger dams and two additional saddle dams. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility, which would be smaller, resulting in a reduced disturbance area. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on scenic vistas (**Impact Vis-1**), scenic resources within a State Scenic Highway (**Impact Vis-2**), visual character or quality of a site and its surroundings (**Impact Vis-3**), and a new source of light or glare (**Impact Vis-4**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on scenic vistas (**Impact Vis-1**), scenic resources within a State Scenic Highway (**Impact Vis-2**), visual character or quality of a site and its surroundings (**Impact Vis-3**), and a new source of light or glare (**Impact Vis-4**) as described for Alternative A.

30.3.8 Impacts Associated with Alternative C

30.3.8.1 Extended and Secondary Study Areas – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to scenic vistas (**Impact Vis-1**), scenic resources within a State Scenic Highway (**Impact Vis-2**), visual character or quality of a site and its surroundings (**Impact Vis-3**), and a new source of light or glare (**Impact Vis-4**) would be the same as described for Alternative A for the Extended and Secondary study areas.

30.3.8.2 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to visual resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to visual resources as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area, Sites Reservoir Dams, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to visual resources as described for Alternative B.

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

30.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 30-3 for the impacts that have been identified as significant or potentially significant.

Table 30-3
Summary of Mitigation Measures for NODOS Project Impacts to Visual Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Vis-1: A Substantial Adverse Effect on a Scenic Vista	South Bridge, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR	Potentially Significant	No Feasible Mitigation	Significant and Unavoidable
Impact Vis-3: Substantial Degradation of the Existing Visual Character or Quality of the Site and its Surroundings	Road Relocations & South Bridge, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR; Delevan Pipeline (construction and maintenance)	Potentially Significant	Mitigation Measure Vis-3a: Reduce Construction and Maintenance Impacts Causing Adverse Temporary Impacts on Visual Quality of the Site	Less than Significant
	Sites Reservoir Inundation Area, Road Relocations & South Bridge, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR (operation)	Potentially Significant	Mitigation Measure Vis-3b: Reduce Operational Impacts Causing Adverse Permanent Impacts on Visual Quality of the Site	Significant and Unavoidable

Table 30-3
Summary of Mitigation Measures for NODOS Project Impacts to Visual Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
	Field Office Maintenance Yard, Sites Electrical Switchyard, Holthouse Reservoir Electrical Switchyard (operation)	Potentially Significant	Mitigation Measure Vis-3b: Reduce Operational Impacts Causing Adverse Permanent Impacts on Visual Quality of the Site	Less than Significant
Impact Vis-4: Introduce a New Source of Substantial Light or Glare which Would Adversely Affect Day or Nighttime Views in the Area	Recreation Areas; South Bridge; TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR; Delevan Transmission Line (construction and maintenance)	Potentially Significant	Mitigation Measure Vis-4a: Reduce Construction and Maintenance Impacts Causing Substantial Light or Glare	Less than Significant
	Recreation Areas; Road Relocations & South Bridge; TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR (operation)	Potentially Significant	Mitigation Measure Vis-4b: Reduce Operational Impacts Causing Substantial Light or Glare	Less than Significant
	Sites Reservoir Inundation Area (operation)	Potentially Significant	No Feasible Mitigation	Significant and Unavoidable

Note:
LOS = Level of Significance

Mitigation Measure Vis-3a: Reduce Construction and Maintenance Impacts Causing Adverse Temporary Impacts on Visual Quality of the Site

To minimize the temporary construction impacts on visual resources due to substantial degradation of existing visual quality from construction and maintenance of the Road Relocations, South Bridge, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR, and Delevan Pipeline, DWR and Reclamation shall:

- Water areas where dust is generated, particularly along unpaved haul routes and during earth-moving activities, to reduce impacts to views and the landscape caused by dust.
- Prohibit unnecessary ground disturbance outside of the construction disturbance area.
- Revegetate and restore disturbed ground surfaces at each Project facility to their original condition to the extent feasible.

Mitigation Measure Vis-3b: Reduce Operational Impacts Causing Adverse Permanent Impacts on Visual Quality of the Site

To minimize permanent impacts on visual resources due to substantial degradation of existing visual quality from operation of the Road Relocations and South Bridge, Field Office Maintenance Yard, Sites Electrical Switchyard, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR, and Holthouse Reservoir Electrical Switchyard, DWR and Reclamation shall:

- Use native trees, bushes, and shrubs for screening at the Project facilities that may substantially degrade the existing visual character of the site(s), in a manner that does not compromise facility safety and access.
- Incorporate high quality site design and architecture in order to create an aesthetically pleasing built environment that does not detract from the rural nature of the surroundings.
- Retaining walls and erosion control devices or structures shall be sited, designed, and constructed to avoid detracting from the scenic quality of the area.

Mitigation Measure Vis-4a: Reduce Construction and Maintenance Impacts Causing Substantial Light or Glare

To minimize impacts on day or nighttime views due to substantial light or glare expected from construction and maintenance of the Recreation Facilities, South Bridge, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, GCID Canal Connection to the TRR, and Delevan Transmission Line, DWR and Reclamation shall:

- Minimize light scatter and glare from portable temporary light sources that would be used for nighttime construction by using shielded and directional lighting, and install temporary visual barriers, as needed, to prevent light spill from equipment lighting in areas with sensitive receptors.

- Design, construct, and finish all new buildings and structures using non-reflective materials, non-glare finishes, and colors that would blend with the natural environment and not create a new source of glare.
- Design the transmission line structures to be similar in appearance to the existing transmission lines in the Project vicinity to the extent feasible. Use non-specular conductors and non-reflective and non-refractive insulators.
- Use minimal Project construction signs; signs that would be installed shall be made of non-glare materials, finishes, and unobtrusive colors to the extent possible. The design of any signs required by safety regulations shall conform to the criteria established by those regulations.

Mitigation Measure Vis-4b: Reduce Operations Impacts Causing Substantial Light or Glare

To minimize impacts on day or nighttime views due to substantial light or glare expected during operation of the Recreation Facilities, Road Relocations and South Bridge, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, Delevan Pipeline Electrical Switchyard, and GCID Canal Connection to the TRR, DWR and Reclamation shall:

- Use native trees, bushes, and shrubs for screening at Project facilities that may generate new sources of light or glare, in a manner that does not compromise facility safety and access.
- Minimize nighttime lighting to areas required for safety, security, and operations, and shield lighting from public view to the extent possible. Timers and sensors shall be used to minimize the amount of time that lights are on in areas where lighting is not normally needed for safety, security, or operation. Use shielded and directional permanent lighting.
- Use minimal Project signs; signs that would be installed shall be made of non-glare materials, finishes, and unobtrusive colors to the extent possible. The design of any signs required by safety regulations shall conform to the criteria established by those regulations.
- Design and install guardrails and other roadway fixtures, including retaining walls, safety barriers, light standards, and other structures to adequately provide for the safety of the motorist using non-glare materials, unobtrusive colors, and flat finishes to minimize potential glare.

Implementation of **Mitigation Measures Vis-3a, Vis-3b**, **Vis-4a**, and **Vis-4b** would reduce the level of significance of visual resource impacts from the following Project facilities to **less than significant**: Recreation Areas, Field Office Maintenance Yard, Sites Electrical Switchyard, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline, and Delevan Transmission Line.

There is no feasible mitigation to reduce all impacts to visual resources from the following Project facilities to a less than significant level: Sites Reservoir Inundation Area, Road Relocations and South Bridge, Holthouse Reservoir Electrical Switchyard, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, Delevan Pipeline Electrical Switchyard, and GCID Canal Connection to the TRR. The impacts to visual resources at those locations would remain **significant and unavoidable**.

31. Power Production and Energy

31.1 Introduction

This chapter describes the existing electrical generation and transmission infrastructure, the electricity market structure, the electricity demand forecast for California, and the potential effects of Project operations on future power production and use in the Primary, Secondary and Extended study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for power and energy is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses on the potential impacts to electric power demand and production that could result from operation of the Project. Other energy uses for the Project, including diesel use by construction machinery and electricity use at the Project's recreation facilities, are also discussed. To the extent possible, these discussions are separated into the Extended, Secondary, and Primary study areas. However, due to the highly interconnected nature of the electric grid in the Western Interconnection (made up of all or parts of 14 states, two Canadian provinces, and part of Mexico), the effects of the Project on the delivery and use of electric power in that region are not necessarily limited to the defined geographic study areas, but rather can affect areas throughout the western U.S. Mitigation measures are provided in this EIR/EIS for identified significant or potentially significant impacts, and because no negative power production/use impacts were identified, no mitigation is included in this chapter.

31.2 Environmental Setting/Affected Environment

31.2.1 Extended Study Area

The Extended Study Area for this analysis includes all areas potentially affected by the changes to power grid operations caused by operation of the Project. The Project is located in northern California; therefore, the initial affected power system is comprised of primarily Pacific Gas & Electric (PG&E), Western Area Power Administration (WAPA), and Transmission Agency of Northern California (TANC) transmission systems, numerous generation facilities located in this area and the distribution systems of various entities interconnected to that portion of the Bulk Electric System (BES). The Extended Study Area also includes all or portions of 14 Western U.S. States, two Canadian Provinces, and the northern portion of Baja California Norte in Mexico that currently comprise the Western Interconnection. [1]

The Western Electricity Coordinating Council (WECC) is the Regional Entity responsible for coordinating and promoting BES reliability in the Western Interconnection. In addition, WECC provides an environment for coordinating the operating and planning activities of its members as set forth in the WECC Bylaws. The Balancing Authority (BA) is a key entity charged with complying with many of the reliability standards that WECC implements. The North American Electric Reliability Corporation (NERC) glossary of terms defines BA as the responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance within a Balancing Authority Area, and supports Interconnection frequency in real time. The California Independent System Operator (CAISO) is the largest BA in northern California. The Balancing Authority of Northern California (BANC) is an important municipal BA that

[1] The Western Interconnection is one of three synchronized interconnections in the United States where electricity can flow freely between various parts of the power system, only limited by transmission capacity and operational constraints.

includes WAPA as a sub BA. Both WECC and CAISO have ongoing efforts to plan for the reliable integration of significant amounts of intermittent renewable generation into the grid.

The states and provinces comprising WECC, along with the 2009 and projected 2020 electric energy demand of each state or province, are shown in Figure 31-1. The electric power grid in California is highly interconnected via high-voltage electric transmission lines with many WECC subregions. The grid is used to move power from a generator in one location to power users in another location; at any one time, millions of customers and hundreds of generators are using the grid for electricity service. The Western Interconnection offers many advantages, such as added system stability due to the inertia contributed by the hundreds of generators connected to the grid at any one time. System inertia is a product of the rotational velocity and mass of the rotors of all generators connected to the grid. The greater the system inertia, the greater ability the system has to mitigate disturbances to the grid, such as a generator shutting down unexpectedly. Some types of renewable generation such as solar photovoltaics do not use rotors to generate electricity and so do not provide inertia to the power system. The interconnected nature of the grid also adds stability due to its inherent tendency to cancel out load variability. For example, when one large load is started in one region, it is probable that the resultant instability put into the interconnected grid would be cancelled by the shutdown of one or more loads in another area. In addition, interconnected grids have the benefit of a more efficient bulk transfer of power and make it possible to serve load at the lowest available marginal cost of generation, provide supply reliability, and provide better outage management. The benefits provided by the interconnected grid have limits, however, especially as power flows on the grid reach maximum capacity and create congestion or bottlenecks that limit the ability to move power from one region to another.

The grid in the Western U.S. and Canada is highly interconnected north and south, such that hydroelectric generation in British Columbia can be delivered to California, and vice versa. Seasonal exchanges[2] without firm transmission rights were once common, but have been mostly crowded out of the market due to congestion in the electric transmission grid. This same congestion can also exacerbate the rare times when faults occurring in one area, such as the sudden loss of a generator or transmission line segment, ripple through vast areas of the West, creating widespread blackouts, such as a 1996 incident in which a downed transmission line in Montana led to a cascading outage across the western U.S., including large parts of California (Venkatasubramanian and Li, 1996), or a September 2011 incident in which a series of electrical faults in Arizona and Mexico led to a blackout for more than five million people in California (CEM, 2011). Interconnection to the eastern WECC subregions, as well as to other BAs in the U.S. and Canada, has always been limited by a relative lack of infrastructure, due to population trends and the difficulties and expense of constructing and maintaining electric transmission lines across the Rocky Mountains and other mountain ranges in the West.

Contractual agreements and electric reliability requirements guide the movement of power over the grid. Changes in supply and demand in any given time period can have both direct physical effects on the grid that can affect system reliability, and effects on the economics and contractual instruments that drive the use and operation of the grid. Short-term effects, such as a decrease in supply due to idling of a large power plant for maintenance, are reflected primarily in the cost of electricity, and in the cost of the fuels used to produce that electricity. Longer term effects, such as the introduction of a new large load, new generation, transmission or market products/design can all cause the need to upgrade the impacted system or region.

[2] Seasonal exchanges occur when winter-peaking utilities in the north send power south during the summer, and summer-peaking utilities in the south send power north during the winter.

31.2.2 Secondary Study Area

The Secondary Study Area includes the Balancing Authority Areas of CAISO and BANC from which Project-related transmission services, power sales, and purchases would occur.

31.2.2.1 Electrical Generation

California's electrical infrastructure is a complex grid of energy generation connected by high-voltage electric transmission lines and lower-voltage distribution lines. Table 31-1 shows the breakdown of sources for electric power consumption in the state in 2009 and 2010. California produces approximately 70 percent of its electricity from power plants within the State and from plants located outside the State but owned by California utilities. Approximately 30 percent of California's power supply is imported electricity from the Pacific Northwest and the American Southwest. In 2010, the total electricity imported was 92,130 gigawatt-hours (GWh), up slightly from 91,140 GWh in 2009. The 1,008 in-State power plants (greater than 0.1 megawatt [MW] each) totaled 69,709 MW in installed capacity and produced 205,695 GWh of electricity in 2009. Utilities in California own approximately 6,200 MW of capacity outside of the State, including all or portions of nuclear power plants in Arizona and coal-fired plants in Arizona, Nevada, New Mexico and Utah (CEC, 2011c). Both demand and total energy use in the State declined from 2009 to 2010, due to a generally cooler year and the downturn in the economy.

Since 1983, 90 percent of all new generation in California was natural gas-fired, consisting primarily of either simple-cycle gas turbine peaker plants generally used for meeting peak power demands or to compensate for sudden changes in demand, and combined-cycle power plants used as intermediate or “load-following” power plants that can ramp power production up or down to meet demand through the day (CEC, 2003; CEC, 2012a). Gas-fired power plants are more efficient than other fossil-fueled plants; easier to site, operate, and permit than other options; and are cleaner than other combustion sources. In the mid-1980s, approximately 25 percent of the power plants were gas-fired. By 2009, approximately 42 percent of the energy used in California came from gas-fired plants. California’s fleet of gas-fired power plants is aging. As shown in Table 31-2, almost 60 percent of the gas-fired generation was built before 1980, and almost 50 percent was built before 1970. The older gas-fired power plants are being modernized and some older generation plants are being retired. As shown in Table 31-3, new generation has also come on line in recent years.

During all but the most adverse water conditions, 10,928 MW of dependable generating capacity from hydroelectric resources are available to meet peak electricity demand in California during peak use times in July and August (CEC, 2012c). However, its hydroelectric output is highly variable year to year. In Dry years (e.g., 2001), hydroelectricity contributed only 13 percent of the state's total power (when combining both in-state and out-of-state generation). In wet years (e.g., 1983), hydroelectricity contributed 45 percent of the state's power. This variability must be accounted for in long-term planning.

The seasonal nature of its generation, such as the increased levels of generation that occur during spring runoff, can create difficulties in moving the excess power to markets that can use it, but also can greatly affect the electric power marketplace by reducing the price for off-peak power, potentially to negative values, during high runoff periods when hydroelectric projects would otherwise spill water rather than send it through the powerhouse. Hydroelectricity generation can be highly useful as a resource that can quickly ramp power operations up or down to compensate for sudden changes in demand or in generation, such as that caused by the variable nature of solar and wind generation. Used as a “firming” resource, hydroelectricity (with the proper configuration) can augment other renewable power production to provide a more reliable resource for planning purposes.

In November 2008, California’s former Governor Arnold Schwarzenegger signed Executive Order S-14-08 to raise the State’s renewable portfolio standard (RPS) to 33 percent by 2020 by requiring electricity retail sellers to serve 33 percent of their load with renewable energy by 2020. In the ongoing effort to codify the 33 percent by the 2020 goal, California’s Governor Jerry Brown and Legislature passed Senate Bill X1-2 in April 2011. The legislation requires all of California’s utilities to obtain 33 percent of their overall electricity generation from renewable resources, like solar and wind, by 2020. Federal policy is also supportive of electricity generation from renewable resources. Department of Interior Secretarial Order 3285, issued on March 11, 2009, “establishes the development of renewable energy as a priority for the Department of the Interior.”

The 33 percent renewables target by 2020 triggered the need to plan and build energy storage technologies to sustain grid-reliability and mitigate the inherent fluctuations in solar and wind energy production. Electric transmission grid operators have a limited set of technologies that can be deployed to quickly respond to the uncertainty as net demand changes on the grid, most of them are with limited capacity and/or energy. Hydropower pumped-storage is the leading alternative for grid scale energy storage. An important distinction has to be made between “standalone” pumped-storage assets and those assets capable of pumpback that are an integral component of a conventional hydropower setup. The difference between the two is the limited dispatchability of the latter because of the need to sustain the water delivery objective that a specific project was built to serve in the first place.

Renewable integration is the concept of making available, deploying, and operating generation and/or load resources that are flexible and controllable to ensure the reliability of the electric grid, in response to the inherent variability and uncertainty of renewable generation resources (wind and solar). Nationally, there are ongoing efforts to assess the needs and costs of integrating renewable energy resources as they get developed, deployed, and penetrate different electricity grids. In California, electricity market participants, regulatory agencies, and grid operators are collaborating on developing methodologies and models to identify the State’s resources need for renewable integration. Options, such as adding gas turbines to compensate for the variability of renewable energy, are being considered, but these are the least favorite solutions, as they diminish the benefits and purpose of deploying renewable energy resources. Other options, such as energy storage, curtailments, and smart grids are also being considered.

One of the most viable options for renewable integration would be an advanced energy storage installation. Pumped-storage, batteries, compressed air, and flywheels are among the different energy storage technologies available, being developed, and deployed today. Some storage technologies are better suited for short-term and fast response “capacity” applications (batteries, flywheels) that could be used to manage grid imbalances and volatility through regulation services. Others, such as pumped-storage and compressed air are better suited for long-term and intermediate response “energy” applications needed to firm up highly variable wind and solar generation.

Pumped-storage projects can quickly ramp up power operation by releasing water from the upper reservoir (forebay) to the lower reservoir (afterbay) during high-demand periods. Water is then pumped back up from the lower reservoir to the upper reservoir during off-peak hours, often taking advantage of very low wholesale power prices for power available during off-peak periods. Major pumped-storage facilities in California include:

- Pacific Gas & Electric’s 1,212-MW Helms Pumped Storage Project in Fresno County (standalone)
- DWR’s 644-MW Edward C. Hyatt (Butte County), 126-MW Thermalito (Butte County), and 424-MW San Luis/W.R. Gianelli (Merced County) Pumped-Storage Projects (integral to DWR’s Lake Oroville)
- Los Angeles Department of Water and Power’s (LADWP) 1,331-MW Castaic Pumped Storage Project in Los Angeles County, which takes advantage of SWP deliveries into Castaic Lake (integral to LADWP’s water system)
- Southern California Edison’s (SCE) 200-MW Eastwood project in Fresno County (standalone)

31.2.2.2 Electric Transmission System

California’s high-voltage electric transmission system connects the different regions of the State to each other, to varying degrees, as well as to the transmission systems of the surrounding western states, Canada, and Mexico. The degree to which areas are interconnected depends upon the availability of transmission capacity between the areas. These interconnected electric transmission systems allow power purchases and sales to extend beyond State and national borders. More than 300,000 miles of electrical transmission or distribution lines currently cross California, including more than 32,000 miles of high-voltage electric transmission lines (CEC, 2011a).

Originally, California’s electric transmission system was built by the utility companies to connect their major load centers to the generation sources. Some generation sources were built close to the load centers, requiring relatively short transmission lines; others, such as hydroelectric plants, were located far from the metropolitan areas they serve. The investor-owned utilities (IOUs) – primarily PG&E, San Diego Gas & Electric (SDG&E), and SCE – built much of the electric transmission lines throughout the state to serve their customers. The federal government, through WAPA, also built major electric transmission systems to deliver power from federally owned hydroelectric dams to load centers throughout the west. These public and private electric transmission systems were operated independently of each other, with some ties to the consumer-owned utilities. An example is LADWP, which developed its own transmission system to connect generation in California, Nevada, Arizona, and New Mexico to load centers in the City of Los Angeles. Over time, as development of new power generation close to the load centers became more difficult, the IOUs and the federal government built high-voltage electric transmission systems connecting California to neighboring states – primarily to import less expensive hydroelectricity from the northwest and thermal power from the southwest.

This network of conductors, switchgear, and transformers allows long-distance sales and purchases of power, with deliveries across the grid paid for through tariffs charged by the electric transmission system owners. When a new load or generator comes on line, power flows over the grid must be reconfigured to accommodate the increase in demand or generation. The physical process of inserting or withdrawing additional power from the grid can reduce reliability and may warrant construction of additional infrastructure, such as upgrading an existing electric transmission line to handle more power, or constructing a new power plant in areas where transmission upgrades are not feasible.

The California electric transmission grid is shown in Figure 31-2. The areas that are highlighted are those that are most heavily used. As shown, both the northern and southern regions of the state have an extensively developed grid system. These two areas are connected primarily through one high-voltage line known as “Path 15.” Path 15 is often congested, hampering the ability to transfer power between northern and southern California. The electric transmission system in northern California is owned largely by the federal government (through WAPA) and PG&E. Transmission system planning is driven by Federal Energy Regulatory Commission (FERC) orders 890 and 1000, WECC economic transmission planning through the Transmission Expansion Planning Policy Committee (TEPPC) and California Transmission Planning Group (CTPG) that was formed in 2009 to jointly plan and coordinate transmission planning activities. The CAISO planning process includes both a grid reliability planning process and a more long-term transmission system planning process for all transmission facilities within its control area, which consists of the service territories of the State’s three largest investor-owned utilities. The reliability planning process compares projected load growth against projected generation reserve margins in all areas within the CAISO control area, identifies potential local reliability problems where available generation may not be able to meet maximum local loads, and identifies where the electric transmission system may be too congested to compensate for a system disturbance, such as an unexpected loss of a major generator or transmission line. The short-term solution to any one reliability problem may be to contract for additional generation capacity within the local area, or to construct additional transmission facilities that would allow more remote generation to serve the local load (CAISO, 2011).

The longer term electric transmission planning identifies transmission upgrades needed to serve future loads, as well as to compensate for changes in generation patterns, such as the renewable power generation being introduced into the grid to meet Renewable Portfolio Standards (RPS), which pursuant to State law require that 20 percent of retails sales of all utilities in the state come from renewable resources by the end of 2013, to 25 percent by the end of 2016, and to 33 percent by the end of 2020. Identified reliability-related transmission projects from the reliability planning process are also considered during the transmission system planning process. When needed, transmission system projects are identified during the California Public Utilities Commission (CPUC) transmission planning process which includes CAISO transmission planning process. The transmission system owner then seeks approval for the project through the appropriate regulatory authority, which for PG&E is the CPUC. As one of four power marketing agencies under the Department of Energy, WAPA has its own approval process for upgrading its transmission facilities, although the rates it charges to recover the cost of improvements are approved by FERC.

Reliability planning is also conducted on a wider scale by WECC (Figure 31-3). As designated by the North American Electric Reliability Council (NERC), WECC is the regional entity that was delegated responsibility to implement NERC’s mandatory reliability standards in the Western Interconnection, and provides an environment for coordinating the operating and planning activities of its members. WECC works closely with PG&E and other California utilities to gather data regarding projected future generation reserve margins and planned transmission upgrades to ensure that reliability standards are met throughout the region.

WECC data show that, of the 120,763 circuit-miles[3] of high-voltage transmission lines in use throughout the WECC region in 2009, 15,531 miles are north of the Path 15 transmission line in northern California, and 12,057 miles are south of Path 15 in southern California. WECC projected in its 2011 Long-Term Reliability Assessment that the total circuit-miles would rise to 138,012 miles WECC-wide, with 19,238 miles located in northern California and 13,598 miles located in southern California in 2019 (NERC, 2010 and WECC, 2011).

31.2.2.3 Demand Forecast

Over the 10-year period from 2000 to 2010, census data show that California's population increased from 33.9 million to 37.2 million, representing an average annual compounded growth rate of 0.95 percent. Using an estimate made in 2007, prior to the downturn in the economy, California's Department of Finance projected that over the next decade (2010 to 2020) the state population would increase by 5 million people, for an average compounded growth rate of 1.2 percent (DOF, 2009; DOF, 2007).

The increasing demand for electrical energy is based on growth in both population (i.e., households) and commerce (commercial and industrial businesses). Weather can also significantly influence electricity demand. California's peak load was approximately 54,000 megawatts (MW) of electric power in 2009. For that year, the commercial sector accounted for approximately 37 percent of the state's electricity demand, followed by the residential sector, which accounted for approximately 33 percent, and the industrial sector, at approximately 28 percent. The remaining two percent came from government buildings and lighting, such as streetlights and airport lights. Residential demand is projected to grow by 18 percent over the period 2009 to 2035, spurred by population growth, rising disposable income, and continued population shifts to warmer regions with greater cooling requirements. Commercial sector electricity demand is projected to increase by 43 percent over that same period, led by the service industries. Industrial electricity demand is projected to grow by nine percent, slowed by increased competition from overseas manufacturers and a shift of U.S. manufacturing toward consumer goods that require less energy to produce. Increased use in the residential sector will come both from an increased average use per household (i.e., larger homes, more homes with air conditioning, and increased home electronics) and a population increase. Historically, the amount of electricity used per household increased by approximately 0.7 percent per year. This trend is expected to continue, with the decrease in electricity use for home lighting, refrigeration, air conditioning, and heating use as the efficiency of these products improve, balanced against the increase in popularity of consumer electronics (DOE, 2011).

In a 10-year forecast released in November 2007, the California Energy Commission projected that electricity demand in the State would increase at a rate of 1.3 percent per year from 2010 to 2018, with peak demand increasing at an annual average rate of 1.4 percent, and the maximum peak load increasing at an annual rate of 1.35 percent (CEC, 2007a). However, the downturn in the economy in 2009 to 2010 had a significant effect on electricity use in the State, such that the projected maximum demand for the summer of 2011 was actually two percent lower than the projected maximum demand for the summer of 2010 (CEC, 2011a). Across the WECC region, the 2010 total region-wide demand of 148,365 MW is projected to increase by 1.4 percent per year to 168,237 MW in 2019, while California summer and winter total internal demands are projected to increase at annual compound rates of 0.8 percent and 1.2 percent, respectively. California annual energy use is projected to grow at an annual compound rate of 1.2 percent (NERC, 2010). However, these projections are between 2.0 and 6.2 percent lower than the

[3] A circuit-mile is one mile of a single circuit, which for alternating current (AC) circuits are generally three-phase, and therefore, have three separate conductors making up a single circuit. Direct current (DC) circuits consist of two phases, and therefore, have two conductors needed per single circuit.

2009 projections, showing the effect of the downturn in the economy, and the difficulty of accurately predicting future demand.

Electricity use is expected to increase over the long-term, but will be balanced in California by the continued application of cost-effective energy efficiency programs, and replacement of appliances and other devices with more efficient technology. California has led the nation in efficiency gains for decades, with the result that it uses less energy per capita than any other state. California's 6,721 kWh per capita energy use is approximately half the national average of 12,167 kWh per capita (CEC, 2010).

Demand for electricity in northern California can ebb and flow dramatically, both within each year and from year to year, as can available generation. Demand is highest during heat waves[4] and is generally lowest at night during spring and fall, when heating and cooling demand is low. Competition for off-peak power purchases is much more robust during summer months, as is reflected in the considerably higher market prices. Northern California's summer peak demand is projected to grow from 25,310 MW in 2010 to 27,502 MW in 2019, for an annual compound growth rate of 0.9 percent. Winter peak demand is expected to grow from 18,155 MW in 2010 to 20,177 MW in 2019, an annual compound growth rate of 1.2 percent. Annual energy use in northern California is expected to grow from 128,119 GWh in 2010 to 140,378 GWh in 2019, for an annual compound growth rate of 1.1 percent (NERC, 2010).

31.2.3 Primary Study Area

The Primary Study Area is limited to those areas that would be most directly affected by Project power operations, including the specific transmission lines that the Project would connect to, and other CVP and SWP projects that would be re-operated by the alternatives. The Primary Study Area includes the service territories of entities that currently purchase power from the SWP and CVP.

31.2.3.1 Central Valley Project

The Central Valley Project, one of the Nation`s major water conservation developments, extends from the Cascade Range in the north to the plains along the Kern River in the south. The CVP is managed by the U.S. Bureau of Reclamation (Reclamation). Initial features of the project were built primarily to protect the Central Valley from water shortages and floods, but the CVP also improves Sacramento River navigation, supplies domestic and industrial water, generates electric power, conserves fish and wildlife, creates opportunities for recreation, and enhances water quality. The CVP is comprised of 20 dams and reservoirs, 39 pumping plants, 11 power plants, and 500 miles of major canals manage nearly nine million acre-feet of water annually, delivering water to customers from Redding to Bakersfield. The CVP includes four major canals: the Tehama-Colusa, the Contra Costa, the Delta-Mendota, and the Friant-Kern. CVP also includes storage reservoirs on the Trinity, Sacramento, American, Stanislaus, and San Joaquin rivers, and offstream storage at San Luis Reservoir.

San Luis Reservoir is part of both the CVP and SWP; it is a pumped-storage operation that takes water from, and makes deliveries to, both the California Aqueduct and the Delta-Mendota Canal, provides storage for later use, and generates up to 424 MW of power. The federal-only portion of the San Luis Unit includes the O'Neill Pumping-Generating Plant and Intake Canal, Coalinga Canal, Pleasant Valley Pumping Plant, and San Luis Drain. The C.W. "Bill" Jones Pumping Plant (formerly the Tracy Pumping Plant) lifts Delta water 197 feet up and into the Delta-Mendota Canal, and moves water through the canal to San Luis Reservoir. Each of the six pumps at the plant is capable of pumping 767 cfs. Farther south,

[4] Heat waves are defined as three or more days of greater than 100-degree temperatures.

Dos Amigo Pumping Plant, a joint CVP and SWP facility located 17 miles south of O'Neill Forebay, lifts water 113 feet to permit gravity flow to the end of San Luis Canal at Kettleman City. The plant contains six pumping units, each capable of delivering 2,200 cfs at 125 feet of head (WAPA, 2004).

Of the water conveyed by the CVP, approximately five million acre-feet is delivered to farms in northern California, and approximately 600,000 acre-feet is delivered to municipal and industrial users. The CVP is a net energy producer. The CVP's hydroelectric facilities produce approximately 5,600 GWh of electricity annually; 1,300 to 1,400 GWh are used by its pumping facilities. Total maximum power production capacity is approximately 2,100 MW; total pumping demand is approximately 600 MW. The CVP facilities most affected by a new pumped-storage hydroelectric project in northern California would be Folsom (1.0 MAF, 221 MW), New Melones (2.4 MAF, 380 MW), San Luis (2.0 MAF, 227 MW), Shasta (4.5 MAF, 710 MW) and Trinity (2.4 MAF, 575 MW). Together, these facilities produced 2,113 MW and 4,557 MWh on average between 2004 and 2010 (Reclamation, 2011).

Production capacity and pumping power vary significantly from year to year and day to day, depending upon hydrological conditions, reservoir levels, and operational constraints such as fish protection measures. For example, for the one-year period beginning in July 2011, the projected effective generating capacity of the CVP was expected to vary between a low of 715 MW (October 2011) and a high of 1,575 MW (July 2011) (Reclamation, 2011).

CVP power is marketed by WAPA, which sells CVP power to preference power customers, primarily to consumer-owned or government entities, including municipal utilities, irrigation districts, public utility districts, Native American tribes, and large government facilities, such as Department of Energy laboratories. As with all power produced by federally owned hydropower facilities, consumer-owned and government entities are given preference to CVP power sales. Approximately 85 preference power customers purchased CVP power in fiscal year 2005, although 71 percent was allocated to just six customers: Sacramento Municipal Utility District, the City of Redding, Silicon Valley Power (City of Santa Clara), the City of Roseville, the City of Palo Alto and the U.S. governmental facilities in the San Francisco Bay Area (TCCA and Reclamation, 2006).

CVP power and energy allocations are based on predicted hydrological conditions, using a long-term generation model that determines available capacity and energy, and the needed reserve margin. Energy available after serving CVP loads plus a reserve margin is called the Base Resource, which is allocated pursuant to long-term contracts for each year based on this formula:

> Base Resource = Gross Generation - Transmission Losses + Project Use Purchase - CVP Use Load - First Preference Customer Load[5]

Energy generation beyond the allocated amounts is marketed by WAPA to preference customers pursuant to long-term contracts, with any surplus sold on a short-term basis to others when available. Customers are generally divided into three groups for the marketing plan: base resource, variable resource, and full load service customers. Base resource customers are those customers that will only receive base resource energy from WAPA. Variable resource customers are customers that opt for base resource firming service and/or supplemental energy from WAPA in addition to their base resource. These first two categories of customers receive approximately 85 percent of the base resource. Full load service customers are

---

[5]Pursuant to the Trinity River Act of 1955, 25 percent of the power delivered from the CVP's Trinity River Division must be reserved for customers within Trinity County. Similarly, the Rivers and Harbor Act of 1962 authorizing the New Melones Project specified that up to 25 percent of the energy resulting from that project is reserved for customers in Calaveras and Tuolumne counties. Customers receiving energy pursuant to these authorizations are referred to as "First Preference" customers.

customers that will have their total load met by WAPA through a combination of their base resource and additional purchases by WAPA on their behalf. This category of customers receives approximately 15 percent of the base resource.

31.2.3.2 State Water Project

The SWP is a complex network of 34 storage facilities, reservoirs, and lakes; 20 pumping plants; four pumping-generating plants; five hydroelectric power plants; and approximately 701 miles of open canals and pipelines designed to move water from the Feather River basin and Lake Oroville in northern California to users in the Central Valley and southern California. It is the nation's largest state-built water and power development and conveyance system, and the largest electricity user in the state. DWR manages the SWP to deliver water to its 29 long-term water contractors and their member water agencies. The service areas of these contracting agencies extend from Plumas County in the north to San Diego County adjacent to the Mexican border. These contractors' service areas comprise almost one quarter of California's land area and more than two-thirds of its population. SWP facilities also provide flood control, recreation, and fish and wildlife enhancement. The SWP contractors repay all costs related to project construction and operation, with annual repayments of approximately $1 billion per year (based on 2007 data). Of that amount, operation and maintenance costs account for 30 percent; power purchases, less generation and sales, amount to 20 percent; and bond service payments of principal and interest and repayments for other capital financing account for 50 percent (DWR, 2012).

The SWP has a net energy use of approximately 4,600 GWh, making it the largest single consumer of electric power in California, consuming approximately 2.5 percent of the State's total electric energy production. In 2007, energy used at the SWP pumping and generating plants totaled 9.77 GWh, and 2.26 GWh was sold to 20 utilities and 22 power marketers (DWR, 2012). SWP energy use and production is highly variable, depending on hydrologic and storage conditions. For example, over the period 1990 to 2001, net energy use varied from a low of 3,421 GWh in 1998 (a very wet year with high hydroelectric production) to a high of 8,171 GWh in 1990 (in the middle of the 1987 to 1992 drought).

The SWP's hydroelectric plants (Hyatt, Thermalito, Gianelli, Warne, Alamo, Thermalito Diversion, Mojave, and Devil Canyon) have a total generating capacity of approximately 1,475 MW. In northern California, the Hyatt Pumping/Generating Plant pumps water from the Thermalito Afterbay to Lake Oroville, in pumping mode, and also produces power when water is released from the lake to the afterbay. Hyatt has three pumping/generating units, each producing 173,000 horsepower and up to 1,870 cfs of flow in pumping mode, and 113 MW (at 615 feet of static head and 2,850 cfs flow) in generating mode; and three generating units, each capable of producing 106 MW (at 615 feet of static head and 2,800 cfs flow). In total the Hyatt plant has a generating and pumping flow capacity of 16,950 cfs and 5,610 cfs, respectively, and can generate up to 645 MW of power. Just downstream, the 114-MW Thermalito Pumping-Generating Plant is designed to operate in tandem with the Hyatt Pumping-Generating Plant and has generating and pumpback flow capacities of 17,400 cfs and 9,120 cfs, respectively. Thermalito Diversion Dam, four miles downstream of Oroville Dam, creates a tailwater pool for the Hyatt Pumping-Generating Plant and is used to divert water to the 10,000-foot-long Thermalito Power Canal designed to convey generating flows up to 16,900 cfs to Thermalito Forebay and pumpback flows to the Hyatt Pumping-Generating Plant. Storage in Thermalito Forebay and Thermalito Afterbay is used to generate power and maintain uniform flows in the Feather River downstream of the Oroville Facilities. Thermalito Afterbay storage also can be used for pumpback operations, which in total may consume about 390,000 MWh of energy annually. Generation provided by pumpback activity has the potential to contribute approximately six or seven percent to the total annual Oroville Facilities generation of approximately 2.08 GWh per year[6] (DWR, 2012).

Further south (as described above) is the San Luis Unit, part of both the CVP and SWP, consisting of the O’Neill Dam and Forebay, B.F. Sisk San Luis Dam, San Luis Reservoir, William R. Gianelli Pumping-Generating Plant, Dos Amigos Pumping Plant, Los Banos and Little Panoche Reservoirs, and San Luis Canal from O’Neill Forebay to Kettleman City. O’Neill Pumping-Generating Plant takes water from the Delta-Mendota Canal and discharges it into the O’Neill Forebay, where the California Aqueduct (a SWP feature) flows directly. The William R. Gianelli Pumping-Generating Plant lifts water from O’Neill Forebay using eight 63,000 horsepower pumps and discharges it into San Luis Reservoir. During releases from the reservoir, these plants can generate up to 424 MW of electric power by reversing flow through the turbines. Water for irrigation is released into the San Luis Canal and flows by gravity to Dos Amigos Pumping Plant, where the water is lifted more than 100 feet to permit gravity flow to the end of San Luis Canal at Kettleman City.

Moving water through the California Aqueduct is a series of large pumping plants, starting with the Harvey O. Banks Pumping Plant, located 2.5 miles southwest of the Clifton Court Forebay on the California Aqueduct. Farther south along the California Aqueduct, the Chrisman, Edmonston, and Pearblossom pumping plants historically consumed the highest amount of energy. The Chrisman and Edmonston pumping plants provide 524 and 1,970 feet of lift, respectively, to convey California Aqueduct water across the Tehachapi Mountains. The Pearblossom Pumping Plant lifts water approximately 540 feet and discharges the water 3,479 feet above mean sea level, the highest point along the California Aqueduct.

Using gravity on the downhill side of the Tehachapis, flows through the Alamo Power Plant, Mojave Siphon Power Plant, Devil Canyon Power Plant, and Warne Power Plant, together with generation from the William R. Gianelli Plant (located north of the Tehachapis), generated 1.99 GWh of electric energy in 2007, approximately one-fifth of the total energy used by the SWP. The Alamo Power Plant uses the 133-foot head between Tehachapi Afterbay and Pool 43 of the California Aqueduct to generate electricity. The Mojave Siphon Power Plant generates electricity from water flowing downhill after its 540-foot lift by the Pearblossom Pumping Plant. The Devil Canyon Power Plant generates electricity with water from Silverwood Lake with more than 1,300 feet of head, the highest water head in a power plant in the SWP system. The Warne Power Plant uses the 725-foot drop from the Peace Valley Pipeline to generate electricity (DWR, 2012).

SWP manages its loads and generation resources to maximize off-peak pumping load and peak generation to minimize water delivery costs. The SWP’s power resources portfolio also includes contracts for power purchases, sales, and exchanges. The SWP is operated as an independent bulk power entity and is interconnected with the PG&E, Southern California Edison (SCE), and WAPA transmission systems. DWR dispatches the SWP’s own loads and resources and coordinates its power operations through CAISO. The SWP makes yearly projections for energy needs to ensure it has enough power to make scheduled deliveries. SWP-related pump load is met through SWP generation, long-term, mid-term, and short-term contracts and purchases.

[6] This value is the average generation from 1982 to 2001.

31.2.3.3 Northern California Transmission System

The transmission system in northern California consists of dozens of high-voltage (230-kV to 500-kV) transmission circuits, most aligned north and south, which connect the region's diverse network of power plants to load centers throughout the State. PG&E, WAPA, and the Transmission Agency of Northern California (TANC)[7] each own major transmission lines in the region, including in the immediate vicinity of the Project. PG&E has more than 18,600 circuit-miles of transmission lines and 141,000 miles of distribution lines connecting its customers from Eureka to Bakersfield. WAPA's 856 circuit-miles of high-voltage transmission lines can deliver power from the Oregon border as far south as the San Luis Reservoir.

As shown in Figure 31-4, four high-voltage transmission lines are located in western Colusa County in the vicinity of Project facility locations, and the Project could interconnect with any or all of these lines. These are:

- A 230-kV WAPA line extending from the Olinda (Vic Fazio) Substation in Shasta County, south through Tehama, Glenn, Colusa, Yolo, Solano, Contra Costa, and Alameda counties to connect to the Jones Pumping Station at the Tracy Substation, and farther south to other pumping plants along the Delta-Mendota Canal. This line distributes power from CVP facilities to federally owned pumping stations.
- Two 230-kV lines owned by PG&E, which roughly parallel the WAPA-owned line along most of its northern California route, including in Glenn, Colusa, Yolo, Solano, Contra Costa, and Alameda counties. These lines are part of PG&E's 230-kV network, which interconnects PG&E's hydroelectric facilities and various other power plants to load centers throughout northern California.
- The COTP, a 500-kV line owned by a consortium of public and private utilities, including TANC, which is comprised of the COTP manager, PG&E, WAPA, the City of Redding, and the Carmichael and San Juan water districts. The COTP extends from the Bonneville Power Administration's Captain Jack Substation in Southern Oregon south to WAPA's Tracy Substation near the CVP's and SWP's delta pumping plants, and on to PG&E's Tesla Substation. It is interconnected with and parallel to the Pacific Intertie, and consists of three segments: a 148.5-mile-long Northern Segment between the Captain Jack Substation and the Olinda (Vic Fazio) Substation in Tehama County; the 190-mile-long CVP Upgrade Segment between the Olinda Substation and the Tracy Substation in San Joaquin County, near the Tracy Pumping Station; and the Tesla Bypass Segment, a seven-mile-long double circuit from the Tracy Substation to an interconnection with the Pacific AC Intertie on PG&E's 500-kV transmission line between the Tesla and Los Banos substations. The COTP also includes the Maxwell Compensation Station, located approximately six miles south of the Funks Reservoir, which helps condition the power on the 500-kV line.

In addition to the large hydroelectric projects of the CVP and SWP, more than 200 power plants are located in the Primary Study Area; most are smaller than 50 MW. Most of the larger power plants in northern California are located near Sacramento or the San Francisco Bay areas. Only a few power plants of any size are located in the five counties surrounding the Project (Tehama, Glenn, Colusa, Lake, and Mendocino counties), the largest of which is PG&E's 660-MW Colusa Generating Station, located approximately three miles north of the proposed Sites Reservoir site (CEC, 2012a). The Colusa

[7] TANC is a joint powers agency created in 1984 by a group of publicly-owned utilities to plan and construct the California-Oregon Transmission Project (COTP).

Generating Station, which began commercial operations in December 2010, interconnects to the two 230-kV PG&E lines described above, and takes water from the Tehama-Colusa Canal for plant use (CEC, 2007b).

31.3 Environmental Impacts/Environmental Consequences

31.3.1 Regulatory Setting

The California electrical utility sector is regulated at the federal, State, and local levels. Below is a list of federal and State legislation, regulation and policy affecting California's electric utility industry. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

31.3.1.1 Federal Plans, Policies, and Regulations

- Federal Clean Air Act of 1970 and 1990
- Federal Power Act of 1920, and its various updates, including:
  - Public Utility Regulatory Policies Act (PURPA) of 1978
  - Electric Consumers Protection Act (ECPA) of 1986
  - Energy Policy Acts of 1992 and 2005

31.3.1.2 State Plans, Policies, and Regulations

- California Global Warming Solutions Act of 2006 (AB-32)
- California Clean Air Act of 1988
- The Warren-Alquist Act
- The Electric Utility Industry Restructuring Act of 1996 (AB 1890)
- Diesel Risk Reduction Plan/Diesel Fuel Regulations of 2000
- California Renewables Portfolio Standard Program of 2002 (SB1078)

31.3.1.3 Regional and Local Plans, Policies, and Regulations

- Regional Clean Air Incentives Market (RECLAIM) program for NO_x and SO_x of 1993
- Glenn County General Plan
- Colusa County General Plan

The Glenn County General Plan does not currently address electric power transmission or generating projects. GCID does not own or operate any power facilities, but instead purchases all of its power from WAPA and PG&E.

The Colusa County General Plan, approved in July 2012, endorses renewable energy project development, renewable energy use, and energy conservation; and commercial alternative energy facilities, including solar, wind, and biomass are allowed in the Agriculture General, Agriculture Upland, Industrial, Forest, and Resource Conservation land use designations with a Conditional Use Permit. It also states that any proposed pipeline or transmission line within the county shall be aligned to minimize interference with agriculture and "should be undergrounded to the greatest extent feasible;" and it allows for the development of sustainable energy production facilities within the county on non-prime agricultural lands (Colusa County, 2012).

31.3.2 Project Operational Scenario

31.3.2.1 NODOS as an Energy Storage Asset

Energy storage is the concept of storing excess (and/or low cost) energy during low demand periods for later use during high energy demand (and/or high cost) periods. Energy storage technologies, their capital installation costs, and their electricity grid applications vary significantly from one technology to another and from one market to another. Today, pumped-storage is considered to be one of the most viable forms of energy storage, due its high potential capacity and energy (100s MW and 1,000s MWh), and long discharge time (minutes to hours). Other available energy storage technologies include, but are not limited to, batteries, compressed air, capacitors, and flywheels. Most of these technologies are limited by capacity and/or discharge (time of sustained generation).

Typically, pumped-storage setup includes lower and upper reservoirs, interconnected through hydraulic conveyance/conduit, and a pumping-generating plant. The pumping-generating plant would be interconnected to the electrical grid via a switchyard and transmission lines. Sizing the different components of a pumped-storage setup is a complex multidisciplinary exercise (e.g., engineering, economics, and environmental) that is beyond the scope of this chapter. Operating a pumped-storage facility entails pumping the water from the lower reservoir into the upper reservoir when excess and/or low cost energy is available. The consumed energy (minus losses) would be transformed to potential energy through the hydrostatic head of the water stored in the upper reservoir. When there is a need for energy, capacity, and/or ancillary services (including renewable integration services), water would be released from the upper reservoir into the lower reservoir through the hydraulic turbines to generate electricity. The energy (in MWh) generated from releasing a unit volume of water relative to the energy consumed to pump that unit volume of water into the upper reservoir would be the cycle efficiency (or recovery rate) of that specific pumped-storage plant. Cycle efficiency varies with the net head across the pumping-generating units and the discharge of the water at the time of pumping and generation (subject to water surface elevation in the upper and lower reservoirs, and plant efficiencies). Average cycle efficiency of a pumped-storage setup (which would be site- and technology-specific) may range between 70 percent and 80 percent (with new pumping-generating technology units cycle efficiencies are approaching 85 percent).

The Project is being planned as a multi-objective project, and one of these objectives would be pump-back operations. Another objective for the Project would be potential participation in providing renewable integration services to the electrical grid. The Project would perform as an energy storage asset either through daily time-shifting (from off-peak to on-peak hours), or through seasonal-shifting (from low spring demand to high summer demand). The Project’s benefits in this context would be numerous, including economic incentives, GHG emissions reduction, renewable energy integration, system reliability, and transmission support. The Project, through its water diversion and release cycles from the Sacramento River (seasonal-shifting), and/or daily pump-back operations (time-shifting) would perform as an invaluable energy storage asset that could support the State’s electrical grid.

31.3.2.2 NODOS Project Operations

The Project is expected to operate in a similar manner to the San Luis Reservoir/O’Neil Forebay/Gianelli Powerhouse complex without the limitation of age and design of these facilities that do not allow them to operate in a daily pump-back manner. A detailed description of this daily pump-back operation and the associated benefits is provided in the following paragraphs. On a seasonal basis, water would be pumped from the Sacramento River through the existing Tehama-Colusa (T-C) and Glenn-Colusa Irrigation

District (GCID) canals and/or the proposed Delevan Pipeline into Holthouse Reservoir, where it would be lifted as much as 328 feet by the Sites Pumping/Generating Plant into Sites Reservoir throughout the winter and spring months for storage. The water would later be released for irrigation in the Central Valley, or for M&I use for any entity capable of receiving water deliveries from the Sacramento River or the Sacramento-San Joaquin Delta. Water releases from the Project would be coordinated with releases from Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, and San Luis Reservoir to obtain the optimal benefits from both systems while still meeting ecosystem goals.

For Project operations, the base assumptions and scenarios used in developing the CALSIM II model were maintained for the different Project components. The CALSIM II model was used to simulate the operations of the Project, as a component of the integrated SWP and CVP operations. The CALSIM II model is a tool that was setup to emulate the operations strategy set forth for the Project, and to help determine many of the Project benefits and impacts. More details on the CALSIM II model formulation are available in Section 31.3.4.2.

For the purpose of modeling the power operations of the Project, three modes for Project operations were identified: Diversion mode (pumping from the Sacramento River to fill up Sites Reservoir); Release mode (generation) from Sites Reservoir to meet Project water release objectives; and a Pump-back mode to better use residual capacities of the different Project components. The Project Pump-back mode is meant to enhance the Project economics by capturing opportunities offered by the energy market (energy price differentials between on-peak and off-peak hours), and to provide the support/products needed to integrate renewable energy (e.g., wind, solar).

In modeling the power needs for the Diversion mode, an optimization strategy was developed to shift most of the pumping operations (i.e., pump load) to off-peak hours, when excess renewable and/or lower GHG emissions energy is available. Therefore, minimizing energy costs of pumping operations, reducing GHG emissions resulting from pumping operations, and potentially providing renewable integration services, yet, maintaining Project water operations objectives. Flat monthly pumping operations would be maintained (where/when applicable, 24 hours a day, seven days a week), for all three diversion points along the Sacramento River, so the Project would maintain its primary objective of capturing excess flood water in the Sacramento River. Once water is diverted from the Sacramento River into Holthouse Reservoir, the rest of the diversion operations (i.e., pumping into Sites Reservoir) could be optimized to better use Sites Pumping Plant capacity, and the available storage in Holthouse Reservoir. It would retain the on-peak diversions from the Sacramento River in Holthouse Reservoir (as scheduled) and to pump that water into Sites Reservoir in the off-peak hours (on a daily basis). The intent of reshaping the Diversion mode is to allow the Project to participate in providing renewables integration services, reduce its GHG emissions, and avoid on-peak high electricity costs. This shift in operations would allow generating facilities to operate during the on-peak hours (through a controlled water release from Sites Reservoir into Holthouse Reservoir), and provide an opportunity to superimpose the Pump-back mode on the Project Diversion mode. In an optimized mode and in the on-peak (or super-peak) hours, Sites Pumping/Generating Plant would be available for generation. In the off-peak hours, the residual pumping capacity would be available to pump the water back into Sites Reservoir.

For the water Release mode (i.e., generation) of the Project, an optimization strategy was developed to shift water releases and generation to the on-peak hours, to be able to displace high GHG generating plants, provide integration services to renewable generation, and to maximize generation revenues from the Project's generation facilities. For this strategy, and to the extent physically possible, all intended daily water releases from Sites Reservoir into Holthouse Reservoir would occur during the on-peak hours (or super peak hours). Incidental to the on-peak releases from Sites Reservoir into Holthouse Reservoir, water would be released into the Terminal Regulating Reservoir (TRR), T-C Canal, and the Sacramento River up to the capacities of these facilities (and within the planned limits for the water release). The residual water in Holthouse Reservoir (from the on-peak Sites Reservoir releases) would be released during the off-peak hours to satisfy water delivery obligations of the Project. A key requirement for this strategy to be effective is that Holthouse Reservoir's active storage would be made available before the beginning of the next on-peak cycle (i.e., next day's cycle). Optimizing the Release mode would better use Sites generation capacity (through shifting renewable generation from off-peak hours, provide renewable integration services, and maximize revenues), and provide an opportunity to superimpose a pump-back operation cycle on the Release mode.

The Project, through its water diversion and release cycles from the Sacramento River and/or daily pump-back operations, would perform as an invaluable renewable integration and an energy storage (resource-shifting) asset that could support the State's electrical grid. If the Project were to deploy variable speed pumping-generating units (a decision would be made during the design stage), then the Project would be able to provide integration services needed to firm up highly variable wind and solar generation. In the pumping mode, some of the Project's pumping load (subject to physical and operational constraints) would follow the variable wind generation (mostly in off-peak hours). In the generation mode, some of the generation capacity would be offered to provide regulation services needed to firm up wind and solar generation (mostly in on-peak hours).

The net result from the Project's operations is that the Project would be able to help the grid by shifting cleaner (renewable energy, including hydropower, or at least energy with lower GHG emissions) resources from the off-peak hours to the on-peak hours. In addition, and if properly equipped with variable speed units, it could provide renewable integration services, thereby displacing single cycle combustion turbines and combined cycle gas turbines, otherwise, it would be needed to firm up renewable energy resources. Although the Project is a net energy consumer, when Project's operations get optimized, the Project would have a positive impact through its ability to perform resource shifting, renewable integration, and lower overall energy market's GHG emissions.

A third component of the Project power operations is a daily pump-back operation. For periods when the Project is in neither Diversion nor in Release modes, Sites Reservoir pumping and generation facilities can operate in a pure pump-back mode to participate in shifting excess renewable energy resources (excess wind energy) from off-peak to on-peak hours, provide renewable integration services needed to firm-up renewable energy resources in both the on-peak and off-peak hours, and reduce overall GHG emissions for the California electrical grid. In a pure pump-back operation mode, water would be released from Sites Reservoir into Holthouse Reservoir during the on-peak (or super peak) hours to generate energy and would be pumped back into Sites Reservoir in the off-peak hours to complete the pump-back cycle. The pump-back operation could be superimposed on the Diversion and Release modes when the energy market economics relative to the Sites Pumping/Generating Plant's efficiency (cycle efficiency) are conducive to do that. At Sites Reservoir, the extent of the pure pump-back operations, and pump-back incidental to the Project diversion and release modes, would be driven by market economics, pumping-generating cycle efficiency, residual pumping capacity, residual generation capacity, and residual storage capacity in Holthouse Reservoir.

It is important to note that Project power operations is likely to be designed to first sustain water delivery objectives, and then to choose whether the residual pumping–generating capacity could be offered in the energy and/or in the ancillary markets (including renewable integration services).

Power delivered to or taken from the Project would be transmitted over the interconnected transmission system through one or more interconnection points. Any one or a combination of the four high-voltage transmission lines that are located near the Project could interconnect with the Project to move power into or out of the Project. A transmission system impact study, conducted by the transmission system owner or owners, would be needed to determine the optimal interconnection costs, as well as to identify potential reliability problems that may be caused by the interconnection, and potential system upgrades needed to mitigate the impact of the new interconnection.

Because of the already highly limited capability of transferring additional power between northern and southern California, the effects of Project operations would occur primarily north of the Path 15 transmission line in central and northern California. This region also effectively represents the service area of the CVP. However, as is shown in the modeling conducted to date as part of analyzing the effects of Project operations on the overall power system, detailed in Section 31.3.4.2, the water operation of the Project would also have a ripple effect on energy use in all of California.

For example, the Project would act as an additional storage facility, up to 1.8 MAF, much like the 2-MAF San Luis Reservoir. During drought years especially, the increased storage would increase operations of several pumping plants as water would be released to the Sacramento River and into the Delta, where it would be pumped into the California Aqueduct and the Delta-Mendota Canal, and on through the SWP or CVP pumping stations to projects' service areas throughout central and southern California. Any increased storage in northern California would have the same effect: increased flexibility and quantity in storage would allow or cause increased operations of all pumping plants, including at the SWP's Lake Oroville/Thermalito Complex, where the increased storage of the Project may allow increased pump-back operations there. Increased storage would lead to increased pumping throughout the SWP because of the increased amount of water available to help meet demand while operating within existing environmental restrictions. Increased storage could also lead to increased generation from the SWP and CVP powerhouses from water releases in general.

The diversions from the Sacramento River into Holthouse Reservoir would occur when water is available for diversion. Pumping into Sites Reservoir from Holthouse Reservoir would occur mostly during off-peak hours. From a power perspective, the Project's pumping load would use excess renewable energy (wind energy), and/or excess capacity from fossil generation units. As a result, the Project would shift renewable energy generated during off-peak hours to on-peak hours. As the modeling for the Project shows, Project pumping and generation for water delivery objectives would be seasonal, with high pumping demand in winter months (December through February) and high generation in summer months.

Pump-back operations would be superimposed on Project operations during periods when the Project is not being operated to meet water delivery objectives, or excess capacities are available and could be better used. The intent would be to optimize Project operations to meet water delivery objectives, and to provide integration services to renewable energy generation plants. The Project represents a medium-sized generator (either 127.6 MW, 130.8 MW, or 141.6 MW, depending upon the alternative), with operations optimized to meet scheduled water releases, and to provide valuable renewable integration services As shown in Tables 31-4 and 31-5, the Project in isolation would represent a large, but mostly off-peak electric load (210 MW to 276 MW, depending upon alternative). This load includes pumping for the water diverted from the Sacramento River to Holthouse Reservoir, including at the T-C Canal (where a new 250-cfs pump would be installed at the Red Bluff Pumping Plant), and at the proposed Delevan Pipeline Intake Facilities. During maximum pumping operations, the Project would have the potential to increase total demand in northern California by as much as 276 MW (181.35 MW at the Sites Pumping/Generating Plant, 65.65 MW at the Delevan Pipeline Intake Facilities, 19.68 MW at the TRR, 6 MW at the Red Bluff Pumping Plant Intake, and 3.39 MW at the GCID Intake).

Table 31-4
Project Maximum Pumping Demand by Alternative

Location	Alternative A	Alternative B	Alternative C
Sites Pumping/Generating Plant	158 MW	181.35 MW	181.35 MW
Delevan Pipeline Intake Facilities	65.65 MW	0 MW	65.65 MW
Terminal Regulating Reservoir	19.68 MW	19.68 MW	19.68 MW
Red Bluff Pumping Plant	6 MW	6 MW	6 MW
GCID Intake	3.39 MW	3.39 MW	3.39 MW
Total	**252.72 MW**	**210.42 MW**	**276.07 MW**

Table 31-5
Project Maximum Generating Capacity by Alternative

Generating Plant	Alternative A	Alternative B	Alternative C
Sites Pumping/Generating Plant	107 MW	121 MW	121 MW
Delevan Pipeline Intake Facilities	10.8 MW	0 MW	10.8 MW
Terminal Regulating Reservoir	9.8 MW	9.8 MW	9.8 MW
Total	**127.6 MW**	**130.8 MW**	**141.6 MW**

Note:
MW = megawatt

Pump-back operations would involve the daily procurement of excess renewable energy and relatively low GHG emissions in the off-peak hours (relatively inexpensive power sources) to pump water from the Holthouse Reservoir up to Sites Reservoir and release water during peak hours to generate power and displace energy with relatively higher GHG emissions. Also, Pump-back operations provide flexible load and generation, and would be used to compensate for rapid changes in electric power demand as well as for changes in power production from variable renewable power sources. Although water delivery and power production are given equal weight in the planning goals for the Project, pump-back power operations would likely be secondary to water delivery operations because of the various restrictions on water operations from contracts and from environmental restrictions, but would be optimized within those restrictions to produce the greatest value to support the California electricity grid through providing renewable energy integration services. Pump-back operations from the afterbay to the forebay of each of the two or three (depending upon the chosen alternative) Project pumping/generating facilities would be possible, but only the Sites Pumping/Generating Plant would be used for daily pump-back operations because of the operational limitations placed on the smaller forebays and afterbays of the other Project pumping/generating facilities.

Table 31-6 shows a summary of a preliminary level analysis performed to assess the benefits from optimizing the Project's hydropower operations, including pump-back operations, so it can participate as an energy storage and renewable integration asset using three renewable integration scenarios, and sustain its intended water delivery objectives.

The maximum direct potential adverse effect on the northern California grid from future Project operations would be the instability of the grid caused by simultaneous starting of all Project pumps at a time when insufficient additional generation and transmission capacity would be available to compensate for the resultant instability put into the grid. When started, motors often initially draw 10 or more times their running current as the motor comes up to speed. Motor control designs and pumping management procedures would ensure that pumps are started sequentially, allowing each to come up to speed before the next pump is started, thus reducing the amount of starting current, and resultant instability. Soft-start and motor-generator technology, such as those used at SWP pumping plants, could also be used to reduce starting currents to minimal levels.

Therefore, with appropriate motor control designs and operating procedures in place, the effective maximum adverse direct effect of the Project would most likely be during periods of maximum pumping when generation reserve margins[8] in northern California are low. Indirectly, during times of high demand for water in southern California, Project water releases would cause increased pumping energy use throughout the SWP, especially during drought periods. Low generation reserve margins can occur during summer months when heat waves cause large increases in air conditioning loads, but also during spring and fall months when many generators are off-line for maintenance, reducing the pool of generators available to meet sudden increases in demand or to compensate for other system disturbances, such as the unexpected loss of a transmission line or large generator.

Table 31-6
Summary of Project Optimized Hydropower Operations, including Pump-back Operations

	Operational Mode	Average Annual Load-Gen	Wind or Solar Used or Shifted	Baseload Used or Displaced	Firming Energy Displaced
		MWh	MWh	MWh	MWh
Alternative A					
Scenario 1					
Excess Wind (80%) + Integration Service (20%)	Pumping	398,677	318,941	0	79,735
Resource Shifting (80%) + Integration Service (20%)	Generation	242,568	194,054	0	48,515
Scenario 2					
Excess Wind (50% + Baseload (30%) + Integration Service (20%)	Pumping	398,677	199,338	119,603	79,735
Resource Shifting (80%) + Integration Service (20%)	Generation	242,568	121,284	72,770	48,515
Scenario 3					
Baseload (80%) + Integration Service (20%)	Pumping	398,677	0	318,054	79,735
Resource Shifting (80% + Integration Service (20%)	Generation	242,568	0	194,054	48,515

[8] Reserve margin is defined as the difference in percentage between the maximum generating capacity available to serve load in the region, and the total power demand in that region.

Table 31-6
Summary of Project Optimized Hydropower Operations, including Pump-back Operations

	Operational Mode	Average Annual Load-Gen	Wind or Solar Used or Shifted	Baseload Used or Displaced	Firming Energy Displaced
		MWh	MWh	MWh	MWh
Alternative B					
Scenario 1					
Excess Wind (80%) + Integration Service (20%)	Pumping	365,728	292,583	0	73,146
Resource Shifting (80%) + Integration Service (20%)	Generation	241,830	193,464	0	48,366
Scenario 2					
Excess Wind (50% + Baseload (30%) + Integration Service (20%)	Pumping	365,728	182,864	109,718	73,146
Resource Shifting (80%) + Integration Service (20%)	Generation	241,830	120,915	72,549	48,366
Scenario 3					
Baseload (80%) + Integration Service (20%)	Pumping	365,728	0	292,583	73,146
Resource Shifting (80%) + Integration Service (20%)	Generation	241,830	0	193,464	48,366
Alternative C					
Scenario 1					
Excess Wind (80%) + Integration Service (20%)	Pumping	421,237	336,990	0	84,247
Resource Shifting (80%) + Integration Service (20%)	Generation	261,060	208,848	0	52,212
Scenario 2					
Excess Wind (50% + Baseload (30%) + Integration Service (20%)	Pumping	421,237	210,619	126,371	84,247

Scenario 3					
Baseload (80%) + Integration Service (20%)	Pumping	421,237	0	336,990	84,247
Resource Shifting (80%) + Integration Service (20%)	Generation	261,060	0	208,848	52,212

Notes:

Load-Gen = Load and Generation
MWh = megawatt-hour

The indirect effects of Project operations on power and energy use, especially during times of high demand for CVP and SWP water releases, are more difficult to identify and assess because of the difficulty in predicting the mix of generating resources that would be available to meet increased power and energy demand, as well as to provide ancillary services to help maintain reliability standards. However, as load increases, less-efficient generation would be added to the mix, to the point that during periods of very high demand, all available power plants would be made available to maintain resource adequacy, including those that are so inefficient that they otherwise remain idle for all but a few days per year. Inefficient power plants also tend to be the oldest and most polluting plants available, and significantly increase systemwide air emissions per MWh when operating.

To help assess the range of potential systemwide effects of the alternatives, DWR and Reclamation have commissioned several modeling efforts that simulate system operations under various scenarios. The modeling conducted regarding the effect of the Project on power operations throughout the CVP and SWP (Appendixes 31A and 31B) show that the increased storage offered by the Project would:

- Increase the flexibility of water operations throughout the year
- Increase operations of all pumped-storage projects in the SWP
- Increase operations of SWP pumping plants due to the increased water releases from the Project

This increased energy use (from the last bullet above) would be offset somewhat by the increased generation available from the Project and from other projects within the CVP and SWP because of the overall increase in water releases. Any overall increase in energy use indirectly caused by the increased storage offered by the Project could be partially offset by the energy or cost savings offered by releasing Project water from storage. Similarly, the increased systemwide flexibility provided by the Project may also allow increased pump-back operations at other facilities, such as at Lake Oroville/Thermalito Complex and San Luis Reservoir/Gianelli.

31.3.3 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* does not include evaluation criteria related to power production and energy. Appendix F of the *CEQA Guidelines* requires a discussion of the potential energy impacts of proposed projects, with particular emphasis on avoiding or reducing inefficient, wasteful, and unnecessary consumption of energy.

Appendix F includes the following goals:

- Decreasing overall per capita energy consumption
- Decreasing reliance on fossil fuels, such as coal, natural gas, and oil
- Increasing reliance on renewable energy sources

The evaluation criteria used for this impact analysis represent a combination of the Appendix F criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. An adverse effect on power production and energy would occur if an alternative resulted in a substantial expenditure of energy that was not balanced by corresponding beneficial effects (or would result in a wasteful use of energy), or if it would reduce production of renewable energy within the Extended, Secondary, or Primary study areas. Therefore, for the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities.

- Inefficient, wasteful, or unnecessary consumption of energy during operational activities.

- A substantial reduction in the generation of renewable energy.

Various thresholds have been used in previous NEPA and CEQA investigations of SWP- or CVP-related projects in determining significance. For this analysis, an adverse effect would potentially occur if the construction, operation, or maintenance activities result in a net energy use that exceeds five percent of the No Project/No Action Alternative energy use for CVP and SWP pumping. The average combined CVP and SWP energy use for pumping and delivery of water from the Delta, including storage in San Luis Reservoir, pumping over the Tehachapi Mountains, and recovery of some of this energy at generating stations along the California Aqueduct, is approximately 7,000 GWh per year. Therefore, a five percent increase would be approximately 350 GWh.

Although all facilities for each alternative would be constructed, operated, and maintained to minimize the energy required to pump and transport water through the CVP and SWP, each would require energy. An increase in joint CVP and SWP pumping energy use of more than five percent would suggest a wasteful use of energy resources to move water supplies through the CVP and SWP; however, the increased energy use must be balanced against the beneficial attributes of the flexible generation provided by each alternative. The five percent threshold is, therefore, a trigger requiring additional analysis of adverse and beneficial effects to determine overall significance.

31.3.4 Impact Assessment Assumptions and Methodology

31.3.4.1 Assumptions

The following assumptions were made regarding Project-related impacts (construction, operation, and maintenance impacts) to power production and energy use:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge Facilities would be required.
- DWR and Reclamation would operate the Project primarily as a water storage and delivery project, with an additional primary purpose of providing electric power services within the contractual and legal obligations that restrict water operations.

- To the extent possible within constraints imposed by water delivery operations, power operations would be conducted in such a way as to provide maximum value to the California power system. Pump-back power operations would be limited to the Sites Pumping/Generating Plant.
- The direct Project-related adverse impacts on power production and energy use would primarily relate to its demand on electric power, which would be offset by its beneficial effects of producing flexible generation to integrate renewable power on demand and/or on-peak energy.
- Indirect Project-related impacts on power production and energy use include both the displaced energy used for Project pumping and the energy use associated with the changes in water storage and conveyance that the Project would cause. For instance, although the Project could increase demand for electric power for its pumping operations, later release of water in storage could avoid use of other more energy-intensive water sources, such as deep groundwater.

31.3.4.2 Methodology

This analysis examines both adverse and beneficial effects of each alternative, and makes a determination of whether an impact would be significant using the significance criteria listed above, and whether feasible mitigation could avoid, eliminate, reduce, or compensate for a significant impact. To determine overall effects, potential adverse effects were balanced with the potential beneficial effects. To help quantify these effects, DWR and Reclamation have conducted extensive computer modeling of the alternatives to assess the potential benefits and impacts of each, including the No Project/No Action Alternative. The modeling conducted to date for this analysis focused on Project-related operations and the resulting direct and indirect effects within the CVP and SWP systems. The modeling did not attempt to predict all power operations in the WECC, or in all of California, for any alternative.

Whether the alternatives would result in significant impacts to power production and energy was determined based on an assessment of:

- Energy requirements and energy use efficiencies for each stage of the alternative.
- The effects on local and regional energy supplies and on requirements for additional capacity.
- The effects on demands for electricity and other forms of energy.
- The effects of the alternative on other energy resources in particular renewable resources.
- A comparison of the alternatives in terms of overall energy consumption and in terms of reducing wasteful, inefficient, and unnecessary consumption of energy.

To examine the range of potential effects of Project operations on the electric power system in the western U.S., computer modeling of CVP, SWP, and Project power and energy use over a wide range of hydrological conditions was conducted, including multiple Dry years as well as Wet years. This modeling was used in a preliminary analysis of the direct and indirect effects of future Project operations on power and energy use in the Primary, Secondary, and Extended study areas.

The power analysis used spreadsheet post-processors to evaluate the power impacts of flow scenarios from CALSIM II operations studies on a monthly time step. CALSIM II is a planning model developed by DWR and Reclamation that simulates operations of the SWP and CVP and areas tributary to the Sacramento-San Joaquin Delta. CALSIM II provides quantitative hydrologic-based information to those responsible for planning, managing, and operating the SWP and CVP. CALSIM II is typically the system model that is used for any interregional or statewide analysis in California.

The following tools used the monthly output from CALSIM II as input to perform power production and benefits analyses. These tools evaluate facility-specific and systemwide generation, load, and net generation:

- LTGen: analyzes CVP facilities
- SWP_Power: analyzes SWP facilities
- NODOS_Power: analyzes existing and proposed Project facilities

These tools estimated average annual energy generation and use at SWP and CVP facilities and at proposed Project generation and pumping facilities, including existing facilities that would be operated differently if the Project is constructed. For generation facilities, the tools estimated average annual energy generation, as well as average annual peaking power capacity, based on projected reservoir levels. For pumping facilities, the tools estimated average annual energy requirements. The tools also checked to determine whether off-peak energy use targets were met. Transmission losses were estimated for both pumping and generation facilities. The methods, assumptions, and results of the LTGen, SWP_Power, and NODOS_Power spreadsheet models are described in Appendix 31B. A summary description of flow and storage conditions associated with the alternatives, based on the CALSIM II model results, is in Chapter 6. The CALSIM II model description and detailed results are included in Appendix 6B.

Flow and storage levels used in the power analysis tool were taken from CALSIM II studies, using the results of the entire simulation period of October 1921 to September 2003. The monthly time step in CALSIM II is not sufficiently granular to evaluate the on-peak and ancillary service benefits associated with a daily pump-back operation. The CALSIM II data was disaggregated to model the daily-pump back feature to optimize generation benefits and minimize the cost of pumping. DWR’s Power and Risk Office (PARO) performed two studies. The first phase study (Phase 1) was completed in 2009, in which the designed capacities and the corresponding operational scenarios for the Project’s components were analyzed, and some design modifications were recommended. The second phase study (Phase 2) analyzed the three alternatives identified for the Project, relative to the No Project/No Action Alternative, and to optimize power operations (with sustained water operations) to better capture power market opportunities and use the inherent excess capacities (resulting from hydrology swings) for the different components of the Project. The full Phase 1 and Phase 2 reports are included in Appendix 31A.

The analysis of each alternative also included consideration of direct adverse and beneficial effects from Project operations on electric power use and production. Adverse effects include:

- Displaced use of CVP or SWP power for Project pumping operations.
- Increased pumping throughout the CVP and SWP system, especially during drought years, due to the increased storage available at Sites Reservoir.
- Increased competition for off-peak network power purchases for Project pumping operations.

Beneficial effects include:

- Increased use of excess renewable energy (especially wind energy) to serve Project’s pump loads during off-peak hours.
- Increased peak power generation and flexibility from Project pump-back power production during peak hours.

- Increased availability of ancillary services from Project operations, including firming other renewable power resources, such as wind and solar power, as well as spinning and non-spinning reserves, frequency support, voltage support, and load-following.
- Increased flexibility of water operations throughout the SWP and CVP may allow increased use of pump-back operations at other facilities to maximize revenues, and increasing the ability to meet contract obligations while maintaining required environmental standards.

These direct effects could cause a ripple effect throughout the SWP and CVP, as well as the PG&E and WAPA transmission systems and the interconnected electric utility system in California and beyond, creating indirect effects as utilities, other generators, and large end-users adjust to the changes in market pricing and availability caused by Project operations. For example, direct effects would include changes in pumping power usage to move Project-stored water to some SWP and CVP service areas. Indirect effects could include a need to construct additional power system infrastructure to compensate for the loss of access to CVP power. The increased availability of peak power created by the Project could avoid the need to construct other infrastructure, such as a gas-turbine peaker plant.

31.3.5 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

31.3.6 Impacts Associated with the No Project/No Action Alternative

31.3.6.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, Maintenance, and Recreation Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for inefficient, wasteful, or unnecessary power production and energy has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions**.**

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

If the No Project/No Action Alternative is implemented, the Project would not be built, and there would be no direct increase in demand for electric power due to the Project, nor would the benefit of additional storage be available, and therefore, no additional pumping through the SWP would occur. Electric power demand and energy use throughout the Extended Study Area would continue to slowly increase as the population increases, and regulatory agencies and investor-owned and consumer-owned utilities would continue to plan and construct improvements to their systems to ensure reliability standards are maintained. Overall, the No Project/No Action Alternative would likely result in a moderately increased overall demand for electric power in the western U.S. when compared to Existing Conditions (2009), due to load growth caused by an increased population. Total maximum electric demand in the western U.S. and Canada would increase from approximately 148,000 MW in 2009, to 159,000 MW in 2014, and to 168,000 MW in 2019. Generation reserve margin (defined as the percentage that total available electric generating capacity exceeds electric demand) in the western U.S. and Canada in 2009 was approximately 29 percent; projected reserve margin in summer 2014 is 39 percent, and for summer 2019 is 33 percent, indicating that sufficient generating capacity would be available to accommodate any new loads added to the system during that time frame (NERC, 2010).

If the No Project/No Action Alternative is implemented, the facilities and operations of the SWP and CVP would continue to be similar to Existing Conditions with the following changes:

- An increase in demands and build-out of facilities associated with CVP contracts of approximately 253,000 acre-feet per year north of the Delta at the future level of development. This is a result of an increase in CVP M&I service contracts related primarily to urban M&I use within the American River Basin (198,000 acre-feet), especially in the communities in El Dorado, Placer, and Sacramento counties.
- An increase in demands associated with SWP contracts, up to full contract amounts, south of the Delta at the future level of development. SWP demands, which under the existing level of development, vary on hydrologic conditions between 3.0 to 4.1 MAF per year, would be at maximum contract amounts in all hydrologic conditions under the No Project/No Action Alternative. This represents a potential 25 percent increase on average in south of the Delta demands pursuant to SWP contracts between existing and future levels of development.
- An increase in non-Project water rights demand of 184,000 acre-feet in the American River Basin.

New urban intake/Delta export facilities include:

- Freeport Regional Water Project
- City of Stockton Delta Water Supply Project
- Delta-Mendota Canal–California Aqueduct Intertie
- Contra Costa Water District Alternative Intake Project and Los Vaqueros expanded storage capacity (160 TAF)
- South Bay Aqueduct rehabilitation, to 430 cfs capacity, from its junction with the California Aqueduct to Alameda County FC&WSD Zone 7

An increase in supplies for Wildlife Refuges including Firm Level 2 supplies of approximately 8,000 acre-feet per year, and Level 4 supplies of approximately 50,000 acre-feet per year at the future level of development. However, Firm Level 2 supplies would be met by CVP contract supply and Level 4 supplies would be met through local water acquisitions in both existing and future levels of development.

For the power sector, new infrastructure would be constructed, as necessary, to maintain reliability standards, and would likely consist of a mixture of transmission system upgrades and development of a diverse mixture of generating resources, especially renewable energy resources as required by the Renewable Portfolio Standards (RPS) mandated by state law, and resources capable of rapid ramp-up and ramp-down operations to more easily accommodate the variable generation of solar and wind generation. Similarly for the water sector, the various agencies and companies involved in water system planning would continue to plan and construct system improvements to ensure adequate water sources are available to meet the demands of their customers and constituents.

Predicting exact infrastructure development for the No Project/No Action Alternative would be speculative; therefore, an assessment of potential impacts of future infrastructure development is not possible or practical at this time. This is due to the uncertainties of future power demand and supplies, although sufficient generation reserve margin is predicted through at least 2019 to accommodate reasonably foreseeable increased demand in electric power or energy. Similarly, predicting the water-related infrastructure development that would occur in the absence of the Project is also difficult. Southern California especially faces significant challenges in retaining existing or obtaining new water supply resources; and although demand for water has remained flat throughout the 1990s and 2000s (through aggressive conservation and efficiency programs and standards), maintaining the current or projected level of supply in the future is uncertain. Lowering aquifer levels in many areas of the State caused by overpumping and/or reduced recharge means that groundwater pumping energy use, and related costs, would likely continue to increase as water is pumped from deeper and deeper depths. Other geographic areas of the State are considering the use of desalination, which is also an energy intensive alternative, as a future supply option. State water policy currently calls for a 20 percent reduction in urban water and associated energy use by the year 2020 (DWR et al., 2010), and effective efficiency and conservation programs would likely continue to be the least-cost alternative to addressing future demand increases or supply reduction; but it is also likely that many water agencies would develop infrastructure to access existing or new water resources, or to improve existing resources, such as through groundwater recharge programs. The construction, operational, and maintenance-related impacts of these projects would be evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to power levels would be addressed in those environmental documents.

Table 31-7 provides a summary of the predicted changes in power and energy use in CVP, SWP and other related facilities if the No Project/No Action Alternative is implemented. The modeling for the Project using the CALSIM II model of CVP and SWP water and power operations (Appendixes 31A and 31B) shows that net generation and energy use at the CVP,SWP and other related facilities would remain at approximately the same levels for the No Project/No Action Alternative as for Existing Conditions, although the long-term average net generation for all existing facilities is expected to decline from plus 51 GWh to minus 132 GWh because of changes in water operations, as described above. The modeling predicts modest changes in energy use and generation for this alternative when compared to Existing Conditions, although power costs are expected to continue to rise, such that long-term power costs for the SWP pumping plants are expected to increase by nearly 50 percent by 2025 if the No Project/No Action Alternative is implemented, even though actual energy use would increase by only three percent, and therefore, does not meet the five percent threshold requiring additional analysis of energy and power use impacts.

Table 31-7
CVP, SWP, and Other Related Facilities Energy Use (in GWh)[a] – No Project/No Action Alternative

Parameter	Long-Term Average or Dry and Critical Water Year Type Average	Existing Conditions	No Project/No Action Alternative	No Project/No Action Alternative minus Existing Conditions
CVP Facilities				
Energy Generation	Long-Term[b]	4,712	4,701	-11
	Dry and Critical[c]	3,533	3,513	-20
Energy Use	Long-Term	1,124	1,116	-9
	Dry and Critical	894	878	-16

Table 31-7
CVP, SWP, and Other Related Facilities Energy Use (in GWh)[a] – No Project/No Action Alternative

Parameter	Long-Term Average or Dry and Critical Water Year Type Average	Existing Conditions	No Project/No Action Alternative	No Project/No Action Alternative minus Existing Conditions
Net Generation[d]	Long-Term	3,588	3,585	-2
	Dry and Critical	2,639	2,635	-4
SWP Facilities				
Energy Generation	Long-Term	4,326	4,386	59
	Dry and Critical	3,033	2,909	-124
Energy Use	Long-Term	7,848	8,088	239
	Dry and Critical	6,354	6,013	-340
Net Generation	Long-Term	-3,522	-3,702	-180
	Dry and Critical	-3,321	-3,104	217
Other Related Facilities[d]				
Energy Generation	Long-Term	0	0	0
	Dry and Critical	0	0	0
Energy Use	Long-Term	13	13	0
	Dry and Critical	11	12	0
Net Generation	Long-Term	-13	-13	0
	Dry and Critical	-11	-12	0
All Facilities (CVP, SWP, and Other Related Facilities)[e]				
Energy Generation	Long-Term	9,038	9,087	48
	Dry and Critical	6,566	6,422	-144
Energy Use	Long-Term	8,983	9,214	231
	Dry and Critical	7,257	6,901	-356
Net Generation	Long-Term	51	-132	-183
	Dry and Critical	-694	-482	212

[a]Results are estimated using LTGEN, SWP_Power, and NODOS_Power using data from the CALSIM II model.
[b]Long-Term is the average quantity for the calendar years 1922 to 2002.
[c]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
[d]Other Related Facilities include Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities.
[e]Energy Use and Net Generation for all facilities does not equal sum of Energy Use and Net Generation for CVP, and SWP, and proposed Other Related Facilities because energy use at Red Bluff Pumping Plant (RBPP) is included in both CVP and Other Related Facilities. Results for RBPP from LTGEN are subtracted from Energy Use and Net Generation for all facilities to avoid double-counting.

Notes:

CVP = Central Valley Project
GWh = gigawatt-hours
SWP = State Water Project

The No Project/No Action Alternative would not support the CEQA Appendix F goals of decreasing per capita energy consumption, decreasing reliance on fossil fuels, and increasing reliance on renewable energy resources, when compared to Existing Conditions. Additional infrastructure would likely be constructed to meet reliability standards, and to allow better integration of variable renewable energy resources into the grid. Projected generation reserve margins indicate that sufficient generation resources would be in place for any increase in demand in any area of the western U.S., and the present planning process that is in place to assure reliability standards are met has proved effective in planning and implementing needed system improvements.

Although the exact nature of future infrastructure development is uncertain, the power and water resource and reliability planning regime currently in place would continue to ensure that utility infrastructure and resources would be sufficient to meet reliability standards, and that all infrastructure and generating capacity built would comply with all applicable laws, ordinances, regulations, and standards; therefore, the No Project/No Action alternative is not expected to result in inefficient, wasteful, or unnecessary energy use and **would not have a substantial adverse effect**, when compared to Existing Conditions**.**

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

The No Project/No Action alternative is not expected to result in a reduction in the generation of renewable generation. The RPS requirement for renewable energy purchases by the State's electric utilities would continue to drive development and integration of renewable energy generation, and the current system reliability processes would ensure that sufficient infrastructure is in place to compensate for the variable nature of solar and wind generation. Therefore, **there would not be a substantial adverse effect** to power production or energy use in the Extended Study area, when compared to Existing Conditions.

31.3.6.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, Maintenance, and Recreation Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

Refer to the **Impact Power-1** discussion for the Extended Study Area. The discussion also applies to the Secondary Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

The effects of the No Project/No Action Alternative on power production and energy use, when compared to Existing Conditions in the Secondary Study Area, would be similar to that described for the Extended Study Area.Total maximum load in California in 2009 was approximately 59,000 MW, with a generation reserve margin of approximately 28.5 percent; projected California load in 2014 is 61,621 MW, with a generation reserve of 60.3 percent; and projected California load in 2019 is 64,655 MW, with a generation reserve of 53 percent (NERC, 2010). Similar to that described for the Extended Study Area, predicting exact infrastructure development if the No Project/No Action Alternative is implemented would be speculative. Similar to that for the Extended Study Area, the computer modeling effort that was conducted predicts that net SWP/CVP energy use would not increase by five percent or more in the Secondary Study Area if the No Project/No Action Alternative is implemented, and therefore, does not meet the threshold for requiring additional analysis for significance. Therefore, with sufficient planning, the No Project/No Action alternative is not expected to result in inefficient, wasteful or unnecessary energy use, and **would not have a substantial adverse effect.**

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Refer to the **Impact Power-3** discussion for the Extended Study Area. The discussion also applies to the Secondary Study Area.

31.3.6.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, Maintenance, and Recreation Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

Refer to the **Impact Power-1** discussion for the Extended Study Area. The discussion also applies to the Primary Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Total maximum load in northern California in 2009 was approximately 25,000 MW, with a generation reserve margin of approximately 23.5 percent; projected northern California load in 2014 is 26,645 MW, with a generation reserve of 48.7 percent; and projected northern California load in 2019 is 27,502 MW, with a generation reserve of 39.5 percent. Similar to that for the Extended and Secondary study areas, sufficient generation reserve margin in the Primary Study Area is predicted through at least 2019, and the power resource and reliability planning regime currently in place would continue to ensure utility infrastructure and resources would be sufficient to meet reliability standards. Therefore, the No Project/No Action Alternative is not expected to result in inefficient, wasteful or unnecessary energy use, and **would not have a substantial adverse effect.**

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Refer to the **Impact Power-3** discussion for the Extended Study Area. The discussion also applies to the Primary Study Area.

31.3.7 Impacts Associated with Alternative A

31.3.7.1 Extended Study Area – Alternative A

Construction, Operation, Maintenance, and Recreation Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

If Alternative A is implemented, Project construction, maintenance, and recreation activities within the Extended Study Area would not occur, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

When compared to Existing Conditions, Alternative A would result in a net increase in maximum demand in the Extended Study Area of approximately 253 MW for Project pumping power, and a net increase in generating capacity of 127.6 MW. When compared to the No Project/No Action Alternative, the net change in demand and generation caused by implementation of Alternative A would likely be approximately the same, based on normal load growth and the processes in place to ensure sufficient water supply and electric power generation and transmission capacity remain in place to meet reliability standards.

The Project's water operation and pump-back operations would be optimized to maintain the best and efficient use of Project's pumping and generating assets. Most pumping from Holthouse Reservoir into Sites Reservoir would be done during off-peak and shoulder hours when power demands (and power prices) are low. During these periods, it is anticipated that there would be an excess in wind generation and there would be a need for load to keep combined cycle gas generation units (low GHG emissions) at the minimum allowed generation. Water stored in Sites Reservoir would represent stored energy in the context of power operations of the Project. Stored water (i.e., energy) would be released through Project generating facilities during on-peak and super-peak hours, either on a seasonal basis to meet water delivery objectives, or on a daily basis to meet pump-back power operations objectives. Either way, the generated power would likely displace single-cycle gas generation units. The net result is that the Project could help to lower overall GHG emissions from the generating sector by shifting cleaner/lower GHG emission resources from the off-peak hours to the on-peak hours. Although the Project would be a net energy consumer, Project operations, when optimized, would have a positive effect in integrating renewable energy resources and lower overall energy market's GHG emissions.

Power would be procured for Alternative A pumping operations from CAISO or WAPA, including power needed for pump-back operations. The increased demand caused by Alternative A pumping would be partially offset by the generating capacity from Alternative A power operations.

Maximum electric demand for Alternative A pumping would equal approximately 0.17 percent of the total 2009 electric demand in the Western Interconnection, and would reduce generation reserve margin by that amount during maximum pumping operations. Alternative A pumping load would be approximately 0.16 percent of total load in that region in 2019. When operated at maximum generating capacity, the Alternative A would add approximately 0.07 percent to the 2009 generation reserve in the same region; it would add approximately 0.06 percent in 2019.

When compared to the entire Western Interconnection, this increase in demand or generation would not be significant, although the addition or sudden loss of Alternative A pumping load or generation could have a ripple effect on the interconnected grid in the western U.S. and Canada, potentially creating cascading reliability problems similar to what occurred during the 1996 electric blackouts in the western U.S. and Canada, where faults occurring in Montana and Idaho created blackouts in California and other parts of the West.

The timing of power use and generation is also important. Project modeling indicates that Alternative A-related pumping would occur mostly in winter months, with lesser amounts into spring and early summer. The modeling also predicts that high generated power levels at the Project would occur mostly during summer months, when water is released to meet CVP and SWP obligations. This matches well for northern California's power system, which has peaks in power and energy use in summer months during periods of high air conditioning demand, and generally has significantly lower demand in winter months.

Alternative A water operations, however, would have a ripple effect on power use and generation throughout the CVP and SWP system, as is examined in the Project modeling that is summarized in Appendixes 31A and 31B. Alternative A water releases in summer months can be partially moved as far as southern California through SWP canals and pumping stations, causing increased energy use at all affected pumping plants.

As shown in Table 31-8, the modeling results for implementation of Alternative A indicate relatively modest effects on generation reserves, and modest increases in energy use of the CVP and SWP as a result of adding the Project facilities to their systems, as would be expected for any increase in water storage in northern California. Table 31-8 does not show the increase in ancillary service production, which would serve to increase system reliability. When considered alone, the energy use by Alternative A would not exceed the 350 GWh trigger requiring additional analysis, whether compared to Existing Conditions and the No Project/No Action Alternative.

Table 31-8
CVP, SWP, and Proposed Project Facilities Energy Use (in GWh)[a] – Alternative A

Parameter	Long-Term Average or Dry and Critical Water Year Type Average	Existing Conditions	No Project/No Action Alternative	Alternative A	Alternative A Minus Existing Conditions	Alternative A Minus No Project/No Action Alternative

	Dry and Critical	6,566	6,422	6,771	206	350
Pumping Energy Use	Long-Term	8,983	9,214	9,818	835	604
	Dry and Critical	7,257	6,901	7,850	592	948
Net Generation	Long-Term	51	-132	-499	-550	-367
	Dry and Critical	-694	-482	-1,085	-391	-603

[a]Results are estimated using LTGEN, SWP_Power, and NODOS_Power using data from the CALSIM II model.

[b]Long-Term is the average quantity for the calendar years 1922 to 2002.

[c]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.

[d]Proposed Project Facilities include Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities.

[e]Energy Use and Net Generation for all facilities does not equal sum of Energy Use and Net Generation for CVP, SWP, and Project facilities because energy use at Red Bluff Pumping Plant (RBPP) is included in both CVP and Project facilities. Results for RBPP from LTGEN are subtracted from Energy Use and Net Generation for all facilities to avoid double-counting.

Notes:

CVP = Central Valley Project
GWh = gigawatt-hours
SWP = State Water Project

However, by making up to 1.27 MAF of additional storage available to the water system, water releases from Alternative A would lead to increased use of energy for pumping the released water as far as southern California. According to the modeling results, the net CVP and SWP energy use increase caused by Alternative A (energy use minus energy production) would be as much as 550 GWh more than Existing Conditions and as much as 367 GWh more than the No Project/No Action Alternative, both of which are above the threshold requiring additional analysis. When compared to 2009 total electrical energy use of 858,793 GWh in the Extended Study Area, and projected 2019 energy use of more than 1 million GWh, the increased energy use caused by Alternative A in 2025 would be 0.04 percent of the projected total electrical energy use in the Extended Study Area. However, Alternative A would also create beneficial effects, such as increasing the flexibility of both the electric system and water system in California in meeting demand and maintaining reliability standards, due to the power and ramping capability that Alternative A would create. Project facilities would be designed and built to the maximum feasible efficiency, and both water and power operations would provide considerable benefit to the citizens of the State; therefore the energy used to store water would not be considered an inefficient, wasteful, or unnecessary use of energy because it would be used to store water and potential electric energy for later use when needed. This would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

For the Project, and in addition to the aforementioned seasonal operational profile, pumping-generating assets would be optimized on daily basis to better use and synchronize the Project's facilities with power market opportunities (e.g., prices, ancillary services). The optimized operations would shift all pumping from Holthouse Reservoir to Sites Reservoir to off-peak and shoulder hours, and would shift all water releases and incidental power generation to super-peak and on-peak hours. The benefits from optimized operations of the Project would not only enhance the economics of the Project (minimize net energy costs), but would also make the Project's facilities available to superimpose a pump-back operation cycle on Project operations. It is important to note that through pump-back operations, the Project would be able to offer renewable integration services to the grid and would reduce the overall GHG emissions through shifting excess renewable energy from off-peak hours to on-peak hours. This would, therefore, displace on-peak high GHG emissions generating assets, such as single-cycle combustion turbines.

Alternative A would not likely decrease per capita energy consumption in the Extended Study Area, but would promote increased reliance on renewable resources, decreased reliance on fossil fuels, and reduce greenhouse gas emissions by displacing high emission peaking power plants due to its ability to assist integration of variable renewable power resources, such as wind and solar. Therefore, Alternative A is expected to promote the use of renewable energy, and would not cause a reduction in generation of renewable energy. Therefore, operation of Alternative A would result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.7.2 Secondary Study Area – Alternative A

Construction, Operation, Maintenance, and Recreation Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The only use associated with the Project that would occur in the Secondary Study Area, but not in the Primary Study Area, is that associated with the installation and operation of a pump at the Red Bluff

Pumping Plant. Installing the proposed pump into an existing bay at the existing Red Bluff Pumping Plant would require the direct and indirect use of energy resources. Direct energy use would involve using petroleum products and electricity to operate construction and maintenance equipment, as well as fuel use by workers commuting to and from the Project site. Indirect energy use would involve the consumption of energy to extract raw materials to manufacture the pump and construction/maintenance equipment and vehicles, and to transport the pump. These activities would require the use of gasoline and diesel fuel.

Project construction activities would temporarily increase energy consumption during the Project construction period, when compared to Existing Conditions. No substantial long-term energy use would be required for the installation of the pump as part of Alternative A. Also, it is not anticipated that such energy use would be inefficient, wasteful, or unnecessary. This impact is considered to be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Various types of fuel-consuming equipment would be necessary for maintenance of the pump (including routine inspections and repairs); however, this additional energy use would be relatively minor when compared to overall maintenance energy use at the facility that currently occurs (i.e., Existing Conditions) and the No Project/No Action Alternative, and the energy usage would be temporary and intermittent. Also, it is not anticipated that such energy use for Project maintenance would be inefficient, wasteful, or unnecessary because it would ensure that the pump would continue to operate properly for its designed life cycle. Impacts to power and energy use related to Project maintenance would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, no Project Recreation Areas would be constructed within the Secondary Study Area if Alternative A is implemented, resulting in **no impact** on power and energy use in the Secondary Study Area for Recreation Area maintenance and use, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Although Alternative A power operations would have some effects across the Western Interconnection, its major effects would occur in California, due to its effect on CVP and SWP operations. Maximum electric energy demand for Alternative A pumping would equal approximately 0.43 percent of the total 2009 electric demand in California, and may reduce reserve margin by that amount only if pumping occurs during super peak hours. Alternative A pumping demand would represent approximately 0.41 percent of total projected demand in 2014, and 0.39 percent of total demand in 2019. When operated at maximum generating capacity, the Alternative A would add approximately 0.17 percent to the 2009 generation reserve in the same region. In comparison to the all of California, this increase in demand or generation would not be significant.

When compared to 2009 total electrical energy use of 285,913 GWh in the Secondary Study Area (California), and projected 2019 energy use of 321,649 GWh, the increased energy use caused by Alternative A in 2025 (390 GWh) would be 0.14 and 0.12 percent, respectively, of the projected total electrical energy use in the Secondary Study Area. Similar to that for the Extended Study Area, the energy use of Alternative A would not be considered inefficient, wasteful, or unnecessary, and the water stored through that energy use would provide substantial benefits both to power and energy use and to water resources, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Regarding the power and energy use goals set forth in Appendix F of the *CEQA Guidelines*, Alternative A would not decrease per capita energy consumption in the Secondary Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. Therefore, the Project is expected to promote use of renewable energy, and would not cause a reduction in generation of renewable energy. Operation of Alternative A would result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.7.3 Primary Study Area – Alternative A

Construction, Operation, Maintenance, and Recreation Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

Power production and energy use within the Primary Study Area during Project construction and/or maintenance activities, and during recreation use, is not expected to be inefficient, wasteful, or unnecessary if Alternative A is implemented.

The proposed modification or demolition of existing facilities, as well as the construction of new facilities, would require the direct and indirect use of energy resources. Direct energy use would involve using petroleum products and electricity to operate construction equipment, such as trucks, bulldozers, and tunnel boring equipment, as well as fuel use by workers commuting to and from the Project sites. Indirect energy use would involve consuming energy to extract raw materials, manufacture construction equipment and materials, and transport the goods necessary for construction and maintenance activities. These activities would require the use of gasoline and diesel fuel.

The use of fuel-consuming equipment during Project construction would increase energy consumption from Existing Conditions temporarily during the Project construction period. No long-term energy use would be required for construction of Alternative A. Also, it is not anticipated that such energy use would be inefficient, wasteful, or unnecessary. This impact would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Various types of fuel-consuming equipment would be necessary for maintenance of all proposed Project facilities (including routine inspections and repairs), such as sediment removal/dredging, and for maintenance and use of the Recreation Areas. Work conducted during maintenance activities would be relatively minor, when compared to overall energy use in the Primary Study Area for Existing Conditions and the No Project/No Action Alternative, and the energy usage would be temporary and intermittent. Also, it is not anticipated that such energy use would be inefficient, wasteful, or unnecessary because it would ensure that the facilities would continue to operate properly for their designed lifetimes, and would provide benefits to the State. Depending on the activity undertaken at the Recreation Areas, recreation use may require energy in the form of electricity and/or gas; this would also be temporary and intermittent. Impacts to power and energy use related to Project maintenance and recreational use would, therefore, be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Other than for Project pumping, energy use during Project operations would be minimal, limited to lighting and potable water pumping proposed for the Stone Corral and Peninsula Hills recreation areas, and the lighting of Project facilities. These areas would use minimal amounts of energy on an ongoing basis, when compared to Project pumping, and do not reach the trigger thresholds requiring additional analysis. Therefore, impacts to power and energy use at the Stone Corral and Peninsula Hills recreation areas, and the lighting of Project facilities would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Maximum electric demand for Alternative A (252.7 MW) would equal approximately 1.0 percent of the total 2009 electric demand in northern California, and would reduce generation reserve margin by that amount in the State during maximum pumping operations. Alternative A pumping demand would be approximately 0.95 percent of total demand in the region 2014, and 0.92 percent of total demand in 2019. When operated at maximum generating capacity, Alternative A would add approximately 0.41 percent to the 2009 generation reserve in the same region; Alternative A would add a projected 0.32 percent of total northern California generation capacity in 2014, and 0.33 percent in 2019.

A preliminary transmission interconnection feasibility analysis conducted in 2007 concluded that power flows expected for Alternative A, using the assumptions at that time, could be accommodated within the then-existing transmission system, with no upgrades, without creating reliability impacts in the Primary Study Area. Three Interconnection Configuration Alternatives were considered for power flow analysis and cost estimating:

- Interconnect to PG&E's (then-proposed but now operating) Colusa 230-kV Switching Station via a 1-mile 230-kV transmission line
- Interconnect by looping onto PG&E's 230-kV transmission line from the then-proposed Colusa Switching Station to Vaca-Dixon 230-kV substation, circuit #3
- Interconnect by looping onto WAPA's Olinda - Obanion 230-kV transmission line

Power flow analysis showed that all three interconnection points had acceptable NERC/WECC Category A, B and C performance and the Project would not cause any criteria violations. The results of the power flow analysis did not identify a preferred interconnection alternative because all three were feasible and would not require any associated transmission network upgrades (USE, 2007).

By making up to 1.27 MAF of additional storage available to the water system, water releases from Alternative A could lead to increased use of energy. Adverse energy use effects from Project operations are likely to be very small when compared to total energy use in the Primary Study Area. The modeling projects up to a 550-GWh increase per year in energy use by CVP and SWP facilities with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative. The increase in energy consumption would be less than 1 percent of 2009 total electrical energy use of 124,405 GWh in the Primary Study Area (northern California), and projected 2019 energy use of 140,378 GWh. The increased CVP and SWP energy use caused by Alternative A in 2025 and 2060 would be 0.29 and 0.26 percent, respectively, of the 2009 and projected 2019 total electrical energy use in the Primary Study Area.

This net increase in power and energy use would likely be accommodated by proper planning, especially given the projected large generation margins in the region. However, operation of Alternative A could cause changes in energy production and transmission patterns that could lead to localized effects, such as a need to build additional infrastructure to compensate for changes in power flows. Determining the future need for new infrastructure due to direct or indirect effects of Alternative A operations would be speculative, given the changes that are likely to happen before Alternative A could be operational. However, all future infrastructure additions would be subject to environmental review by the approving agency, thereby assuring that the environmental effects of such addition would be fully analyzed, with appropriate mitigation imposed for all identified significant impacts.

Alternative A would offer as a benefit to the electric power system in northern California the ability to effectively store energy through pump-back operations. Currently, pumped-storage hydroelectric projects are among the best available technologies to store energy on a large scale, using surplus power during times of low cost to pump water to a higher elevation for later release, with accompanying power production, during times of high demand and high cost.

When compared to all of northern California, the increase in power and energy use caused by Alternative A operations would likely result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative, and would not be inefficient, wasteful, or unnecessary when considering the benefits that Alternative A would offer to the electric power system in northern California.

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Alternative A power capabilities would also offer benefits to the system through its ability to firm up the generation of renewable power resources in the region, and especially for solar- and wind-powered resources. It would also offer benefits through its capability to provide ancillary services to the grid. Alternative A power operations would bring stability to the grid by providing the ability to quickly ramp power generation up or down to balance sudden unexpected changes in solar and/or wind generation and compensate for uncertainties in load forecasts (water operations are a primary objective). Alternative A operations could provide ancillary services to the grid in the Primary Study Area by curtailing power use for pumping (up to 253 MW in essentially instantaneous reduction for Alternative A), as well as by ramping up power production (up to 127.6 MW).

Similar to that for the Secondary Study Area, Alternative A would not likely decrease per capita energy consumption in the Primary Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. Operation of Alternative A would, therefore, result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.8 Impacts Associated with Alternative B

31.3.8.1 Extended Study Area – Alternative B

Construction, Operation, Maintenance, and Recreation Use Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The impacts associated with Alternative B as they relate to inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities would be the same as described for Alternative A for the Extended Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Impacts on power production and energy use if Alternative B is implemented are expected to be similar to those described for Alternative A, except that Alternative B would have a somewhat reduced total electric demand for Project pumping operations (210 MW instead of 253 MW), and a somewhat higher generating capacity (131 MW instead of 128 MW). When compared to Existing Conditions, Alternative B would result in a net increase in maximum demand in the Extended Study Area of approximately 210.4 MW for Project pumping power, and a net increase in generating capacity of 130.8 MW. However, the net change in demand and generation caused by development of Alternative B would likely be approximately the same as for Existing Conditions and the No Project/No Action Alternative, based on normal load growth and the processes in place to ensure sufficient water supply and electric power generation and transmission capacity are available to meet system requirements.

Table 31-9 summarizes the modeling results of the CVP and SWP systemwide effects of Alternative B, showing the resultant changes in energy use throughout both systems. Table 31-9 does not show the increase in ancillary service production, which would serve to increase system reliability. The overall effect of Alternative B would be a somewhat reduced effect on total power and energy use, when compared with Alternative A. Regarding generation, because of the increased Sites Pumping/Generating Plant generating capacity due to higher Sites Reservoir level (121 MW for Alternative B versus 107 MW for Alternative A) offset by the lack of the Delevan Pipeline powerhouse (0 MW for Alternative B versus 10.8 MW for Alternative A), Alternative B would result in a small increase in renewable generating capacity (3.2 MW) when compared to Alternative A. Because the adverse impacts on power production and energy use associated with Alternative B would be less than for Alternative A, and the benefits offered would be equal to or greater than for Alternative A, impacts to power production and energy use in the Extended Study Area for Alternative B would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Table 31-9
CVP, SWP, and Proposed Project Facilities Energy Use (in GWh)[a] – Alternative B

Parameter	Long-Term Average or Dry and Critical Water Year Type Average	Existing Conditions	No Project/No Action Alternative	Alternative B	Alternative B minus Existing Conditions	Alternative B minus No Project/No Action Alternative

[a]Results are estimated using LTGEN, SWP_Power, and NODOS_Power using data from the CALSIM II model.
[b]Long-Term is the average quantity for the calendar years 1922-2002.
[c]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.
[d]Proposed Project Facilities include Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities.
[e]Energy Use and Net Generation for all facilities does not equal sum of Energy Use and Net Generation for CVP, SWP, and Project facilities because energy use at Red Bluff Pumping Plant (RBPP) is included in both CVP and Project facilities. Results for RBPP from LTGEN are subtracted from Energy Use and Net Generation for all facilities to avoid double-counting.

Notes:

CVP = Central Valley Project
GWh = gigawatt-hours
SWP = State Water Project

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Alternative B would not likely decrease per capita energy consumption in the Extended Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. Therefore, Alternative B is expected to promote the use of renewable energy, and would not cause a reduction in generation of renewable energy. Therefore, operation of Alternative B would result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.8.2 Secondary Study Area – Alternative B

Construction, Operation, Maintenance, and Recreation Use Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The impacts associated with Alternative B as they relate to inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities would be the same as described for Alternative A for the Secondary Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Impacts on power production and energy use associated with Alternative B would be less than that for Alternative A. Alternative B would have approximately the same effect on overall energy generation and consumption as Existing Conditions and the No Project/No Action Alternative, but would offer the benefit of additional renewable generation, and services to better integrate other sources of renewable energy into the grid. Impacts to power production and energy use in the Secondary Study Area for Alternative B would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Similar to Alternative A, Alternative B would not likely decrease per capita energy consumption in the Secondary Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. Operation of Alternative B would, therefore, result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.8.3 Primary Study Area – Alternative B

Construction, Operation, Maintenance, and Recreation Use Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The impacts associated with Alternative B as they relate to inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities would be the same as described for Alternative A for the Primary Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Alternative B would include a larger Sites Reservoir than Alternative A, allowing an increase in Sites Pumping/Generating Plant capacity to 121 MW, but also an increase in pumping demand of 181.35 MW. Power generation at the TRR, and pumping mode at the Sites and TRR pumping/generating plants, would be the same as described for Alternative A, but the Delevan Pipeline Discharge Facility would be a release-only facility with no pumping or power generation capabilities. Adverse effects on power production and energy use in the Primary Study Area for Alternative B would be reduced, when compared to Alternative A because Alternative B would have more ability to integrate renewable energy into the grid, and benefits would be greater than Alternative A due it its potential to offset fossil fuel generation during times of peak demand. Alternative B would have approximately the same effect on overall energy generation and consumption as Existing Conditions and the No Project/No Action Alternative, but would offer the benefit of additional renewable generation, and services to better integrate other sources of renewable energy into the grid. Therefore, with effective planning efforts for transmission system and power generation capacity additions accounting for the future effects of Project operations, impacts to power or energy use from implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Alternative B would not likely decrease per capita energy consumption in the Primary Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. Operation of Alternative B would, therefore, result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.9 Impacts Associated with Alternative C

31.3.9.1 Extended Study Area – Alternative C

<u>Construction, Operation, Maintenance, and Recreation Use Impacts</u>

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The impacts associated with Alternative C as they relate to inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities would be the same as described for Alternative A for the Extended Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

When compared to Existing Conditions, Alternative C would result in a net increase in maximum demand of approximately 276 MW for Project pumping power, and a net increase in maximum generating capacity of 141.6 MW. When compared to the No Project/No Action Alternative, the net change in demand and generation in the Extended Study Area caused by development of Alternative C would likely be approximately the same, based on normal load growth and the processes in place to ensure sufficient water supply and electric power generation and transmission capacity remain in place to meet reliability standards.

From a power production and energy use perspective, Alternative C would increase electricity demand by approximately 23 MW when compared to Alternative A (an 8.5 percent increase), and would increase generating capacity by approximately 10 MW when compared to Alternative B (an 8 percent increase). Alternative C would, therefore, offer comparable potential for adverse impact on power demand and energy use when compared to Alternative A. It would also offer the same level of benefit to the system due it its similar generating capacity. Maximum electricity demand for Alternative C pumping would equal approximately 0.19 percent of the total 2009 electric demand in the western U.S. and Canada (compared to 0.17 percent for Alternative A), and would reduce the generation reserve margin by that amount during maximum pumping operations. Alternative C pumping load would be approximately 0.16 percent of total load in the region in 2019 (identical to Alternative A). When operated at maximum generating capacity, Alternative C would add approximately 0.07 percent to the 2009 generation reserve; it would add approximately 0.06 percent in 2014, and 0.06 percent in 2019 (all identical to Alternative A).

As shown in Table 31-10, modeling showed that the addition of Alternative C to the CVP and SWP would cause a net increase in energy use of 594 GWh by CVP and SWP facilities, when compared to Existing Conditions, and a net increase in energy use of 411 GWh by CVP and SWP facilities, when compared to the No Project/No Action Alternative. Table 31-10 does not show the increase in ancillary service production, which would serve to increase system reliability. When compared to 2009 total electrical energy use of 858,793 GWh in the Extended Study Area (Western Interconnection), and projected 2019 energy use of more than 1 million GWh, the increased energy use that would result from Alternative C in 2025 would be 0.05 and 0.04 percent, respectively, of the 2009 actual energy use and 2019 projected electrical energy use in the Extended Study Area (identical to Alternative A). Project-related energy use associated with Alternative C is not expected to be inefficient, wasteful, or unnecessary because it would be used to store water and potential electric energy for later use when needed and would therefore result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Table 31-10
CVP,SWP, and Proposed Project Facilities Energy Use (in GWh)[a] – Alternative C

Parameter	Long-Term Average or Dry and Critical Water Year Type Average	Existing Conditions	No Project/No Action Alternative	Alternative C	Alternative C minus Existing Conditions	Alternative C minus No Project/No Action Alternative
CVP Facilities						
Energy Generation	Long-Term[b]	4,712	4,701	4,715	3	14
	Dry and Critical[c]	3,533	3,513	3,479	-54	-34
Energy Use	Long-Term	1,124	1,116	1,155	31	40
	Dry and Critical	894	878	901	8	24
Net Generation[d]	Long-Term	3,588	3,585	3,559	-28	-26
	Dry and Critical	2,639	2,635	2,578	-62	-58

Table 31-10
CVP, SWP, and Proposed Project Facilities Energy Use (in GWh)[a] – Alternative C

Parameter	Long-Term Average or Dry and Critical Water Year Type Average	Existing Conditions	No Project/No Action Alternative	Alternative C	Alternative C minus Existing Conditions	Alternative C minus No Project/No Action Alternative
SWP Facilities						
Energy Generation	Long-Term	4,326	4,386	4,496	170	110
	Dry and Critical	3,033	2,909	3,168	136	259
Energy Use	Long-Term	7,848	8,088	8,473	625	385
	Dry and Critical	6,354	6,013	6,848	494	834
Net Generation	Long-Term	-3,522	-3,702	-3,977	-455	-275
	Dry and Critical	-3,321	-3,104	-3,679	-358	-575
Proposed Project Facilities[d]						
Energy Generation	Long-Term	0	0	157	157	0
	Dry and Critical	0	0	173	173	0
Energy Use	Long-Term	13	13	278	265	13

Net Generation	Long-Term	-13	-13	-121	-108	-13
	Dry and Critical	-11	-12	-26	-15	-11
All Facilities (CVP, SWP and Proposed Project)[e]						
Energy Generation	Long-Term	9,038	9,087	9,368	329	281
	Dry and Critical	6,566	6,422	6,821	255	399
Energy Use	Long-Term	8,983	9,214	9,901	918	687
	Dry and Critical	7,257	6,901	7,945	687	1,044
Net Generation	Long-Term	51	-132	-543	-594	-411
	Dry and Critical	-694	-482	-1,131	-437	-649

[a]Results are estimated using LTGEN, SWP_Power, and NODOS_Power using data from the CALSIM II model.

[b]Long-Term is the average quantity for the calendar years 1922-2002.

[c]Dry and Critical is the average quantity for Dry and Critical years according to the Sacramento River 40-30-30 index.

[d]Proposed Project Facilities include Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal pumping facilities.

[e]Energy Use and Net Generation for all facilities does not equal sum of Energy Use and Net Generation for CVP, SWP, and Project facilities because energy use at Red Bluff Pumping Plant (RBPP) is included in both CVP and Project facilities. Results for RBPP from LTGEN are subtracted from Energy Use and Net Generation for all facilities to avoid double-counting.

Notes:

CVP = Central Valley Project
GWh = gigawatt-hours
SWP = State Water Project

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Similar to Alternative A, Alternative C would not likely decrease per capita energy consumption in the Extended Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. The increased energy use resulting from the additional water storage available from Alternative C to CVP or SWP customers, when compared to Existing Conditions and the No Project/No Action Alternative, would displace energy use associated with other water sources, perhaps leading to a net reduction in water-related energy use in the Extended Study Area. Operation of Alternative C is, therefore, expected to result in a **less-than-significant impact** to power and energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.9.2 Secondary Study Area – Alternative C

Construction, Operation, Maintenance, and Recreation Use Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The impacts associated with Alternative C as they relate to inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities would be the same as described for Alternative A for the Secondary Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

Maximum electric demand for pumping if Alternative C is implemented would equal approximately 0.47 percent of the total 2009 electric demand in California, and would reduce the generation reserve margin by that amount in the state during maximum pumping operations. Alternative C pumping demand would be approximately 0.45 percent of total demand in 2014 in the Secondary Study Area, and 0.43 percent of total demand in 2019, compared to 0.41 percent and 0.36 percent, respectively, for Alternative A. When operated at maximum generating capacity, Alternative C would add approximately 0.19 percent to the 2009 generation reserve in the same region, compared to 0.17 percent for Alternative A. The modeling projection of a 411 GWh increase in energy use by CVP and SWP facilities, when compared to the No Project/No Action Alternative, would be 0.29 percent of the 2009 total electrical energy use of 124,405 GWh, and 0.26 percent of the 2019 energy use of 140,378 GWh, in the Primary Study Area (northern California). This increased energy use caused by Alternative C in 2025 would be 0.14 percent of the 2009 total Secondary Study Area electrical energy use of 285,913 GWh, and 0.13 percent of the projected 2019 energy use of 321,649 GWh.

By making up to 1.81 MAF of additional storage available for the water system, water releases from Alternative C would lead to increased use of energy for pumping the released water as far as Southern California. Energy use associated with Alternative C would not be inefficient, wasteful, or unnecessary because it would be used to store water and potential electric energy for later use when needed. Impacts to power and energy caused by operation of Alternative C would, therefore, be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Similar to Alternative A, Alternative C would not likely decrease per capita energy consumption in the Secondary Study Area, but would promote increased reliance on renewable resources and decreased reliance on fossil fuels due to its ability to assist integration of variable renewable power resources, such as wind and solar. Operation of Alternative C would, therefore, result in a **less-than-significant impact** to power or energy use, when compared to Existing Conditions and the No Project/No Action Alternative.

31.3.9.3 Primary Study Area – Alternative C

Construction, Maintenance, and Recreation Use Impacts

Impact Power-1: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Construction, Maintenance, and Recreation Activities

The impacts associated with Alternative C as they relate to inefficient, wasteful, or unnecessary consumption of energy during construction, maintenance, and recreation activities would be the same as described for Alternative A for the Primary Study Area.

Impact Power-2: Inefficient, Wasteful, or Unnecessary Consumption of Energy during Operational Activities

For Alternative C, the Sites Pumping/Generating Plant would use up to 181.4 MW in pumping mode, and would generate up to 121 MW; the TRR Pumping/Generating Plant would use up to 19.68 MW in pumping mode, and generate up to 9.8 MW; and the Delevan Pipeline Intake Facilities would use up to 65.5 MW in pumping mode, and generate up to 10.8 MW. Maximum electricity demand for Alternative C (276 MW) would equal approximately 1.1 percent of the total 2009 electric demand in northern California, and would reduce the generation reserve margin by that amount in the State during maximum pumping operations. Alternative C pumping demand would be approximately 1.04 percent of total 2014 demand in the region, and 1.0 percent of total 2019 demand. When operated at maximum generating capacity, Alternative C would add approximately 0.46 percent to the 2009 generation reserve; it would add a projected 0.36 percent of total northern California generation capacity in 2014, and 0.37 percent in 2019. The modeling projection of a 265 GWh increase in energy use by CVP and SWP facilities, when compared to Existing Conditions and the No Project/No Action Alternative, would be 0.21 percent of the 2009 total electrical energy use of 124,405 GWh, and 0.19 percent of the 2019 energy use of 140,378 GWh, in the Primary Study Area (northern California). The overall effect on power and energy use by Alternative C is, therefore, nearly identical to that of Alternative A, including beneficial effects. Project-related energy use associated with Alternative C is not expected to be inefficient, wasteful, or unnecessary because it would be used to store water and potential electric energy for later use when needed and would therefore result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Power-3: A Substantial Reduction in the Generation of Renewable Energy

Similar to Alternative A, this net increase in demand would likely be accommodated by proper power planning studies, especially given the projected large generation margins in the region.

Alternative C operations could increase the reliability of the grid both by curtailing power use for pumping (up to 276 MW in essentially instantaneous reduction for Alternative C), and by ramping up power production (up to 141.6 MW). This ability will also assist in integrating renewable energy generation into the grid as utilities increase purchases of renewable energy to meet RPS requirements. Alternative C water operations also could provide at least a partial offset of pumping energy use if the water released from Alternative C storage displaces a more intensive water source, such as deep groundwater or desalination. Impacts to power and energy use from Alternative C would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

31.4 Mitigation Measures

With continued effective planning for California transmission grid improvements and generation capacity additions, impacts to power production and energy use associated with operation of the Project would be **less than significant.** Therefore, no mitigation is required or recommended.

32. Relationship Between Short-Term Uses and Long-Term Productivity

32.1 Introduction

The Council on Environmental Quality (CEQ) NEPA regulations (40 CFR 1502.16) require consideration of "the relationship between local short-term uses of man's environment and the maintenance and enhancement of long-term productivity". This consideration involves using all practicable means and measures, including financial and technical assistance, in a manner calculated to foster and promote the general welfare, to create and maintain conditions under which humans and nature can exist in productive harmony, and fulfill the social, economic, and other requirements of present and future generations of Americans. This section of the NEPA regulations recognizes that short-term uses and long-term productivity of the environment are linked, and that opportunities that are acted upon have consequences that could have continuing effects well into the future.

In addition, California Public Resources Code §21001(g) indicates that it is the policy of the State to "require governmental agencies at all levels to consider qualitative factors as well as economic and technical factors and long-term benefits and costs, in addition to short-term benefits and costs…"

The Project's three action alternatives (Alternatives A, B, and C) analyzed in this EIR/EIS would involve construction of new facilities, including a reservoir, dams, recreation areas, roads, a bridge, pumping/generating plants, electrical switchyards, an inlet/outlet structure and tunnel, a spillway and stilling basin, pipelines, a canal connection, a transmission line, and pipeline intake/discharge facilities. Alternatives A, B, and C also include improvements to existing facilities, such as installation of a new pump at an existing pumping plant, road relocations, dredging and expanding an existing reservoir, and modifications to an existing canal and its facilities. In addition, the three alternatives include the demolition of 108 structures[1], the removal of several existing paved and gravel roads, and the inundation of lands to create a reservoir. The specific impacts of the Project alternatives would vary in type, intensity, and duration according to the activities occurring at any given time. Implementation of the NODOS Project would require tradeoffs between long-term productivity and short-term uses of the environment.

32.2 Short-Term and Long-Term Effects of the Alternatives

The expected impacts on environmental resources as a result of constructing, operating, and maintaining Alternatives A, B, and C were presented in Chapters 6 through 31. The conclusions presented in those chapters were the basis for developing Table 32-1; the table summarizes the short-term[2] and long-term[3] effects of implementing the three alternatives.

---

[1] This includes 26 residences, 31 barns, 27 sheds, 4 shops, and 20 other peripheral structures.

[2] For the purposes of this chapter, a short-term effect would occur during Project construction and could last from the time construction ceases to within three to five years after Project construction. A temporary effect would last less than three to four years and typically would occur only during Project construction. As such, temporary effects are included in Table 32-1 in the Short-Term Effects columns.

[3] For the purposes of this chapter, a long-term effect would last longer than five years after the completion of Project construction. In some cases, a long-term effect could be a permanent effect.

To provide a balanced discussion for each environmental resource, Table 32-1 lists the "potentially significant" or "significant" short-term effects (both beneficial and adverse) and the long-term "potentially beneficial" and "beneficial" and "significant unavoidable" adverse effects associated with each environmental resource.

In this chapter, "short-term effects" relate to the "short-term uses of environmental resources", and "long-term effects" relate to the "maintenance and enhancement of long-term productivity" – in particular, the consistency of the Proposed Project/Proposed Action with long-term economic, social, regional, and local planning objectives.

It should be noted that the relationship between short-term uses and long-term productivity of the Proposed Project/Proposed Action would not be appreciably different between Alternatives A, B, and C, but instead, the effects would result from the implementation of the Proposed Project/Proposed Action itself.

Table 32-1
Short-Term and Long-Term Effects of Alternatives A, B, and C by Environmental Resource

Resource	Short-Term Effects*		Long-Term Effects*	
	Beneficial	Adverse	Beneficial	Adverse
Surface Water Resources	None	None	When compared to Existing Conditions, over the long-term averages, the total annual average CVP deliveries for all hydrologic regions show increases would occur for the three alternatives. Over the long-term averages, Wildlife Refuge Level 2 deliveries would increase in the Sacramento River Hydrologic Region, and would decrease in the San Joaquin River and Tulare Lake hydrologic regions. Over the long-term averages, Wildlife Refuge Level 4 supplies for Alternatives A, B, and C would increase in the Sacramento River, San Joaquin River, and Tulare Lake hydrologic regions.	None

Table 32-1
Short-Term and Long-Term Effects of Alternatives A, B, and C by Environmental Resource

Resource	Short-Term Effects*		Long-Term Effects*	
	Beneficial	Adverse	Beneficial	Adverse
			When compared to Existing Conditions, over the Dry and Critical water years averages, the total annual average CVP deliveries for all hydrologic regions show increases would occur for the three alternatives. Over the Dry and Critical water years averages, annual Wildlife Refuge Level 2 deliveries would increase in the Sacramento River Hydrologic Region, and would decrease in the San Joaquin River and Tulare Lake hydrologic regions. Over the Dry and Critical water years averages, Wildlife Refuge Level 4 supplies for the Alternatives A, B, and C would increase in the Sacramento River, San Joaquin River, and Tulare Lake hydrologic regions.	None
			When compared to the No Project/No Action Alternative, over the long-term averages, the total annual CVP deliveries for all hydrologic regions show that increases would occur for the three alternatives. Over the long-term averages, Wildlife Refuge Level 2 deliveries would increase in only the Sacramento River Hydrologic Region for the three alternatives. Over the long-term averages, Wildlife Refuge Level 4 supplies for the Alternatives A, B, and C would be the same, when compared to the No Project/No Action Alternative.	None
			When compared to the No Project/No Action Alternative, over the Dry and Critical water years averages, the total annual CVP deliveries for all hydrologic regions show increases would occur for the three alternatives. Over the Dry and Critical water years averages, annual Wildlife Refuge Level 2 deliveries would increase in only the Sacramento River Hydrologic Region. Over the Dry and Critical water years averages, Wildlife Refuge Level 4 supplies for the Alternatives A, B, and C would be the same.	None

Table 32-1
Short-Term and Long-Term Effects of Alternatives A, B, and C by Environmental Resource

Resource	Short-Term Effects*		Long-Term Effects*	
	Beneficial	Adverse	Beneficial	Adverse
			When compared to Existing Conditions, over the long-term averages, total annual SWP deliveries to all hydrologic regions show an increase would occur for the three alternatives.	None
			When compared to Existing Conditions, over the Dry and Critical water years averages, total SWP deliveries for all hydrologic regions show an increase would occur for the three alternatives.	None
			When compared to the No Project/No Action Alternative, over the long-term averages, total annual SWP deliveries for all hydrologic regions show an increase would occur for the three alternatives.	None
			When compared to the No Project/ No Action Alternative, over the Dry and Critical water years averages, the total annual SWP deliveries to all hydrologic regions show an increase would occur for the three alternatives.	None
Surface Water Quality	None	None	None	None
Fluvial Geomorphology and Riparian Habitat	None	None	Suspended sediment that could deposit in spawning gravel, agricultural fields, navigable water, and in weirs and bypasses would be reduced in the Secondary Study Area.	None
			A slight increase in bank erosion and meander rates would occur in the Secondary Study Area, resulting in more benefits to riparian vegetation, fish, and wildlife because of a slight increase in floodplain rejuvenation.	None
			Flow would be reduced downstream of the intakes in the Sacramento River, which would reduce the mobility of the bedload in the channel. This may have a slight aggradational effect to the channel downstream of each intake because bedload derived from bank erosion and tributaries would continue to move into the area. This would be beneficial to salmon spawning gravel riffle habitat.	None

Table 32-1
Short-Term and Long-Term Effects of Alternatives A, B, and C by Environmental Resource

Resource	Short-Term Effects*		Long-Term Effects*	
	Beneficial	Adverse	Beneficial	Adverse
Flood Control and Management	None	None	The magnitude of peak flow on Funks and Stone Corral creeks would decrease downstream of the dams.	None
Groundwater Resources	None	None	None	None
Groundwater Quality	None	None	The increase in surface water supply reliability in the Extended Study Area could reduce groundwater extraction rates, allowing groundwater recharge to improve groundwater quality.	None
			Surface water seepage and percolation from the Sites Reservoir, Holthouse Reservoir, Terminal Regulating Reservoir, and the forebay at Delevan Pipeline Intake Facilities could benefit shallow groundwater quality.	None
Aquatic Biological Resources	None	None	Beneficial effects would occur to coldwater fish species and warmwater fish species.	None
			Beneficial effects would occur to winter-run and spring-run Chinook salmon in the Sacramento River.	None
			Beneficial effects would occur to Pacific lamprey and river lamprey in the American River.	None
			Beneficial effects would occur to striped bass and American shad in the American River.	None
			The establishment of the Ecosystem Enhancement Fund as an endowment to provide long-term funding for aquatic habitat restoration actions on the Sacramento River and its tributaries would result in beneficial effects to anadromous salmonids and sturgeon.	None
Botanical Resources	None	None	None	Impact on a vegetation community would occur from Holthouse Reservoir Complex.
	None	None	None	Impact on an alkaline wetland would occur from Holthouse Reservoir Complex.

Resource	Short-Term Effects*		Long-Term Effects*	
	Beneficial	Adverse	Beneficial	Adverse
			Operation of the proposed Project facilities (without consideration of pumpback operations) would require additional energy beyond what would be generated. However, the way the facilities would be operated and integrated into the California electricity market would actually result in annual reductions in GHG emissions. Maintenance of proposed Project facilities would generate emissions. Because increases in GHG emissions associated with construction of the proposed Project would be more than offset by reductions in GHG emissions from operation, there would be no long-term increase over the net-zero threshold. Over the life of the proposed Project, Alternative A would be likely to substantially reduce GHG emissions.	None
			Proposed Project operation would result in a net increase in the amount of energy needed annually to operate the SWP. However, given the scale of additional emissions that the proposed Project would add to DWR's total GHG emissions, no additional actions or commitments would be required. The proposed Project would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the GGERP and would not conflict with any of the specific action GHG emissions reduction measures set forth in the GGERP.	None

Table 32-1

Resource	Short-Term Effects*		Long-Term Effects*	
	Beneficial	**Adverse**	**Beneficial**	**Adverse**
			None	Implementation of the proposed Project would result in an increase in CVP electricity use. This additional demand would be served by energy generated at CVP hydroelectric facilities that emit no GHGs, and therefore, would result in no GHG emissions. However, the small increase in electricity usage to operate the CVP with the proposed Project would result in a corresponding reduction in the supply of GHG-emissions-free electricity available to sell to California electricity users. This reduction in hydroelectric energy available for sale could result in a potential indirect effect of the proposed Project. These emissions could contribute to a cumulatively considerable effect, when compared to Existing Conditions and the No Project/No Action Alternative.

Table 32-1

	None	None	None	The Sites Reservoir Inundation Area would introduce a new source of light or glare that would adversely affect day or nighttime views in the area.
Power Production and Energy	None	None	None	None

*This table lists the "potentially significant" or "significant" short-term effects (both beneficial and adverse) associated with each environmental resource, and the long-term "potentially beneficial", "beneficial", and "significant unavoidable" effects (i.e., impacts that would remain significant after the implementation of mitigation measures).

32.3 Conclusion

In conclusion, the long-term benefits of the improved operational flexibility of the State's water system, as a result of implementing the Project (any of the three action alternatives, A, B, or C) would outweigh the short-term and long-term adverse effects on the individual resources evaluated in this EIR/EIS.

33. Irreversible or Irretrievable Resource Commitments

33.1 Introduction

The California Environmental Quality Act (CEQA) *Guidelines* requires a discussion of the significant irreversible environmental changes that would be caused by the proposed Project if it is implemented. *CEQA Guidelines* §15126.2(c) states that "Uses of nonrenewable resources during the initial and continued phases of the project may be irreversible since a large commitment of such resources makes removal or nonuse thereafter unlikely. Primary impacts and, particularly, secondary impacts (such as highway improvement which provides access to a previously inaccessible area) generally commit future generations to similar uses. Also, irreversible damage can result from environmental accidents associated with the project. Irretrievable commitments of resources should be evaluated to assure that such current consumption is justified" (AEP, 2011).

The National Environmental Policy Act (NEPA) (Section 101(2)(c)(v) and 40 CFR 1502.16) requires that the environmental analysis identify "any irreversible and irretrievable commitment of resources which would be involved in the proposed action should it be implemented." The Act, Council on Environmental Quality (CEQ) NEPA regulations, and NEPA guidance, however, do not define "resources" or describe how this requirement should be applied.

The U. S. Bureau of Reclamation (Reclamation) and other federal agencies have interpreted irreversible and irretrievable commitments to mean the use of nonrenewable resources and the effects this use would have in the future. Reclamation defines the irreversible commitment of resources to be the result of the use or destruction of a specific resource (e.g., minerals extraction or the destruction of cultural resources) that cannot be replaced or, at a minimum, restored over a long period of time and possibly at great expense. Reclamation also defines the irretrievable commitment of resources to the loss of production or use of natural resources, indicating that it represents opportunities that are foregone for the period of time that a resource cannot be used (e.g., land conversion to new uses or the construction of levees preventing the natural flooding of floodplains). Reclamation also indicates that the analysis shall, for each alternative, identify those commitments of resources that are irreversible and irretrievable (Reclamation, 2012).

The following discussions identify those commitments of resources that are irreversible and irretrievable, as well as the uses in which irreversible damage could result from a potential environmental accident associated with any of the proposed Project's three action alternatives.

33.2 Commitments of Resources by the Proposed Project's Action Alternatives

The commitment of resources would be similar for all of the proposed Project's action alternatives. Therefore, the following discussions of the proposed Project's commitments of resources apply to Alternatives A, B, and C. The proposed Project would result in the irreversible and irretrievable commitment of the following resources during Project construction, operation, and maintenance:

- Construction materials, including such resources as wood, rocks, soil, and metal

- Energy expended in the form of electricity, gasoline, diesel fuel, oil, and lubricants for construction equipment and vehicles, and construction worker vehicles that would be needed for Project construction, operation, and maintenance
- Construction labor
- Permanent changes in land use, including the conversion of prime agricultural land to other uses, at Project facility locations due to land that would be committed to new and modified Project facilities and land areas inundated with water
- Changes in the visual resources and landscape character of lands where Project facilities would be located
- Effects on biological and cultural resources located at Project facility locations

Some of the materials that would be used for the proposed Project are nonrenewable resources and are considered irretrievably and irreversibly committed because reuse is not possible or is highly unlikely. Nonrenewable resources are expected to account for a minimal portion of the region's resources; any of the proposed Project's action alternative's use of nonrenewable resources would not affect the availability of these resources for other needs within the region. These resources are discussed in further detail below.

33.2.1 Construction Materials

Construction of the proposed Project facilities would result in the use of construction materials, including wood, cement, sand, gravel, other rock and earthen materials, and metal materials, all considered to be non-renewable or slowly renewable resources. These materials would be irretrievably committed toward the construction of the proposed Project facilities. Most of these materials would be obtained from within the proposed Sites Reservoir Inundation Area, and some materials would be imported to the proposed Project facility sites from nearby commercial sources.

33.2.2 Energy Consumption

Construction of the proposed Project facilities would result in the consumption of energy (considered a commitment of nonrenewable energy resources), primarily in the form of fossil fuels including fuel oil, natural gas, and gasoline for automobiles and construction equipment. In addition, nonrenewable energy resources would be required to manufacture and transport many of the Project equipment components that would be assembled at the proposed Project facility sites. Project construction activities are not expected to result in the inefficient use of energy because DWR and Reclamation would require that Project construction contractors use best available engineering techniques, construction and design practices, and equipment operating procedures during construction of the proposed Project facilities.

Long-term Project operation and maintenance would require the long-term consumption of electricity that could otherwise be available to other power customers, and would add to the overall electrical demand in California. The proposed Project would produce energy from the additional water storage capacity, and would require power to pump the water as far south as southern California.

33.2.3 Construction Labor

Human effort would be irretrievably committed during the construction of the proposed Project. The proposed Project is expected to require an estimated average of 95 construction workers on an annual basis during the Project construction period.

33.2.4 Land Use Changes

The proposed Project (depending on alternative) would permanently affect up to approximately 26,500 acres of land from its existing land use (including the conversion of prime agricultural land to other uses) to a Project facility land use and/or open space buffer. In addition, Project implementation would require the relocation of human graves. The commitment of land would not necessarily be irreversible or irretrievable because the removal of the proposed Project facilities and the restoration of disturbed areas could return that land to Existing Conditions. However, the substantial costs and the loss of energy, recreational, and socioeconomic benefits from decommissioning and removing the proposed Project facilities would make removal of the Project facilities unlikely in the foreseeable future. Therefore, for the purposes of this discussion, the change in the land use at the proposed Project facility sites is considered irreversible and irretrievable. The relocation of graves that would be necessary to implement the Project is considered irreversible (i.e., although the graves would be relocated and buried in new locations, their connection with their existing setting would be irreversibly changed).

33.2.5 Landscape Character Changes

Implementation of any of the proposed Project's action alternatives would result in a change in the existing landscape character of the areas surrounding each Project facility site. This change in landscape character would not necessarily be irreversible or irretrievable because removal of the proposed Project and the restoration of disturbed areas could return the Project facility sites to Existing Conditions. However, as mentioned above, the substantial costs and the loss of energy, recreational, and socioeconomic benefits from decommissioning and removing the proposed Project facilities makes it unlikely that it would happen. Therefore, for the purposes of this discussion, the change in the landscape at the proposed Project facility sites is considered irreversible.

The permanent conversion of a vegetated landscape to the proposed Sites Reservoir, its associated facilities, and up to five campgrounds would be a major change to the landscape, and the reservoir would introduce a new permanent source of daytime and nighttime glare in the area. The proposed South Bridge across the new reservoir would introduce urban infrastructure in an area that is largely characterized by its rural open space, thus altering the visual character of the area. The proposed Terminal Regulating Reservoir would cover approximately 200 acres of existing agricultural land. The new waterbody would also be distinct to the area due to its height approximately six feet above the existing surrounding lands. The proposed Holthouse Reservoir would result in a major enlargement of the existing Funks Reservoir. All other associated proposed Project facilities would also change the landscapes at the individual facility locations.

In addition, new sources of permanent nighttime light would be required for safety purposes at most of the proposed Project facilities, including along the South Bridge and in the Recreation Areas. Vehicles traveling on the proposed South Bridge and the new roads, as well as visitors to the new campgrounds at Sites Reservoir, would also create a new source of nighttime light in the area.

33.2.6 Biological and Cultural Resources Impacts

The proposed Project would result in the removal and/or disturbance of vegetation at Project facility sites, with associated impacts on wildlife species that inhabit those areas. The proposed Project would affect existing wetlands at Project facility sites, and would also result in effects to aquatic biological species.

The proposed Project also would disturb cultural resources, including those that are eligible for the California Register of Historical Resources and the National Register of Historic Places, that currently exist within the footprints of the proposed Project facilities.

These effects to biological and cultural resources are all considered irreversible and irretrievable commitments of those resources.

33.3 Potential Environmental Accidents

The *CEQA Guidelines* also require a discussion of the potential for irreversible environmental damage caused by an accident associated with a project (AEP, 2011). Construction of the all of the proposed Project's action alternatives would result in the use, transport, storage, and disposal of hazardous wastes. DWR and Reclamation would require all construction, operation, and maintenance activities to comply with applicable federal, State, and local laws related to hazardous materials, which would significantly reduce the likelihood and severity of accidents that could cause irreversible environmental damage as a result of Project construction, operation, and maintenance.

In addition, because the potential exists for dams to fail, DWR prepared a potential dam break inundation map that reflects the inundation scenario associated with the proposed Sites Reservoir and its dams. The flood wave that would result from a hypothetical breach of Golden Gate Dam or Sites Dam has a small probability of occurring, but would present a significant hazard to both occupied and non-occupied structures downstream of the proposed Sites Reservoir.

The proposed Sites Reservoir dams would be designed and constructed pursuant to conservative guidelines and criteria designed to prevent failure. The design would incorporate multiple lines of defense or design redundancy. As required by the Division of Safety of Dams (DSOD), the dam would be designed to withstand the largest and strongest earthquake (Maximum Credible Earthquake), as well as the largest possible flood (Probable Maximum Flood). The proposed Sites Reservoir would include an emergency spillway to release flows with an elevation set to the potential probable maximum flood water surface elevation. Operation of Golden Gate and Sites dams would be monitored by instrumentation measuring such parameters as seepage, settlement, and earthquake-induced accelerations, which could provide early warning signs of potential dam failure. With modern design criteria and construction practices, combined with DSOD review, the probability of dam failure is extremely small. In addition, DSOD requires that large reservoirs, such as Sites Reservoir, have facilities capable of allowing rapid emergency drawdown of the water in the reservoir in the event of an unsafe condition at the dam. The proposed Sites Reservoir would accomplish this drawdown via the outlet tunnel in the proposed Sites Reservoir Inlet/Outlet Structure, which could discharge emergency release flows directly into Funks Creek; some of this drawdown could be attenuated by the proposed Holthouse Reservoir or released via the proposed Delevan Pipeline, the existing T-C Canal, or the existing GCID Canal.

33.4 Commitment of Future Generations to Similar Uses

As indicated previously for the impacts to existing graves within the footprint of the proposed Sites Reservoir and the landscape character of the proposed Project facility sites, the impacts of implementation of any of the proposed Project's action alternatives on these resources are considered irreversible. Similarly, the changes in land use and the impacts on biological and cultural resources from the implementation of any of the proposed Project's action alternatives are considered irreversible and irretrievable. These impacts are considered irreversible and irretrievable because once the proposed Project facilities are constructed and operational, it is not expected that the facilities would be decommissioned and demolished, and the land recontoured and restored to its existing condition, prior to the end of the proposed Project's lifespan (100 years). The proposed Project is expected to operate until the end of the Project lifespan due to the monetary investment that would be made to construct, operate, and maintain the Project, as well as the benefits that the Project would provide.

For these same reasons, implementation of any of the proposed Project's action alternatives would commit future generations to similar uses at the proposed Project facility sites. This proposed long-term commitment of lands for Project purposes is a change from Existing Conditions, but is not necessarily adverse. DWR and Reclamation would comply with all federal, State, and local laws, ordinances, regulations, and standards to minimize impacts on the environment during the proposed Project's construction, as well as during its long-term operation and maintenance.

34. Growth-Inducing Impacts

34.1 Introduction

This chapter presents an analysis of the potential growth-inducing impacts of the No Project/No Action Alternative and the three proposed Project action alternatives, Alternatives A, B, and C. To provide context for this assessment, this chapter also briefly describes population projections in the three study areas, which were presented in Chapter 22 Socioeconomics.

34.2 California Environmental Quality Act and National Environmental Policy Act Requirements

To comply with the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA), an Environmental Impact Report (EIR) and an Environmental Impact Statement (EIS), respectively, must discuss the ways in which the alternatives could result in indirect effects to the environment, including growth-inducing effects. This section briefly describes the CEQA and NEPA requirements related to growth-inducing impacts.

34.2.1 California Environmental Quality Act Requirements

CEQA requires that an EIR evaluate the growth-inducing impacts of a proposed project (California Public Resource Code Section 21100(b)(5)). The State CEQA Guidelines, Section 15126.2(d), state that an EIR should discuss the:

> *"Growth-Inducing Impact of the Proposed Project. Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects. Also discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment."*

Consideration of growth-inducing impacts pursuant to CEQA has been further described in *Napa Citizens for Honest Government v. Napa County Board of Supervisors* (2001) (91 Cal.App.4th 342, 367-371[110 Cal.Rptr.2d 579]) in which the California Court of Appeal, Fourth District stated:

> *"Neither CEQA itself, nor the cases that have interpreted it, require an EIR to anticipate and mitigate the effects of a particular project on growth in other areas. In circumstances such as these, it is sufficient that the final EIR (FEIR) warns interested persons and governing bodies of the probability that additional housing will be needed so that they can take steps to prepare for or address that probability. The FEIR need not forecast the impact that the housing will have on as yet unidentified areas and propose measures to mitigate that impact."*

34.2.2 National Environmental Policy Act Requirements

The EISs prepared by the Department of the Interior (DOI) agencies, including Reclamation, are prepared using regulations implementing NEPA as prepared by DOI and the Council on Environmental Quality (CEQ). The CEQ regulations require an EIS to consider indirect effects of a project, which are often related to growth-inducing effects (40 CFR 1508.8(b)), as described below:

> *"Indirect effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems."*

34.3 Environmental Setting/Affected Environment

This analysis includes an Extended Study Area, Secondary Study Area, and a Primary Study Area, as described in more detail below.

34.3.1 Extended Study Area

The Extended Study Area includes the entire service areas of the State Water Project (SWP) and Central Valley Project (CVP). These two service areas are located within all or portions of the following 39 counties: Alameda, Butte, Calaveras, Colusa, Contra Costa, El Dorado, Fresno, Glenn, Imperial, Kern, Kings, Los Angeles, Madera, Merced, Monterey, Napa, Nevada, Orange, Placer, Plumas, Riverside, Sacramento, San Benito, San Bernardino, San Diego, San Joaquin, San Luis Obispo, Santa Barbara, Santa Clara, Santa Cruz, Shasta, Solano, Stanislaus, Sutter, Tehama, Tulare, Tuolumne, Ventura, and Yolo. The proposed Project's primary objective of improved water supply reliability has the potential for long-term direct and indirect effects within those two service areas. The Extended Study Area is shown on Figure 1-6 in Chapter 1 Introduction.

34.3.2 Secondary Study Area

The Secondary Study Area is defined as the area of potential Project-related operational effects, including SWP and CVP facilities that could experience reservoir water surface elevation fluctuations and stream flow changes downstream from their facilities. Those facilities are located within the following 22 counties: Alameda, Butte, Colusa, Contra Costa, Del Norte, El Dorado, Glenn, Humboldt, Marin, Placer, Sacramento, San Francisco, San Mateo, Santa Clara, Shasta, Solano, Sonoma, Sutter, Tehama, Trinity, Yolo, and Yuba.

The potential operational changes could occur as a result of the coordinated and integrated operation of the proposed Project facilities with State and federal projects located on the American River, Trinity River, Sacramento River, Clear Creek, Spring Creek, Feather River, and the Sacramento-San Joaquin Delta (Delta). The Secondary Study Area is shown on Figure 1-8 in Chapter 1 Introduction.

34.3.3 Primary Study Area

The Primary Study Area is defined as the areas within Glenn and Colusa counties where short-term and long-term direct effects from constructing, operating, and/or maintaining proposed Project facilities may occur. This area includes the footprints of the proposed Sites Reservoir Inundation Area and the associated facilities (e.g., dams, bridge, regulating reservoirs, intakes/discharge facilities, pipelines, electrical transmission line, electrical distribution lines, pumping/generating plants, recreation areas, and new and relocated roads). The Primary Study Area is shown on Figures 1-9A, 1-9B, and 1-9C in Chapter 1 Introduction for Alternatives A, B, and C.

34.4 Project Components Potentially Related to Growth

A project could result in growth-inducing impacts through several means, including the removal of obstacles to population growth, or actions that encourage and facilitate other activities beyond those proposed by the project. Growth-inducing impacts are generally related to actions that could increase economic or population growth, including the need for additional housing or community services, that could result in direct or indirect changes in the environment in addition to direct impacts related to implementation of that project.

Direct growth inducement would occur if a project directly results in new permanent employment opportunities or new permanent residents, which would increase long-term demands for public services and utilities or result in changes to land use and potentially effects on other environmental resources.

Indirect growth inducement could occur if a project eliminates an obstacle to population growth or land development that currently prevents achievement of adopted growth projections, such as increased water supply availability. Indirect growth inducement also could occur if a project results in improved economic activity that causes population growth in excess of adopted growth projections. Potential impacts related to growth projections in adopted land use plans and growth management policies (e.g., transportation management plans) generally are addressed by measures to avoid or mitigate direct and indirect impacts to the extent feasible.

For this EIR/EIS, growth inducement is primarily related to expected changes in water supply reliability and/or water quality for agricultural, municipal, and industrial water users, as described below.

- **Improve water supply reliability for agricultural, urban, and environmental uses.** One primary objective of the proposed Project is to improve water supply reliability. Water supply reliability requires the delivery of specified amounts of water at predictable locations and times. During prolonged drought periods, water supplies are less reliable, which increases competition and can lead to conflict among users. This can be exacerbated by a lack of surface water storage due to increased environmental requirements, and reduced natural rainfall for agriculture. The proposed Project is intended to help ease the pressure on a system that is already having difficulty serving California's water needs. By providing additional surface water storage capacity to capture early runoff, additional fresh water would be available to improve water supply reliability.

- **Improve water quality.** The Delta is the diversion point for drinking water for millions of Californians, and is critical to California's agricultural economy. The proposed Project could improve water quality with increased flows by releasing high quality stored water into the Sacramento River during periods when Delta water quality is impaired.

- **Provide more options for water management.** The existing State and federal water systems, SWP and CVP, are relatively rigid in terms of timing, location, and how water is pumped from the Delta. Urban, agricultural, and environmental water needs have each increased and have created conflicting demands for limited water supplies. Water management flexibility can create a more rapid response to meeting these demands, but also for unexpected incidents, such as Delta levee breaks. Strategically located surface water storage would provide flexibility in the system for agricultural, environmental, and municipal and industrial users.

- **Increased recreational opportunities.** The proposed Project would include up to five new recreation areas. Collectively, recreation opportunities at the five recreation areas could provide: boating, camping, picnicking, fishing, swimming, and hiking. Depending on the recreation area, proposed facilities may include boat launch sites, trails, designated swimming and fishing access, picnic tables, shaded canopies, campfire rings/barbeques, vault toilets, and dumpsters.
- **Increased temporary and permanent employment opportunities.** The proposed Project would require part-time and full-time construction workers during its construction and operation. The proposed Project also would improve water supply reliability for agricultural water users in the Extended Study Area, which would increase agriculturally-related employment.

34.5 Environmental Impacts/Environmental Consequences

34.5.1 Regulatory Setting

The regulatory requirements pursuant to CEQA and NEPA are summarized in Section 34.2.

34.5.2 Evaluation Criteria and Significance Thresholds

The evaluation criteria used for this impact analysis represent thresholds that were used to identify whether an impact would be significant pursuant to CEQA. Although CEQA does not provide specific significance thresholds for Growth-Inducing Impacts, the proposed Project was evaluated based on the following general requirements of Section 15126.2(d) of CEQA and professional judgment that considered current regulations, standards, and knowledge of the area. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Growth that is not consistent with or accommodated by the land use plans and growth management plans and policies for the area affected.
- Secondary growth effects, including increased demand on community and public services and infrastructure, increased traffic and noise, and adverse environmental impacts, such as degradation of air and water quality and conversion of agricultural and open space land to developed uses.

Similar evaluation criteria were used for the environmental analysis pursuant to NEPA; however, levels of significance for impacts are not defined.

34.5.3 Impact Assessment Assumptions

This analysis necessarily takes a general approach to determining potential growth-inducing impacts of the proposed Project. The specific areas of delivery and end use of proposed Project water are unforeseeable and too speculative for site-specific analysis. Furthermore, the CEQA Guidelines do not require that an EIR predict (or speculate) specifically where such growth would occur, in what form it would occur, or when it would occur. The answers to such questions require speculation, which CEQA discourages (CEQA Guidelines Section 15145).

This impact assessment analyzes the effects of the proposed Project facilities listed above that could influence growth, including:

- Improved water supply reliability, water quality, and options for urban water supplies
- Additional recreational opportunities
- Increased temporary and permanent employment opportunities

34.5.3.1 Improved Water Supply Reliability, Water Quality, and Options for Urban Water Supplies

As described in Chapter 22 Socioeconomics, population projections have been developed for the Extended Study Area that would include urban areas that could use improved water supplies from the proposed Project. The causal link between improved water supply reliability (including conditions related to increased options for urban water supplies) and water quality and any increase in population or economic growth could be speculative because the specific location of users with improved water supply conditions and the quantitative incremental improvement is not known. Because this issue cannot be determined with certainty, for the purposes of this EIR/EIS, the assumption was made that improved water supply conditions could stimulate growth.

The potential to stimulate growth does not necessarily result in "growth-inducement" or secondary growth impacts that have not been provided for in existing land use, public works, utilities, and community services plans. The determination if the growth is to be considered "growth-inducing" has been analyzed with respect to the ability of existing water supplies to meet the demand of population projections in existing planning documents. Information provided to the California Department of Water Resources (DWR) through submittals of Urban Water Management Plans was used to determine if urban water supplies have adequate water supplies to meet the water demands for 2030 population growth projections.

34.5.3.2 Improved Recreational Opportunities

As described in Chapter 21 Recreation Resources and Chapter 22 Socioeconomics, estimates for increased recreational use and recreational employment have been developed for the proposed Project alternatives, and compared to Existing Conditions and the No Project/No Action Alternative. The increased recreational use and employment could stimulate growth. As described above, the potential to stimulate growth does not necessarily result in "growth-inducement" or secondary growth impacts that have not been provided for in existing land use, public works, utilities, and community services plans. The increase in recreation use and employment are discussed in this chapter relative to existing community plans.

34.5.3.3 Increased Temporary and Permanent Employment Opportunities

As described in Chapter 22 Socioeconomics, estimates for increased temporary and permanent employment opportunities have been developed for the proposed Project alternatives, and compared to Existing Conditions and the No Project/No Action Alternative. The increased employment could stimulate growth. As described above, the potential to stimulate growth does not necessarily result in "growth-inducement" or secondary growth impacts that have not been provided for in existing land use, public works, utilities, and community services plans. The increase in employment is discussed in this chapter relative to existing community plans.

It should be noted that DWR, Reclamation, and/or water supply agencies that are not part of cities cannot make local decisions regarding the extent and location of growth. Cities and counties are responsible for considering the environmental effects of their growth and land use planning decisions with appropriate mitigation measures in accordance with CEQA.

34.5.4 Growth-Inducing Impacts Associated with the No Project/No Action Alternative

34.5.4.1 Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009, as described in Chapter 3, Description of Proposed Project/Proposed Action and Alternatives and listed in Tables 3-1, 3-2, and 3-3. The impacts of the projects included in the No Project/No Action Alternative have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for growth-inducing impacts has been addressed in those environmental documents.

In addition, if the No Project/No Action Alternative is implemented, no facilities would be constructed pursuant to the proposed Project alternatives, resulting in no direct or indirect growth inducement within the three study areas related to those facilities.

Economic Growth Opportunities Related to Improved Water Supply Reliability, Water Quality, and Options for Urban Water Supplies

Changes in water supply reliability, water quality, and options for urban water supplies associated with implementation of the No Project/No Action Alternative would affect long-term average water deliveries and water deliveries. Historically, urban development depended upon the availability of long-term water supplies and would implement water conservation measures to maintain community services during Dry and Critical Dry years. In the future, water conservation measures would be included in long-term average water demand projections, and there would be fewer opportunities to reduce water demands without substantial effects to water users.

Expected water supply conditions with implementation of the No Project/No Action Alternative for urban water users within the Extended and Secondary study areas are difficult to define with specificity due to the wide range of water supplies, including surface water rights, groundwater resources, supplies from wastewater and stormwater reclamation, water transfers, water conservation, carryover storage in surface water reservoirs and groundwater aquifers, and ocean and brackish water desalination along the coastlines and in areas with brackish groundwater. Also, by 2020, the State has mandated the statewide reduction of urban water demand by 20 percent. Recently, more than 300 urban water agencies and private utilities submitted Urban Water Management Plans (UWMPs) to DWR that provide a broad perspective on water supplies through 2030. The UWMPs consider water demands following the reduction in statewide urban water demand by 2020, implementation of future water supplies, and the ability of water supplies to meet water demands in Normal, Single-Dry, and Multiple-Dry water years.

Many water supply agencies have indicated in their UWMPs that long-term average water supplies in Year 2030 would be managed at a level greater than long-term water demands, including storage of water during wetter years to be used during drier years. Overall, comparison of the long-term water supplies to the long-term water demands can be used to evaluate the potential for economic growth and for removal of obstacles to growth. The UWMPs include continuing implementation of existing water supply facilities and facilities that were under construction during preparation of this EIR/EIS, including water supply projects listed in Tables 3-1 and 3-2.

Information from representative UWMPs submitted to DWR by communities that could use water supplied through SWP or CVP conveyance facilities are summarized in Table 34-1. This table summarizes information presented in UWMPs submitted to DWR between 2010 and 2013 related to projected population, urban water use or demand in Normal water years, and urban water supplies in Normal water years. The values for urban water use in 2030 include assumptions related to the statewide 20 percent reduction in urban water use by 2020.

Table 34-1
Projected Population, Water Use, and Long-Term Water Supplies in Normal Water Years[a] for Major Communities in Water Delivery Regions that Use SWP and CVP Water Supplies

	Sacramento Valley[b]	San Joaquin Valley[c]	San Francisco Bay Area[d]	Central Coast[e]	Southern California[f]	TOTAL
2010 Population	1036,000	734,000	4,911,000	292,000	21,568,000	**28,541,000**
2030 Population	1,424,000	1,106,000	5,920,000	335,000	26,054,000	**34,839,000**
2010 Urban Water Use (Demand) in a “Normal” Water Year (af/yr)	359,000	374,000	1,088,000	29,000	4,689,000	**6,539,000**
2030 Urban Water Use (Demand) in a “Normal” Water Year (af/yr and % increase from 2010)	591,000 (64%)	390,000 (4%)	1,288,000 (18%)	28,000 (0)	5,306,000 (13%)	**7,603,000 (16%)**
2010 Urban Water Supplies in a “Normal” Water Year (af/yr)	690,000	383,000	1,304,000	43,000	5,496,000	**7,916,000**
2030 Urban Water Supplies in a “Normal” Water Year (af/yr and % increase from 2010)	852,000 (24%)	468,000 (22%)	1,386,000 (6%)	43,000 (0)	5,882,000 (7%)	**8,631,000 (9%)**

[a]Normal water years are defined as long-term average water year values, pursuant to the DWR “Guidebook to Assist Urban Water Suppliers to Prepare a 2010 Urban Water Management Plan.”

[b]Includes information from 2010 Urban Water Management Plans (UWMPs) for El Dorado Irrigation District, Folsom, Placer County Water Agency, Roseville, Sacramento County Water Agency, Sacramento Suburban Water District, San Juan Water District, West Sacramento, and Yuba City.

[c]Includes information from 2010 UWMPs for Fresno, Stockton, and Tracy.

[d]Includes information from 2010 UWMPs for Alameda County Water District, Contra Costa Water District, East Bay Municipal Utility District, Hollister, Napa, Santa Clara Valley Water District, Solano County Water Agency, and Zone 7 Water Agency.

[e]Includes information from 2010 UWMP for Central Coast Water Authority.

[f]Includes information from 2010 UWMPs for Antelope Valley-East Kern Water Agency, Coachella Valley Water District, Crestline-Lake Arrowhead Water Agency, Desert Water Agency, Metropolitan Water District of Southern California, Mojave Water Agency, Palmdale Water District, San Bernardino Valley, San Gorgonio Pass Water Agency, and Santa Clarita Valley (Castaic Lake Water Agency et al).

Notes:

af/yr = acre feet per year
CVP = Central Valley Project
SWP = State Water Project

Sources: ACWD, 2011; AVEK, 2011; CCWA, 2011; CCWD, 2011; CLAWA, 2011; CLWA et al., 2011; CVWD, 2011; DWA, 2011; EBMUD, 2011; EID, 2011; Folsom, 2011; Fresno, 2012; Hollister, 2011; Metropolitan, 2010; MWA, 2011; Napa, 2011; PCWA, 2011; PWD, 2011; Roseville, 2011; SBVWD et al., 2011; SCVWD, 2011; SCWA, 2011; SGPWA, 2010; SJWD, 2011; Solano CWA, 2011; SSWD, 2011; Stockton, 2011; Tracy, 2011; West Sacramento, 2011; Yuba City, 2011; and Zone 7, 2010.

The values in Table 34-1 indicate that, in Normal water years, water supplies are generally greater than urban water demand. The portion of water supplies not used in Normal or Wet years generally is directly or indirectly stored in surface water storage reservoirs or groundwater aquifers for use in drier years.

Information in the UWMPs indicates that water supplies can be substantially reduced in drier years, which require implementation of strict water conservation to continue to meet the water demands. Information from the UWMPs is used by land use planning agencies to determine if adequate water supplies exist for future population projections and land use development. The UWMPs generally indicate that existing and projected water supplies for the No Project/No Action Alternative are adequate for population projections in existing land use plans. The No Project/No Action Alternative includes facilities that were approved for construction or under construction during preparation of this EIR/EIS. The effects of implementation of those facilities are already included in adopted planning documents and UWMPs.

In summary, implementation of planned projects included in the No Project/No Action Alternative is not anticipated to result in growth-inducing effects in addition to those discussed in adopted general plans and associated environmental documentation in the Extended, Secondary, or Primary study areas because the water supply agencies are already planning on implementation of the facilities included in the No Project/No Action Alternative, including those related to improved water supply reliability, water quality, and options for urban water supplies.

Economic Growth Opportunities Related to Improved Recreational Opportunities

The No Project/No Action Alternative includes future projects that would either maintain or improve existing recreational opportunities within the Extended and Secondary study areas due to projected facilities. Additional recreational opportunities could occur due to increased fishing opportunities in the Sacramento Valley due to implementation of the projects included in the No Project/No Action Alternative. Most of the projects included in the No Project/No Action Alternative do not include specific facilities to improve recreational opportunities. The Oroville FERC License Renewal, Los Vaqueros Reservoir Expansion, Yolo Bypass Wildlife Area Land Management Plan, San Joaquin River Restoration, Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan, and North American Waterfowl Management Plan include actions that could improve recreational opportunities.

As described in Chapter 22 Socioeconomics, it is anticipated that, if the No Project/Action Alternative is implemented, recreation expenditure patterns in the Extended and Secondary study areas would be similar to those described for Existing Conditions. Growth in population is expected to cause growth in recreation economic activity. **Therefore, expected increased recreational opportunities in the Extended and Secondary study areas associated with implementation of the No Project/No Action Alternative are not anticipated to result in growth-inducing impacts not previously addressed in existing environmental documentation for adopted general plans.**

As described in Chapter 21, Recreation Resources, none of the projects and programs included in the No Project/No Action Alternative are or would be located within the Primary Study Area, or would directly or indirectly affect existing recreation opportunities in the Primary Study Area.

Economic Growth Opportunities Related to Increased Temporary and Permanent Employment

As described in Chapter 22 Socioeconomics, the No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. **The impacts of these projects have already been evaluated on a project by project basis, pursuant to CEQA and/or NEPA, and their potential to exceed established standards has been addressed in those environmental documents (e.g., the Oroville FERC License Renewal and Los**

Vaqueros Reservoir Expansion); therefore, these projects are not anticipated to result in growth-inducing impacts.

34.5.5 Growth-Inducing Impacts Associated with Alternative A

34.5.5.1 Extended, Secondary, and Primary Study Areas – Alternative A

Implementation of Alternative A is expected to improve water supply reliability, increase water supply, improve water quality and provide water management flexibility in the Extended, Secondary, and Primary study areas. Alternative A is also expected to provide increased employment and recreational opportunities. The potential of Alternative A to induce growth is discussed below.

Economic Growth Opportunities Related to Improved Water Supply Reliability, Water Quality, and Options for Urban Water Supplies

Improved water supply reliability, water quality, and options for urban water supplies would affect long-term average water deliveries and water deliveries in Dry and Critical water years. Historically, urban development depended upon the availability of long-term water supplies, and urban users would implement water conservation measures to maintain community services during Dry and Critical Dry years. In the future, water conservation measures would be included in long-term average water demand projections, and there would be fewer opportunities to reduce water demands without substantial effects to water users. Therefore, many water supply agencies have indicated in their UWMPs that long-term average water supplies would be managed at a level greater than long-term water demands to allow for storage of water to be used during Dry and Critical Dry years. Overall, comparison of the long-term water supplies to the long-term water demands can be used to evaluate the potential for economic growth and for removal of obstacles to growth.

With implementation of Alternative A, long-term average CVP water deliveries to municipal and industrial (M&I) water users (primarily located in urban communities) in the Sacramento Valley and San Francisco Bay Area could increase by 29 to 151 percent, when compared to Existing Conditions (refer to Table 6-118[1]). However, that increase in water deliveries could occur with implementation of the No Project/No Action Alternative (refer to Table 6-37) and not be related to implementation of Alternative A. With Alternative A, M&I water deliveries for the CVP could increase zero to one percent, when compared to the No Project/No Action Alternative (refer to Table 6-119).

With Alternative A, long-term average SWP water deliveries to M&I water users in the Sacramento Valley, San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California could increase by one to nine percent, when compared to Existing Conditions (refer to Table 6-120). A portion of that increase could occur with implementation of the No Project/No Action Alternative (refer to Table 6-38) and not be related to implementation of Alternative A. With implementation of Alternative A, M&I water deliveries for the SWP could increase five to six percent, when compared to the No Project/No Action Alternative (refer to Table 6-121).

Similar increases in Dry and Critical Dry water year deliveries are projected with implementation of Alternative A, when compared to the No Project/No Action Alternative, as described in Chapter 6 Surface Water Resources.

[1] All tables "6-XX" refer to tables in Chapter 6 Surface Water Resources.

Changes in long-term average water deliveries of one to six percent with implementation of Alternative A, when compared to the No Project/No Action Alternative, are similar or substantially less than the anticipated increase of 6 to 39 percent in long-term average water supplies for major urban water users in the Sacramento Valley, San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California (refer to Table 34-1). As discussed in Chapter 22 Socioeconomics, implementation of Alternative A could be used to avoid the implementation of other more expensive water supplies that are included in the future assumptions for the UWMPs.

Reduced M&I water supply costs does not necessarily imply a rise in local economic activity. If the cost savings are spent on other goods and services within the local or regional economy, economic growth could be increased. However, if most of the savings are spent outside the local or regional economy, the benefits may not be realized. Because the cost savings could be small relative to the urban economy, and the spending patterns are uncertain, the economic benefits that could occur with implementation of Alternative A would result in a minor growth effect.

Increased water deliveries to agricultural water users in the Extended Study Area are not expected to be growth inducing, and could reduce the potential to change adopted land use plans that would allow conversion of agricultural lands to urban uses. This is because increased agricultural water deliveries, expected with implementation of Alternative A, could range from zero to three percent, when compared to Existing Conditions, and zero to five percent, when compared to the No Project/No Action Alternative (refer to Tables 6-118 through 6-121). Although the expected increased water supply deliveries could result in increased employment and other economic benefits, the effects on housing and population are expected to be minor in the Extended Study Area, when compared to the total housing and population (refer to Chapter 22 Socioeconomics).

In summary, expected improved water supply reliability, water quality, and options for urban water supplies associated with implementation of Alternative A are not anticipated to result in growth-inducing effects through improved economic growth in the Extended, Secondary, or Primary study areas.

Economic Growth Opportunities Related to Improved Recreational Opportunities

Implementation of Alternative A is expected to provide additional recreational opportunities within the Primary Study Area. Total recreation visitation is anticipated to increase by more than 358,000 annual visits, increasing non-local recreation expenditures to approximately $2.9 million (refer to Table 22-36[2]). **Expected increased recreation expenditures associated with implementation of Alternative A would represent less than 0.2 percent of total industrial expenditures in the Primary Study Area and are not anticipated to increase growth within the entire Primary Study Area.**

Increased recreational visits could result in additional demands for public services and utilities, including the use of roadways and utilities. As described in Chapter 26 Navigation, Transportation, and Traffic, the expected increase in recreational visits would not increase traffic in excess of existing acceptable levels of service of existing roadways, with the implementation of mitigation measures (refer to Table 26-20). Alternative A would not be expected to result in the need to expand roadways which could also support future growth, as described in Chapter 26 Navigation, Transportation, and Traffic. Increased demands on public services and utilities with implementation of Alternative A also would not be expected to result in

[2] All tables "22-XX" refer to tables in Chapter 22 Socioeconomics.

the need for expanded infrastructure which could also support future growth, as described in Chapter 29 Public Services and Utilities. However, increased recreation use could adversely affect public services due to increased traffic. The expected increase in traffic would result in a less-than-significant impact with implementation of mitigation measures (refer to Table 29-9). **Therefore, the expected increased recreational opportunities in the Primary Study Area associated with implementation of Alternative A are not anticipated to result in growth-inducing impacts.**

Economic Growth Opportunities Related to Increased Temporary and Permanent Employment

Implementation of Alternative A could result in an increase of 72 jobs in the agricultural sector in the Extended Study Area due to the expected increased water supply reliability (refer to Table 22-26). **The expected magnitude of the impacts would be less than one percent, when compared to the regional economy of the Extended Study Area, and is not anticipated to result in growth-inducing impacts.**

Implementation of Alternative A is expected to provide additional employment opportunities in the Primary Study Area for both construction and operation/maintenance of the proposed Project facilities. Implementation of Alternative A could result in 581 additional temporary jobs (primarily due to construction of the proposed facilities pursuant to Alternative A) and 59 additional permanent jobs (primarily for the proposed water supply facilities operation and recreational facilities), when compared to the No Project/No Action Alternative (refer to Tables 22-33 and 22-34). The majority of the temporary jobs would be associated with construction. It is anticipated that most of the construction jobs would be filled from within the Primary Study Area. However, construction may require specialized worker skills not readily available in the local labor pool. As a result, it is anticipated that some of the non-local workers would travel from outside the two-county Primary Study Area. Considering the multi-year duration of construction, it is anticipated that 20 percent of the imported workers would relocate to the two-county region, adding to the local population. It is anticipated that all of the workers required for operation would relocate to the two-county region. This additional population from construction and operation would constitute a minor increase in the total 2020 projected regional population of 64,605 and would not pose a burden on local public services, utilities, or infrastructure. In addition, these jobs would represent less than a one percent increase in the total labor force in the Primary Study Area, as described in Chapter 22 Socioeconomics.

Most of the construction and operation workforce would most likely commute daily to the proposed Project site from within the two-county region; however, if needed, there are approximately 2,000 available housing units to accommodate workers who may choose to commute to the proposed Project site on a workweek basis or who may choose to relocate to the region, as described in Chapter 22 Socioeconomics. In addition to the available housing units, there are recreational vehicle parks within the two-county region to accommodate construction workers. As a result, construction and operation of the proposed Project is not expected to increase the demand for housing within the two-county region. Within specific local communities, there could be localized effects on housing during proposed Project construction. However, given the availability of housing within the two-county region, predicting where this impact may occur would be highly speculative.

As described above and Chapter 22 Socioeconomics, construction and operation of Alternative A would be expected to result in a minor increase in jobs and population in the Primary Study Area which could be accommodated within available housing units. **An adequate housing supply exists to accommodate the**

change in population, and as such, this expected increase associated with implementation of Alternative A is not anticipated to be growth inducing.

Removing Obstacles to Growth

A variety of factors indirectly influence business, residential, and population growth in a region. Among these are General Plans and policies, and the availability of public utility services, public schools, and transportation services. Water is one of the primary public services needed to support urban development, including businesses, industry (including agriculture), and housing. If a deficiency in water service capacity constrains future development, then improving water supply reliability and increasing water supply would remove a physical impediment to planned development and result in growth-inducing impacts.

However, as described above, the expected increase in water yield associated with implementation of Alternative A would be within the range of projected increases of water supplies by major urban water users in their recent UWMPs to provide adequate water supplies for planned growth. The expected additional water deliveries associated with implementation of Alternative A to urban water users probably could be considered as replacement water supplies instead of implementing other projects identified in the UWMPs. A portion of the expected improved water supply reliability also could be used for agricultural water supplies or to improve environmental conditions in specific streams. However, because the UWMPs have identified adequate water supplies to meet future water demands in 2030 for the Long-Term average and Dry and Critical Dry year conditions, it does not appear that growth is currently being adversely affected due to lack of water supplies in these major urban communities. **Implementation of Alternative A is not anticipated to result in the removal of obstacles to growth, and therefore, is not anticipated to result in growth-inducing impacts.**

It should be noted that DWR, Reclamation, and/or water supply agencies that are not part of cities cannot make local decisions regarding the extent and location of growth. Cities and counties that could receive water from the proposed Project are responsible for considering the environmental effects of their growth and land use planning decisions. When new developments are proposed, the cities and counties must prepare environmental documents pursuant to CEQA; and where appropriate, these agencies must consider mitigation measures to reduce adverse impacts of the growth and/or overriding considerations.

34.5.6 Growth-Inducing Impacts Associated with Alternative B

34.5.6.1 Extended, Secondary, and Primary Study Areas – Alternative B

Similar to Alternative A, implementation of Alternative B would be expected to improve water supply reliability, increase water supply, improve water quality, and provide water management flexibility in the Extended, Secondary, and Primary study areas. Implementation of Alternative B would also be expected to provide increased employment and recreational opportunities. The potential of Alternative B to induce growth is discussed below.

Economic Growth Opportunities Related to Improved Water Supply Reliability, Water Quality, and Options for Urban Water Supplies

The expected long-term average CVP water deliveries to M&I water users in the Sacramento Valley and San Francisco Bay Area associated with implementation of Alternative B would be similar to those described for Alternative A. The expected increase would be from 29 to 149 percent, when compared to

Existing Conditions, rather than the 29 to 151 percent increase associated with Alternative A. This increase in water deliveries could occur with implementation of the No Project/No Action Alternative and not be related to implementation of Alternative B. With Alternative B implementation, expected M&I water deliveries for the CVP would be similar to water deliveries described for the No Project/No Action Alternative and Alternative A.

With Alternative B implementation, long-term average SWP water deliveries to M&I water users in the Sacramento Valley, San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California could increase by one to nine percent, when compared to Existing Conditions (i.e., the same as described for Alternative A). A portion of that increase could occur with implementation of the No Project/No Action Alternative and not be related to implementation of Alternative B. With implementation of Alternative B, M&I water deliveries for the SWP could increase five to six percent (the same as for Alternative A), when compared to the No Project/No Action Alternative.

Similar increases in Dry and Critical Dry water year deliveries are projected with implementation of Alternative B, when compared to expected increases with implementation of the No Project/No Action Alternative and Alternative A.

Expected changes in long-term average water deliveries of one to six percent with implementation of Alternative B, when compared to the No Project/No Action Alternative, are similar or substantially less than the anticipated increase of 6 to 39 percent in long-term average water supplies for major urban water users in the Sacramento Valley, San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California. This change is the same as was described for Alternative A.

Similar to that described for Alternative A, because the water supply cost savings could be small relative to the urban economy and the spending patterns are uncertain, the economic benefits that could occur with Alternative B implementation would be expected to result in a minor growth effect.

Expected increased agricultural water deliveries associated with implementation of Alternative B could range from zero to one percent (whereas it would be expected to range from zero to three percent with Alternative A implementation), when compared to Existing Conditions, and zero to six percent (whereas it would be expected to range from zero to five percent with Alternative A implementation), when compared to the No Project/No Action Alternative. Similar to that described for Alternative A, although the increased water supply deliveries could result in increased employment and other economic benefits, the effects on housing and population are expected to be minor in the Extended Study Area, when compared to the total housing and population.

In summary, similar to that described for Alternative A, expected improved water supply reliability, water quality, and options for urban water supplies associated with implementation of Alternative B is not anticipated to result in growth-inducing effects through improved economic growth in the Extended, Secondary, or Primary study areas.

Economic Growth Opportunities Related to Improved Recreational Opportunities

Similar to that described for Alternative A, Alternative B would be expected to provide additional recreational opportunities within the Primary Study Area, i.e., recreation visitation is anticipated to increase by more than 355,000 annual visits with Alternative B implementation, and 358,000 visits with Alternative A implementation, increasing non-local recreation expenditures to approximately $2.9 million. **Similar to Alternative A, the expected increased recreation expenditures associated**

with implementation of Alternative B would represent less than 0.2 percent of total industrial expenditures in the Primary Study Area and are not anticipated to increase growth within the entire Primary Study Area.

Similar to that described for Alternative A, increased recreational visits could result in additional demands for public services and utilities, including the use of roadways and utilities. The expected increase in recreational visits would not increase traffic in excess of existing acceptable levels of service of existing roadways, with the implementation of mitigation measures (refer to Table 26-20), and Alternative B implementation would not be expected to result in the need to expand roadways which could also support future growth, as described in Chapter 26 Navigation, Transportation, and Traffic. Expected increased demands on public services and utilities associated with implementation of Alternative B would also not be expected to result in the need for expanded infrastructure which could also support future growth, as described in Chapter 29 Public Services and Utilities. However, increased recreation use could adversely affect public services due to expected increased traffic. The expected increase in traffic would result in less than significant impacts with implementation of mitigation measures (refer to Table 29-9). **Therefore, similar to that described for Alternative A, the expected increased recreational opportunities in the Primary Study Area associated with implementation of Alternative B are not anticipated to result in growth-inducing impacts.**

Economic Growth Opportunities Related to Increased Temporary and Permanent Employment

Implementation of Alternative B could result in an increase of 60 jobs in the in the agricultural sector of the Extended Study Area due to the expected increased water supply reliability, whereas, Alternative A implementation could result in an increase of 72 jobs. **Similar to that described for Alternative A, the expected magnitude of the impacts associated with implementation of Alternative B would be less than one percent, when compared to the regional economy of the Extended Study Area, and is not anticipated to result in growth-inducing impacts.**

Implementation of Alternative B could result in 587 additional temporary jobs (primarily due to construction of the proposed facilities pursuant to Alternative B) and 53 additional permanent jobs (primarily for the proposed water supply facilities operation and recreational facilities), when compared to the No Project/No Action Alternative. In comparison, implementation of Alternative A could result in 581, 59, and 23 additional jobs, respectively. Similar to that described for Alternative A, the expected additional population from construction and operation would constitute a minor increase in the total 2020 projected regional population and would not pose a burden on local public services, utilities, or infrastructure. In addition, similar to that described for Alternative A, these jobs would represent less than a one percent increase in the total labor force in the Primary Study Area.

Construction and operation of the proposed Project is not expected to increase the demand for housing within the two-county region. Similar to that described for Alternative A, within specific local communities, there could be localized effects on housing during construction. However, given the availability of housing within the two-county region, predicting where this impact may occur would be highly speculative.

Similar to Alternative A, construction and operation of Alternative B would be expected to result in a minor increase in jobs and population in the Primary Study Area which could be accommodated within available housing units. **An adequate housing supply exists to accommodate the change in population**

and as such, this expected increase associated with implementation of Alternative B is not anticipated to be growth-inducing.

Removing Obstacles to Growth

Similar to that described for Alternative A, the expected increase in water yield with implementation of Alternative B would be within the range of projected increases of water supplies by major urban water users in their recent UWMPs to provide adequate water supplies for planned growth, and additional water deliveries associated with Alternative B implementation to urban water users probably could be considered as replacement water supplies instead of implementing other projects identified in the UWMPs. A portion of the expected improved water supply reliability also could be used for agricultural water supplies or to improve environmental conditions in specific streams. Because the UWMPs have identified adequate water supplies to meet future water demands in 2030 for the Long-Term average and Dry and Critical Dry year conditions, it does not appear that growth is being adversely affected due to lack of water supplies in these major urban communities. **Implementation of Alternative B is not anticipated to result in the removal of obstacles to growth, and therefore, is not anticipated to result in growth-inducing impacts.**

As indicated for Alternative A, DWR, Reclamation, and/or water supply agencies that are not part of cities cannot make local decisions regarding the extent and location of growth. Cities and counties that could receive water from the proposed Project are responsible for considering the environmental effects of their growth and land use planning decisions. When new developments are proposed, the cities and counties must prepare environmental documents pursuant to CEQA; and where appropriate, these agencies must consider mitigation measures to reduce adverse impacts of the growth and/or overriding considerations.

34.5.7 Growth-Inducing Impacts Associated with Alternative C

34.5.7.1 Extended, Secondary, and Primary Study Areas – Alternative C

Similar to that described for Alternative A, implementation of Alternative C would be expected to improve water supply reliability, increase water supply, improve water quality, and provide water management flexibility in the Extended, Secondary, and Primary study areas. Alternative C implementation would also be expected to provide increased employment and recreational opportunities. The potential of Alternative C to induce growth is discussed below.

Economic Growth Opportunities Related to Improved Water Supply Reliability, Water Quality, and Options for Urban Water Supplies

With implementation of Alternative C, long-term average CVP water deliveries to M&I water users (primarily located in urban communities) in the Sacramento Valley and San Francisco Bay Area could increase by 29 to 151 percent, when compared to Existing Conditions (i.e., the same as described for Alternative A). That increase in water deliveries could occur with implementation of the No Project/No Action Alternative and not be related to implementation of Alternative C. With Alternative C implementation, expected M&I water deliveries for the CVP would be similar to water deliveries described for the No Project/No Action Alternative and Alternative A.

With Alternative C implementation, long-term average SWP water deliveries to M&I water users in the Sacramento Valley, San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California could increase by 1 to 10 percent, when compared to Existing Conditions, whereas Alternative A implementation could result in a one to nine percent increase. A portion of that increase could occur with implementation of the No Project/No Action Alternative and not be related to implementation of Alternative C. With implementation of Alternative C, M&I water deliveries for the SWP could increase five to seven percent, when compared to the No Project/No Action Alternative, whereas Alternative A implementation could result in a five to six percent increase.

Similar increases in Dry and Critical Dry water year deliveries are projected with implementation of Alternative C, when compared to the No Project/No Action Alternative and Alternative A.

Expected changes in long-term average water deliveries of one to six percent with implementation of Alternative C, when compared to the No Project/No Action Alternative, are similar or substantially less than the anticipated increase of 6 to 39 percent in long-term average water supplies for major urban water users in the Sacramento Valley, San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California. This is the same as was described for Alternative A.

Similar to that described for Alternative A, because the water supply cost savings could be small relative to the urban economy and the spending patterns are uncertain, the economic benefits that could occur with implementation of Alternative C would be expected to result in a minor growth effect.

Expected increased agricultural water deliveries associated with implementation of Alternative C could range from zero to two percent (whereas it could range from zero to three percent with Alternative A implementation), when compared to Existing Conditions, and zero to five percent (i.e., the same as described for Alternative A), when compared to the No Project/No Action Alternative. Similar to that described for Alternative A, although the increased water supply deliveries could result in increased employment and other economic benefits, the effects on housing and population are expected to be minor in the Extended Study Area, when compared to the total housing and population.

In summary, similar to that described for Alternative A, expected improved water supply reliability, water quality, and options for urban water supplies associated with implementation of Alternative C is not anticipated to result in growth-inducing effects through improved economic growth in the Extended, Secondary, or Primary study areas.

Economic Growth Opportunities Related to Improved Recreational Opportunities

Similar to that described for Alternative A, implementation of Alternative C would be expected to provide additional recreational opportunities within the Primary Study Area, i.e., recreation visitation is anticipated to increase by more than 370,000 annual visits with Alternative C implementation, and 358,000 visits with Alternative A implementation, increasing non-local recreation expenditures by between approximately $2.9 million and approximately $3.0 million. **Similar to that described for Alternative, A, the expected increased recreation expenditures associated with implementation of Alternative C would represent less than 0.2 percent of total industrial expenditures in the Primary Study Area and are not anticipated to increase growth within the entire Primary Study Area.**

Similar to that described for Alternative A, expected increased recreational visits associated with implementation of Alternative C could result in additional demands for public services and utilities, including the use of roadways and utilities. The expected increase in recreational visits would not increase traffic in excess of existing acceptable levels of service of existing roadways, with the implementation of mitigation measures (refer to Table 26-20), and Alternative C implementation would not be expected to result in the need to expand roadways which could also support future growth, as described in Chapter 26 Navigation, Transportation, and Traffic. Increased demands on public services and utilities with implementation of Alternative C would also not be expected to result in the need for expanded infrastructure which could also support future growth, as described in Chapter 29 Public Services and Utilities. However, increased recreation use could adversely affect public services due to increased traffic. The expected increase in traffic would result in less than significant impacts with implementation of mitigation measures (refer to Table 29-9). **Therefore, similar to that described for Alternative A, the expected increased recreational opportunities in the Primary Study Area associated with implementation of Alternative C are not anticipated to result in growth-inducing impacts.**

Economic Growth Opportunities Related to Increased Temporary and Permanent Employment

Implementation of Alternative C could result in an increase of 77 jobs in the agricultural sector in the Extended Study Area due to increased water supply reliability, whereas, Alternative A could result in an increase of 72 jobs. **Similar to that described for Alternative A, the expected magnitude of the impacts associated with implementation of Alternative C would be less than one percent, when compared to the regional economy of the Extended Study Area, and is not anticipated to result in growth-inducing impacts.**

Implementation of Alternative C could result in 648 additional temporary jobs (primarily due to construction of the proposed facilities pursuant to Alternative C) and 60 additional permanent jobs (primarily for the proposed water supply facilities operation and recreational facilities), when compared to the No Project/No Action Alternative. In comparison, implementation of Alternative A could result in 581, 59, and 23 additional jobs, respectively. Similar to that described for Alternative A, the expected additional population from construction and operation would constitute a minor increase in the total 2020 projected regional population and would not pose a burden on local public services, utilities, or infrastructure. In addition, similar to that described for Alternative A, these jobs would represent less than a one percent increase in the total labor force in the Primary Study Area. Construction and operation of the proposed Project is not expected to increase the demand for housing within the two-county region. Similar to that described for Alternative A, within specific local communities, there could be localized effects on housing during construction. However, given the availability of housing within the two-county region, predicting where this impact may occur would be highly speculative.

Similar to that described for Alternative A, construction and operation associated with implementation of Alternative C would be expected to result in a minor increase in jobs and population in the Primary Study Area which could be accommodated within available housing units. **An adequate housing supply exists to accommodate the change in population and as such, this expected increase associated with implementation of Alternative C is not anticipated to be growth-inducing.**

Removing Obstacles to Growth

Similar to that described for Alternative A, the expected increase in water yield associated with implementation of Alternative C would be within the range of projected increases of water supplies by major urban water users in their recent UWMPs to provide adequate water supplies for planned growth, and additional water deliveries associated with Alternative C implementation to urban water users probably could be considered as replacement water supplies instead of implementing other projects identified in the UWMPs. A portion of the expected improved water supply reliability also could be used for agricultural water supplies or to improve environmental conditions in specific streams. Because the UWMPs have identified adequate water supplies to meet future water demands in 2030 for the Long-Term average and Dry and Critical Dry year conditions, it does not appear that growth is being adversely affected due to lack of water supplies in these major urban communities. **Implementation of Alternative C is not anticipated to result in the removal of obstacles to growth, and therefore, is not anticipated to result in growth-inducing impacts.**

As indicated for Alternative A, DWR, Reclamation, and/or water supply agencies that are not part of cities cannot make local decisions regarding the extent and location of growth. Cities and counties that could receive water from the proposed Project are responsible for considering the environmental effects of their growth and land use planning decisions. When new developments are proposed, the cities and counties must prepare environmental documents pursuant to CEQA; and where appropriate, these agencies must consider mitigation measures to reduce adverse impacts of the growth and/or overriding considerations.

34.6 Mitigation Measures

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

35. Cumulative Impacts

35.1 Introduction

Cumulative impacts are impacts on the environment that result from the incremental impacts of a proposed action when added to other past, present, and reasonably foreseeable future actions (CEQA Guidelines section 15355[b], 40 CFR 1508.7). Such impacts can result from individually minor but collectively significant actions taking place over time. This chapter presents the methodology used to evaluate cumulative effects, lists related projects and describes their relationship to the proposed Project, identifies cumulative impacts by resource area, and recommends measures to mitigate significant cumulative effects. The cumulative impact analysis uses both quantitative tools (i.e. hydrologic modeling) and qualitative assessments to determine the potential combined impacts of the proposed Project and other related projects.

35.1.1 Regulatory Setting

The California Code of Regulations' Guidelines for the Implementation of the California Environmental Quality Act (CEQA Guidelines) and federal National Environmental Policy Act (NEPA) regulations require that the cumulative impacts of a proposed project be addressed in an Environmental Impact Report/Environmental Impact Statement (EIR/EIS).

35.1.2 CEQA Requirements

Under CEQA, an EIR is required to discuss the cumulative impacts of a project when the project's incremental effect is cumulatively considerable (CEQA Guidelines section 15130(a)(1)). "Cumulatively considerable" means that the incremental effects of a project are significant when viewed in connection with the effects of past projects, other current projects, and probable future projects (CEQA Guidelines section 15065(a)(3); Public Resources Code section 21083(b)(2)). Cumulative impacts are further defined in the CEQA Guidelines as two or more individual impacts that, even if individually minor, when considered together, are considerable or that compound or increase other environmental impacts (see CEQA Guidelines section 15355).

Per Section 15130 of the CEQA Guidelines, the discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion should be guided by standards of practicality and reasonableness, and should focus on the cumulative impact to which the identified other projects contribute, rather than the attributes of other projects which do not contribute to the cumulative impact.

35.1.3 NEPA Requirements

Under NEPA, the Council of Environmental Quality (CEQ) regulations define cumulative impacts as the impact on environment, human, and community resources that result from the incremental impact of the proposed Project when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal on non-federal) or persons undertakes such actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over time (40 CFR 1508.7, 1508.25.).

Reclamation's NEPA Handbook states that future cumulative impacts should not be speculative but should be based upon known or reasonably foreseeable long-range plans, regulations, operating agreements, or other information that establishes them as reasonably foreseeable (Reclamation 2012).

35.2 Methodology

The methodology used to identify and evaluate cumulative impacts in this DEIR/EIS was based upon both CEQA and NEPA requirements. For purposes of this DEIR/EIS, a cumulative impact was considered to be a change in the physical environment that would result from the combined implementation of the proposed Project or one of the alternatives with other projects that would cause related impacts. Cumulative impacts within the proposed Project's three study areas were identified based on: (1) information extracted from existing environmental documents or studies for the resource categories potentially affected by each project, (2) investigation of future project plans by other State and federal agencies and private entities, and (3) knowledge of expected effects of similar projects.

The cumulative analysis followed applicable guidance provided by CEQ in Considering Cumulative Effects under NEPA (CEQ 1997), Guidance on the Consideration of Past Actions in Cumulative Effects Analysis (CEQ 2005), Reclamation's NEPA Handbook (Reclamation 2012), and Guidelines for Implementation of the California Environmental Quality Act. Based on these resources, the following elements were determined necessary to provide an adequate discussion of significant cumulative impacts:

1. Either: a) a list of past, present, and probable future projects producing related or cumulative impacts, including, if necessary, those projects outside the control of the agency, or b) a summary of projections contained in an adopted local, regional or statewide plan, or related planning document, that describes or evaluates conditions contributing to the cumulative effect.
2. When utilizing a list, factors to consider when determining whether to include a related project should include the nature of each environmental resource being examined, the location of the project and its type.
3. A definition of the geographic scope of the area affected by the cumulative effect and a reasonable explanation for the geographic limitation used.
4. A summary of the expected environmental effects to be produced by those projects with specific reference to additional information stating where that information is available; and
5. A reasonable analysis of the cumulative impacts of the relevant projects, including examining reasonable, feasible options for mitigating or avoiding the project's contribution to any significant cumulative effects.

This cumulative impact assessment considered projects and programs ("projects") identified under Existing Conditions (which includes the current effects of past projects) and reasonably foreseeable and probable future projects. The criterion for considering whether a project was reasonably foreseeable and probable in this DEIR/EIS was whether the project had been defined in adequate detail, either through the completion of publicly available preliminary evaluations, feasibility studies, or draft environmental and engineering documents, to estimate potential impacts. Projects that were only in the development phase without detailed descriptions, operations criteria, or general locations as of April 2013 were not considered further.

35.3 Cumulative Project Selection

As discussed above, to identify the related cumulative projects, CEQA recommends either the “list” or “projection” approach. The list approach was used for this analysis.

For this DEIR/EIS, cumulative impacts within the proposed Project’s study areas were identified based on: (1) assumptions developed as part of CALSIM II water supply modeling; (2) cumulative projects described in the CALFED Bay-Delta Program (CALFED) Programmatic EIS/EIR, and (3) information extracted from existing environmental documents or future project plans for similar projects. In addition, the following criteria, taken from the CALFED Programmatic EIS/EIR, were used to narrow the list of projects considered in the analysis:

- The action is under active consideration.
- The action’s project-level environmental documentation is under preparation or has been completed.
- The action would be completed or operational within the timeframe being considered for the proposed Project (assumed to be 2020).
- The action, in combination with the proposed Project, would have the potential to affect the same resources. For example, the proposed Project would affect flow regimes and water quality along the Sacramento River and in the Sacramento-San Joaquin Delta (Delta). These potential changes, along with ecosystem restoration and/or water quality improvement programs in the Delta, could have a cumulative effect; therefore, the programs in the Delta were included in the cumulative analysis. In contrast, ongoing and future Delta levee repair/improvement projects to maintain existing flood channels or navigation channels or general plan updates/amendments for Delta counties in combination with the proposed Project are not anticipated to cause a cumulative effect and were not included in the discussion of cumulative impacts.

35.3.1 Cumulative Projects described in CALFED EIS/EIR

The CALFED Programmatic EIS/EIR compiled a list of major projects for consideration in its cumulative impact analysis. The list focused on future actions that could affect the physical features of the San Francisco Bay-Delta (Bay-Delta) system, and on the future federal and State policies that could affect operations of the Central Valley Project (CVP) and State Water Project (SWP). The CALFED Programmatic EIS/EIR list of cumulative projects, the CALFED Record of Decision (ROD), and other recent documents were used to identify projects considered in the cumulative effect analysis.

Many of the projects considered in the cumulative impacts analysis in the CALFED Programmatic EIS/EIR have been implemented, modified into other projects, or not pursued based upon results of separate evaluations, including:

- American River Water Resource Investigation (not pursued as a regional project)
- American River Watershed Project (construction either completed or underway – future projects will not affect water supply operations)
- Contra Costa Water District Multi-Purpose Pipeline Project (completed)
- Hamilton City Pumping Plant Fish Screen Improvement Project (completed)

- Montezuma Wetlands Project (long-term project underway for disposal of dredge spoils)
- Pardee Reservoir Enlargement (not pursued)
- Red Bluff Diversion Dam Fish Passage Improvement Project (completed)
- Sacramento River Flood Control System Evaluation (completed)
- Sacramento County CVP Water Service Contracts (completed)
- West Delta Water Management Program (not pursued)

The projects identified as cumulative projects in the CALFED Programmatic EIS/EIR that are considered in this cumulative effects analysis, and described in the following subsection, include:

- Implementation of Central Valley Project Improvement Act (CVPIA) actions
- Delta Wetlands
- South Delta Temporary Barriers
- Sacramento Water Forum Process (underway through Lower American River Flow Management Study)
- Trinity River Restoration Actions
- East Bay Municipal Utility District (EBMUD) Supplemental Water Supply Project

35.3.2 Program List of Related and Reasonably Foreseeable Projects and Actions

Table 35-1 lists projects considered for the cumulative effects section by resource area. Summaries of each project or action are provided below.

The projects and actions are organized in the following order:

- Multi-Region Projects and Actions
- Local Agency Projects and Actions in the vicinity of proposed North-of-the-Delta Offstream Storage (NODOS) Project facilities
- Water Supply, Water Quality, and Hydropower Projects and Actions in the vicinity of proposed NODOS Project facilities and/or potentially affected by SWP and CVP operations (organized geographically from north to south)
- Ecosystem Improvement Projects and Actions in the vicinity of proposed NODOS Project facilities and/or potentially affected by SWP and CVP operations (organized geographically from north to south)

Notes:
CALFED = CALFED Bay-Delta Program
CVP = Central Valley Project
CVPIA = Central Valley Project Improvement Act
EBMUD = East Bay Municipal Utility District
NMFS = National Marine Fisheries Service
NODOS = North-of-the-Delta Offstream Storage
RWQCB = Regional Water Quality Control Board
SWP = State Water Project
USFWS = U.S. Fish and Wildlife Service

PRELIMINARY – SUBJECT TO CHANGE

35.3.3 Multi-Region Projects and Actions

The multi-region projects and actions considered in this cumulative impact assessment include:

- Implementation of the CVPIA
- Implementation of CALFED Objectives
- Bay-Delta Water Quality Control Plan Update
- Bay Delta Conservation Plan
- Delta Plan
- National Marine Fisheries Service (NMFS) Public Draft Recovery Plan for Sacramento River Winter run Chinook Salmon, Central Valley Spring-run Chinook Salmon, and Central Valley Steelhead
- U.S. Fish and Wildlife Service (USFWS) Recovery Plan for the Sacramento-San Joaquin Delta Native Fishes
- Anadromous Fish Screen Program
- California Aquatic Invasive Species Rapid Response Plan
- Regional Advance Mitigation Program
- Central Valley Vision

35.3.3.1 Implementation of Central Valley Project Improvement Act

The CVPIA of 1992 amends previous authorizations of the CVP, which is one of the world's largest systems for storing and moving water, to include fish and wildlife protection and mitigation having equal priority with irrigation, domestic uses, and power generation.

Since 1993, the U.S. Bureau of Reclamation (Reclamation) and USFWS have completed several major river projects under CVPIA, including restoration of Butte Creek and installation of fish screens in the Glenn-Colusa Irrigation District and Anderson-Cottonwood Irrigation District. Overall, the CVPIA Program completed 98 actions from the river restoration plan in 26 watersheds throughout the Central Valley, focusing on removal of barriers from rivers, floodplain restoration, and riverbed gravel supplementation. Reclamation has also assisted the State of California in construction of 29 fish screen diversions. CVPIA river restoration embodies the America's Great Outdoors Initiative[1] in many respects, including expansive ecological restoration.

River restoration within the CVP is a key aspect of meeting the CVPIA fisheries goal, which is to double the natural production of anadromous fish on a sustainable basis. The current scope of the CVPIA includes 15 programs that fall into three resource areas: fisheries, refuges, and other resources. Major ongoing fishery projects include the San Joaquin River Restoration Program in central California

[1] Federal initiative based on the premise that lasting conservation solutions should come from the American people. The initiative seeks to bring a more effective approach to land management, to encourage collaboration among government agencies and private citizens to protect our outdoor legacy, to fund programs that protect land, provide assistance to communities, and improve opportunities to get young people outdoors.

(described below), the Red Bluff Fish Passage Improvement Project (recently completed), and the Trinity River Restoration Program (described below) in northern California.

35.3.3.2 Implementation of CALFED Objectives

CALFED State and federal agencies worked to develop and initiate long-term programs to achieve four interrelated objectives:

- Levee System Integrity – to reduce risks to land use, economic activities, water supply, infrastructure, and ecosystems from catastrophic levee breaches.
- Ecosystem Restoration – to improve and increase aquatic and terrestrial habitats and ecological functions in the Bay-Delta.
- Water Supply Reliability – to provide reliable Bay-Delta water supplies for projected beneficial uses dependent upon the Bay-Delta system.
- Water Quality – to provide good water quality for all beneficial uses.

The CALFED ROD was signed in 2000. Over the following seven years, many conditions occurred that had been unforeseen either in occurrence or in extent during the preparation of the CALFED Programmatic EIS/EIR. These changing conditions included a better understanding of: (1) global climate change on hydrology and sea levels, (2) potential responses to seismic events throughout California, (3) continuing land subsidence in the Bay-Delta, (4) increased populations of introduced species, especially in the Bay-Delta system, and (5) changing population growth projections. At the end of seven years (Stage 1), CALFED prepared a summary of accomplishments that had occurred during the Stage 1 period, as summarized below.

- Levee System Integrity – The Levee System Integrity Program supported programs that increased protection for, maintenance of, and stability of nearly 745 miles of Delta levees, including the reuse of 1.36 million cubic yards of dredged material for levee stability and habitat improvement; and created approximately 50 acres of riparian and wetland habitat and 3,000 feet of shaded riverine aquatic habitat.
- Ecosystem Restoration – The Ecosystem Restoration Program (ERP) supported ecosystem restoration programs upstream of the Delta in the Sacramento and San Joaquin rivers watersheds, as well as in the Delta. Restoration improvements occurred in upland, grassland, wetland, riparian, non-tidal and tidal marsh, and aquatic habitats. The initial ERP reports were completed as part of the CALFED Programmatic EIS/EIR and have been updated several times since 2000. The ERP approach is to restore or mimic ecological processes and improve aquatic and terrestrial habitats to support stable, self-sustaining populations of diverse species.

CALFED's Water Supply Reliability Program objective is achieved through five program elements, including a Storage Program Element. The Storage Program Element includes an action that provides for additional water storage, including the proposed NODOS Project and the Upper San Joaquin River Basin Storage Investigation (described below).

35.3.3.3 Bay-Delta Water Quality Control Plan Update

In accordance with the federal Clean Water Act and the Porter-Cologne Water Quality Control Act, basins plans must be developed for each hydrologic area. Each basin plan must contain water quality objectives to ensure the reasonable protection of beneficial uses, as well as a program of implementation for achieving water quality objectives. Federal regulations require each state to adopt water quality standards to protect the public health or welfare, enhance the quality of water, and serve the purposes of the Clean Water Act. In California, the beneficial uses and water quality objectives form the basis of the water quality control standards. In the Bay-Delta, water quality and flow objectives to meet water quality criteria are included in the *Water Quality Control Plan for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary* (Bay-Delta WQCP). The State Water Resources Control Board (SWRCB) and the Central Valley and San Francisco Regional Water Quality Control Boards (RWQCBs) are in the process of updating the Bay-Delta WQCP. The updates, or amendments, are being prepared in two phases. Initially, the SWRCB and RWQCBs are evaluating new flow objectives for the Lower San Joaquin River and the tributaries of Stanislaus, Tuolumne, and Merced rivers; and southern Delta salinity objectives. The second phase involves evaluating changes to other portions of the Bay-Delta WQCP including Delta outflows, SWP and CVP export restrictions, and other requirements in the Bay-Delta to protect fish and wildlife beneficial uses. A third phase will consider and assign responsibility for implementing measures to achieve the water quality objectives established in the first two phases.

35.3.3.4 Bay Delta Conservation Plan

The Bay Delta Conservation Plan (BDCP) is a multiple-stakeholder Habitat Conservation Plan (HCP) and Natural Community Conservation Plan (NCCP) designed to make significant contributions to the recovery of covered species and restore a more naturally functioning Delta ecosystem while securing a reliable freshwater source from the Delta for human use. The BDCP is currently being developed through a collaboration of DWR, Reclamation, Metropolitan Water District of Southern California, Kern County Water Agency, Santa Clara Valley Water District, Zone 7 Water Agency, San Luis and Delta-Mendota Water Authority, and Westlands Water District. The BDCP includes actions to restore native fish, wildlife, and plant habitat in the Delta; modify SWP and CVP Delta water conveyance facilities and operations in the Delta; and reduce other ecological stressors that impair the function or the use of desirable habitat for ecosystem restoration or recovery in the Delta, such as physical barriers to fish migration (including levees, weirs, or gates), non-native and invasive species, and poor water quality.

The BDCP EIR/EIS was developed by DWR, Reclamation, USFWS, and NMFS. The BDCP EIR/EIS evaluates a range of alternatives that combine ecosystem restoration approaches and Delta conveyance approaches. During the last 50 years, several broad conveyance approaches have been studied to address urban water quality, water supply reliability, and environmental concerns in the Delta: physical barriers, hydraulic barriers, through-Delta facilities, and isolated facilities. Several alternative Delta conveyance facilities are being evaluated as part of the BDCP EIR/EIS. Among these alternatives are use of an isolated facility that would convey water around the Delta for local supply and export through a hydraulically isolated channel or pipeline and with continual use of the existing south Delta intakes (dual conveyance alternatives); and continuation of the use of the through-Delta conveyance with channel modifications.

35.3.3.5 Delta Plan

The Delta Stewardship Council was established by the California legislature in 2009 through the Delta Reform Act. The Delta Reform Act also required development of a legally enforceable, comprehensive, long-term management plan for the Delta, referred to as the Delta Plan. The Delta Plan will be a legally enforceable, comprehensive, long-term management plan for the Delta and the Suisun Marsh that achieves the coequal goals (Water Code section 85300(a)). Water Code section 85054 defines the coequal goals as follows:

> *Coequal goals mean the two goals of providing a more reliable water supply for California and protecting, restoring and enhancing the Delta ecosystem. The coequal goals shall be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource and agricultural values of the Delta as an evolving place.*

The Delta Reform Act states that the policy of the State is:

> *… to achieve the following objectives as inherent in the coequal goals for the management of the Delta:*
>
> *(a) Manage the Delta's water and environmental resources and the water resources of the state over the long term.*
>
> *(b) Protect and enhance the unique cultural, recreational, and agricultural values of the California Delta as an evolving place.*
>
> *(c) Restore the Delta ecosystem, including its fisheries and wildlife, as the heart of a healthy estuary and wetland ecosystem.*
>
> *(d) Promote statewide water conservation, water use efficiency, and sustainable water use.*
>
> *(e) Improve water quality to protect human health and the environment consistent with achieving water quality objectives in the Delta.*
>
> *(f) Improve the water conveyance system and expand statewide water storage.*
>
> *(g) Reduce risks to people, property, and state interests in the Delta by effective emergency preparedness, appropriate land uses, and investments in flood protection.*
>
> *(h) Establish a new governance structure with the authority, responsibility, accountability, scientific support, and adequate and secure funding to achieve these objectives" (Water Code section 85020 et. seq.).*

The Delta Plan could address water resources projects, including improved infrastructure related to storage projects, including the proposed NODOS Project. The Delta Plan also could include recommendations related to the sustainable use of water and reduced reliance on the Delta in meeting California's future water supply needs through a statewide strategy of investing in improved regional supplies, conservation, and water use efficiency.

35.3.3.6 National Marine Fisheries Service Public Draft Recovery Plan for Sacramento River Winter-run Chinook Salmon, Central Valley Spring-run Chinook Salmon, and Central Valley Steelhead

The NMFS Draft Recovery Plan provides a roadmap that describes the steps, strategy, and actions that should be taken to return winter-run Chinook salmon, spring-run Chinook salmon, and steelhead to viable status in the Central Valley, California, thereby ensuring their long-term persistence and evolutionary potential. The general near-term strategic approach to recovery includes the following elements:

- Secure all extant populations.
- Begin collecting distribution and abundance data for *O. mykiss* in habitats accessible to anadromous fish.
- Minimize straying from hatcheries to natural spawning areas.
- Conduct critical research on fish passage above rim dams, reintroductions, and climate change.

The long-term approach to recovery includes the following elements:

- Ensure that every extant diversity group has a high probability of persistence.
- Until all ESU viability criteria have been achieved, no population should be allowed to deteriorate in its probability of persistence.
- High levels of recovery should be attempted in more populations than identified in the diversity group viability criteria because not all attempts will be successful.
- Individual populations within a diversity group should have persistence probabilities consistent with a high probability of diversity group persistence.
- Within a diversity group, the populations restored/maintained at viable status should be selected
- Allow for normative meta-population processes, including the viability of core populations, which are defined as the most productive populations.
- Allow for normative evolutionary processes, including the retention of the genetic diversity as well as an increase in genetic diversity through the addition of viable populations in historic habitats.
- Minimize susceptibility to catastrophic events.

35.3.3.7 USFWS Recovery Plan for the Sacramento-San Joaquin Delta Native Fishes

The USFWS Recovery Plan addresses the recovery needs for several fish species that occupy the Delta, including delta smelt, Sacramento splittail, longfin smelt, green sturgeon, Chinook salmon (spring-run, late fall-run, and San Joaquin fall-run), and Sacramento perch (believed to be extirpated). The objective of the plan is to establish self-sustaining populations of these species that will persist indefinitely. This would be accomplished by managing the estuary to provide better habitat for aquatic life in general and for the fish addressed by the plan. Recovery actions include tasks such as increasing freshwater flows; reducing entrainment losses to water diversions; reducing the effects of dredging, contaminants, and harvest; developing additional shallow-water habitat, riparian vegetation zones, and tidal marsh; reducing effects of toxic substances from urban non-point sources; reducing the effects of introduced species; and conducting research and monitoring.

35.3.3.8 Anadromous Fish Screen Program

The primary objective of the Anadromous Fish Screen Program is to protect juvenile Chinook salmon, steelhead, green and white sturgeon, striped bass, and American shad from entrainment at priority diversions throughout the Central Valley. Section 3406 (b)(21) of the CVPIA requires the Secretary of the Interior to assist the State of California in developing and implementing measures to avoid losses of juvenile anadromous fish resulting from unscreened or inadequately screened diversions on the Sacramento and San Joaquin rivers, their tributaries, the Delta, and the Suisun Marsh.

35.3.3.9 California Aquatic Invasive Species Rapid Response Plan

The California Department of Fish and Wildlife[2] (CDFW) released the final California Aquatic Invasive Species Management Plan in January 2008. As part of this plan, the Aquatic Invasive Species Rapid Response Plan is proposed for the State of California. The Rapid Response Plan establishes a draft general procedure for rapid response following detection of new aquatic invasive species infestation. It provides a framework for developing and implementing a rapid response plan. It is preliminary in that it describes types of information, resources and decisions necessary to finalize the plan. In order to finalize, fund, and implement the draft Rapid Response Plan, CDFW expects that cooperating agencies will assign staff to participate. CDFW Invasive Species Program staff will provide coordination for the interagency activities called for in the agreement(s).

35.3.3.10 Giant Garter Snake Recovery Plan

The Draft Giant Garter Snake Recovery Plan was published by USFWS in 1999, but a final plan was not published. However, USFWS continues to implement the recovery plan with a 5-year analysis that considers threats, conservation measures, and regulatory mechanisms.

The giant garter snake inhabits wetland habitats within the Central Valley. Loss and fragmentation of wetland habitats have extirpated the giant garter snake from the majority of its historic range. The recovery plan also considers several species of concern that occur in Central Valley wetlands that benefit from actions taken to recover the giant garter snake. These species include the tricolored blackbird, white-faced ibis, western pond turtle, and associated waterfowl.

The ultimate goal of the recovery plan is to delist the giant garter snake. Recovery criteria for the giant garter snake are defined for four recovery units in the Central Valley: the Sacramento Valley, Mid-Valley, San Joaquin Valley, and South Valley units. Recovery criteria include:

a) Monitoring shows that in 17 out of 20 years, 90 percent of the subpopulations in four recovery units contain both adults and young.

b) All extant populations within the recovery unit are protected from threats that limit populations.

c) Supporting habitat within the recovery unit is adaptively managed and monitored.

d) Subpopulations are well connected by corridors of suitable habitat.

e) Repatriation (reintroduction) has been successful at a specified number of suitable sites

[2] Formerly known as the California Department of Fish and Game (i.e., prior to January 1, 2013).

Necessary actions described in the plan include protecting existing populations and habitat; restoring populations to former habitat; surveying to determine species distributions; monitoring populations; conducting necessary research, including studies on demographics, population genetics, and habitat use; and developing and implementing incentive programs, and an outreach and education plan.

35.3.3.11 Regional Advance Mitigation Program

The Regional Advance Mitigation Program (RAMP) attempts to provide a method to achieve faster, less expensive, and better mitigation for unavoidable impacts associated with infrastructure projects on a landscape scale rather than by project-by-project mitigation. RAMP Work Group participants include federal and State agencies (including DWR, CDFW, U.S. Environmental Protection Agency, U.S. Army Corps of Engineers (USACE), and California Department of Transportation [Caltrans]).

The basic RAMP concept is twofold. First, it establishes a regional framework for identifying existing and potential mitigation approaches in a geographically specific portion of the State that could support the needs of planned infrastructure projects and meet the needs of regulatory agencies. Second, it identifies which mitigation approaches could best create habitat in advance of potential unavoidable impacts of infrastructure projects. Working together, natural resource and infrastructure funding agencies can estimate mitigation needs early in the projects' timelines, avoiding permitting and regulatory delays and allowing public mitigation dollars to stretch further by securing and conserving valuable natural resources.

DWR and Caltrans are leading development of the RAMP initiative using bond funding, but will actively seek additional voluntary partners as the structure for long-term funding and governance is more clearly defined. RAMP does not supply permits for infrastructure projects; rather, its purpose is to provide a more efficient and cost-effective option for supplying mitigation within existing permitting processes. Infrastructure agencies will individually apply for their permits to perform actions. Within the application materials, they could reference an advance mitigation site created through RAMP. These sites may be authorized by the resource agencies using the same methodology as a private commercial mitigation bank and other agencies, or authorized using alternative methods supported by these same agencies. The RAMP Work Group developed a Draft Statewide Framework for Regional Advance Mitigation Planning in California intended to convey to lawmakers and agency leaders the goals, benefits, and operational framework of a statewide RAMP initiative.

35.3.3.12 Central Valley Vision

In 2003, the California Department of Parks and Recreation (State Parks) began work on a long-term Central Valley Vision to develop a strategic plan for State Parks expansion in the Central Valley. The plan will provide a 20-year road map for State Parks actions to focus on increasing service to Valley residents and visitors. Within the Great Central Valley (San Joaquin Valley, Sacramento Valley and the Delta region), State Parks operates and maintains 32 State park units representing seven percent of the total State park system acreage. The 2009 Central Valley Vision Implementation Plan proposed 11 new parks in the Central Valley and several park expansion projects. Several of the new and expanded parks are/would be located near the proposed NODOS Project facilities, including:

- Proposed Anderson-Sacramento River Park (approximately 225 acres along the Sacramento River with campsites, picnic sites, trails, fishing and boating access, and interpretative services)
- Proposed Big Bend Park (approximately 2,000 acres along the Sacramento River with campsites, picnic sites, trails, fishing and boating access, and interpretative services)

- Expand Woodson Bridge State Recreation Area (add a 700-acre parcel along Kopta Slough and restore 180-acres of habitat)
- Expand Colusa-Sacramento River State Recreation Area (add 13 acres and restore 140 acres of habitat; and add campsites, picnic sites, fishing and boating access, and interpretative services)
- Expand State Park at Sutter Buttes (acquire approximately 1,000 acres and add campsites, picnic sites, trails, and interpretative services)
- Proposed Sacramento River Boating Trail (from Redding to Sacramento with boat-in campsites and day use areas at existing parks and marinas, and interpretative services)

Other new and expanded parks are/would be located near SWP and CVP facilities, including:

- Expand campsites, picnic sites, trails, and boating facilities at Lake Oroville State Recreation Area.
- Expand track, picnic, and day use facilities at Clay Pit State Vehicular Recreation Area
- Proposed Sacramento and Feather River Boating Trail (from Redding to Sacramento and Oroville to Sacramento with boat-in campsites and day use areas and interpretative services)
- Proposed Elkhorn Basin (approximately 1,500 acres along Sacramento River near confluence with Feather River)
- Improve Folsom Lake State Recreation Area and Folsom Powerhouse State Historic Park (add campsites, picnic sites, fishing and boating access, and interpretative services; and add trails to connect to Deer Creek Hills Preserve)
- Proposed Sacramento River Boating Trail (from Sacramento through the Delta)
- Expand Delta Meadows California State Parks property (acquire approximately 230 acres; and add campsites, picnic sites, fishing and boating access, and interpretative services)
- Proposed Barker Slough Park (near the North Bay Aqueduct Pumping Plant – transfer approximately 500 acres from DFW to California State Parks; restore habitat; and add picnic sites, boating access, and interpretative services)
- Expanded Caswell Memorial State Park (acquire approximately 200 acres; restore a portion for habitat; and add campsites, picnic sites, trails, and interpretative services)
- Proposed San Joaquin River Parkway (approximately 1,250 acres of public land along the San Joaquin River; and add campsites, picnic sites, trails, boating access, and interpretative services)

The Central Valley Vision also recommended development of several heritage corridors, including:

- California Delta Heritage Corridor (to connect Delta towns, recreation sites, nature areas, and agricultural sites)
- Cross-California Ecological Corridor (to connect recreation lands such as Sutter National Wildlife Refuge and South Yuba River State Park with natural areas)
- Central Valley Farm Trails Heritage Corridor (to connect agricultural sites, communities, historic sites, and water facilities along the State Highway 99 and Interstate 5 corridors in the Central Valley)

- Echoes of Our Ancestors Heritage Corridor (to connect areas that are representative of California's ethnic diversity in the Central Valley)

35.3.4 Local Agency Projects and Actions in the Vicinity of North-of-the-Delta Offstream Storage Project Facilities

The local agency projects and actions in the vicinity of the proposed NODOS Project facilities considered in this cumulative impact assessment include:

- Colusa County General Plan Update
- Butte County Habitat Conservation Plan

35.3.4.1 Colusa County 2030 General Plan

The County of Colusa 2030 General Plan, adopted on July 31, 2012, supersedes and replaces the County's 1989 General Plan. The 2030 General Plan carries forward much of the major goal and policy framework of the 1989 General Plan, but has been reorganized to make the document more user-friendly. The Plan identifies the County's vision for the future and provides a framework that will guide decisions on growth, development, and conservation of open space and resources in a manner consistent with the quality of life desired by the County's residents and businesses.

35.3.4.2 Butte County Regional Conservation Plan

The Butte Regional Conservation Plan (BRCP) is being coordinated by the Butte County Association of Governments (BCAG) on behalf of Butte County; cities of Chico, Oroville, Gridley, and Biggs; Western Canal Water District, the Richvale Irrigation District, the Biggs West-Gridley Water District, Butte Water District, and Caltrans. The BRCP is both a federal Habitat Conservation Plan (HCP) and a state Natural Community Conservation Plan (NCCP). It is a voluntary plan that will provide streamlined endangered species act permitting for transportation projects, land development and other covered activities over the 30-50 year term of the permits. It will also provide comprehensive species, wetlands and ecosystem conservation and contribute to the recovery of endangered species within the Plan Area. The BRCP will:

- Reduce the cost and increase the consistency of the State and federal permitting process;
- Provide certainty of regulatory costs and requirements;
- Provide local control by consolidating and streamlining environmental permitting under one locally controlled plan;
- Provide improved habitat preserves for species; and
- Protect the right of private property owners- conservation land acquisition will be through willing sellers only.

The first administrative draft of the BRCP was prepared in June 2011. A preliminary public draft was released in November 2012. The scoping process was initiated on December 14, 2012 with the publication of the Notice of Preparation of an EIS/EIR for the plan. The project is scheduled to be completed in 2013.

35.3.5 Water Supply, Water Quality, and Hydropower Projects and Actions in the Vicinity of the Proposed NODOS Project Facilities and/or Potentially Affected by SWP and CVP Operations (organized geographically from north to south)

The water supply, water quality, and hydropower projects and actions in the vicinity of the proposed NODOS Project facilities and/or potentially affected by SWP and CVP operations considered in this cumulative impact assessment include:

- Increased Hydropower Generation Capacity at Lewiston Dam
- Shasta Lake Water Resources Investigation
- Woodland-Davis Water Supply Project
- El Dorado Water and Power Authority Supplemental Water Rights Project
- El Dorado Irrigation District Folsom Lake Temperature Control Device
- Lake Natoma Lower American River Temperature Reduction Project
- EBMUD Camanche Water Rights Permit Extension
- EBMUD Water Supply Management Program 2040
- Eastern San Joaquin Integrated Conjunctive Use Program
- Semitropic Water Storage District Delta Wetlands
- North Bay Aqueduct Alternative Intake
- Bay Area Regional Desalination Project
- Los Vaqueros Reservoir Expansion Phase II
- South Delta Temporary Barriers Operations
- Stockton Deep Water Ship Channel Dissolved Oxygen Project
- Upper San Joaquin River Basin Storage Investigation
- FERC Relicense Renewal for Turlock Irrigation District and Modesto Irrigation District Don Pedro Project
- FERC Relicense Renewal for Merced Irrigation District's Merced River Hydroelectric Project
- Grassland Bypass Project
- Central Valley RWQCB Irrigated Lands Regulatory Program
- Central Valley Salinity Alternatives for Long-term Sustainability (CV-SALTS)
- San Luis Reservoir Low Point Improvement Project
- San Luis Reservoir State Recreation Area Resource Management Plan/General Plan

35.3.5.1 Increased Hydropower Generation Capacity at Lewiston Dam

The Trinity Public Utilities District (TPUD) and Reclamation intend to increase the power generating capacity at the Lewiston Dam, located near Weaverville, California, from the existing 350 kilowatts to approximately 2.2 megawatts. This upgrade will not only allow for better control of the flow from the dam to the Trinity River, but also provide an increase in revenue from power generation. Power generated by this project could be available for CVP water facilities operations, preference power customers served by Western Area Power Administration, or local electricity users served by TPUD.

35.3.5.2 Shasta Lake Water Resources Investigation

The Shasta Lake Water Resources Investigation is currently being conducted by Reclamation to determine the type and extent of federal interest in a multiple purpose plan to modify Shasta Dam and Reservoir to increase the survival of anadromous fish populations in the upper Sacramento River and increase water supplies and water supply reliability for agricultural, municipal, industrial, and environmental purposes. To the extent possible through meeting these objectives, alternatives include features to benefit other identified water and related resource needs including ecosystem conservation and enhancement, improved hydropower generation capability, flood damage reduction, increased recreation opportunities, and improved water quality conditions in the Sacramento River and the Delta consistent with CALFED objectives. Anticipated alternatives for expansion of Shasta Lake include, among other features, raising the dam from 6.5 to 18.5 feet above current elevation, which would result in additional storage capacity of 256,000 to 634,000 acre-feet, respectively. The increased capacity is expected to improve water supply reliability and increase the cold water pool, which would provide improved water temperature conditions for anadromous fish in the Sacramento River downstream of the dam.

35.3.5.3 Woodland-Davis Water Supply Project

The Woodland-Davis Water Supply Project has been proposed by the Woodland Davis Clean Water Agency for the cities of Davis and Woodland, and the University of California, Davis (UCD). The project would divert up to approximately 45,000 acre-feet per year of surface water from the Sacramento River and convey it for treatment and subsequent use in Davis, Woodland, and on the UCD campus. The purpose of the project is to provide a reliable water supply to meet existing and future needs, improve water quality for drinking supply purposes, and improve treated wastewater effluent quality through 2040. Project activities would include construction and operation of a water intake/diversion, conveyance, and water treatment facilities. Surface water supplies would be acquired through new water rights and water rights transfers from senior water rights holders.

The project would be located in the east-central portion of Yolo County, between and within the cities of Woodland and Davis, the UCD campus, and west of the Sacramento River. The new water diversion facility would be constructed on the Sacramento River near the Interstate 5 crossing at the location of the existing Reclamation District 2035 diversion. The water treatment plant to treat the surface water diverted from the Sacramento River would have an ultimate capacity of up to 64 millions of gallons per day.

Project water diversions would be made in compliance with Standard Water Right Permit Term 91, which prohibits surface water diversions when water is being released from CVP or SWP storage reservoirs to meet in-basin entitlements, including water quality and environmental standards for protection of the Delta. Water supply needs during periods applicable to Term 91 would be satisfied by entering into water supply transfer agreements with senior water rights holders within the Sacramento River watershed.

35.3.5.4 El Dorado Water and Power Authority Supplemental Water Rights Project

The El Dorado Water and Power Authority (EDWPA) proposes to establish permitted water rights allowing diversion of water from the American River basin to meet planned future water demands in the El Dorado Irrigation District (EID) and Georgetown Divide Public Utility District (GDPUD) service areas, and other areas located within El Dorado County that are outside of these service areas. EDWPA will be filing with the State Water Resources Control Board, Division of Water Rights, petitions for partial assignment of each of State Filed Applications 5644 and 5645, and accompanying applications allowing for the total withdrawal for use of 40,000 acre-feet per year, consistent with the diversion and storage locations allowed under the El Dorado-Sacramento Municipal Utility District (SMUD) Cooperation Agreement.

35.3.5.5 El Dorado Irrigation District Folsom Lake Temperature Control Device

The El Dorado Irrigation District (EID), in collaboration with Reclamation, proposes to construct facilities on the bank of Folsom Lake to withdraw water from the warm upper reaches of the lake while preserving the cold water pool at the bottom of the lake to protect downstream aquatic species. The facilities will include a large diameter concrete-lined vertical shaft and five lined horizontal adits extending from the shaft. This structure, known as a Temperature Control Device (TCD), will replace the District's five existing raw pump casings that currently extract water from Folsom Lake. The new facility will be sized to accommodate over twice the current capacity.

35.3.5.6 Lake Natoma Lower American River Temperature Reduction Project (Formerly the Lake Natoma Temperature Curtains Pilot Project)

The USFWS, Reclamation, and Sacramento Water Forum are proposing the Lower American River Temperature Reduction Modeling Project. The objective of the project is to develop predictive tools that will: 1) Reduce uncertainties in the performance of identified temperature control actions that could be implemented to improve the management of cold water resources in the Folsom/Natoma reservoir system and the lower American River, and 2) Be available for daily operations, planning, and salmon and steelhead habitat studies by other project operators and other stakeholders.

The project adapted, calibrated, and verified existing thermodynamic and hydrologic mathematical models for application at Folsom Reservoir, Lake Natoma and the lower American River. The models were used to assess the effectiveness of the identified actions individually and in combination and develop a recommendation for development and implementation of one or more actions for the purpose of reducing temperatures in the lower American River. The actions identified to improve transport of cold water through Lake Natoma and reduce the temperature of the lower American River included: a Nimbus Dam curtain, a Lake Natoma plunge zone curtain, Nimbus powerplant debris wall removal, dredging Lake Natoma, and modifying Folsom Powerplant peak loading operation.

35.3.5.7 EBMUD Camanche Water Rights Permit Extension

The Camanche Permit Extension would extend the term of the existing East Bay Municipal Utility District's (EBMUD) Camanche water right Permit 10478 through the year 2040 to divert water from the Mokelumne River for use in the EBMUD service area. Extending the Camanche Permit would allow EBMUD additional time to apply the water provided under Permit 10478 to municipal and industrial use within EBMUD's designated service area. Additionally, EBMUD has submitted documentation that describes that the full entitlement of Permit 10478 through 2040 is needed to maintain operational flexibility to meet future projected water demand and address system vulnerabilities associated with several factors, including emergencies and potential effects of climate change.

35.3.5.8 EBMUD Water Supply Management Program 2040

EBMUD's current Water Supply Management Program (WSMP 2020), adopted in 1993, serves as the basis for water conservation and recycling programs and for development of supplemental supply initiatives such as the Freeport Regional Water Project. The WSMP 2040 updates the current plan and extends the planning horizon another 20 years. It identifies and recommends a Preferred Portfolio of solutions to meet dry-year water needs through 2040, including desalination and enlargement of Mokelumne River reservoirs.

The primary objectives of the WSMP 2040 are to maintain and improve EBMUD's water supply reliability to its customers and help meet the need for water in the future. WSMP 2040 will also adapt the EBMUD's water planning approach to circumstances that have changed since WSMP 2020 was adopted, such as competing and changing demands for water, the availability of Freeport water after 2009, and long-term climate change. EBMUD adopted the Revised WSMP 2040 Final Plan in April 2012.

35.3.5.9 Eastern San Joaquin Integrated Conjunctive Use Program

The purpose of the Integrated Conjunctive Use Program is to develop approximately 140,000 to 160,000 acre-feet per year of new surface water supply for the Eastern San Joaquin Basin that will be used to directly and indirectly support conjunctive use by the Northeastern San Joaquin County Groundwater Banking Authority (GBA) member agencies. This amount of water would support groundwater recharge at a level consistent with the GBA's objectives for conjunctive use and the underlying groundwater basin. Within this framework, the program would implement the following categories of conjunctive use projects and actions:

- Water conservation measures
- Water recycling
- Groundwater banking
- Water transfers
- Development of surface storage facilities
- Groundwater recharge
- River withdrawals
- Construction of pipelines and other facilities

To enable and facilitate sustainable and reliable management of San Joaquin County's water resources, the GBA developed a series of Basin Management Objectives to support conjunctive use and address a variety of water resources issues, including groundwater overdraft, saline groundwater intrusion, degradation of groundwater quality, environmental quality, land subsidence, supply reliability, water demand, urban growth, recreation, agriculture, flood protection, and other issues. The purpose of the Basin Management Objectives is to ensure the long-term sustainability of water resources in the San Joaquin Region.

35.3.5.10 Semitropic Water Storage District Delta Wetlands

In 1987, Delta Wetlands, a California Corporation, proposed a project for water storage and wildlife habitat enhancement on four privately owned islands in the Delta. The four islands were Bacon Island and Bouldin Island in San Joaquin County, and Holland Tract and Webb Tract in Contra Costa County, encompassing approximately 23,000 acres. The Delta Wetlands Project would store water on two Reservoir Islands (Bacon Island and Webb Tract) for subsequent release into the Delta, and habitat enhancement to compensate for wetland and wildlife effects of the water storage operations with a Habitat Management Plan (HMP) on two Habitat Islands (Bouldin Island and Holland Tract).

In 2007, the Delta Wetlands Project partnered with the Semitropic Water Storage District (Semitropic WSD) to: 1) provide water to Semitropic WSD to augment its water supply, and bank water within the Semitropic Groundwater Storage Bank and Antelope Valley Water Bank. The designated places of use for Delta Wetlands Project water would include: Semitropic Water Storage District; Member Agencies of the Metropolitan Water District of Southern California, the Western Municipal Water District of Riverside County, and select service areas of the Golden State Water Company. The project would include improvements of 27 miles of levees and screened diversions to divert water during high-flow periods in the winter months of December through March into Webb Tract (100,000 acre-feet of storage) and Bacon Island (115,000 acre-feet of storage). The water would not be diverted in a manner that would adversely affect senior legal water rights holders, including the SWP and CVP. Stored water would be discharged into False River (from Webb Tract) and Middle River (from Bacon Island) for export when excess SWP or CVP diversion capacity is available, in the summer and fall months of July through November. Any water that could not be exported from the Delta in a given year would be available to increase Delta outflow in the fall months of September through November. Semitropic WSD issued a Draft EIR in 2010 and a Final EIR in 2011.

35.3.5.11 North Bay Aqueduct Alternative Intake

DWR issued a Notice of Preparation on December 2, 2009 to construct and operate an alternative intake on the Sacramento River, generally upstream of the Sacramento Regional Wastewater Treatment Plant, and connect it to the existing North Bay Aqueduct system by a new segment of pipe. The proposed alternative intake would be operated in conjunction with the existing North Bay Aqueduct intake at Barker Slough. The proposed project would be designed to improve water quality and to provide reliable deliveries of State Water Project supplies to its contractors, the Solano County Water Agency, and the Napa County Flood Control and Water Conservation District.

35.3.5.12 Bay Area Regional Desalination Project

The Bay Area's four largest water agencies (EBMUD, Contra Costa Water District (CCWD), Santa Clara Valley Water District, and the San Francisco Public Utility Commission) are jointly exploring the development of regional desalination facilities that would benefit Bay Area residents and businesses served by these agencies. The Bay Area Regional Desalination Project could consist of one or more desalination facilities, with an ultimate total capacity of up to 71 million gallons per day. The project would provide an additional source of water during emergencies, such as earthquakes or levee failures, increase supply reliability, and provide water during droughts or maintenance of other facilities. A pilot plant was constructed at Mallard Slough. The water agencies are reviewing the results of the pilot study.

35.3.5.13 Los Vaqueros Reservoir Expansion Phase II

Los Vaqueros Reservoir is an off-stream reservoir in the Kellogg Creek watershed to the west of the Delta. The Los Vaqueros Reservoir initial construction was completed in 1997 as a 100,000 acre-foot off-stream storage reservoir owned and operated by CCWD to improve delivered water quality and emergency storage reliability for CCWD's customers. In 2012, the Los Vaqueros Reservoir was expanded to a total storage capacity of 160,000 acre-feet (Phase 1) to provide additional water quality and supply reliability benefits, and to adjust the timing of its Delta water diversions to accommodate the life cycles of Delta aquatic species, thus reducing species impact and providing a net benefit to the Delta environment. As part of the Storage Investigation Program described in the CALFED ROD, additional expansion up to 275,000 acre-feet (Phase 2) is being evaluated by CCWD, DWR, and Reclamation. The alternatives considered in the evaluation also consider methods to convey water from Los Vaqueros Reservoir to the South Bay Aqueduct to provide water to Zone 7 Water Agency, Alameda County Water District, and Santa Clara Valley Water District.

35.3.5.14 South Delta Temporary Barriers Operations

The South Delta Temporary Barriers Project was initiated as a test project in 1991. The South Delta Temporary Barriers Project consists of three rock barriers and one non-physical barrier across South Delta channels to increase water levels, improve water circulation patterns and water quality in the southern Delta for local agricultural diversions, and improve operational flexibility of the SWP to help reduce fishery impacts and improve fishery conditions. The barriers have been installed at the Head of Old River (HOR), Middle River, Old River near Tracy, and Grantline Canal. Installation of the barriers is dependent upon flow conditions, presence of specific fish species in the South Delta near water intakes, requirements of water users, and regulatory requirements of CDFW, USFWS, NMFS, and USACE. The barrier at the HOR serves as a fish barrier (intended to primarily benefit migrating San Joaquin River Chinook salmon) and is installed and operated in April-May and again in September-November. The remaining three barriers (Old River at Tracy, Grant Line Canal, Middle River) serve as agricultural barriers (intended to primarily benefit agricultural water users in the south Delta) and are installed and operated between April 15 and November 30 of each season. In 2008, a court order designed to protect delta smelt prohibited the installation of the spring HOR barrier pending fishery agency actions or further order of the court. The remaining three barriers serve as agricultural barriers and are installed between April 15 and September 30 of each season. An experimental underwater, non-physical barrier was installed near the HOR in 2009.

35.3.5.15 Stockton Deep Water Ship Channel Demonstration Dissolved Oxygen Project

The Stockton Deep Water Ship Channel Demonstration Dissolved Oxygen Project is a multiple-year study of the effectiveness of elevating dissolved oxygen (DO) concentrations in the channel. DO concentrations drop as low as two to three milligrams per liter (mg/L) during warmer and lower water flow periods in the San Joaquin River. The low DO levels can adversely affect aquatic life including the health and migration behavior of anadromous fish (e.g., salmon). The objective of the study is to maintain DO levels above the minimum recommended levels specified in the State of California WQCP (Basin Plan) for the Sacramento River and San Joaquin River basins. The Basin Plan water quality objectives for DO are 6.0 mg/l in the San Joaquin River (between Turner Cut and Stockton, 1 September through 30 November) and 5.0 mg/l the remainder of the year.

The project's full-scale aeration system includes two 200-foot-deep u-tube aeration tubes; two vertical turbine pumps capable of pumping over 11,000 gallons of water each; a liquid-to-gas oxygen supply system; and numerous pieces of ancillary equipment and control systems. The system has been sized to deliver approximately 10,000 pounds of oxygen per day into the Deep Water Ship Channel. The aeration system is anticipated to be operated only when channel DO levels are below the Basin Plan DO water quality objectives (approximately 100 days per year). The project includes an on-going assessment of DO levels in the channel and vicinity and a study of potential adverse effects of low DO on salmon.

35.3.5.16 Upper San Joaquin River Basin Storage Investigation (Previously described as Temperance Flat Reservoir)

The Upper San Joaquin River Basin Storage Investigation is being conducted by Reclamation and DWR to evaluate alternative plans to increase Upper San Joaquin River Storage to enhance the San Joaquin River restoration efforts and improve water supply reliability for agricultural, municipal and industrial, and environmental uses in the Friant Division, the San Joaquin Valley, and other regions of the state. The investigation will also evaluate integration of conjunctive management and water transfer concepts into project formulations. Additional storage is also expected to provide incidental flood damage reduction benefits.

Reclamation is analyzing alternatives for a new dam and a 1.26 million acre-foot reservoir at San Joaquin River Mile 274, in an area known as Temperance Flat. Primary planning objectives are to: 1) increase water supply reliability, and 2) enhance flow and temperature conditions to support the San Joaquin River Restoration Program. To the extent possible, the investigation will explore opportunities to provide other benefits that could include hydropower, flood control, and recreation. Operation variables include reservoir carryover, new or shifting water supply beneficiaries, and alternative conveyance routes. Operations alternatives evaluated in the draft Feasibility Report will be selected from combinations that most economically accomplish the planning objectives.

35.3.5.17 FERC Relicense Renewal for Turlock Irrigation District and Modesto Irrigation District Don Pedro Project

The Don Pedro Project is located on the Tuolumne River in Tuolumne County. The initial license was issued for operations between 1971 and 1991 followed by requirements to evaluate fisheries water needs in the Tuolumne River. In 1987, after the Turlock Irrigation District and Modesto Irrigation District applied to amend their license to add a fourth generating unit, FERC approved an amended fish study plan with possible changes in 1998. In 1996, FERC amended the license to implement amended minimum flow criteria and require fish monitoring studies for completion in 2005. In 2002, NMFS requested that FERC initiate formal consultation on the effects of the Don Pedro Project on Central Valley steelhead that were listed as threatened in 1998. FERC approved the Summary Report on fisheries in 2008. In 2009, NMFS, USFWS, CDFW, and several environmental interest groups filed requests for rehearing on the license. FERC denied portions of the request but required instream flow studies to be conducted and required NMFS to be included for consultation on any authorized changes to minimum flow release schedules. FERC also directed the appointment of an administrative law judge to assist in assessing the need for and feasibility for interim measures prior to relicensing. A final report was completed in 2010. Following the completion of the report and a monitoring plan by the affected districts, FERC approved an order modifying and approving instream flow and monitoring study plans. The initial license will expire in 2016. The objective of the relicensing process is to continue operation and maintenance of the Don Pedro Project facilities for electric power generation, along with implementation of any terms and conditions to be considered for inclusion in a new FERC hydroelectric license. The FERC relicensing procedures include an Endangered Species Act consultation by USFWS and NMFS.

35.3.5.18 FERC Relicense Renewal for Merced Irrigation District's Merced River Hydroelectric Project

The Merced River Hydroelectric Project is located on the Merced River in Mariposa County and includes both Lake McClure and McSwain Reservoir, two powerhouses (New Exchequer and McSwain), and recreation facilities. The initial FERC license will expire on February 28, 2014. The objective of the relicensing process is to continue operation and maintenance of the Merced River Hydroelectric Project facilities for electric power generation, along with implementation of any terms and conditions to be considered for inclusion in a new FERC hydroelectric license. The FERC relicensing procedures include an Endangered Species Act consultation by USFWS and NMFS.

35.3.5.19 Grassland Bypass Project

The purposes and objectives of the proposed continuation of the Grassland Bypass Project, 2010–2019 are to: 1) extend the San Luis Drain Use Agreement in order to allow the Grassland Basin Drainers time to acquire funds and develop feasible drainwater treatment technology to meet revised Basin Plan objectives (amendment underway) and Waste Discharge Requirements by December 31, 2019; 2) continue the separation of unusable agricultural drainage water discharged from the Grassland Drainage Area from wetland water supply conveyance channels for the period 2010–2019; and 3) facilitate drainage management that maintains the viability of agriculture in the Project Area and promotes continuous improvement in water quality in the San Joaquin River. All discharges of drainage water from the Grassland Drainage Area into wetlands and refuges have been eliminated. The selenium load discharged from the Grassland Drainage Area has been reduced by 61 percent (from 9,600 lbs to 3,700 lbs) and the salt load has been reduced by 39 percent (from 187,300 tons to 113,600 tons). Prior to the project, the monthly mean concentration of selenium in Salt Slough was 16 parts per billion. Since October 1996, the concentration has been less than the water quality objective of two parts per billion. The drainage water is conveyed to Mud Slough. Grasslands Water District and others are currently evaluating alternative plans to comply with Central Valley RWQCB water quality objectives for selenium and salinity in the San Joaquin River at the end of this project in 2019. One of the alternatives could be zero discharge with complete recycle of the drainwater to salinity-tolerant crops.

35.3.5.20 Central Valley RWQCB Irrigated Lands Regulatory Program

The Irrigated Lands Regulatory Program regulates discharges from irrigated agricultural lands. Its purpose is to prevent agricultural discharges from impairing the waters that receive the discharges. The California Water Code authorizes the SWRCB and RWQCBs to conditionally waive waste discharge requirements if this is in the public interest. On this basis, the Los Angeles, Central Coast, Central Valley, and San Diego RWQCBs have issued conditional waivers of waste discharge requirements to growers that contain conditions requiring water quality monitoring of receiving waters. In 2010, the Central Valley RWQCB proposed to expand the requirements to groundwater especially for regulation of discharges with higher concentrations of nutrients. Participation in the waiver program is voluntary; however, non-participant dischargers must file a permit application as an individual discharger, stop discharging, or apply for coverage by joining an established coalition group. The waivers must include corrective actions when impairments are found.

35.3.5.21 Central Valley Salinity Alternatives for Long-term Sustainability

In 2006, the Central Valley RWQCB, the SWRCB, and stakeholders began a joint effort to address salinity and nitrate problems in California’s Central Valley and adopt long-term solutions that will lead to enhanced water quality and economic sustainability. This effort is referred to as the Central Valley Salinity Alternatives for Long-term Sustainability (CV-SALTS) Initiative. The goal of CV-SALTS is to develop a comprehensive region-wide Salt and Nitrate Management Plan (SNMP) describing a water quality protection strategy that will be implemented through a mix of voluntary and regulatory efforts. The SNMP may include recommendations for numeric water quality objectives, beneficial use designation refinements, and/or other refinements, enhancements, or basin plan revisions. The SNMP will serve as the basis for amendments to the three Basin Plans that cover the Central Valley Region (Sacramento River and San Joaquin River Basin Plan, the Tulare Lake Basin Plan, and the Sacramento/San Joaquin Rivers Bay-Delta Plan). The basin plan "amendments" will likely establish a comprehensive implementation plan to achieve water quality objectives for salinity (including nitrate) in the Region's surface waters and groundwater; and the SNMP may include recommendations for numeric water quality objectives, beneficial use designation refinements, and/or other refinements, enhancements, or basin plan revisions.

35.3.5.22 San Luis Reservoir Low Point Improvement Project

The San Luis Reservoir Low Point Improvement Project is proposed by Reclamation, the Santa Clara Valley Water District, and the San Luis and Delta Mendota Water Authority. As part of this project, Reclamation is investigating three alternatives to address the water quality problems within the CVP's San Felipe Division (Santa Clara and San Benito counties) that arise when San Luis Reservoir levels drop below 300,000 acre-feet during late summer in dry water years, resulting in large algal blooms. The alternatives being considered are to (1) expand the 6,000 acre-feet Pacheco Reservoir to 80,000 acre-feet or 130,000 acre-feet, (2) lower the San Felipe Intake at San Luis Reservoir, or (3) implement a combination comprehensive plan. The combination comprehensive plan would involve increasing groundwater recharge and recovery capacity, implementing desalination measures, re-operating Santa Clara Valley Water District's raw- and treated-water systems, and implementing institutional measures. If Pacheco Reservoir were to be enlarged, the reservoir would be filled with Delta water; thus, additional impacts on Delta aquatic species (e.g., juvenile salmonids and delta smelt) could result from an increase in Delta exports. The environmental scoping report for the San Luis Reservoir Low Point Improvement Project was released in January 2009 and the plan formulation report was published in January 2011.

35.3.5.23 San Luis Reservoir State Recreation Area Resource Management Plan/General Plan

The Resource Management Plan/General Plan for San Luis Reservoir, O'Neill Forebay, and Los Banos Creek Reservoir are being developed. State Parks manages the San Luis Reservoir State Recreation Area. Lands have been identified at O'Neill Forebay Wildife Area and San Luis Wildlife Area by Reclamation for management by CDFW. The Resource Management Plan/General Plan EIS/EIR evaluated three alternatives plus the No Action Alternative. One alternative would limit new access and development of the recreation areas. A second alternative would have moderate new access and recreation development. The third alternative would have the most new access and recreation development. The Revised Draft EIS/EIR was issued by Reclamation and State Parks in August 2012.

35.3.6 Ecosystem Improvement Projects and Actions in the Vicinity of Proposed NODOS Project facilities and/or Potentially Affected by SWP and CVP Operations (organized geographically from north to south)

The ecosystem improvement projects and actions in the vicinity of the proposed NODOS Project facilities and/or potentially affected by SWP and CVP operations considered in this cumulative impact assessment include:

- Trinity River Restoration Program
- Clear Creek Fisheries Habitat Restoration Program
- Clear Creek Mercury Abatement and Fisheries Restoration Project
- Iron Mountain Mine Superfund Site (on Spring Creek)

- Mainstem Sacramento River Gravel Augmentation Program
- Cottonwood Creek Geomorphological Analyses and Sediment Budget
- Cottonwood Creek Non-Native Invasive Species Eradication Program
- Mill Creek Riparian Assessment
- Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project
- Yolo County Habitat/Natural Community Conservation Plan
- Yolo Bypass Wildlife Area Land Management Plan
- Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan
- Cache Slough Complex Restoration
- Lower Mokelumne River Spawning Habitat Improvement Project
- North Delta Flood Control and Ecosystem Restoration Project
- Fish Screen Project at Sherman and Twitchell Islands
- Dutch Slough Tidal Marsh Restoration
- Franks Tract Project
- Solano County Multi-species Habitat Conservation Plan
- Suisun Marsh Habitat Management, Preservation, and Restoration Plan Implementation
- San Joaquin River Restoration Program

35.3.6.1 Trinity River Restoration Program

Trinity River Restoration Program is conducted by eight partners that form the Trinity Management Council, including Reclamation, USFWS, NMFS, U.S. Forest Service, Hoopa Valley Tribe, Yurok Tribe, California Resources Agency, and Trinity County. The Trinity River Flow Evaluation Final Report was adopted in 1999 and the Trinity River Record of Decision (ROD) was signed in 2000 to implement restoration of the physical processes and rescale the Trinity River as foundation for fisheries recovery. The ROD described four restoration methods (flow management through releases from Lewiston Dam, construction of channel rehabilitation sites, augmentation of spawning gravels, and control of fine sediments); infrastructure improvements to accommodate high flow releases from Lewiston Dam; environmental compliance with improvements to riparian vegetation and wetlands, reduced turbidity, and improved water temperatures; and science-based adaptive management. The Trinity River Restoration Program 2011 Annual Report stated that approximately half of the projects described in the Flow Evaluation Study had been completed and intensive assessments of the physical responses of the Trinity River and geomorphic assessments of the 40-mile restoration reach had been initiated.

35.3.6.2 Clear Creek Fisheries Habitat Restoration Program

The Clear Creek fisheries habitat restoration is being implemented by USFWS and Reclamation in accordance with CVPIA actions (3406(b)(12). The restoration project’s purpose is to support spring-run, fall-run, and late-fall-run Chinook salmon and steelhead, including improved flows for spawning, incubation, rearing, and outmigration; instream flow studies; removal of McCormick-Saeltzer Dam, improved fish passage, reduction in channel erosion, channel and floodplain restoration, gravel augmentation, and adaptive management with monitoring programs.

The Clear Creek Gravel Augmentation Program is part of the CVPIA actions to reduce impacts created by the construction and operation of Whiskeytown Dam. Whiskeytown Dam blocks gravel from moving downstream into the areas of Clear Creek where salmonids spawn. The injection of spawning-sized gravel will maintain quality spawning habitat for the production of salmonids. By the year 2020 the overall goal is to provide 347,288 square feet of usable spawning habitat between Whiskeytown Dam downstream to the former McCormick-Saeltzer Dam, the amount that existed before construction of Whiskeytown Dam. Between 1996 and 2009, a total of approximately 130,925 tons of spawning gravel was added to the creek. The programs' interim annual spawning gravel addition target is 25,000 tons per year, but due to a lack of funding, only an average of 9,358 tons has been placed annually since 1996.

In 2010, the first annual evaluation of spawning gravel implementation and monitoring was submitted to NMFS as a requirement under the 2009 Biological Opinion. In 2012, Reclamation prepared a Categorical Exclusion Checklist to place 10,000 tons of spawning gravel at four locations: Guardian Rock/Below N.E.E.D. Camp, Placer Bridge, Clear Creek Crossing/Bridge, and Tule Backwater.

35.3.6.3 Clear Creek Mercury Abatement and Fisheries Restoration Project

The Lower Clear Creek Aquatic Habitat and Waste Discharge Improvement Project was initiated to remove the long-term impacts of mercury contamination in Lower Clear Creek and to create over five acres of new wetlands. The mercury sources are dredge-mined tailings from more than 200 historic gold and gravel mines in the watershed. The tailings are located on the properties adjacent to Clear Creek and in gravels historically used for spawning gravel supplementation. This is being completed in accordance with CVPIA actions. One of the first projects was the removal of the McCormick-Saeltzer Dam in 2000, which had blocked fish passage to upper Clear Creek. Other projects include gravel augmentation of over 10,000 tons of gravel (as described below), revegetation of some parts of the channel, monitoring, and modeling,

35.3.6.4 Iron Mountain Mine Superfund Site

The Iron Mountain Mine Superfund Site on Spring Creek had discharged acid mine drainage into several creeks that are tributary to Keswick Reservoir and the Sacramento River since the late 1890s. The interim remedies include source control, acid mine drainage collection and treatment, and water management, including water diversions and coordinated releases of contaminated surface water from Spring Creek Debris Dam with dilution flows released from Shasta Lake. In 2008, the U.S. Environmental Protection Agency indicated that the interim remedies were operational and had reduced metal loading discharges by 95 percent as compared to pre-project conditions. A final restoration plan for natural resources injuries due to Iron Mountain Mine was adopted in 2002 by USFWS, CDFW, National Oceanic and Atmospheric Administration, U.S. Bureau of Land Management, and Reclamation, and those programs are being implemented.

35.3.6.5 Mainstem Sacramento River Gravel Augmentation Program

The Mainstem Sacramento Gravel Augmentation Program is an ongoing Reclamation project that helps meet requirements of Section 3406 (b)(13) of the CVPIA to restore and replenish spawning gravel and rearing habitat for salmonid species.

Reclamation began placing salmonid spawning gravel in the Sacramento River approximately 0.25 miles downstream of Keswick Dam in August 2011. The project will place approximately 5,000 tons/year of gravel into the river to help improve spawning habitat for Chinook salmon and steelhead.

35.3.6.6 Cottonwood Creek Geomorphological Analyses and Sediment Budget

Severe streambank erosion along the main channels of Cottonwood Creek, particularly in the lower watershed, is prompting landowners to implement piecemeal "emergency" responses, which can include significant bank armoring and may cause new problems or exacerbate existing problems elsewhere along the channel. As a result, a coordinated stream restoration/management effort that emphasizes watershed-wide processes and is supported by the most recent geomorphic analyses tools is needed. To meet this need, the Cottonwood Creek Geomorphological Analyses and Sediment Budget goal is to develop a sediment budget for Cottonwood Creek based upon geomorphological data from 1939 to present; quantify spatial and temporal characteristics of sediment supply, storage, and transport in the system, and to identify the effects of sediment transport dynamics on perceived channel and watershed changes. The project will include the collection of needed additional data; and synthesis of currently available data to complete the sediment budget and answer the questions posed below.

A comprehensive synthesis of previously existing and supplemental data would be conducted incorporating the most current geomorphic analysis methods. The interpretation would call on cross-disciplinary expertise and will target specific questions of practical interest to local stakeholders such as: 1) How “stable” is the stream channel given historic and current natural conditions and land management?; 2) What roles do in-channel islands play and how might the practice of moving these islands affect the upstream and downstream channel and habitat conditions?; 3) Is current channel configuration a limiting factor to aquatic or terrestrial organisms of concern?; 4) Is the channel instability due to the amount of aggregate being removed by gravel mining?; and 5) Are current land use practices affecting the sediment budget in such a way as to create channel instability, and if so, how? The main concern is the channel instability of the lower watershed and how the bed material budget may be affecting channel response to differing flow events.

The Cottonwood Creek Working Group (CCWG) is working with Graham Matthews & Associates to insert three separate gages into the Cottonwood Creek system. Other portions of the creek will have sporadic samples taken to also assist with the project. The first gage went into the creek in January 2010.

35.3.6.7 Cottonwood Creek Non-Native Invasive Species Eradication Program

The Cottonwood Creek Non-Native Invasive Species Eradication Program is part of the Anadromous Fish Restoration Program (AFRP) and is being administered by the CCWG. The Nonnative Invasive Plant Management and Control Project was funded in Fiscal Year 2009 to complete the environmental compliance documents and permitting to eradicate non-native noxious and invasive (NIS) plants within the riparian corridor of Cottonwood Creek. Non-native plant inventories of the targeted species were completed this year to assist with the NEPA effects analysis.

35.3.6.8 Mill Creek Riparian Assessment

The need to restore and maintain riparian habitat in Mill Creek is identified by AFRP and in the CALFED ERP goals, objectives, and targets. The AFRP is one of five CVPIA programs that has been integrated with the ERP. Both of these programs prioritize establishment, restoration, and maintenance of anadromous fish habitat on this stream, particularly in the arena of riparian habitat and flow enhancement. In response to this identified need, Reclamation and USFWS are implementing the Mill Creek Riparian Assessment. The project includes: 1) riparian habitat and condition mapping and vegetation classification of the Mill Creek watershed, 2) identifying and prioritizing areas that should be restored, enhanced, and/or preserved in addition to existing conservation easements, and 3) identifying the types of restoration actions that should occur at the prioritized sites.

35.3.6.9 Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project

Deer Creek, in Tehama County, features unique habitat that makes it a very important resource for anadromous fish in the Sacramento Valley. There are three diversion dams and four screened diversion ditches in Deer Creek. Inadequate flow for upstream passage is the most significant problem in Deer Creek. The Deer Creek Irrigation District (DCID) Dam is the uppermost dam on Deer Creek. The DCID Dam is a flashboard dam with a screened diversion. During the floods in 1997, portions of this structure were damaged, creating fish passage issues.

DWR staff is monitoring the upstream and downstream stage differential at the DCID Dam. Work is also underway by DCID, DWR, and CDFW to develop an environmental flow enhancement program in lower Deer Creek. The goal of the enhancement program is to increase fish transportation flows downstream of the DCID Dam. There are over 25 miles of prime spawning habitat upstream of the DCID Dam. DWR's Fish Passage Improvement Program (FPIP) and Northern Region staff are completing the detailed topographic survey of the area and preliminary engineering investigation.

In August 2007, DCID, DWR's Northern Region Office, and CDFW signed a Memorandum of Agreement (Agreement) for the construction, operation, maintenance and monitoring of a flow enhancement program on Deer Creek. DCID recognizes the need for a long-term solution to the fish transportation issues in Deer Creek and has continued to work with the DWR, Deer Creek Watershed Conservancy, Tehama County, CDFW, and NMFS. A Conceptual Framework for the Deer Creek Flow Enhancement Program was developed by DWR. This framework was designed to fulfill the water needs of local agricultural and domestic water users, while achieving the fisheries water flow objectives in Deer Creek.

35.3.6.10 Yolo County Habitat/Natural Community Conservation Plan

The Yolo County Habitat Joint Powers Authority, consisting of five local public agencies, launched the Yolo Natural Heritage Program in March 2007. This effort includes the continuing preparation of a joint HCP/NCCP. Member agencies include Yolo County and the Cities of Davis, Woodland, West Sacramento, and Winters.

The HCP/NCCP describes the measures that local agencies will implement in order to conserve biological resources, obtain permits for urban growth and public infrastructure projects, and continue to maintain the agricultural heritage and productivity of Yolo County. The nearly 653,820-acre planning area provides habitat for covered species occurring within five dominant habitats/natural communities. The plan proposes to address 63 covered species, including seven state-listed species: palmate-bracted bird's-beak, Colusa grass, Crampton's tuctoria, giant garter snake, Swainson's hawk, western yellow-billed cuckoo, and bank swallow. Interim conservation activities include acquiring permanent conservation easements for sensitive species habitat in the plan area.

35.3.6.11 Yolo Bypass Wildlife Area Land Management Plan

The Yolo Bypass Wildlife Area consists of approximately 16,770 acres of managed wildlife habitat and agricultural land within the Yolo Bypass. The bypass conveys seasonal high flows from the Sacramento River to help control river stage and protect the cities of Sacramento, West Sacramento, and Davis, as well as other local communities, farms, and lands from flooding. Substantial environmental, social, and economic benefits are provided by the Yolo Bypass, benefiting the people of the State of California.

The stated purposes of the Yolo Bypass Wildlife Area Land Management Plan are to: (1) guide the management of habitats, species, appropriate public use, and programs to achieve CDFW's mission; (2) direct an ecosystem approach to managing the Yolo Bypass Wildlife Area in coordination with the objectives of the CALFED ERP; (3) identify and guide appropriate, compatible, public-use opportunities within the Yolo Bypass Wildlife Area; (4) direct the management of the Yolo Bypass Wildlife Area in a manner that promotes cooperative relationships with adjoining private-property owners; (5) establish a descriptive inventory of the sites and the wildlife and plant resources that occur in the Yolo Bypass Wildlife Area; (6) provide an overview of the Yolo Bypass Wildlife Area's operation, maintenance, and personnel requirements to implement management goals, and serve as a planning aid for preparation of the annual budget for the Bay- Delta Region (Region 3); and (7) present the environmental documentation necessary for compliance with State and federal statutes and regulations, provide a description of potential and actual environmental impacts that may occur during plan management, and identify mitigation measures to avoid or lessen these impacts.

35.3.6.12 Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan

The Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan is being prepared jointly by DWR and Reclamation to address Reasonable and Prudent Alternative (RPA) Actions I.6.1 and I.7 of the 2009 NMFS Biological Opinion to restore floodplain rearing habitat and reduce migratory delays and loss of salmon, steelhead, and sturgeon in the Yolo Bypass. The implementation plan describes the objectives and performance measures for these actions and potential actions for further evaluation. The implementation plan was submitted to NMFS in September 2012 for concurrence of the plan and for the initiation of environmental documentation. The NMFS concurred with the implementation plan in November 2012. The environmental documentation is currently being completed.

35.3.6.13 Cache Slough Complex Restoration

The Cache Slough Complex is located in the northern Delta where Cache Slough and the southern Yolo Bypass meet. It currently includes Liberty Island, Little Holland Tract, Prospect Island, Little Egbert Tract and the surrounding waterways. Levee height on these tracts is restricted and designed to allow overtopping in large flow events to convey water from the upper Yolo Bypass. Since 1983 and 1998 respectively, Little Holland Tract and Liberty Island have remained breached. Restoration is occurring naturally on the islands. Restoration in the Cache Slough Complex was identified as an Interim Delta Action by Governor Schwarzenegger in July 2007.

The Cache Slough Complex has potential for restoration success because of its relatively high tidal range, historic dendritic channel network, minimal subsidence, and remnant riparian and vernal pool habitat. Restoration efforts would support native species, including delta smelt, longfin smelt, Sacramento splittail, and Chinook salmon, by creating or enhancing natural habitats and improving the food web fish require. Surrounding lands that are at elevations that would function as floodplain or marsh if not separated by levees could also be included in the Cache Slough Area. This broader area includes roughly 45,000 acres of existing and potential open water, marsh, floodplain, and riparian habitat. The goals of restoration in the Cache Slough Complex are to: 1) re-establish natural ecological processes and habitats to benefit native species, 2) contribute to scientific understanding of restoration ecology, and 3) maintain or improve flood safety. Three restoration actions are being considered in the Cache Slough Complex, including restoration actions at Calhoun Cut, Little Holland Tract, and Prospect Island.

35.3.6.14 Lower Mokelumne River Spawning Habitat Improvement Project

The Mokelumne River is tributary to the Delta and supports five species of anadromous fish. The proposed project would initially place 4,000 to 5,000 cubic yards of suitably sized salmonid spawning gravel annually for a three-year period at two specific sites, and then provide annual supplementation of 600 to 1,000 cubic yards thereafter. Fall-run Chinook salmon and steelhead are the primary management focus in the river. Availability of spawning gravel in this section of the Mokelumne River has been determined to be deficient because historic gold and aggregate mining operations removed gravel annually and upstream dams have reduced gravel transport to the area. This area was chosen because it is known to have supported fall-run Chinook salmon and steelhead spawning in the past and because the substrate is suitable for habitat improvement.

35.3.6.15 North Delta Flood Control and Ecosystem Restoration Project

The North Delta Flood Control and Ecosystem Restoration Project is proposed near the confluence of the Cosumnes and Mokelumne rivers by DWR and encompasses approximately 197 square miles. Consistent with objectives contained in the CALFED ROD, the project is intended to improve flood management and provide ecosystem benefits in the North Delta area through actions such as construction of setback levees and configuration of flood bypass areas to create quality habitat for species of concern. These actions are focused on McCormack-Williamson Tract and Staten Island. The project would implement flood control improvements in a manner that benefits aquatic and terrestrial habitats, species, and ecological processes. Flood control improvements are needed to reduce damage to land uses, infrastructure, and the Bay-Delta ecosystem resulting from overflows caused by insufficient channel capacities and catastrophic levee failures in the 197 square-mile project study area.

The proposed project as described in the Final EIR included: levee modifications to allow controlled flow across McCormack-Williamson Tract and to mitigate hydraulic impacts; channel dredging to increase flood conveyance capacity; an off-channel detention basin on Staten Island; ecosystem restoration where floodplain forests and marshes would be developed at McCormack-Williamson Tract and the Grizzly Slough property; setback levee on Staten Island to expand the floodway conveyance; opening up the southern portion of McCormack-Williamson Tract to boating; improving the Delta Meadows property; providing access and interpretive kiosks for wildlife viewing; and providing restroom, circulation, parking, and signage infrastructure to support such uses.

35.3.6.16 Fish Screen Project at Sherman and Twitchell Islands

The Fish Screen Project south of Rio Vista is proposed by CDFW and involves installing fish screens on up to 10 unscreened agricultural intakes used to irrigate State-owned lands on Sherman and Twitchell islands in the Delta. The project is intended to contribute to the protection of delta smelt and other sensitive aquatic species and the restoration of habitat in the Delta.

35.3.6.17 Dutch Slough Tidal Marsh Restoration

The Dutch Slough Tidal Marsh Restoration Project, located near Oakley in Eastern Contra Costa County, would restore wetland and uplands and provide public access to the 1,200-acre Dutch Slough property. The property is composed of three parcels separated by narrow man-made sloughs. The project is a cooperative partnership between DWR, the California Coastal Conservancy, CDFW, the City of Oakley, the Ironhouse Sanitary District, Reclamation Districts 2137 and 799, the Natural Heritage Institute, and landowners. The project will provide ecosystem benefits, including habitat for sensitive species such as winter-run Chinook salmon, Sacramento splittail, and many waterfowl species. It also would be designed and implemented to maximize opportunities to assess the development of those habitats and measure ecosystem responses so that future Delta restoration projects will be more successful. DWR approved the Final EIR for the project in March 2010.

35.3.6.18 Franks Tract Project

DWR and Reclamation are conducting studies to evaluate the feasibility of modifying the hydrodynamic conditions near Franks Tract to improve Delta water quality and enhance the aquatic ecosystem. The results of these studies have indicated that modifying the hydrodynamic conditions near Franks Tract may substantially reduce salinity in the Delta and protect fishery resources, including populations of delta smelt, a federally listed and State-listed species that is endemic to the Delta. As a result, DWR and Reclamation propose to implement the Franks Tract Project to improve water quality and fisheries conditions in the Delta. DWR and Reclamation are evaluating the installation of operable gates to control the flow of water at key locations (Threemile Slough and/or West False River) to reduce sea water intrusion, and to positively influence movement of fish species of concern to areas that provide favorable habitat conditions. The project gates would be operated seasonally and during certain hours of the day, depending on fisheries and tidal conditions. Boat passage facilities would be included to allow for passing of watercraft when the gates are in operation. The Franks Tract Project is consistent with ongoing planning efforts for the Delta to help balance competing uses and create a more sustainable system for the future. By protecting fish resources, this project also could improve operational reliability of the SWP and CVP because curtailments in water exports (pumping restrictions) are likely to be less frequent. Franks Tract was previously evaluated as part of DWR’s Flooded Island Pre-Feasibility Study Report.

35.3.6.19 Solano County Multi-species Habitat Conservation Plan

The Solano HCP is intended to support the issuance of an incidental take permit under the federal Endangered Species Act for a period of 30 years. This permit is required for the Solano Project Contract Renewal Biological Opinion between USFWS and Reclamation. The scope of the Solano HCP was expanded beyond the requirements of the Biological Opinion to include additional voluntary applicants and additional species for incidental take coverage. These additional species include federally listed fish species under the jurisdiction of NMFS and species listed as threatened or endangered under the California Endangered Species Act. The HCP further addresses other species of concern (i.e., species recognized by groups such as the CDFW and the California Native Plant Society as having declining or vulnerable populations, but not officially listed as threatened or endangered species). Thirty-seven species are proposed to be covered under the Solano HCP. The minimum geographical area to be covered is the Solano County Water Agency’s contract service area that includes the cities of Fairfield, Vacaville, Vallejo, Suisun City, the Solano Irrigation District, and the Maine Prairie Water District. The area covered by the HCP includes all of Solano County and a small portion of Yolo County. The HCP includes a Coastal Marsh Natural Community Conservation Strategy designed to maintain the water and sediment quality standards, hydrology, and ecological functions of this natural community; contribute to the restoration of tidally influenced coastal marsh habitat; contribute to the conservation and recovery of associated covered species; and promote habitat connectivity. Primary conservation actions include preservation (primarily through avoidance), restoration, invasive species control, and improvement of water quality. The plan area covers 580,000 acres, which includes 12,000 acres of proposed development and 30,000 acres that will be preserved.

35.3.6.20 Suisun Marsh Habitat Management, Preservation, and Restoration Plan Implementation

On March 2, 1987, the Suisun Marsh Preservation Agreement was signed by DWR, CDFW, Reclamation, and the Suisun Resource Conservation District. The purpose of the agreement was to establish mitigation for impacts on salinity from the SWP, CVP, and other upstream diversions.

In 2001, USFWS, Reclamation, CDFW, DWR, NMFS, the Suisun Resource Conservation District, and CALFED (the Principal Agencies) directed the formation of a charter group to develop a plan for Suisun Marsh that would balance the needs of CALFED, the Suisun Marsh Preservation Agreement, and other plans by protecting and enhancing existing land uses, existing waterfowl and wildlife values including those associated with the Pacific Flyway, endangered species, and State and federal water project supply quality. In addition to the Principal Agencies, the charter group included other regulatory agencies such as USACE, the San Francisco Bay Conservation and Development Commission, SWRCB, and RWQCBs. In 2011, the Principal Agencies published a Final EIS/EIR for the Suisun Habitat Management, Preservation, and Restoration Plan. The plan purposes/objectives are:

- Habitats and Ecological Processes to implement CALFED Ecosystem Restoration Program Plan
- Public and Private Land Use to maintain the heritage of waterfowl hunting and other recreational opportunities and increase the surrounding communities' awareness of the ecological values of Suisun Marsh
- Levee System Integrity to protect property, infrastructure, and wildlife habitats from catastrophic flooding
- Water Quality to protect, and where possible, improve water quality for beneficial uses in Suisun Marsh

The proposed project will restore 5,000 to 7,000 acres of tidal marsh and provide protection and enhancement of 40,000 to 46,000 acres of managed wetlands. The plan includes environmental commitments and mitigation measures, adaptive management programs, and reporting through annual reports over the 30-year time frame of the plan.

35.3.6.21 San Joaquin River Restoration Program

The San Joaquin River Restoration Program is a comprehensive long-term effort to restore flows to the San Joaquin River from Friant Dam to the confluence of Merced River and restore a self-sustaining Chinook salmon fishery in the river while reducing or avoiding adverse water supply impacts from restoration flows. The restoration program is the product of more than 18 years of litigation, which culminated in a Stipulation of Settlement on the lawsuit known as Natural Resources Defense Council (NRDC), et al., v. Kirk Rodgers, et al. The settling parties reached agreement on the terms and conditions of the settlement, which was subsequently approved by Federal Court on October 23, 2006. The settling parties include the NRDC, Friant Water Users Authority, and the U.S. Departments of the Interior and Commerce. The settlement's two primary goals are to:

- Restore and maintain fish populations in "good condition" in the main stem of the San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish, and

- Reduce or avoid adverse water supply impacts to all of the Friant Division long-term contractors that may result from the Interim Flows and Restoration Flows provided for in the settlement.

The settlement requires specific releases of water from Friant Dam to the confluence of the Merced River, which are designed primarily to meet the various life stage needs for spring- and fall-run Chinook salmon. The release schedule assumes continuation of the current average Friant Dam release of 116,741 acre-feet, with additional flow requirements depending on the year type. The project was authorized and funded with the passage of the San Joaquin River Restoration Settlement Act, part of the Omnibus Public Land Management Act of 2009 (Public Law 111-11). Interim flows began in October, 2009. There are many physical improvements within and near the San Joaquin River that will be undertaken to fully achieve the river restoration goal. The improvements will occur in two separate phases that will focus on a combination of water releases from Friant Dam, as well as structural and channel improvements.

35.4 Cumulative Effects Analysis by Resource

The potential for implementation of the range of alternatives evaluated in this DEIR/EIS to result in a cumulatively considerable incremental contribution was determined for each resource based upon the significance criteria for each resource, as described in Chapters 6 through 31. To reduce any cumulatively considerable incremental contributions from the NODOS Project action alternatives to an overall cumulative effect, feasible mitigation measures are proposed for all potentially substantial direct and indirect effects. In some cases, no feasible mitigation could be applied to reduce effects. In these cases, the cumulative effects are considered to be substantial and unavoidable.

35.4.1 Surface Water Resources

In Chapter 6 Surface Water Resources, changes in surface water resources are described but not assessed or evaluated to determine the significance of surface water resources changes. Impact and significance determinations that rely on the surface water resources data that are presented in Chapter 6 Surface Water Resources are described and evaluated in other resource chapters (e.g., changes in reservoir storage and river flows could affect recreation resources). Therefore, the cumulative analysis of surface water resources does not provide an assessment of significance.

Alternatives A, B, and C would be integrated with the CVP and SWP systems, and would affect CVP and SWP operations, reservoir storage, river flows downstream of the reservoirs, Delta outflow, and water supply deliveries. The alternatives were developed to improve cold water pool management in Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, and the Sacramento River in drier years; increase Delta exports and SWP allocations in drier years; improve Delta water quality for municipal and industrial water users in the Delta and south of Delta, especially in summer and fall of most years, and for enhancement of aquatic resources through X2 location criteria; and stabilize Sacramento River flows to improve spawning and rearing conditions in most years. Major differences between Alternatives A, B, and C are related to the size of the proposed Sites Reservoir and the inclusion of the proposed Delevan Pipeline Intake Facilities. These differences would affect diversion patterns from the Sacramento River into the proposed Sites Reservoir, and release patterns from CVP and SWP reservoirs to provide for or respond to the operations of Sites Reservoir.

When combined with other past, present, and reasonably foreseeable future projects, there could be changes in operations of CVP and SWP facilities and related changes in reservoir storage, river flows downstream of the reservoirs, and CVP and SWP water supply deliveries under Alternatives A, B, or C.

The quantitative analysis of surface water conditions under Alternatives A, B, or C presented in Chapter 6 Surface Water Resources included conditions under past, present, and future projects under the No Project/No Action Alternative. Implementation of other reasonably foreseeable projects included in the cumulative effects analysis that are less defined than future projects under the No Project/No Action Alternative also could change CVP and/or SWP reservoir operations to meet downstream minimum instream flows or water quality objectives. The changes in operations also could change available water supplies and related CVP and SWP water deliveries. The changes could occur in three different ways:

- **Future projects that could affect overall CVP and SWP water supply operations.** These projects could result in changes to minimum instream flow in rivers affected by CVP and SWP operation, Delta outflow criteria to maintain flow and/or salinity (e.g., X2 location), reverse flow criteria for Old and Middle rivers, and diversion criteria at the south Delta intakes. Future projects which could change these criteria include the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation. However, the changes associated with the future projects would be complimentary with many of the changes associated with the proposed Project because they also would encourage improved cold water management, decreased Delta salinity, and improved spawning and rearing conditions. It is possible that the future projects in addition to this proposed Project could result in reductions in CVP and SWP exports.
- **Future projects that could change inflow patterns to CVP and SWP reservoirs or the Delta.** In response to future projects that change inflows to the reservoirs or the Delta, the CVP and SWP may need to change operations to maintain compliance with flow and water quality. These changes could result in less water available for diversion to the proposed Sites Reservoir or for CVP and SWP water deliveries. It should be noted that the No Project/No Action Alternative and Alternatives A, B, and C include an assumption that water demands in the Sacramento Valley would increase by approximately 500,000 acre-feet/year. Future projects not included in the No Project/No Action Alternative would either increase the water demand further or change the diversion pattern throughout the year. The Woodland-Davis Water Supply Project and El Dorado Water and Power Authority Supplemental Water Rights Project could reduce Sacramento River flows downstream of the City of Sacramento in some months due to an increase in diversions for these regional water supplies. The EBMUD Camanche Water Rights Permit Extension, Semitropic Water Storage District Delta Wetlands, Los Vaqueros Reservoir Expansion Phase II, and Upper San Joaquin River Basin Storage Investigation could change flow patterns in the Delta.
- **Future projects that could increase flexibility in water demand patterns.** Water users that expand their water supply portfolio may have more flexibility to change the historical patterns of CVP and SWP water deliveries. For example, water users that have diverted water during the summer months for irrigation could change their delivery patterns to other months if the water was diverted for groundwater recharge. The water user would then use groundwater during the irrigation season. Future projects that may be able to increase flexibility in water demand patterns include the EBMUD Water Supply Management Program 2040, Eastern San Joaquin Integrated Conjunctive Use Program, and the Bay Area Regional Desalination Project.

35.4.2 Surface Water Quality

Water quality degradation does exist in the Central Valley streams when considering past and present conditions. As described in Chapter 7 Surface Water Quality, the No Project/No Action Alternative would not result in substantial adverse effects to surface water quality as compared to Existing Conditions.

Several factors related to future projects evaluated in the cumulative effects analysis could affect water quality in the Extended Study Area (regions south of the Delta where Delta exports are used) and the Secondary Study Area (waterbodies that could be affected by proposed Project operations). None of the future projects evaluated in the cumulative effects analysis would result in construction projects within the Primary Study Area (area where the proposed Project storage and conveyance facilities would be constructed).

35.4.2.1 Alternative A

Extended Study Area and Secondary Study Area

Alternative A was developed to improve cold water management and Delta water quality, and to stabilize flows downstream of the CVP and SWP reservoirs. These actions would result in either no change or improvements to surface water quality including salinity, bromides, and chlorides in the Delta; and metals, sediment, nutrients, and other constituents, including mercury, in the waterbodies affected by proposed Project operations.

Alternative A also would result in changes in the operation of San Luis Reservoir to reduce the potential for algal blooms and associated water quality degradation. The associated water quality improvement under Alternative A and water quality improvement under the future San Luis Reservoir Low Point Improvement Project would result in improved water quality for users of water from San Luis Reservoir.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the implementation of CVPIA and CALFED, SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally are being developed to improve water quality. Other future projects also are being considered to improve water quality in the San Joaquin River and the Delta, including the continuation of the South Delta Temporary Barriers Operations, Franks Tract Project, Stockton Deep Water Ship Channel Dissolved Oxygen Project, Grassland Bypass Project, San Luis Reservoir Low Point Improvement Project, Central Valley Irrigated Lands Regulatory Program, CV-SALTS, and San Joaquin River Restoration Program. Implementation of Alternative A and these future projects that are being considered to improve water quality would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on surface water quality, and could result in cumulatively beneficial effects.

Implementation of projects that could result in increased amounts of wetland habitat that would be subject to periodic inundation and drying cycles could result in increased water quality degradation due to sediment and methylmercury. As described in Chapter 7 Surface Water Quality, Alternative A would not result in substantial adverse effects from increased contributions of mercury from upstream sources due to changes in flow patterns on the Sacramento and Feather rivers; and would not include expansion of ecosystem restoration areas that would contribute to methylmercury water quality degradation. Future projects considered in the cumulative effects analysis could contribute to mercury water quality issues, including the Bay Delta Conservation Plan, Delta Plan, Regional Advanced Mitigation Program, Clear Creek Mercury Abatement and Fisheries Restoration Project, Iron Mountain Mine Superfund Site, Yolo

County Habitat/Natural Community Conservation Plan, Yolo Bypass Wildlife Area Land Management Plan, Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan, and Cache Slough Complex Restoration. Other future projects could be operated in a manner to avoid mercury water quality issues, including the Dutch Slough Tidal Marsh Restoration and the Suisun Marsh Habitat, Management, Preservation, and Restoration Plan Implementation.

Because Alternative A would improve cold water management and Delta water quality, and would not contribute to the mercury concentrations in the Delta, implementation of Alternative A and the identified future projects would not result in a cumulatively considerable incremental contribution to an overall substantial adverse cumulative effect on surface water quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Without mitigation, Alternative A could have potentially substantial effects on water quality in the Primary Study Area. These effects could be caused by temporary or short-term construction-related activities that cause sediment, petroleum, or other substances to enter the waterways in runoff. As described in Chapter 7 Surface Water Quality, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation or maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and the identified future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on surface water quality.

35.4.2.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 7 Surface Water Quality, water quality effects from implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on surface water quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Water quality effects in the Primary Study Area under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative B could have potentially substantial adverse effects on water quality in the Primary Study Area. These effects could be caused by temporary or short-term construction-related activities that cause sediment, petroleum, or other substances to enter the waterways in runoff. As described in Chapter 7 Surface Water Quality, mitigation measures would eliminate or reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on surface water quality in the Primary Study Area.

35.4.2.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 7 Surface Water Quality, water quality effects from implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on surface water quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Water quality effects in the Primary Study Area under Alternative C would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative C could have potentially substantial effects on water quality in the Primary Study Area. These effects could be caused by temporary or short-term construction-related activities that cause sediment, petroleum, or other substances to enter the waterways in runoff. As described in Chapter 7 Surface Water Quality, mitigation measures would eliminate or reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on surface water quality in the Primary Study Area.

35.4.3 Fluvial Geomorphology and Riparian Habitat

Fluvial geomorphologic changes are occurring in the Central Valley streams that alter natural river processes including bank erosion, sediment transport, and changes in river sinuosity and river bed dimensions. As described in Chapter 8 Fluvial Geomporphology and Riparian Habitat, the No Project/No Action Alternative would not result in substantial adverse effects to fluvial geomorphologic conditions as compared to Existing Conditions.

Future projects evaluated in the cumulative effects analysis could affect fluvial geomorphologic conditions in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.3.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 8 Fluvial Geomporphology and Riparian Habitat, the amount of alteration to natural river processes and characteristics associated with implementation of Alternative A in the Extended Study Area and Secondary Study Area would be minor as compared to Existing Conditions and the No Project/No Action Alternative because the hydraulic changes would not substantially change flood flows, which is when most geomorphic effects occur. The effects would not be substantial. Changes in sediment transport and local flow patterns near the intakes under Alternative A are not anticipated to affect sediment concentration in the Sacramento River, and therefore, would not have a substantial effect on sediment concentration, turbidity, and water clarity. Alternative A also is not anticipated to result in substantial adverse effects on natural river meandering, bank erosion, large woody debris occurrence, riparian aquatic habitat, and spawning gravel conditions as compared to Existing Conditions and the No Project/ No Action Alternative.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, Butte County Regional Conservation Plan, and Shasta Lake Water Resources Investigation) generally are being developed to improve flow regimes in the Sacramento, Feather, and American rivers. However, implementation of some projects, including the Trinity River Restoration Program, Mainstem Sacramento River Gravel Augmentation Program, Cottonwood Creek Geomorphological Analyses and Sediment Budget, Cache Slough Complex Restoration, North Delta Flood Control and Ecosystem Restoration Project, Dutch Slough Tidal Marsh Restoration, Franks Tract Project, and San Joaquin River Restoration Program, could result in changes to fluvial geomorphologic conditions that would include both beneficial effects, such as beneficial effects due to Cottonwood Creek Geomorphological Analysis and Sediment Budget, and potentially locally substantial adverse effects. However, the local effects could be reduced after implementation of mitigation measures similar to measures described in Chapter 8 Fluvial Geomporphology and Riparian Habitat to reduce fluvial geomorphologic effects.

Implementation of projects that could result in increased amounts of wetland habitat that would be subject to periodic inundation and drying cycles could result in changes in sediment transport and deposition in the Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay. These effects could be potentially substantial and would occur without implementation of Alternative A. Alternative A would not contribute to the changes in sediment transport and deposition. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on fluvial geomorphologic conditions in the Extended Study Area or Secondary Study Area.

Primary Study Area

As described in Chapter 8 Fluvial Geomporphology and Riparian Habitat, alteration to natural river processes and characteristics in the Primary Study Area would not occur at the proposed Delevan Pipeline Intake Facilities location due to local geology and existing upstream bank protection; the fish screen would also stabilize a portion of the river bank. Local removal of riparian vegetation at the proposed intake location also would not result in a substantial adverse effect on habitat complexity in the Sacramento River. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and the identified future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on fluvial geomorphologic conditions.

35.4.3.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 8 Fluvial Geomporphology and Riparian Habitat, the fluvial geomorphologic effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and most of the Secondary Study Area. Fluvial geomorphologic effects in parts of the Secondary Study Area along the Sacramento River under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. However, the amount of alteration to natural river processes and characteristics associated with Alternative B implementation in the Extended Study Area and Secondary Study Area would be minor as compared to Existing Conditions and the No Project/No Action Alternative, and the effects would not be substantial. The cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on fluvial geomorphologic conditions in the Extended Study Area and Secondary Study Area.

Primary Study Area

Fluvial geomorphologic effects in the Primary Study Area along the Sacramento River under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. The amount of alteration to natural river processes and characteristics in the Primary Study Area would be minor as compared to Existing Conditions and the No Project/No Action Alternative, and the effects would not be substantial. The cumulative effects of Alternative B would be similar to those described for Alternative A in the Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on fluvial geomorphologic conditions in the Extended Study Area and Secondary Study Area.

35.4.3.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 8 Fluvial Geomporphology and Riparian Habitat, fluvial geomorphologic effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and most of the Secondary Study Area. Fluvial geomorphologic effects in parts of the Secondary Study Area along the Sacramento River under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. However, the amount of alteration to natural river processes and characteristics in the Extended Study Area and Secondary Study Area would be minor as compared to Existing Conditions and the No Project/No Action Alternative, and the effects would not be substantial. The cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on fluvial geomorphologic conditions in the Extended Study Area and Secondary Study Area.

Primary Study Area

Fluvial geomorphologic effects in the Primary Study Area along the Sacramento River under Alternative C would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. The amount of alteration to natural river processes and characteristics in the Primary Study Area would be minor as compared to Existing Conditions and the No Project/No Action Alternative, and the effects would not be substantial. The cumulative effects of Alternative B would be similar to those described for Alternative A in the Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on fluvial geomorphologic conditions in the Extended Study Area and Secondary Study Area.

35.4.4 Flood Control and Management

Adverse effects to flood control and management are caused by substantially altering drainage patterns, placement of structures within a 100-year Flood Hazard Area, and/or exposure of people or structures to substantial risks from flooding. As described in Chapter 9 Flood Control and Management, the No Project/No Action Alternative would result in no effects to flood control and management as compared to Existing Conditions.

Future projects evaluated in the cumulative effects analysis could affect flood management conditions in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.4.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 9 Flood Control and Management, anticipated changes in CVP and SWP reservoir storage and release operations under Alternative A are not anticipated to reduce flood storage potential or increase river flows during flood events.

Implementation of projects considered under the cumulative effects analysis that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, and Shasta Lake Water Resources Investigation) generally are being developed to improve flow regimes in the Sacramento, Feather, American, and San Joaquin rivers and to not increase flood risks on those rivers. Implementation of local water supply, flood management, and ecosystem improvement projects (including Delta Plan, North Delta Flood Control and Ecosystem Restoration Project, and San Joaquin River Restoration Program) are not anticipated to increase flood risks on the major rivers or minor streams except for areas that are to be inundated under the project-specific actions, such as expansion of ecosystem habitat in currently non-inundated lands. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on flood control and management in the Extended Study Area and Secondary Study Area.

Primary Study Area

As described in Chapter 9 Flood Control and Management, construction of facilities under Alternative A are not anticipated to result in substantial effects to flood management due to use of standard design criteria to avoid alteration of drainage patterns or impede or redirect flood flows within a 100-year Flood Hazard Area. Implementation of Alternative A would result in a potentially beneficial effect to areas located downstream of the proposed Sites and Golden Gate dams because future flood flows would be captured in the proposed Sites Reservoir and other proposed storage facilities. Implementation of Alternative A also could be operated to reduce peak flows in the Sacramento River downstream of Colusa by up to 5,900 cfs.

Potential effects from increased exposure to flood risks also are not considered to be substantial because the proposed Sites Reservoir would be designed and constructed pursuant to conservative guidelines and design criteria to prevent failure with multiple lines of defense or design redundancy as required to meet both DWR’s Division of Safety of Dams and Reclamation’s design standards. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on flood control and management in the Primary Study Area.

35.4.4.2 Alternative B

As described in Chapter 9 Flood Control and Management, flood management effects from implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area, and Primary Study Area,. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area, and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on flood control and management.

35.4.4.3 Alternative C

As described in Chapter 9 Flood Control and Management, flood management effects from implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area, and Primary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area, and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on flood control and management.

35.4.5 Groundwater Resources

Adverse effects to groundwater resources are caused by depletion of groundwater supplies or increased groundwater elevations that are incompatible with neighboring land uses. As described in Chapter 10 Groundwater Resources, the No Project/No Action Alternative would result in no effects to groundwater resources as compared to Existing Conditions.

Future projects evaluated in the cumulative effects analysis could affect groundwater resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.5.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 10 Groundwater Resources, improved CVP and SWP water supply reliability in the Extended Study Area could result in reduced use of groundwater in those areas, or additional groundwater recharge. These conditions would not result in substantial effects as compared to Existing Conditions or the No Project/No Action Alternative. Changes in flow regimes in the Secondary Study Area rivers under Alternative A are not expected to substantially affect groundwater recharge in areas adjacent to the rivers and streams and therefore would not result in substantial effects as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects analysis that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally are being developed to either provide increased water supply reliability of historic water deliveries or increase water supply availability. Increased CVP and SWP water supply availability would result in reduced use of groundwater in those areas, or additional groundwater recharge, and no substantial effects to groundwater levels along streams that convey CVP and SWP water supplies.

Implementation of ecosystem restoration projects also could affect groundwater by raising groundwater levels on adjacent lands. In some cases, the increased groundwater levels could be beneficial. However, if the groundwater levels rose into the root zones of agricultural lands or caused effects to levee and building foundations, the effects could be adverse. Future ecosystem projects considered in the cumulative effects analysis that could contribute to improved recreation resource conditions include the implementation of CVPIA and CALFED objectives; Delta Plan; Regional Advanced Mitigation Program; Semitropic Water Storage District Delta Wetlands; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Deer Creek Irrigation District Dam Fish Passage and Improvement and Flow Enhancement Project; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures, such as monitoring and installation of groundwater dewatering wells, could reduce the effects. In some cases, the effect could be substantial and unavoidable. For example, the San Joaquin River Restoration Program EIS/EIR identified potential groundwater effects to be substantial and unavoidable in some locations.

Although potentially substantial and unavoidable effects to groundwater resources could occur under future projects, Alternative A would not result in similar effects. Therefore, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 10 Groundwater Resources, without mitigation, operation of the proposed Holthouse Reservoir Complex, proposed Terminal Regulating Reservoir, and the forebay at the proposed Delevan Pipeline Intake Facilities are anticipated to result in potentially substantial effects due to increased groundwater levels that could adversely affect adjacent agricultural areas. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater resources.

35.4.5.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 10 Groundwater Resources, groundwater effects from implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Groundwater effects in the Primary Study Area under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative B could have potentially substantial effects on groundwater resources in the Primary Study Area near the proposed Holthouse Reservoir Complex and proposed Terminal Regulating Reservoir. As described in Chapter 10 Groundwater Resources, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and the future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater resources.

35.4.5.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 10 Groundwater Resources, groundwater effects from implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Groundwater effects in the Primary Study Area under Alternative C would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative C could have potentially substantial effects on groundwater resources in the Primary Study Area near the proposed Holthouse Reservoir Complex, proposed Terminal Regulating Reservoir, and the forebay at the proposed Delevan Pipeline Intake Facilities. As described in Chapter 10 Groundwater Resources, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater resources.

35.4.6 Groundwater Quality

Adverse effects to groundwater quality are caused by depletion of groundwater supplies that result in groundwater quality changes or contamination during construction and operation of new facilities. As described in Chapter 11 Groundwater Quality, groundwater quality under the No Project/No Action Alternative would be degraded as compared to Existing Conditions because of continued withdrawals of groundwater or minimal groundwater recharge in areas with groundwater overdraft.

Future projects evaluated in the cumulative effects analysis could affect groundwater quality in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.6.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 11 Groundwater Quality, improved CVP and SWP water supply reliability in the Extended Study Area could result in improved groundwater quality due to reduced use of groundwater in those areas, or additional groundwater recharge. These conditions would result in a potentially beneficial effect or minimal effects as compared to the Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally are being developed to either provide increased water supply reliability of historic water deliveries or increase water supply availability. Increased CVP and SWP water supply availability would result in reduced use of groundwater in those areas or additional groundwater recharge which would improve groundwater quality. Therefore, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater quality in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Without mitigation, construction and operation activities associated with Alternative A could result in potentially substantial effects from hazardous materials contamination during use of equipment or exposure during excavation. Groundwater contamination also could occur if septic system and well abandonment actions, installation of groundwater dewatering equipment and disposal of withdrawn groundwater, or installation of vault toilets at the proposed recreation facilities are not completed in a manner required by the State and Colusa and Glenn counties to prevent groundwater contamination. As described in Chapter 11 Groundwater Quality, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater quality.

35.4.6.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 11 Groundwater Quality, groundwater quality effects due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Groundwater quality in the Primary Study Area under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative B could have potentially substantial effects on groundwater quality in the Primary Study Area near the proposed Holthouse Reservoir Complex and proposed Terminal Regulating Reservoir. As described in

Chapter 11 Groundwater Quality, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater quality in the Primary Study Area.

35.4.6.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 11 Groundwater Quality, groundwater quality effects due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Groundwater quality in the Primary Study Area under Alternative C would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative C could have potentially substantial effects on groundwater quality in the Primary Study Area near the proposed Holthouse Reservoir Complex, proposed Terminal Regulating Reservoir, and the forebay at the proposed Delevan Pipeline Intake Facilities. As described in Chapter 11 Groundwater Quality, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on groundwater quality in the Primary Study Area.

35.4.7 Aquatic Biological Resources

Adverse effects to aquatic biological resources are caused by degraded water quality, habitat modification, interference with fish passage, and predation risk. The No Project/No Action Alternative would not result in substantial effects to aquatic biological resources in most waterbodies as compared to Existing Conditions. As described in Chapter 12 Aquatic Biological Resources, aquatic habitat conditions in the American River would continue to be degraded under the No Project/No Action Alternative as compared to Existing Conditions because of more frequent occurrences of low flows and increased water temperatures that would adversely affect steelhead, green sturgeon, Pacific lamprey, river lamprey, Sacramento splittail, striped bass, and American shad.

Future projects evaluated in the cumulative effects analysis could affect aquatic biological resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.7.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 12 Aquatic Biological Resources, implementation of Alternative A could affect aquatic biological resources. Alternative A was developed to enhance the ability to improve cold water management and Delta water quality, augment Delta outflows, and stabilize flows in the rivers, which in general could result in beneficial effects. However, implementation of Alternative A would reduce the frequency of inundation of the Yolo Bypass as compared to Existing Conditions and the No Project/No Action Alternative. Alternative A also could result in potentially substantial effects to steelhead, green sturgeon, and white sturgeon as compared to both Existing Conditions and the No Project/No Action Alternative, and potentially substantial effects to Sacramento splittail and largemouth bass as compared to the No Project/No Action Alternative. As described in Chapter 12 Aquatic Biological Resources, mitigation measures would reduce the effects.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally are being developed to benefit aquatic biological resources and would not be approved if existing regulatory requirements adopted to protect aquatic biological resources were not incorporated into the future projects. Implementation of ecosystem restoration projects also would enhance aquatic habitat conditions. Future ecosystem projects considered in the cumulative effects analysis that could benefit aquatic biological resources include the implementation of CVPIA and CALFED objectives; Delta Plan; Anadromous Fish Restoration Program; California Aquatic Invasive Species Rapid Response Plan; Regional Advanced Mitigation Program; Butte County Regional Conservation Plan; El Dorado Irrigation District Folsom Lake Temperature Control Device; Lake Natoma Lower American River Temperature Reduction Project; North Bay Aqueduct Alternative Intake; South Delta Temporary Barriers Project; Stockton Deep Water Ship Channel Dissolved Oxygen Project; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Clear Creek Mercury Abatement and Fisheries Restoration Project; Iron Mountain Mine Superfund Site; Mainstem Sacramento River Gravel Augmentation Program; Cottonwood Creek Geomorphological Analysis and Sediment Budget; Mill Creek Riparian Assessment; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; Lower Mokelumne River Spawning Habitat Improvement Project; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Implementation of Alternative A and these future projects could result in beneficial effects, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on aquatic biological resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Without mitigation, sediment removal activities near the proposed Project intakes and construction of the proposed Delevan Pipeline Intake Facilities could result in potentially substantial effects in the Sacramento River to Central Valley winter-run Chinook salmon, Central Valley spring-run Chinook salmon, Central Valley fall-run Chinook salmon, Central Valley late-fall-run Chinook salmon, steelhead, Pacific lamprey, river lamprey, hardhead, Sacramento-San Joaquin roach, Sacramento splittail, striped bass, American shad, largemouth bass, green sturgeon, and white sturgeon as compared to Existing Conditions and the No Project/No Action Alternative. Construction and sediment removal activities could have potentially substantial effects in waterbodies in the Primary Study Area.

As described in Chapter 12 Aquatic Biological Resources, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on aquatic biological resources.

35.4.7.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 12 Aquatic Biological Resources, the effects of implementation of Alternative B on aquatic biological resources would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on aquatic biological resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

The effects of implementation of Alternative B on aquatic biological resources in the Primary Study Area would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative B could have potentially substantial effects on aquatic biological resources in waterbodies in the Primary Study Area due to construction and operation effects, and the periodic removal of sediment as compared to Existing Conditions and the No Project/No Action Alternative. As described in Chapter 12 Aquatic Biological Resources, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on aquatic biological resources in the Primary Study Area.

35.4.7.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 12 Aquatic Biological Resources, the effects of implementation of Alternative C on aquatic biological resources would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on aquatic biological resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

The effects of implementation of Alternative C on aquatic biological resources in the Primary Study Area would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative C could have potentially substantial effects on aquatic biological resources in the Sacramento River and to waterbodies in the Primary Study Area due to construction and operation effects, and the periodic removal of sediment as compared to Existing Conditions and the No Project/No Action Alternative. As described in Chapter 12 Aquatic Biological Resources, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on aquatic biological resources in the Primary Study Area.

35.4.8 Botanical Resources

Degradation of botanical resources does exist in the Central Valley when considering past and present conditions. As described in Chapter 13 Botanical Resources, the No Project/No Action Alternative would result in potentially beneficial or minimal effects to botanical resources as compared to Existing Conditions in most locations. However, implementation of the No Project/No Action Alternative would decrease fall flows in the Feather River in dry water years, and late summer and fall flows in the American River in above normal, below normal, and critical dry years as compared to Existing Conditions and would therefore result in potentially substantial effects.

In the Primary Study Area, continued harvest of blue oaks for firewood and other uses under the No Project/No Action Alternative would result in potentially substantial effects to the blue oak woodlands and associated edge habitat.

Several factors associated with future projects evaluated in the cumulative effects analysis could affect botanical resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.8.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 13 Botanical Resources, Alternative A was developed to increase CVP and SWP reservoir storage elevations and stabilize flows in the downstream rivers, which would result in beneficial effects to botanical resources in the Extended Study Area and Secondary Study Area.

Implementation of projects considered under the cumulative effects analysis that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, Butte County Regional Conservation Plan, and Shasta Lake Water Resources Investigation) generally are being developed to improve flow regimes in water bodies, which would benefit riparian habitat. However, the Shasta Lake Water Resources Investigation also could inundate substantial botanical resources along the existing shoreline of Shasta Lake.

Implementation of ecosystem restoration projects also could benefit botanical resources. Future ecosystem restoration projects considered in the cumulative effects analysis that could benefit botanical resources include the implementation of CVPIA and CALFED objectives; Delta Plan; California Aquatic Invasive Species Rapid Response Plan; Regional Advanced Mitigation Program; Semitropic Water Storage District Delta Wetlands; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Cottonwood Creek Non-native Invasive Species Eradication Program; Mill Creek Riparian Assessment; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Solano County Multi-Species Habitat Conservation Plan; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. However, future projects that result in changes or inundation of vegetation could result in substantial effects. Mitigation measures, including preservation and/or restoration of other botanical resources, could reduce the effects. Avoidance of adverse effects is not always feasible. For example, the San Joaquin River Restoration Program EIS/EIR and the Dutch Slough Tidal Marsh Restoration Project EIR identified loss of some botanical resources due to inundation as substantial and unavoidable.

Implementation of Alternative A and these future projects could result in beneficial effects. However, because Alternative A would result in potentially substantial and unavoidable effects in the Primary Study Area (as described below), and some future projects also could result in substantial and unavoidable effects, implementation of Alternative A could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on botanical resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Implementation of Alternative A could have potentially substantial effects on botanical resources in the Primary Study Area due to temporary and permanent loss of vegetation at construction locations. As described in Chapter 13 Botanical Resources, mitigation measures would reduce the effects, with the exception of botanical resources within the inundation area of the proposed Sites Reservoir, and within and adjacent to the inundation area of the proposed Holthouse Reservoir. In these areas, the effects would potentially remain substantial and unavoidable following implementation of mitigation measures. None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the potentially substantial and unavoidable effects that would occur under Alternative A, implementation of Alternative A could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on botanical resources in the Primary Study Area.

35.4.8.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 13 Botanical Resources, effects on botanical resources due to implementation of Alternative B would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on botanical resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on botanical resources in the Primary Study Area under Alternative B would be greater than under Alternative A due to the increased size of the proposed Sites Reservoir. Implementation of Alternative B could have potentially substantial effects on botanical resources in the Primary Study Area due to temporary and permanent loss of vegetation at construction locations. As described in Chapter 13 Botanical Resources, mitigation measures would reduce the effects, with the exception of botanical resources within the inundation area of the proposed Sites Reservoir, and within and adjacent to the inundation area of the proposed Holthouse Reservoir. In these areas, the effects would potentially remain substantial and unavoidable following implementation of mitigation measures. None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the potentially substantial and unavoidable effects that would occur under Alternative B, implementation of Alternative B could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on botanical resources in the Primary Study Area.

35.4.8.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 13 Botanical Resources, effects on botanical resources due to implementation of Alternative C would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on botanical resources that could exist in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on botanical resources in the Primary Study Area under Alternative C would be greater than under Alternative A due to the increased size of the proposed Sites Reservoir. Implementation of Alternative C could have potentially substantial effects on botanical resources in the Primary Study Area due to temporary and permanent loss of vegetation at construction locations. As described in Chapter 13 Botanical Resources, mitigation measures would reduce the effects, with the exception of botanical resources within the inundation area of the proposed Sites Reservoir, and within and adjacent to the inundation area of the proposed Holthouse Reservoir. In these areas, the effects would potentially remain substantial and unavoidable following implementation of mitigation measures. None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the potentially substantial and unavoidable effects that would occur under Alternative C, implementation of Alternative C could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on botanical resources in the Primary Study Area.

35.4.9 Terrestrial Biological Resources

Degradation of terrestrial biological resources does exist in the Central Valley when considering past and present conditions. As described in Chapter 14 Terrestrial Biological Resources, the No Project/No

Action Alternative would result in potentially beneficial or minimal effects to terrestrial biological resources as compared to Existing Conditions in most locations. However, implementation of the No Project/No Action Alternative would decrease fall flows in the Feather River in dry water years, and late summer and fall flows in the American River in above normal, below normal, and critical dry years as compared to Existing Conditions, resulting in potentially substantial effects.

In the Primary Study Area, continued cattle grazing in multiple wildlife habitat types and harvest of blue oaks for firewood and other uses under the No Project/No Action Alternative would result in potentially substantial effects to wildlife habitats.

Several factors associated with future projects evaluated in the cumulative effects analysis could affect terrestrial biological resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.9.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 14 Terrestrial Biological Resources, Alternative A was developed to increase CVP and SWP reservoir storage elevations and stabilize flows in the downstream rivers, which would result in beneficial effects to terrestrial biological resources in the Extended Study Area and Secondary Study Area.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally are being developed to improve flow regimes in water bodies, which would benefit riparian habitat.

Implementation of ecosystem restoration projects also would improve wildlife habitat. Future ecosystem projects considered in the cumulative effects analysis that could contribute to improved wildlife habitat include the implementation of CVPIA and CALFED objectives; Delta Plan; California Aquatic Invasive Species Rapid Response Plan; Regional Advanced Mitigation Program; Butte County Regional Conservation Plan; Semitropic Water Storage District Delta Wetlands; Grassland Bypass Project; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Clear Creek Mercury Abatement and Fisheries Restoration Project; Cottonwood Creek Non-native Invasive Species Eradication Program; Mill Creek Riparian Assessment; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Solano County Multi-Species Habitat Conservation Plan; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. However, future projects that result in changes or inundation of habitat could result in substantial effects. Mitigation measures, including preservation and/or restoration of replacement habitat areas, could reduce the effects. Avoidance of adverse effects is not always feasible. For example, the San Joaquin River Restoration Program EIS/EIR and the Dutch Slough Tidal Marsh Restoration Project EIR identified loss of some wildlife habitat due to inundation as substantial and unavoidable.

Implementation of Alternative A and these future projects could result in beneficial effects. However, because Alternative A would result in potentially substantial and unavoidable effects in the Primary Study Area (as described below), Alternative A could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on terrestrial biological resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Implementation of Alternative A could cause potentially substantial effects on terrestrial biological resources in the Primary Study Area due to temporary and permanent loss of habitat at construction locations. As described in Chapter 14 Terrestrial Biological Resources, mitigation measures would reduce the effects, with the exception of the loss of golden eagle foraging habitat due to inundation of the proposed Sites Reservoir. In the proposed reservoir inundation area, the effects to golden eagles would remain substantial and unavoidable following implementation of mitigation measures.

None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the substantial and unavoidable effects that would occur under Alternative A, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on terrestrial biological resources.

35.4.9.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 14 Terrestrial Biological Resources, effects on terrestrial biological resources due to implementation of Alternative B would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on terrestrial biological resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on terrestrial biological resources in the Primary Study Area under Alternative B would be greater than under Alternative A due to the increased size of Sites Reservoir. Implementation of Alternative B could cause potentially substantial effects on terrestrial biological resources in the Primary Study Area due to temporary and permanent loss of habitat at construction locations. As described in Chapter 14 Terrestrial Biological Resources, mitigation measures would reduce the effects, with the exception of the loss of golden eagle foraging habitat due to inundation of the proposed Sites Reservoir. In the proposed reservoir inundation area, the effects to golden eagles would remain substantial and unavoidable following implementation of mitigation measures.

None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the substantial and unavoidable effects that would occur under Alternative B, implementation of Alternative B result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on terrestrial biological resources.

35.4.9.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 14 Terrestrial Biological Resources, effects on terrestrial biological resources due to implementation of Alternative C would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on terrestrial biological resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on terrestrial biological resources in the Primary Study Area under Alternative C would be greater than under Alternative A due to the increased size of the proposed Sites Reservoir. Implementation of Alternative C could cause potentially substantial effects on terrestrial biological resources in the Primary Study Area due to temporary and permanent loss of habitat at construction locations. As described in Chapter 14 Terrestrial Biological Resources, mitigation measures would reduce the effects, with the exception of the loss of golden eagle foraging habitat due to inundation of the proposed Sites Reservoir. In the proposed reservoir inundation area, the effects to golden eagles would remain substantial and unavoidable following implementation of mitigation measures.

None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the substantial and unavoidable effects that would occur under Alternative C, implementation of Alternative C would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on terrestrial biological resources.

35.4.10 Wetlands and Other Waters of the United States

Degradation of wetlands and other waters of the United States does exist in the Central Valley when considering past and present conditions. As described in Chapter 15 Wetlands and Other Waters of the United States, the No Project/No Action Alternative would result in potentially beneficial or minimal effects to wetlands and other waters as compared to Existing Conditions in most locations. However, implementation of the No Project/No Action Alternative would decrease flows in several rivers in the Secondary Study Area which would result in potentially substantial effects to the waterbodies and associated wetlands. On the Trinity River, decreased flows would occur in March and April in wet years under the No Project/No Action Alternative as compared to Existing Conditions. On the Feather River, decreased flows would occur in November and December in below normal years; August, October, and January through March in dry years; and July, November, and December in critical dry years. On the American River, decreased flows would occur in all months except December, and especially in August, September, and/or October in drier years. Flows in the Sutter Bypass and Yolo Bypass would directly affect wetlands in the bypasses. Flows under the No Project/No Action Alternative would decrease in December in wet, below normal, and dry years, and in November in below normal and dry years, as compared to Existing Conditions. Flows in the Yolo Bypass would decrease in late fall months in dry and below normal years as compared to Existing Conditions. These flow changes would result in potentially substantial effects to wetlands and other waters of the United States.

Several factors associated with future projects evaluated in the cumulative effects analysis could affect wetlands and other waters in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.10.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 15 Wetlands and Other Waters of the United States, Alternative A was developed to increase CVP and SWP reservoir storage elevations and stabilize flows in the downstream rivers, which would result in beneficial effects in the Extended Study Area and Secondary Study Area.

Implementation of projects considered under the cumulative effects analysis that could result in changes in CVP and SWP operation, surface water flow patterns, and ecosystem restoration (as described above as cumulative projects considered for Surface Water Resources, Fluvial Geomorphology and Riparian Habitat, Aquatic Biological Resources, Botanical Resources, and Terrestrial Biological Resources) generally are being developed to improve flow regimes in water bodies, which would benefit riparian habitat. Implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on wetlands and other waters in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Implementation of Alternative A could cause potentially substantial effects on wetlands and other waters in the Primary Study Area due to temporary and permanent loss of habitat at construction locations. As described in Chapter 15 Wetlands and Other Waters of the United States, mitigation measures would reduce the effects.

None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on wetlands and other waters.

35.4.10.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 15 Wetlands and Other Waters of the United States, effects on wetlands and other waters due to implementation of Alternative B would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on wetlands and other waters in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Implementation of Alternative B could cause potentially substantial effects on wetlands and other waters in the Primary Study Area due to temporary and permanent loss of habitat at construction locations. As described in Chapter 15 Wetlands and Other Waters of the United States, mitigation measures would reduce the effects.

None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on wetlands and other waters in the Primary Study Area.

35.4.10.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 15 Wetlands and Other Waters of the United States, effects on wetlands and other waters due to implementation of Alternative C would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on wetlands and other waters in the Extended Study Area and Secondary Study Area.

Primary Study Area

Implementation of Alternative C could cause potentially substantial effects on wetlands and other waters in the Primary Study Area due to temporary and permanent loss of habitat at construction locations. As described in Chapter 15 Wetlands and Other Waters of the United States, mitigation measures would reduce the effects.

None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on wetlands and other waters in the Primary Study Area.

35.4.11 Geology, Minerals, Soils, and Paleontology

For the proposed Project, adverse effects to geology and soils are caused by changes in erosion potential and the ability of soils to support use of septic systems with on-site wastewater disposal. Adverse effects to minerals are caused by loss of availability of known mineral resources and increased exposure of people to naturally occurring asbestos. Adverse effects to paleontological resources are caused by potential disturbance during deep excavation.

As described in Chapter 16 Geology, Minerals, Soils, and Paleontology, the No Project/No Action Alternative would result in no effects to geology, soils, minerals, and paleontology as compared to Existing Conditions.

Future projects evaluated in the cumulative effects analysis could result in changes to geological, soil, mineral, and paleontological resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.11.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 16 Geology, Minerals, Soils, and Paleontology, implementation of Alternative A would result in either no effects or minimal effects to geological, soil, mineral, and paleontological resources in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment could result in changes to geological, soil, mineral, and paleontological resources depending upon the location-specific conditions and construction methods used for each project. Changes could occur during construction of future projects including the Bay Delta Conservation Plan; Anadromous Fish Screen Program; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Mainstem Sacramento River Gravel Augmentation Program; Cottonwood Creek Geomorphological Analysis and Sediment Budget; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures would be available to reduce potential effects. In some cases, the effects could remain substantial and unavoidable. For example, soil loss due to erosion at the modified surface water elevation of Shasta Lake and use of aggregate and sand for construction were considered to be substantial and unavoidable effects in the Shasta Lake Water Resources Investigation Preliminary Draft EIS.

Although these projects could result in adverse effects to geological, soil, mineral, and paleontological resources, implementation of Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on geological, soils, minerals, and paleontological resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Without mitigation, construction and operation of facilities under Alternative A would result in potentially substantial effects due to erosion along the shorelines of the reservoirs and at construction locations; loss of topsoil due to construction activities; placement of some structures on soils with high shrink-swell potential which could adversely affect structural foundations; placement of septic systems on soils with limited ability for on-site wastewater disposal; and deep excavations which could adversely affect paleontological resources. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on geological, soil, mineral, and paleontological resources.

35.4.11.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 16 Geology, Minerals, Soils, and Paleontology, effects on geological, soil, mineral, and paleontological resources due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on geological, soil, mineral, and paleontological resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on geological, soil, mineral, and paleontological resources in the Primary Study Area under Alternative B would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative B could cause potentially substantial effects on geological, soil, and paleontological resources in the Primary Study Area. As described in Chapter 16 Geology, Minerals, Soils, and Paleontology, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on geological, soil, mineral, and paleontological resources in the Primary Study Area.

35.4.11.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 16 Geology, Minerals, Soils, and Paleontology, effects on geological, soil, mineral, and paleontological resources due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on geological, soil, mineral, and paleontological resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on geological, soil, mineral, and paleontological resources in the Primary Study Area under Alternative C would be different than under Alternative A due to the increased size of the proposed Sites Reservoir. Without mitigation, Alternative C could cause potentially substantial effects on geological, soil, and paleontological resources in the Primary Study Area. As described in Chapter 16 Geology, Minerals, Soils, and Paleontology, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on geological, soil, mineral, and paleontological resources in the Primary Study Area.

35.4.12 Faults and Seismicity

For the proposed Project, risks associated with faults and seismicity are related to exposure of people or structures to risks during and after a seismic event and associated with liquefaction or landslides; inundation by seiches or tsunamis; and increase risk due to reservoir-induced seismic events. As described in Chapter 17 Faults and Seismicity, risks associated with faults and seismicity under the No Project/No Action Alternative would be comparable to Existing Conditions.

Future projects evaluated in the cumulative effects analysis could result in increased risks due to liquefaction or landslides near future construction locations in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.12.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 17 Faults and Seismicity, implementation of Alternative A would result in either no effects or minimal effects related to risks from faults and seismicity in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of future projects considered under the cumulative effects assessment could result in risks from faults and seismicity depending upon the location-specific conditions and construction methods used for each project. Changes could occur during construction of future projects including the Bay Delta Conservation Plan; Anadromous Fish Screen Program; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Mainstem Sacramento River Gravel Augmentation Program; Cottonwood Creek Geomorphological Analysis and Sediment Budget; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures would reduce these effects. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effects related to faults and seismicity in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Without mitigation, construction and operation of proposed facilities under Alternative A would result in potentially substantial effects related to seismically-induced localized landslides or liquefaction at construction locations of some proposed Project facilities. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect related to faults and seismicity.

35.4.12.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 17 Faults and Seismicity, effects related to faults and seismicity due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect related to faults and seismicity in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects related to faults and seismicity in the Primary Study Area under Alternative B would be similar to effects under Alternative A. Without mitigation, Alternative B could cause potentially substantial effects related to seismically-induced localized landslides or liquefaction at construction sites of some proposed Project facilities in the Primary Study Area. As described in Chapter 17 Faults and Seismicity, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect related to seismically-induced localized landslides or liquefaction at construction sites of some proposed Project facilities in the Primary Study Area.

35.4.12.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 17 Faults and Seismicity, effects related to faults and seismicity due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect related to faults and seismicity in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects related to faults and seismicity in the Primary Study Area under Alternative C would be similar to effects under Alternative A. Without mitigation, Alternative C could cause potentially substantial effects related to seismically-induced localized landslides or liquefaction at construction sites of some proposed Project facilities in the Primary Study Area. As described in Chapter 17 Faults and Seismicity, mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect related to seismically-induced localized landslides or liquefaction at construction sites of some proposed Project facilities in the Primary Study Area.

35.4.13 Cultural Resources

For the proposed Project, adverse effects to cultural resources are caused by substantial changes in the significance of archaeological or historic resources, or disturbance of traditional cultural properties or human remains. Conditions of cultural resources under the No Project/No Action Alternative would be comparable to Existing Conditions, with the exception of San Luis Reservoir. As described in Chapter 18 Cultural Resources, projected fluctuations of surface water elevations at San Luis Reservoir could result in potentially substantial effects under the No Project/No Action Alternative, as compared to Existing Conditions, because complete assessment of the effects of water level fluctuations on cultural resources has never been conducted.

Future projects evaluated in the cumulative effects analysis could result in potentially substantial effects to cultural resources due to construction and operation activities in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.13.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 18 Cultural Resources, implementation of Alternative A would result in potentially substantial effects to cultural resources in the regulating reservoirs of the Extended Study Area because complete assessment of the effects of water level fluctuations on cultural resources has never been conducted. Minimal effects are anticipated under Alternative A in the Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment could result in effects to cultural resources depending upon the location-specific conditions and construction methods used for each project. Changes could occur during construction of future projects including Bay Delta Conservation Plan; Anadromous Fish Screen Program; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures could reduce these effects; although, in many cases, the effects would remain substantial and unavoidable. For example, effects to cultural and historical resources due to disturbance or inundation were identified as substantial and unavoidable in Shasta Lake Water Resources Investigation Preliminary Draft EIS; Suisun Marsh Habitat Management, Preservation, and Restoration Plan EIS/EIR; North Delta Flood Control and Ecosystem Restoration Project EIR; and Dutch Slough Tidal Marsh Restoration Project EIR. Because it is not possible to predict all future effects to cultural resources within the Extended Study Area and

Secondary Study Area, and because implementation of Alternative A would potentially result in substantial and unavoidable effects in the Primary Study Area (as described below); implementation of Alternative A and these future projects could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to cultural resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 18 Cultural Resources, without mitigation, construction and operation of the proposed Project facilities under Alternative A would result in potentially substantial effects to cultural resources due to construction and operation activities. Mitigation measures would reduce some of the effects. However, potential effects to historic resources and traditional cultural properties could remain substantial and unavoidable.

None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. However, because some of the effects could be substantial and unavoidable, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to cultural resources in the Primary Study Area.

35.4.13.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 18 Cultural Resources, effects to cultural resources due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and implementation of Alternative A and these future projects could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to cultural resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 18 Cultural Resources, effects to cultural resources in the Primary Study Area under Alternative B would be similar to effects under Alternative A. Without mitigation, construction and operation of the proposed Project facilities under Alternative B would result in potentially substantial effects to cultural resources. Mitigation measures would reduce some of the effects. However, potential effects to historic resources and traditional cultural properties could remain substantial and unavoidable. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. However, because some of the effects could be substantial and unavoidable, implementation of Alternative B could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to cultural resources in the Primary Study Area.

35.4.13.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 18 Cultural Resources, effects to cultural resources due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and

Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and implementation of Alternative A and these future projects could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to cultural resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Effects to cultural resources in the Primary Study Area under Alternative C would be similar to effects under Alternative A. As described in Chapter 18 Chapter 18 Cultural Resources, without mitigation construction and operation of the proposed Project facilities under Alternative B would result in potentially substantial effects to cultural resources. Mitigation measures would reduce some of the effects. However, potential effects to historic resources and traditional cultural properties could remain substantial and unavoidable. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. However, because some of the effects could be substantial and unavoidable, implementation of Alternative C could result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to cultural resources in the Primary Study Area.

35.4.14 Indian Trust Assets

For the proposed Project, adverse effects to an Indian Trust Asset (ITA) are caused by direct changes to the ITA conditions or indirect changes to current activities within an ITA. As described in Chapter 19 Indian Trust Assets, there would be no effects under the No Project/No Action Alternative as compared to Existing Conditions in the Extended Study Area, Secondary Study Area, or Primary Study Area because there are no ITAs within the vicinities of these study areas.

Future projects evaluated in the cumulative effects analysis generally are not located in the vicinity of ITAs.

35.4.14.1 Alternative A

As described in Chapter 19 Indian Trust Assets, implementation of Alternative A would result in no effects as compared to the No Project/No Action Alternative in the Extended Study Area, Secondary Study Area, or Primary Study Area because there are no ITAs within the vicinities of these study areas. Future projects evaluated in the cumulative effects analysis generally are not located in the vicinity of ITAs. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to ITAs in the Extended Study Area, Secondary Study Area, or Primary Study Area.

35.4.14.2 Alternative B

As described in Chapter 19 Indian Trust Assets, implementation of Alternative B would result in no effects as compared to the No Project/No Action Alternative in the Extended Study Area, Secondary Study Area, or Primary Study Area because there are no ITAs within the vicinities of these study areas. Future projects evaluated in the cumulative effects analysis generally are not located in the vicinity of ITAs. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to ITAs in the Extended Study Area, Secondary Study Area, or Primary Study Area.

35.4.14.3 Alternative C

As described in Chapter 19 Indian Trust Assets, implementation of Alternative C would result in no effects as compared to the No Project/No Action Alternative in the Extended Study Area, Secondary Study Area, or Primary Study Area because there are no ITAs within the vicinities of these study areas. Future projects evaluated in the cumulative effects analysis generally are not located in the vicinity of ITAs. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to ITAs in the Extended Study Area, Secondary Study Area, or Primary Study Area.

35.4.15 Land Use

Changes to land use in the Central Valley occurs as agricultural lands and open space are converted to other uses. Generally, land use conversion is associated with development of municipal and industrial land uses which require changes to existing general plans and land use designations. Land use conversions can result in loss of agricultural lands depending upon the historical land use.

As described in Chapter 20 Land Use, the No Project/No Action Alternative would result in no effects or minimal effects to land uses as compared to Existing Conditions.

Several factors associated with future projects evaluated in the cumulative effects analysis could affect land uses in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in land use conversions within the Primary Study Area.

35.4.15.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 20 Land Use, Alternative A would not result in substantial changes to land uses in the Extended Study Area and Secondary Study Area because CVP and SWP water deliveries would range from a minor decrease to a slight increase as compared to Existing Conditions, and would increase slightly as compared to the No Project/No Action Alternative. The place of use of this water would remain within the areas designated by the SWRCB for the CVP and SWP water rights. Therefore, no changes in land uses would occur due to changes in CVP and SWP water supply deliveries that would occur under Alternative A as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally would not result in a change in land use for the same reasons that are described above for Alternative A.

Implementation of water supply and ecosystem restoration projects would result in changes in land use. Future projects considered in the cumulative effects analysis that could contribute to changes in land use include the implementation of CVPIA and CALFED objectives; Delta Plan; Regional Advanced Mitigation Program; Central Valley Vision; County of Colusa 2030 General Plan; Butte County Regional Conservation Plan; Semitropic Water Storage District Delta Wetlands Project; North Bay Aqueduct Alternative Intake Project; Los Vaqueros Reservoir Expansion Phase II; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; Trinity River Restoration Program; Clear Creek

Fisheries Habitat Restoration Program; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Solano County Multi-Species Habitat Conservation Plan; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Future projects that result in changes or inundation of vegetation could result in substantial effects. Mitigation measures, including preservation and/or restoration of other agricultural lands and placement of the ecosystem restoration areas to avoid physically dividing communities could reduce the effects. Avoidance of adverse effects is not always feasible. For example, the San Joaquin River Restoration Program EIS/EIR and the Shasta Lake Water Resources Investigation identified changes in some land uses and loss of agricultural lands to be substantial and unavoidable.

Because Alternative A would result in potentially substantial and unavoidable effects in the Primary Study Area (as described below) and some future projects also could result in substantial and unavoidable effects, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on land uses, including agricultural resources, in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Implementation of Alternative A could cause potentially substantial effects on land uses, especially agricultural resources, in the Primary Study Area due to construction of the proposed Project facilities. As described in Chapter 20 Land Use, mitigation measures would reduce some of the effects, but some conflicts or incompatibilities with existing and designated land uses and existing zoning for agricultural and forest land use, as well as the conversion of lands that have Williamson Act contracts, could remain substantial and unavoidable. In addition, the physical division of the community of Sites caused by inundation of the lands within the proposed Sites Reservoir would result in a substantial and unavoidable effect. None of the future projects evaluated in the cumulative effects analysis would result in additional construction or additional operation and maintenance activities within the Primary Study Area. However, due to the potentially substantial effects that would occur under Alternative A, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on land uses, including agricultural resources, in the Primary Study Area.

35.4.15.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 20 Land Use, effects on land uses, including agricultural resources, due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on land uses, including agricultural resources, in the Extended Study Area and Secondary Study Area.

Primary Study Area

As described in Chapter 20 Land Use, effects on land uses, including agricultural resources, in the Primary Study Area under Alternative B would be similar to those described for Alternative A. Implementation of Alternative B could cause potentially substantial effects on land uses, including agricultural resources, in the Primary Study Area at construction locations. Mitigation measures would reduce some of the effects, but some conflicts or incompatibilities with existing and designated land uses and existing zoning for agricultural and forest land use, as well as the conversion of lands that have Williamson Act contracts, could remain substantial and unavoidable In addition, the physical division of the community of Sites caused by inundation of the lands within the proposed Sites Reservoir would result in a substantial and unavoidable effect. None of the future projects evaluated in the cumulative effects analysis would result in additional construction or operation and maintenance activities within the Primary Study Area. However, due to the potentially substantial effects that would occur under Alternative B, implementation of Alternative B would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on land uses, including agricultural resources, in the Primary Study Area.

35.4.15.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 20 Land Use, effects on land uses, including agricultural resources, due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on land uses, including agricultural resources, in the Extended Study Area and Secondary Study Area.

Primary Study Area

Effects on land uses, including agricultural resources, in the Primary Study Area under Alternative C would be similar to those described for Alternative A. Implementation of Alternative C could cause potentially substantial effects on land uses, including agricultural resources, in the Primary Study Area at construction locations. As described in Chapter 20 Land Use, mitigation measures would reduce some of the effects, but some conflicts or incompatibilities with existing and designated land uses and existing zoning for agricultural and forest land use, as well as the conversion of lands that have Williamson Act contracts, could remain substantial and unavoidable. In addition, the physical division of the community of Sites caused by inundation of the lands within the proposed Sites Reservoir would result in a substantial and unavoidable effect. None of the future projects evaluated in the cumulative effects analysis would result in additional construction or operation and maintenance activities within the Primary Study Area. However, due to the potentially substantial effects that would occur under Alternative C, implementation of Alternative C would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on land uses, including agricultural resources, in the Primary Study Area.

35.4.16 Recreation Resources

Recreation resources that could be affected by operation of the proposed Project exist throughout the Extended Study Area and Secondary Study Area. As described in Chapter 21 Recreation Resources, the

No Project/No Action Alternative would result in no effects, potentially beneficial effects, or minimal effects to recreation resources as compared to Existing Conditions in most locations. However, implementation of the No Project/ No Action Alternative could result in changes to the amount of water stored in CVP and SWP reservoirs in the Extended Study Area and Secondary Study Area, which could result in a potentially substantial effect to recreation use levels. If CVP and/or SWP exports decrease, water stored in those reservoirs also may decrease to levels that could reduce the ability to use the reservoir for boating, swimming, and fishing. Surface water elevations in Lake Oroville and Folsom Lake and surface water flows in the American River would be reduced more frequently, which would adversely affect recreational opportunities under the No Project/No Action Alternative as compared to Existing Conditions. These conditions would result in potentially substantial effects under the No Project/No Action Alternative.

Several factors associated with future projects evaluated in the cumulative effects analysis could affect recreation resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.16.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 21 Recreation Resources, Alternative A was developed to increase CVP and SWP reservoir storage elevations and stabilize flows in the downstream rivers, which would result in beneficial effects in most locations in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative. However, Alternative A would result in potentially substantial effects at San Luis Reservoir as compared to the No Project/No Action Alternative due to more frequent occurrence of low water storage elevations that would reduce the availability of the existing campground water intake. Mitigation measures would reduce the effects.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) could further reduce summer water storage elevations and flows in rivers downstream of the CVP and SWP reservoirs. These changes could result in substantial recreation effects at the reservoirs and streams located downstream of the reservoirs.

Implementation of ecosystem restoration projects could increase recreation opportunities if public access is provided. Future ecosystem projects considered in the cumulative effects analysis that could contribute to improved recreation resource conditions include the implementation of CVPIA and CALFED objectives; Delta Plan; California Aquatic Invasive Species Rapid Response Plan; Regional Advanced Mitigation Program; Central Valley Vision; Butte County Regional Conservation Plan; Semitropic Water Storage District Delta Wetlands; Los Vaqueros Reservoir Expansion Phase II; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Clear Creek Mercury Abatement and Fisheries Restoration Project; Cottonwood Creek Non-Native Invasive Species Eradication Program; Mill Creek Riparian Assessment; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Solano County Multi-species Habitat Conservation Plan; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Implementation of Alternative A and these future projects could increase recreational opportunities.

Due to the potential for reductions in reservoir water surface elevations in San Luis Reservoir and downstream flows during summer months on the American River under Alternative A and the potential for reductions under future projects, Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on recreation resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 21 Recreation Resources, implementation of Alternative A would result in no or minimal effects on recreation resources in the Primary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to recreation resources in the Primary Study Area.

35.4.16.2 Alternative B

Extended Study Area and Secondary Study Area

Effects on recreation resources due to implementation of Alternative B would be similar to those under implementation of Alternative A in the Extended Study Area and Secondary Study Area. Alternative B would result in potentially substantial effects in San Luis Reservoir as compared to the No Project/No Action Alternative due to more frequent occurrence of low water storage elevations that would reduce the availability of the existing campground water intake. Mitigation measures would reduce the effects. The cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Due to the potential for reductions in reservoir water surface elevations in San Luis Reservoir and downstream flows during summer months on the American River under Alternative B and the potential for reductions under future projects, Alternative B would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on recreation resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Effects on recreation resources in the Primary Study Area under Alternative B would be the same as under Alternative A. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on recreation resources in the Primary Study Area.

35.4.16.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 21 Recreation Resources, effects on recreation resources due to implementation of Alternative C would result in potentially substantial effects at San Luis Reservoir as compared to the No Project/No Action Alternative due to more frequent occurrence of low water storage elevations that would reduce the availability of the existing campground water intake and the existing boat ramp. Mitigation measures would reduce the effects. The cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Due to the potential for future reductions in reservoir water surface elevations in San Luis Reservoir and downstream flows during summer months on the American River under Alternative C and the potential for reductions under future projects, Alternative C would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on recreation resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Effects on recreation resources in the Primary Study Area under Alternative C would be the same as under Alternative A. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on recreation resources in the Primary Study Area.

35.4.17 Socioeconomics

Adverse effects to socioeconomic conditions are caused by changes in regional economic conditions, including effects on population and housing, effects on local government fiscal conditions, recreation economics, agricultural economics, and municipal and industrial water use economics. As described in Chapter 22 Socioeconomics, the No Project/No Action Alternative would result in no effects to socioeconomic conditions as compared to Existing Conditions.

Future projects evaluated in the cumulative effects analysis could affect socioeconomic conditions in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.17.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 22 Socioeconomics, under Alternative A, improved CVP and SWP water supply reliability in the Extended Study Area and Secondary Study Area could result in reduced use of groundwater that either could be more expensive to use than CVP and SWP water supplies and/or result in less agricultural production than CVP and SWP water supplies. These conditions would result in minimal effects as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation (including the SWRCB Bay-Delta Water Quality Plan Update, Bay Delta Conservation Plan, NMFS recovery plan for salmonids, USFWS recovery plan of delta smelt, and Shasta Lake Water Resources Investigation) generally are being developed to either provide increased water supply reliability of historic water deliveries or increase water supply availability. Increased CVP and SWP water supply availability would result in reduced use of groundwater in those areas which could result in no or minimal effects to socioeconomic conditions as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of water supply and ecosystem restoration projects also could affect socioeconomic conditions either by reducing agricultural productivity if agricultural lands are converted, or increasing recreation economic activity for visitors at the restoration locations or locations with increased waterfowl and other bird populations that use the restored ecosystem. Future projects considered in the cumulative effects analysis that could contribute to improved recreation resource conditions include the implementation of CVPIA and CALFED objectives; Delta Plan; California Aquatic Invasive Species Rapid Response Plan; Regional Advanced Mitigation Program; Central Valley Vision; County of Colusa 2030 General Plan; Butte County Regional Conservation Plan; Woodland-Davis Water Supply Project; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; Central Valley RWQCB Irrigated Lands Regulatory Program; CV-SALTS; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Cache Slough Complex Restoration; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Solano County Multi-species Habitat Conservation Plan; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures, such as avoidance of highly productive agricultural lands for ecosystem restoration could reduce the effects. However, in some cases, the effect could be substantial and unavoidable.

Although potentially substantial and unavoidable effects to socioeconomic conditions could occur under future projects, Alternative A would not result in similar effects. Therefore, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on socioeconomics in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 22 Socioeconomics, Alternative A would result in increased economic activity due to land acquisition within the Primary Study Area, increases in employment and income during construction and operation of the proposed Project, and increases in recreation expenditures associated with increased recreational opportunities. Alternative A would also result in decreased property tax receipts in Glenn and Colusa counties, but these losses would not result in substantial effects to the regional economy. Implementation of Alternative A would result in substantial loss of prime agricultural land in the Primary Study Area, but compensation to property owners would reduce this effect. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities, or projects that would change economic conditions within the Primary Study Area. Implementation of Alternative A and these future projects therefore would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to socioeconomic conditions in the Primary Study Area.

35.4.17.2 Alternative B

As described in Chapter 22 Socioeconomics, socioeconomic effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on socioeconomic conditions in the Extended Study Area, Secondary Study Area and Primary Study Area.

35.4.17.3 Alternative C

As described in Chapter 22 Socioeconomics, socioeconomic effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on socioeconomic conditions in the Extended Study Area, Secondary Study Area and Primary Study Area.

35.4.18 Environmental Justice

Disproportional effects on minority or low-income populations are caused by changes in the physical, biological, and human environment. As described in Chapter 23 Environmental Justice, the potential for disproportional effects on minority or low-income populations under the No Project/No Action Alternative would be similar to Existing Conditions and result in no effects.

Future projects evaluated in the cumulative effects analysis could affect minority or low-income populations in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in changes within the Primary Study Area.

35.4.18.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 23 Environmental Justice, under Alternative A, improved CVP and SWP water supply reliability in the Extended Study Area and Secondary Study Area would result in no effects to minority or low-income populations as compared to Existing Conditions and the No Project/No Action Alternative.

Projects considered under the cumulative effects assessment that could result in changes in CVP and SWP operation include those identified in Table 35-1 for botanical resources, cultural resources, land use, recreation resources, air quality, and visual resources. These projects generally are being developed to either provide increased water supply reliability of historic water deliveries or increase water supply availability. Increased CVP and SWP water supply availability could result in improved socioeconomic conditions which would result in no or minimal effects to minority or low-income populations as compared to Existing Conditions and the No Project/No Action Alternative.

Ecosystem restoration projects generally are not located on or adjacent to lands with communities to avoid future conflicts with re-established wildlife populations. Therefore, implementation of ecosystem restoration projects is anticipated to result in no or minimal effects to minority or low-income populations.

Because Alternative A and the future projects would not result in substantial adverse effects to minority or low-income populations, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to minority or low-income populations in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 23 Environmental Justice, implementation of Alternative A would result in no or minimal effects on minority or low-income populations in the Primary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities and therefore would not affect minority or low-income populations within the Primary Study Area. Implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to minority or low-income populations in the Primary Study Area.

35.4.18.2 Alternative B

As described in Chapter 23 Environmental Justice, effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to minority or low-income populations.

35.4.18.3 Alternative C

As described in Chapter 23 Environmental Justice, effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to minority or low-income populations.

35.4.19 Air Quality

For the proposed Project, changes in air quality could occur during construction and operations. During proposed Project construction, vehicle emissions and dust could result in total volume of pollutants that exceed objectives in adopted air quality management plans, exceed criteria in the adopted plans, or result in a cumulatively considerable net increase in nonattainment pollutants. During proposed Project operation, the primary activity that could affect air quality would be power generation.

As described in Chapter 24 Air Quality, air quality under the No Project/No Action Alternative would be similar to Existing Conditions. Therefore, there would be no or minimal effects on air quality under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could result in changes to air quality in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area; however, air quality in the Primary Study Area would be influenced by air quality in the Secondary Study Area.

35.4.19.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 24 Air Quality, implementation of Alternative A would result in either no effects or minimal effects to air quality in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment could result in changes to air quality depending upon the location-specific conditions and construction methods used for each project. Changes to air quality in the Secondary Study Area could occur during construction of future projects including the Bay Delta Conservation Plan; Anadromous Fish Screen Program; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; Clear Creek Fisheries Habitat Restoration Program; Mainstem Sacramento River Gravel Augmentation Program; Cottonwood Creek Geomorphological Analysis and Sediment Budget; Deer Creek Irrigation District Dam Fish Passage Improvement and Flow Enhancement Project; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures would be available to reduce potential effects. In some cases, the effects could remain substantial and unavoidable. For example, air quality effects that would occur during construction were identified to be substantial and unavoidable for projects evaluated in the Shasta Lake Water Resources Investigation Preliminary Draft EIS, San Joaquin River Restoration Program EIS/EIR, and North Delta Flood Control and Ecosystem Restoration Project.

Because Alternative A would result in potentially substantial and unavoidable effects in the Primary Study Area (as described below) and some future projects also could result in substantial and unavoidable effects, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on air quality in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Construction and operation of proposed Project facilities under Alternative A would result in potentially substantial effects to air quality. Mitigation measures would reduce the effects during operation. However, effects during construction would remain substantial and unavoidable.

None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

Due to the potential for substantial and unavoidable effects during construction under Alternative A and future projects in the Secondary Study Area which could affect air quality in the Primary Study Area, Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on air quality in the Primary Study Area.

35.4.19.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 24 Air Quality, effects on air quality due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Alternative B would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on air quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Construction and operation of proposed Project facilities under Alternative B would result in potentially substantial effects to air quality. Mitigation measures would reduce the effects during operation. However, effects during construction would remain substantial and unavoidable. Due to the potential for substantial and unavoidable effects during construction under Alternative B and future projects in the Secondary Study Area which could affect air quality in the Primary Study Area, Alternative B would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on air quality in the Primary Study Area.

35.4.19.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 24 Air Quality, effects on air quality due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Alternative C would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on air quality in the Extended Study Area and Secondary Study Area.

Primary Study Area

Construction and operation of proposed Project facilities under Alternative C would result in potentially substantial effects to air quality. Mitigation measures would reduce the effects during operation. However, effects during construction would remain substantial and unavoidable. Due to the potential for substantial and unavoidable effects during construction under Alternative C and future projects in the Secondary Study Area which could affect air quality in the Primary Study Area, Alternative C would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on air quality in the Primary Study Area.

35.4.20 Climate Change and Greenhouse Gas Emissions

For the proposed Project, changes in greenhouse gas emissions (GHG emissions) could occur during construction and operation due to direct GHG emissions or indirect GHG emissions from pumping and power generation. Potential for an increase or reduction in GHG emissions from open water surfaces was not evaluated in detail in Chapter 25 Climate Change and Greenhouse Gas Emissions, due to limited availability of protocol, guidance, and tools for the analysis.

Under the No Project/No Action Alternative, no proposed Project facilities would be constructed or operated, and no direct construction or operations activities with related GHG emissions would occur as compared to Existing Conditions. As described in Chapter 25 Climate Change and Greenhouse Gas Emissions, there would be no GHG emissions effects under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could result in changes to GHG emissions in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities, or other changes within the Primary Study Area that would result in changes in GHG emissions.

35.4.20.1 Alternative A

As described in Chapter 25 Climate Change and Greenhouse Gas Emissions, implementation of Alternative A would result in no effects or minimal effects from direct GHG emissions during construction and operation of the proposed Project. Alternative A also would result in minimal effects from indirect GHG emission caused by electricity generation for operation of SWP facilities because the projected reduction in GHG emissions for SWP facilities also would provide adequate reductions for the portion of the proposed Project that would serve the SWP or its water users.

Operation of facilities under Alternative A would require a small increase in electricity usage to operate the CVP and would consequently reduce supply of GHG-emissions-free electricity available to sell to California electricity users. Because it is unknown which type of power source would be used to substitute for the lost power, these effects would be potentially substantial and unavoidable.

Implementation of projects considered under the cumulative effects assessment could result in changes to GHG emissions depending upon specific energy demands and construction and operation methods for each project. In general, mitigation measures can be implemented to minimize GHG emissions during construction for future projects. However, GHG emissions would increase to meet future increases in electricity demand to support future projects. Increased GHG emissions from power generation could occur during construction of future projects including the Bay Delta Conservation Plan; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Restoration; and San Joaquin River Restoration Program. Operation of future facilities would result in potentially substantial effects to GHG emissions because it is unknown which type of power source would be used to provide the additional electricity for these projects. Therefore, these effects are considered to be substantial and unavoidable.

Because Alternative A would result in potentially substantial and unavoidable effects and some future projects also could result in substantial and unavoidable effects, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on GHG emissions.

35.4.20.2 Alternative B

As described in Chapter 25 Climate Change and Greenhouse Gas Emissions, effects on GHG emissions due to implementation of Alternative B would be similar to those described for Alternative A. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on GHG emissions.

35.4.20.3 Alternative C

As described in Chapter 25 Climate Change and Greenhouse Gas Emissions, effects on GHG emissions due to implementation of Alternative C would be similar to those described for Alternative A. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on GHG emissions.

35.4.21 Navigation, Transportation, and Traffic

For the proposed Project, effects to navigation, transportation, and traffic could occur during construction and operation. Construction activities along the navigation channels and roadways and construction traffic could result in substantial effects. During operation, recreation-related traffic could result in substantial effects.

As described in Chapter 26 Navigation, Transportation, and Traffic, effects to navigation, transportation, and traffic under the No Project/No Action Alternative would be similar to Existing Conditions. Therefore, there would be no effects or minimal effects to navigation, transportation, and traffic under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could result in changes to navigation, transportation, and traffic in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.21.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 26 Navigation, Transportation, and Traffic, implementation of Alternative A would result in either no effects or minimal effects to navigation, transportation, and traffic in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment could result in changes to transportation and traffic depending upon the location-specific conditions and construction methods used for each project. Changes to transportation and traffic in the Secondary Study Area could occur during construction of future projects including the Bay Delta Conservation Plan; Shasta Lake Water Resources Investigation, Woodland-Davis Water Supply Project; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project, San Luis Reservoir Low Point Improvement Project; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Changes to navigation would be limited to local effects on boat traffic during gravel placement or levee construction. Mitigation measures would be available to reduce potential effects.

Because Alternative A and the future projects would not result in substantial adverse effects, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to navigation, transportation, and traffic in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 26 Navigation, Transportation, and Traffic, implementation of Alternative A would result in minimal effects to navigation in the Primary Study Area, but potentially substantial effects to transportation and traffic during construction due to roadway hazards or road damage due to oversized or overweight construction vehicles. Operation of the proposed recreation areas and the associated recreational traffic would result in potentially substantial effects to traffic during the summer months. Mitigation measures, such as development of a traffic control plan, would reduce the effects during construction and operations.

None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to navigation, transportation, and traffic in the Primary Study Area.

35.4.21.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 26 Navigation, Transportation, and Traffic, effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to navigation, transportation, and traffic.

Primary Study Area

As described in Chapter 26 Navigation, Transportation, and Traffic, effects of implementation of Alternative B would be similar to those described for Alternative A in the Primary Study Area. Without mitigation, Alternative B could cause potentially substantial effects to transportation and traffic in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to navigation, transportation, and traffic in the Primary Study Area.

35.4.21.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 26 Navigation, Transportation, and Traffic, effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to navigation, transportation, and traffic.

Primary Study Area

As described in Chapter 26 Navigation, Transportation, and Traffic, effects of implementation of Alternative C would be similar to those described for Alternative A in the Primary Study Area. Without mitigation, Alternative C could cause potentially substantial effects to transportation and traffic in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to navigation, transportation, and traffic in the Primary Study Area.

35.4.22 Noise

For the proposed Project, effects to noise levels could occur during construction. Construction activities near houses and businesses could result in exposure of people to noise or groundborne vibrations.

As described in Chapter 27 Noise, noise levels under the No Project/No Action Alternative would be similar to Existing Conditions. Therefore, there would be no effects or minimal effects to noise levels under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could affect noise levels in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.22.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 27 Noise, implementation of Alternative A would result in no effects or minimal effects to noise levels in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment could result in changes to noise levels and groundborne vibrations depending upon the location-specific conditions and construction methods used for each project. Changes to noise levels and groundborne vibrations in the Secondary Study Area near houses, businesses, or communities could occur during construction of future projects including the Bay Delta Conservation Plan; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Trinity River Restoration Program; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures would be available to reduce potential effects. However, in some cases, mitigation measures may not be available to reduce the effects. For example, noise levels would remain substantial and unavoidable during portions of the construction activities described in the San Joaquin River Restoration Program EIS/EIR.

Because Alternative A and most future projects would not result in substantial adverse effects, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to noise levels in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 27 Noise, implementation of Alternative A would result in potentially substantial effects to noise levels during construction near houses, businesses, or communities, including along County Road 69 at the proposed North Road; at the railroad siphon location in Willows; at the Glenn-Colusa Irrigation District Canal headworks; along the proposed Delevan Pipeline corridor; at the proposed Delevan Pipeline Intake Facilities location, at the proposed Terminal Regulating Reservoir location; and near the proposed structure demolition locations. Mitigation measures would reduce the effects.

None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative A and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to noise levels in the Primary Study Area.

35.4.22.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 27 Noise, effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to noise levels in the Extended Study Area and Secondary Study Area.

Primary Study Area

As described in Chapter 27 Noise, effects of implementation of Alternative B would be similar to those described for Alternative A in the Primary Study Area. Without mitigation, Alternative B could cause potentially substantial effects to noise levels in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to noise levels in the Primary Study Area.

35.4.22.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 27 Noise, effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to noise levels in the Extended Study Area and Secondary Study Area.

Primary Study Area

As described in Chapter 27 Noise, effects of implementation of Alternative C would be similar to those described for Alternative A in the Primary Study Area. Without mitigation, Alternative C could cause potentially substantial effects to noise levels in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to noise levels in the Primary Study Area.

35.4.23 Public Health and Environmental Hazards

For the proposed Project, effects to public health and environmental hazards could occur during construction and operation. Adverse effects to public health and environmental hazards are caused by creation of a public health or environmental health hazard, adverse effects to emergency response plan or evacuation plan, increased risk of wildland fires, and increased risk of exposure to mosquito or vector-borne diseases.

As described in Chapter 28 Public Health and Environmental Hazards, risks to public health and environmental hazards under the No Project/No Action Alternative would be similar to Existing Conditions. Therefore, there would be no effect to public health and environmental hazards under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could result in effects to public health and environmental hazards in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.23.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 28 Public Health and Environmental Hazards, because there would be no direct Project-related construction or maintenance occurring in the Extended Study Area or in most of the Secondary Study Area, there would be no direct or indirect effects on public health related to hazardous materials as compared to Existing Conditions and the No Project/No Action Alternative. During the proposed pump installation at the Red Bluff Pumping Plant in the Secondary Study Area, there could be accidental releases of hazardous materials that would contaminate soil or degrade water quality. Mitigation measures would reduce the effects.

Implementation of projects considered under the cumulative effects assessment could result in changes to public health and environmental hazards due to use or storage of fuels, oils, grease, and lubricants at future project locations. Future projects could that could affect public health and environmental hazards include the Bay Delta Conservation Plan; Anadromous Fish Screen Program; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay

Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; Iron Mountain Mine Superfund Site; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures would be available to reduce potential effects.

Because Alternative A and most future projects would not result in substantial adverse effects, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public health and environmental hazards in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 28 Public Health and Environmental Hazards, implementation of Alternative A would result in potentially substantial effects to public health and environmental hazards during construction and operation due to use and storage of fuels, oils, grease, and lubricants, or from the presence of unreported hazardous spills or unlisted underground storage tanks. Potential effects also could occur due to road closure, detour, or traffic congestion during construction that would reduce emergency access or evacuation responses. Operation of the proposed recreation areas under Alternative A would result in increased traffic congestion during the recreation season and an increased need for emergency response or evacuation response providers; increased risk of wildland fire hazards; and increased risk of exposure to insect stings (bees, yellowjackets, and stinging ants), ticks with tick-borne diseases, rodents, flies, Giardia, Swimmer’s Itch, liver flukes, rattlesnakes, and poison oak. The presence of surface water in the reservoirs would increase the risk of mosquitoes and vector population and the public health hazard of vector-borne diseases. Mitigation measures would reduce the effects.

None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Implementation of Alternative A and these future projects therefore would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public health and environmental hazards in the Primary Study Area.

35.4.23.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 28 Public Health and Environmental Hazards, effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public health and environmental hazards.

Primary Study Area

As described in Chapter 28 Public Health and Environmental Hazards, effects of implementation of Alternative B would be similar to those described for Alternative A in the Primary Study Area. However, the larger size of the proposed Sites Reservoir associated with Alternative B could increase the risk of exposure to mosquitoes and several vectors. Without mitigation, Alternative B could cause potentially substantial effects related to public health and environmental hazards in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public health and environmental hazards in the Primary Study Area.

35.4.23.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 28 Public Health and Environmental Hazards, effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public health and environmental hazards.

Primary Study Area

As described in Chapter 28 Public Health and Environmental Hazards, effects of implementation of Alternative C would be similar to those described for Alternative A in the Primary Study Area. However, the larger size of the proposed Sites Reservoir associated with Alternative B could increase the risk of exposure to mosquitoes and several vectors. Without mitigation, Alternative C could cause potentially substantial effects to public health and environmental hazards in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public health and environmental hazards in the Primary Study Area.

35.4.24 Public Services and Utilities

For the proposed Project, effects to public services and utilities could occur during construction and operation. Adverse effects to public services are caused by an increased demand for emergency response services or increased emergency response time that results in the need for new or physically altered facilities. Adverse effects to utilities are caused by disruption to utilities.

As described in Chapter 29 Public Services and Utilities, effects to public services and utilities under the No Project/No Action Alternative would be similar to Existing Conditions. Therefore, there would be no effect to public services and utilities under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could result in effects to public services and utilities in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.24.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 29 Public Services and Utilities, implementation of Alternative A would result in no effects or minimal effects to public services and utilities as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment could result in changes to public services and utilities due to potential disruption to utilities during construction. Future projects that could result in changes to public services and utilities include the Bay Delta Conservation Plan; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; El Dorado Irrigation District Folsom Lake Temperature Control Device; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; North Delta Flood Control and Ecosystem Restoration Project; Dutch Slough Tidal Marsh Project; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures would be available to reduce potential effects.

Because Alternative A and most future projects would not result in substantial adverse effects, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public services and utilities in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 29 Public Services and Utilities, implementation of Alternative A would result in no effects or minimal effects to public services and the need to for new or altered facilities, but would result in potentially substantial effects to utilities during construction. Potential effects during construction could occur if utilities were disrupted during relocation of eight transmission towers from the inundation area of the proposed Holthouse Reservoir, or if any unidentified utilities are disrupted. Mitigation measures would reduce the effects.

None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Implementation of Alternative A and these future projects therefore would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public services and utilities in the Primary Study Area.

35.4.24.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 29 Public Services and Utilities, effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public services and utilities in the Extended Study Area and Secondary Study Area.

Primary Study Area

As described in Chapter 29 Public Services and Utilities, effects of implementation of Alternative B would be similar to those described for Alternative A in the Primary Study Area. Without mitigation, Alternative B could cause potentially substantial effects to utilities in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative B and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public services and utilities in the Primary Study Area.

35.4.24.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 29 Public Services and Utilities, effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public services and utilities in the Extended Study Area and Secondary Study Area.

Primary Study Area

As described in Chapter 29 Public Services and Utilities, effects of implementation of Alternative C would be similar to those described for Alternative A in the Primary Study Area. Without mitigation, Alternative C could cause potentially substantial effects to utilities in the Primary Study Area. Mitigation measures would reduce the effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area. Therefore, implementation of Alternative C and these future projects would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to public services and utilities in the Primary Study Area.

35.4.25 Visual Resources

For the proposed Project, changes in visual resources could occur during construction and operation. During construction, the presence of construction equipment, light and glare from construction lighting and construction vehicles, and disruption of agricultural activities along the valley floor near construction locations would affect visual resources. During operation, light and glare would occur from several sources and changes in the visual landscape would affect visual resources.

As described in Chapter 30 Visual Resources, visual resources under the No Project/No Action Alternative would be similar to Existing Conditions. Therefore, there would be no effects or minimal effects on visual resources under the No Project/No Action Alternative.

Future projects evaluated in the cumulative effects analysis could result in changes to visual resources in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

35.4.25.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 30 Visual Resources, implementation of Alternative A would result in either no effects or minimal effects to visual resources in the Extended Study Area and Secondary Study Area as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects analysis could result in changes to visual resources depending upon the location-specific conditions and construction methods used for each project. Changes to visual resources in the Secondary Study Area could occur during construction or implementation of future projects including implementation of CVPIA and CALFED objectives; Bay Delta Conservation Plan; Delta Plan; Anadromous Fish Screen Program; Regional Advance Mitigation Program; Central Valley Vision; County of Colusa 2030 General Plan; Butte County Regional Conservation Plan; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; South Delta Temporary Barriers Operations; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; San Luis Reservoir Low Point Improvement Project; Trinity River Restoration Program; Yolo County Habitat/Natural Community Conservation Plan; Yolo Bypass Wildlife Area Land Management Plan; Yolo Bypass Salmonid Habitat Restoration and Fish Passage Implementation Plan; Cache Slough Complex Restoration; North Delta Flood Control and Ecosystem Restoration Project; Fish Screen Project at Sherman and Twitchell Islands; Dutch Slough Tidal Marsh Project; Franks Tract Project; Solano County Multi-species Habitat Conservation Plan; Suisun Marsh Habitat Management, Preservation, and Restoration Plan; and San Joaquin River Restoration Program. Mitigation measures generally would be available to reduce potential effects. In some cases, the effects could remain substantial and unavoidable. For example, visual effects were identified to be substantial and unavoidable for projects evaluated in the Shasta Lake Water Resources Investigation Preliminary Draft EIS and the San Joaquin River Restoration Program EIS/EIR.

Because Alternative A would result in potentially substantial and unavoidable effects in the Primary Study Area in the Sacramento Valley floor (as described below) and some future projects also could result in substantial and unavoidable effects, implementation of Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on visual resources in the Extended Study Area and the Secondary Study Area.

Primary Study Area

Construction and operation of facilities under Alternative A would result in potentially substantial effects to visual resources. In many cases, mitigation measures would reduce the effects. However, substantial and unavoidable effects would occur due to glare from the water surface of the proposed Sites Reservoir; changes in the visual characteristic of the area from rural and undeveloped to an area with more infrastructure such as the proposed South Bridge and connecting roadways; and change in views across the valley floor due to the six-foot high embankments of the proposed Terminal Regulating Reservoir. The inundation area of the proposed Sites Reservoir would eliminate the large contiguous areas of grazing land that are protected by the goals and objectives of the Colusa County and Glenn County general plans, resulting in substantial and unavoidable effects. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities within the Primary Study Area.

Due to the potential for substantial and unavoidable effects under Alternative A and from future projects in the Secondary Study Area which could affect visual resources in or near the Primary Study Area, Alternative A would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on visual resources in the Primary Study Area.

35.4.25.2 Alternative B

Extended Study Area and Secondary Study Area

As described in Chapter 30 Visual Resources, effects on visual resources due to implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative B would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on visual resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Construction and operation of proposed Project facilities under Alternative B would result in potentially substantial effects to visual resources, similar to the effects described under Alternative A. However, the extent of the effects due to glare from the water surface of the proposed Sites Reservoir would be greater under Alternative B because the reservoir would be larger than under Alternative A. Mitigation measures would reduce many of the effects. However, substantial and unavoidable effects would occur due to glare from the water surface of the proposed Sites Reservoir; changes in the visual characteristic of the area from rural and undeveloped to an area with more infrastructure such as the proposed South Bridge and connecting roadways; and change in views across the valley floor due to the six-foot high embankments of the proposed Terminal Regulating Reservoir. The inundation area of the proposed Sites Reservoir would eliminate the large contiguous areas of grazing land that are protected by the goals and objectives of the Colusa County and Glenn County general plans, resulting in substantial and unavoidable effects. Due to the potential for substantial and unavoidable effects under Alternative B and from future projects in the Secondary Study Area which could affect visual resources in or near the Primary Study Area, Alternative B would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on visual resources in the Primary Study Area.

35.4.25.3 Alternative C

Extended Study Area and Secondary Study Area

As described in Chapter 30 Visual Resources, effects on visual resources due to implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area. The cumulative effects of Alternative C would therefore be similar to those described for Alternative A in the Extended Study Area and Secondary Study Area, and would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on visual resources in the Extended Study Area and Secondary Study Area.

Primary Study Area

Construction and operation of facilities under Alternative C would result in potentially substantial effects to visual resources, similar to the effects described under Alternative A. However, the extent of the effects due to glare from the water surface of the proposed Sites Reservoir would be greater under Alternative C because the reservoir would be larger than under Alternative A. Mitigation measures would reduce many of the effects. However, substantial and unavoidable effects would occur due to glare from the water surface of the proposed Sites Reservoir; changes in the visual characteristic of the area from rural and undeveloped to an area with more infrastructure, such as the proposed South Bridge and connecting roadways; and change in views across the valley floor due to the six-foot high embankments of the Terminal Regulating Reservoir. The inundation area of the proposed Sites Reservoir would eliminate the large contiguous areas of grazing land that are protected by the goals and objectives of the Colusa County and Glenn County general plans, resulting in substantial and unavoidable effects. Due to the potential for substantial and unavoidable effects under Alternative C and from future projects in the Secondary Study Area which could affect visual resources in or near the Primary Study Area, Alternative C would result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on visual resources in the Primary Study Area.

35.4.26 Power Production and Energy

Adverse effects to power production and energy use are caused by wasteful or unnecessary consumption of energy and reduction of the generation of renewable energy. As described in Chapter 31 Power Production and Energy, power production and energy use under the No Project/No Action Alternative would be similar to Existing Conditions and result in no effects.

Future projects evaluated in the cumulative effects analysis could affect power production and energy in the Extended Study Area and the Secondary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in changes within the Primary Study Area.

35.4.26.1 Alternative A

Extended Study Area and Secondary Study Area

As described in Chapter 31 Power Production and Energy, implementation of Alternative A would not result in wasteful or unnecessary consumption of energy and would not result in reduction of the generation of renewable energy in the Extended Study Area and Secondary Study Area. Implementation of Alternative A would therefore result in no effects or minimal effects as compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of projects considered under the cumulative effects assessment that could result in changes in increased energy use and/or changes in hydropower generation include the SWRCB Bay-Delta Water Quality Plan Update; Bay Delta Conservation Plan; NMFS recovery plan for salmonids; Increased Hydropower Generation Capacity at Lewiston Dam; Shasta Lake Water Resources Investigation; Woodland-Davis Water Supply Project; Semitropic Water Storage District Delta Wetlands; North Bay Aqueduct Alternative Intake; Bay Area Regional Desalination Project; Los Vaqueros Reservoir Expansion Phase II; Upper San Joaquin River Basin Storage Investigation; Grassland Bypass Project; CV-SALTS; San Luis Reservoir Low Point Improvement Project; and San Joaquin River Restoration Program. All of these projects are assumed to be designed to avoid wasteful or unnecessary consumption of energy. Implementation of the Shasta Lake Water Resources Investigation and San Joaquin River Basin Storage Investigation are being developed to avoid reduction in hydropower generation.

Because Alternative A and the future projects would not result in substantial adverse effects, Alternative A would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to power production and energy in the Extended Study Area and the Secondary Study Area.

Primary Study Area

As described in Chapter 31 Power Production and Energy, implementation of Alternative A would result in no effects or minimal effects to power production and energy in the Primary Study Area. None of the future projects evaluated in the cumulative effects analysis would result in construction or additional operation and maintenance activities, nor would they change c power production and energy within the Primary Study Area. Implementation of Alternative A and these future projects therefore would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect to power production and energy in the Primary Study Area.

35.4.26.2 Alternative B

As described in Chapter 31 Power Production and Energy, effects of implementation of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area. Therefore, the cumulative effects of Alternative B would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on power production and energy in the Extended Study Area, Secondary Study Area and Primary Study Area.

35.4.26.3 Alternative C

As described in Chapter 31 Power Production and Energy, effects of implementation of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area. Therefore, the cumulative effects of Alternative C would be similar to those described for Alternative A in the Extended Study Area, Secondary Study Area and Primary Study Area, and would not result in a cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect on power production and energy in the Extended Study Area, Secondary Study Area and Primary Study Area.

36. Consultation and Coordination

36.1 Introduction

This chapter summarizes the public and agency involvement activities undertaken by the California Department of Water Resources (DWR) and the U.S. Bureau of Reclamation (Reclamation) to date for the North-of-the-Delta Offstream Storage Project (NODOS Project or proposed Project), which satisfy the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA) requirements for public scoping and agency coordination and consultation. Chapter 39 EIR/EIS Distribution List presents the entities receiving the Notice of Availability of the Draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS).

DWR and Reclamation continue to solicit input from these entities regarding the proposed Project by encouraging review of this DEIR/EIS.

36.2 Notice of Preparation and Notice of Intent

DWR and Reclamation notified interested parties of the scoping period and upcoming public scoping meetings through electronic and postal mailings and through publication of a Notice of Preparation (NOP) and Notice of Intent (NOI), consistent with CEQA and NEPA, respectively. Copies of the NOP and NOI are included in Appendix 36A.

DWR filed the NOP with the State Clearinghouse on November 5, 2001, and Reclamation published the NOI in the *Federal Register* on November 9, 2001. The NOP and NOI notified the public of the NODOS Project proposal, announced the dates and locations of public meetings, and solicited public comments to help guide development of the pending DEIR/EIS, pursuant to CEQA and NEPA, respectively. Public notifications were also made through direct mailings to local landowners in and near the proposed Sites and Newville reservoir locations, and by advertisements in four local newspapers prior to the public meetings. In addition, a news release was placed on the DWR and Reclamation website homepages.

36.3 Public Scoping

Public scoping activities were conducted in compliance with both CEQA and NEPA requirements. The scoping process aided in identifying the range of actions, alternatives, mitigation measures, and potential effects to be analyzed in depth in the DEIR/EIS.

At the scoping meetings and during the scoping comment period, the public was invited to submit written comments regarding the scope, content, and format of the environmental document by mail, fax, or email to representatives at DWR and Reclamation.

36.3.1 Scoping Meetings

During the public scoping process, DWR and Reclamation conducted three formal scoping meetings to seek public input and comments prior to the preparation of the DEIR/EIS. The dates and locations of the meetings are listed in Table 36-1. In addition, DWR and Reclamation held a scoping meeting with the Native American tribes.

Table 36-1
NODOS Project Public Scoping Meetings

Sacramento, CA Date: Tuesday, January 8, 2002 Time: 1:00 p.m. to 4:00 p.m. Location: Department of Water Resources, Bonderson Building, Public Hearing Room – 1st Floor Address: 901 P Street, Sacramento, CA	**Maxwell, CA** Date: Wednesday, January 9, 2002 Time: 6:00 p.m. to 9:00 p.m. Location: Maxwell Inn Address: 81 Oak Street, Maxwell, CA
Fresno, CA Date: Tuesday, January 15, 2002 Time: 6:00 p.m. to 9:00 p.m. Location: Piccadilly Inn – University Address: 4961 N. Cedar Avenue, Fresno, CA	**Williams, CA** Date: Wednesday, January 23, 2002 6:00 to 9:00 p.m. Location: Cortina Indian Rancheria Office Address: 570 Sixth Street, Williams, CA

The format for each public meeting was identical. The meetings began with DWR and Reclamation representatives giving a 30-minute Powerpoint presentation that described the water resources challenges in the Sacramento River region, the CALFED[1] Bay-Delta Program (CALFED) and the CALFED storage element[2], objectives of the NODOS Project, potential alternatives, and opportunities for public participation. Following the presentation, 60 minutes were allotted for public comments on the scope and content of the NODOS DEIR/EIS. Comments were accepted in writing, and oral comments were recorded by a court reporter.

36.3.2 Scoping Report

A Scoping Report, which was prepared at the end of the scoping meetings and comment period, is included in Appendix 36A. The Scoping Report outlines the process and outcomes of the scoping meetings. It includes a summary of all comments received during the scoping process, both written and oral, and appendixes that include the NOP and NOI, meeting announcements, newspaper ads announcing the scoping meetings, the Powerpoint presentation used during the scoping meetings, transcripts of the scoping meetings, and an initial outline of the DEIR/EIS.

36.4 Consultation

Since late 2001, DWR and Reclamation have met with stakeholders, interested parties, and State and federal regulatory agencies. The purpose of these meetings was to provide briefings about the proposed Project and to seek input. These consultations assisted the lead agencies in determining the scope of the DEIR/EIS, identifying the range of alternatives and mitigation measures, and identifying potential environmental impacts. The consultation participants are described below.

36.4.1 Environmental Interests, County Boards of Supervisors, and Water Contractors

DWR and Reclamation provided briefings to stakeholder groups and interested parties between September 2003 and February 2004. The briefings included presentations and discussions regarding the planning objectives, the technical studies underway, preliminarily identified potential benefits and impacts, and the status of the proposed Project. Briefings were provided to the following groups:

- Bay-Area Environmental Water Caucus

---

[1] CALFED is a cooperative interagency effort of State and federal agencies to develop and implement a long-term comprehensive plan to restore ecological health and improve water management for beneficial uses of the Bay-Delta system.

[2] Storage is one of five program elements identified by CALFED to achieve the Water Supply Reliability objective. The other four program elements are conveyance, water transfers, water use efficiency, and the Environmental Water Account.

- Chico Environmental Caucus
- Colusa County Board of Supervisors
- Glenn County Board of Supervisors
- Sacramento River Conservation Area Forum
- San Luis and Delta-Mendota Water Authority
- State Water Contractors
- Tehama County Flood Control and Water Conservation District

36.4.2 Sacramento River Flow Regime Technical Advisory Group

At the request of the NODOS Project management team, the Sacramento River Flow Regime Technical Advisory Group (TAG) was formed in 2002 (Table 36-2). The TAG held meetings regularly from 2002 through 2004. The TAG was asked to consider the flow regime of the upper Sacramento River. Specifically, the TAG was asked to help identify potential NODOS Project flow regime impacts and benefits, and to improve the overall understanding of the flow regime of the Sacramento River and related ecosystem processes. In addition, the TAG provided ideas and identified issues to be addressed during NODOS Project studies. The TAG consisted of the NODOS Project study team, technical staff members from other State and federal agencies, technical staff members from various environmental interest groups, and university researchers. With input from the TAG, the NODOS Project study team prepared the administrative draft *Sacramento River Flow Regime Status Report* (Reclamation and DWR, 2007). The report describes the historic changes in the Sacramento River flow regime and presents preliminary concepts that might improve the habitat and ecological processes of the Sacramento River, both with and without an implemented NODOS Project. The report also documents the need for additional studies related to flow regime and ecosystem processes.

University of California Davis	Eric Larsen Steve Greco Cindy Lowney (formerly associated with UCD)

36.4.3 California Bay-Delta Public Advisory Committee, Water Supply Subcommittee Briefings

DWR and Reclamation briefed the CALFED Water Supply Subcommittee regularly about the planning and status of the NODOS Project, modeling tool development, and technical findings. These briefings were intended to inform the Water Supply Subcommittee members so that the Subcommittee could then inform the California Bay-Delta Public Advisory Committee. The Water Supply Subcommittee meetings were open to the public. Reclamation and DWR staff members, staff members from other State and federal agencies, environmental interest groups, water contractors, and members of the public typically attended the meetings. Briefings to the Water Supply Subcommittee ended in 2007. The Water Supply Subcommittee subsequently ceased to exist.

36.4.4 Common Assumptions Stakeholder Technical Workgroup

Common Assumptions was an effort by DWR, Reclamation, and CALFED to develop consistent methodologies and assumptions for the surface storage investigations through the development of a "common model" package. At the request of the Water Supply Subcommittee in October 2003, a technical stakeholder workgroup, consisting of technical participants from environmental interest groups and water user groups, was formed to help provide informed feedback to Water Supply Subcommittee members about the Common Assumptions activities relating to the development of the "common model" package. The "common model" package is a suite of models that includes hydrologic, hydraulic, hydrodynamic, water quality, temperature, fisheries, and economics models that were adapted to represent the NEPA and CEQA baseline conditions for the NODOS Project and all other CALFED surface-water storage and conveyance investigations. The NODOS Project study team and the Common Assumptions technical team held five meetings with the technical workgroup to provide updates and technical information about Common Assumptions activities.

36.4.5 Landowner Meetings

DWR and Reclamation held numerous meetings with landowners in and near the proposed Sites Reservoir location to brief them about the proposed Project features and the status of the proposed Project. These meetings were organized by the landowners group, and the agencies were invited periodically to attend and address specific issues. Landowners used these opportunities to voice issues of concern and provide input to DWR and Reclamation. The meetings were held in the town of Sites on the following dates:

- July 30, 2001
- August 27, 2001
- October 2002
- December 5, 2002

36.4.6 Study Area Tours

DWR conducted tours of the proposed Sites Reservoir location for agency staff, the press, and interested stakeholders, when requested. During each tour, DWR staff provided updates regarding the Project status and technical findings. The tours provided interested parties with firsthand views of the area and the locations of proposed facilities. DWR staff continued to conduct tours of the proposed Sites Reservoir location during the preparation of this DEIR/EIS. The Water Education Foundation (WEF) has included tours of the proposed Sites Reservoir location in its Northern California Tour itinerary since 2001. The WEF's Northern California Tour stopped at the proposed Sites Reservoir location on the following dates:

- October 5, 2001
- October 4, 2002
- September 26, 2003
- September 17, 2004
- September 23, 2005
- September 15, 2006
- September14, 2007
- September 12, 2008
- October 9, 2009
- September 24, 2010
- October 14, 2011
- October 19, 2012
- October 18, 2013

36.5 Coordination

The following sections describe coordination efforts with local water interests, counties, and other State and federal agencies throughout the environmental documentation process.

36.5.1 Sites Memorandum of Understanding

The CALFED Record of Decision (ROD) directed DWR and Reclamation to develop a joint planning program through a Memorandum of Understanding (MOU) with local water interests, counties, and State and federal agencies to carry out the NODOS Project. Beginning in November 2000, two State, and three federal agencies, along with several local entities, signed the MOU. Other local entities subsequently signed the MOU. The MOU signatories are shown in Table 36-3. DWR and Reclamation held coordination meetings with the MOU parties from 2001 to 2005.

Table 36-3
Sites MOU Signatories

State Agencies	Local agencies
California Department of Fish and Game* California Department of Water Resources **Federal Agencies** U.S. Bureau of Reclamation, Mid-Pacific Region U.S. Fish and Wildlife Service Western Area Power Administration	County of Colusa Colusa Drain Mutual Water Company Glenn-Colusa Irrigation District Maxwell Irrigation District Natomas Mutual Water Company Orland Unit Water User's Association Princeton Cordora Glenn Irrigation District Provident Irrigation District Reclamation District 108 Sutter Mutual Water Company Tehama-Colusa Canal Authority Yolo County Flood Control and Water Conservation District

*At the time that the MOU was signed, the agency was known as the "California Department of Fish and Game". As of January 1, 2013, its name has changed to the "California Department of Fish and Wildlife".

36.5.2 Sites Project Joint Powers Authority

On November 4, 2009, the California Legislature passed, and then-Governor Arnold Schwarzenegger signed into law, a far-reaching legislative package regarding water known as the 2009 Comprehensive Water Package. The Package included four policy bills and a water bond measure aimed at improving water supply reliability and restoring the Sacramento-San Joaquin Delta ecosystem. Senate Bill 7X 2 (SB 7X 2) proposed an $11.14 billion general obligation bond to provide funding for water infrastructure and projects to address ecosystem and water supply reliability. SB 7X 2 allows the formation of local joint powers authorities by irrigation districts and other local water districts and local governments within the applicable hydrologic region to design, acquire, and construct those projects.

Consistent with SB 7X 2, the Sites Project Joint Powers Authority (Sites JPA) was formed in August 2010 to help design, acquire, construct, manage, govern, and operate the NODOS Project to provide local, regional, and Statewide public benefits, improve the State's water system, and enhance the ecosystem. The Sites JPA is comprised of the Glenn-Colusa Irrigation District (GCID), Reclamation District 108, Tehama-Colusa Canal Authority (TCCA), Maxwell Irrigation District, County of Glenn, County of Colusa, and Yolo County Flood Control and Water Conservation District. DWR is a non-voting ex-officio member of the Sites JPA.

DWR and Reclamation have attended many of the monthly Sites JPA meetings since September 2010, at the invitation of the JPA. These meetings are open to the public, and meeting announcements and agendas are posted on the Sites JPA website (http://www.sitesjpa.net/Agendas.html). In addition, Sites JPA representatives have been attending the NODOS Project cooperating agencies' meetings.

36.5.3 Cooperating Agencies

Pursuant to NEPA[3], a cooperating agency may be any agency other than the lead agency that has jurisdiction by law or special expertise, especially with respect to the environmental impacts expected to result from a proposal. An agency has “jurisdiction by law” if it has the authority to approve, veto, or finance all or part of the proposal[4]. An agency has “special expertise” if it has statutory responsibility, agency mission, or related program experience with regard to a proposal[5]. A lead agency must request the participation of cooperating agencies as early as possible in the NEPA process, use the environmental analyses and proposals prepared by cooperating agencies as much as possible, and meet with cooperating agencies at their request[6].

Cooperating agencies have been encouraged to take an active part in the development of this DEIR/EIS. In early 2011, Reclamation (the NEPA lead agency for the NODOS Project) signed cooperating agency memorandums of agreement (MOAs) with the following entities for the NODOS Project:

- Bureau of Indian Affairs
- Western Area Power Administration
- U.S. Army Corps of Engineers
- Colusa Indian Community Council
- Cortina Indian Rancheria
- Sites JPA

Since April 2011, DWR and Reclamation have held regular coordination meetings with the cooperating agencies to provide briefings and seek input regarding the NODOS Project.

36.5.4 Responsible Agencies

Pursuant to CEQA, responsible agencies are the public agencies (other than the lead agency) that have discretionary approval power over a project[7]. There has been ongoing coordination with the following applicable responsible agencies regarding the NODOS Project:

- California Department of Fish and Wildlife[8]
- State Water Resources Control Board
- Central Valley Regional Water Quality Control Board, Central Valley Region 1
- Tehama-Colusa Canal Authority
- Glenn-Colusa Irrigation District
- Sites JPA

36.5.5 Trustee Agencies

Pursuant to CEQA, trustee agencies are State agencies that have jurisdiction by law over natural resources affected by a project that are held in trust for the people of the State of California. Trustee agencies include:

---

[3] 40 CFR 1508.5; 1501.6; Forty Questions No. 14(a), 14(b), 14(c).
[4] 40 CFR 1508.15.
[5] 40 CFR 1508.26.
[6] 40 CFR 1501.6(a).
[7] CEQA Guidelines Section 15381.
[8] Formerly known as the California Department of Fish and Game (i.e., prior to January 1, 2013).

- California Department of Fish and Wildlife[8] (CDFW) with regard to the fish and wildlife of the State, to designated rare or endangered native plants, and to game refuges, ecological reserves, and other areas administered by DFG
- California State Lands Commission with regard to State-owned sovereign lands, such as the beds of navigable waters and state school lands
- California Department of Parks and Recreation with regard to units of the State Park System
- University of California with regard to sites within the Natural Land and Water Reserves System[9]

There has been ongoing coordination with the applicable trustee agencies regarding the NODOS Project.

36.5.6 Native American Representatives

DWR and Reclamation have been coordinating with the following Native American Tribes:

- Colusa Indian Community Council
- Cortina Indian Rancheria
- Grindstone Indian Rancheria
- Paskenta Band of Nomlaki Indians

DWR and Reclamation have met with the four tribal representatives on an informal basis to provide updates regarding NODOS Project progress and to encourage input from the tribes about their issues of concern. In addition to conducting a tribal scoping meeting and one field tour of the proposed Sites Reservoir location and cultural resource sites, eight coordination meetings were held with the tribal representatives during the completion of the NODOS Initial Alternatives Information Report[10] (DWR and Reclamation, 2006). In 2004, Reclamation provided grant funding to the four tribes to develop appraisal-level tribal water resource studies. The studies appraised future water needs and availability, and evaluated whether the proposed Project would impair or enhance that water availability. With Reclamation’s grant funding, three of the four tribes completed the appraisal studies. The Cortina Indian Rancheria and its consultant completed a report titled “North of the Delta Off-Stream Storage Interim Report by Cortina Band of Wintu Indians, March 2010.” The Grindstone Indian Rancheria and its consultant completed three technical memoranda: Grindstone Creek Rancheria Background Information (November 19, 2010), Grindstone Rancheria Water Use (November 19, 2010), and Effects of NODOS Project on Grindstone Rancheria Water Rights (November 19, 2010). A confidential report titled, “North-of-the-Delta Offstream Storage Tribal Asset Study for the Colusa Indian Community Council, August 2011” was developed with funds provided by Reclamation. In addition, Reclamation completed an Engineering Technical Memorandum titled “Water Supply Conveyance Report, May 2011” for the Cortina Indian Rancheria.

Formal consultation between the tribes and Reclamation will be initiated when a preferred alternative has been identified and the Area of Potential Effects (APE) is defined and documented in consultation with the State Historic Preservation Office, pursuant to Section 106 of the National Historic Preservation Act.

[9] CEQA Guidelines Section 15386.

[10] The IAIR identified, discussed, and screened measures to address the problems and needs and introduced the development of potential initial alternatives for further consideration.

36.5.7 Environmental Coordination Advisory Team

DWR and Reclamation have participated in ongoing coordination and consultation meetings with the Environmental Coordination Advisory Team (ECAT). The ECAT consists of DWR, Reclamation, and other State and federal agencies, including CDFW, U.S. Fish and Wildlife Service (USFWS), National Oceanic and Atmospheric Administration, National Marine Fisheries Service (NOAA Fisheries), Central Valley Regional Water Quality Control Board (CVRWQCB), U.S. Environmental Protection Agency (USEPA), and U.S. Army Corps of Engineers (USACE). DWR and Reclamation will continue to proactively engage these agencies throughout the NEPA, CEQA, and NODOS Project permitting processes. The focus of these coordination meetings is to discuss the scope and level of analysis for compliance with the Federal Endangered Species Act and California Endangered Species Act, Federal Water Pollution Control Act (commonly referred to as the Clean Water Act), Fish and Wildlife Coordination Act, and other regulatory requirements related to development of the NODOS Project DEIR/EIS and the 2011 North-of-the-Delta Offstream Storage Investigation Feasibility Report (Feasibility Report).

36.6 Draft EIR/EIS Public Review Process

In compliance with CEQA and NEPA review requirements, this DEIR/EIS is being circulated for public and agency review and comment for a 90-day period following the date when DWR files the Notice of Completion (NOC) with the Office of Planning and Research, State Clearinghouse; and the U.S. Environmental Protection Agency (USEPA) publishes the Notice of Availability (NOA) of Weekly Receipt of Environmental Impact Statement in the Federal Register. The DEIR/EIS is available for download from DWR's and Reclamation's websites at http://www.water.ca.gov/storage/northdelta/index.cfm and http://www.usbr.gov/mp/nepa/nepa_projdetails.cfm?Project_ID=139, respectively. In addition, printed copies of the DEIR/EIS are available at no cost at DWR and Reclamation offices, and are available for viewing at several libraries (Table 36-4).

Table 36-4
NODOS DEIR/EIS Locations of Availability for Printed Copies

Library Locations	DWR and Reclamation Locations
Sacramento Public Library 828 I Street Sacramento, CA 95814	California Department of Water Resources 901 P Street Sacramento, CA. 95814
Red Bluff Public Library 645 Madison Street Red Bluff, CA 96080	California Department of Water Resources Northern Region Office 2440 Main Street Red Bluff, CA 96080
Willows Public Library 201 North Lassen Street Willows, CA 95988	U.S. Bureau of Reclamation Mid-Pacific Regional Office Library 2800 Cottage Way, W-1825 Sacramento, CA 95825-1989
Maxwell Branch Library 340 Oak Street Maxwell, CA 95955	U.S. Department of the Interior Natural Resources Library 1849 C Street N.W., Main Interior Building Washington, DC 20240-0001

During the 90-day DEIR/EIS public and agency review period, public hearings will be held in the counties of Glenn, Colusa, and Sacramento, as well as in the Sacramento-San Joaquin Delta, to solicit public input. Written and oral comments will be accepted at these meetings.

Written comments (either by U.S. mail, fax, or email) will be accepted throughout the DEIR/EIS public and agency review period, but no later than 5:00 p.m. on XXXX. Written comments should be submitted to either of the following individuals:

Sean Sou
California Department of Water Resources
PO Box 942836
Sacramento, CA 94236-0001
sean.sou@water.ca.gov
Fax: (916) 651-9292

Sharon McHale
U.S. Bureau of Reclamation
2800 Cottage Way, MP-700
Sacramento CA. 95825
smchale@usbr.gov
Fax: (916) 978-5094

Reviewers of the DEIR/EIS should focus on the sufficiency of the document in identifying and analyzing possible impacts on the environment and ways in which the significant impacts of the proposed Project alternatives might be avoided or mitigated. Comments are most helpful when they suggest additional specific alternatives or mitigation measures that would provide better ways to avoid or mitigate significant environmental impacts.

36.7 DEIR/EIS and Proposed Project/Proposed Action Approval Process

At the end of the 90-day DEIR/EIS public and agency review period, DWR and Reclamation will consider the comments received, and will prepare responses to the comments and errata (i.e., text and/or graphic changes to the DEIR/EIS), as needed. This response document, along with the DEIR/EIS, will constitute the Final EIR/EIS. The Final EIR/EIS will then be circulated in accordance with CEQA and NEPA requirements.

After the end of the Final EIR/EIS circulation period, DWR and Reclamation management will consider the Final EIR/EIS when deciding whether to certify the EIR, adopt the EIS, and approve one of the proposed Project alternatives. At the time that an alternative is being considered for approval, DWR will adopt written findings of fact for each significant impact that is identified in the Final EIR. The Final EIR/EIS and the alternative being considered will be formally presented to DWR's Director and Reclamation's Mid-Pacific Region Regional Director at meetings that will be held in Sacramento by DWR and Reclamation. The meetings will be open to the public, and the public may comment at the meetings.

Following the approval of one of the proposed Project alternatives (if that is the case), to document its decision, DWR will file a Notice of Determination (NOD) with the Office of Planning and Research, State Clearinghouse, and Reclamation will issue a Record of Decision (ROD) to the public (the DEIR/EIS Distribution List) and the *Federal Register*.

38. List of Preparers and Contributors

38.1 Introduction

This Draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS) was prepared by the California Department of Water Resources (DWR) and the U.S. Bureau of Reclamation (Reclamation). The following individuals led the effort from those agencies:

CEQA Lead Agency (DWR):

- Ajay Goyal (Principal Engineer, Water Resources)
- Sean Sou (Supervising Engineer, Water Resources)
- Jim Wieking (Supervising Engineer, Water Resources)

NEPA Lead Agency (Reclamation):

- Ron Ganzfried (Branch Chief)
- Sharon McHale (Project Manager)
- David Pritchett (Alternate Project Manager)

The following tables list the people who prepared various sections of the DEIR/EIS and/or background materials, or conducted reviews of materials for the DEIR/EIS. This chapter is consistent with the requirements set forth in NEPA and CEQA (40 CFR 1502.17 and Section 15129 of the State CEQA Guidelines), respectively.

38.2 State

Table 38-1 lists the staff from DWR who contributed to the preparation of this DEIR/EIS.

Table 38-1
California Department of Water Resources Staff Contributors to the DEIR/EIS

Name	Title	Qualifications	Years of Experience	Role
Dave Bogener	Environmental Program Manager	B.A. Natural Science; M.A. Wildlife Resource Management and Planning	33	Description of the Proposed Project/Proposed Action and Alternatives; Environmental Compliance and Permit Summary; Document Review
Amy Lyons	Senior Environmental Scientist (Specialist)	B.S. Biological Sciences; M.S. Biological Sciences	18	Alternatives Analysis, Terrestrial Biological Resources; Document Review
Ghassan Alqaser	Senior Engineer, Specialist	Ph.D. Civil Engineering, Hydraulics	30	Power Production and Energy, Power Optimization
David Arrate	Senior Engineer, Water Resources	B.S. Civil Engineering	7	Description of the Proposed Project/Proposed Action and Alternatives; Document Review: Power Production and Energy

Name	Title	Qualifications	Years of Experience	Role
Paul Bergamn	Fisheries Biologist	B.S. Limnology, M.S. Fisheries	8	Fisheries Modeling
Brad Cavallo	Senior Scientist	B.S. Fisheries Biology, M.S. Aquatic Ecology	17	Fisheries Modeling
Steven Zeug	Fisheries Biologist	B.S. Fisheries Biology, Ph.D. Wildlife and Fisheries Sciences	10	Fisheries Modeling

38.5.4 ESSA Technologies, Ltd.

Table 38-7 lists the staff from ESSA Technologies, Ltd. who contributed to the preparation of this DEIR/EIS.

Table 38-7
ESSA Technologies, Ltd. Staff Contributors to the DEIR/EIS

Name	Title	Qualifications	Years of Experience	Role
Clint Alexander	Managing Partner/Team Leader	B.S. Ecology; M.R.M (Master of Resource Management)	15	Sacramento River Ecological Flows Tool (Sac EFT) Report
Frank Poulsen	Quantitative Ecologist/Programmer	M.S. Engineering (Environmental and Computer Science)	9	Sac EFT Report
Don Robinson	Senior Systems Ecologist	B.S. UBC M.S. UBC	29	Sac EFT Report

38.5.5 HDR, Inc.

Table 38-8 lists the staff from HDR, Inc. who contributed to the preparation of this DEIR/EIS.

Table 38-8
HDR, Inc. Staff Contributors to the DEIR/EIS

Name	Title	Qualifications	Years of Experience	Role
Jelica Arsenijevic	Environmental Scientist II – Aquatic Resources	B.S. Environmental Biology/Ecology	8	Aquatic Biological Resources
Heather Bowen	Biologist I	B.S. Fishery Sciences	5	Aquatic Biological Resources
Paul Bratovich	Principal Scientist	B.S. Fisheries; M.S. Fisheries Resources	30	Aquatic Biological Resources
Morgan Neal	Biologist II	B.S. Fisheries Biology; M.S. Marine Affairs	6	Aquatic Biological Resources
Jose Perez-Comas	Senior Scientist	Sc.D. Fishery Sciences; M.S. Fishery Sciences; Ph.D. Fishery Sciences	34	Aquatic Biological Resources
Adrian Pitts	Senior Environmental Scientist	B.S. Biological Sciences	14	Aquatic Biological Resources
Cristina Ramirez	Environmental Scientist 1	B.S. Environmental Policy and Management	4	Aquatic Biological Resources
Amanda Ransom	Associate Environmental Planner	B.S. Environmental Policy/Planning	8	Aquatic Biological Resources
Dianne Simodynes	Senior Environmental Scientist	B.S. Biological Sciences; M.S. Aquatic Resource Management	18	Aquatic Biological Resources

38.5.6 RMEcon

Table 38-9 lists the staff from RMEcon who contributed to the preparation of this DEIR/EIS.

Table 38-9
RMEcon Staff Contributors to the DEIR/EIS

Name	Title	Qualifications	Years of Experience	Role
Roger Mann	Principal	Ph.D. Agricultural Economics and Economics	34	Economics Modeling

38.5.7 The Nature Conservancy

Table 38-10 lists the staff from The Nature Conservancy who contributed to the preparation of this DEIR/EIS.

Table 38-10
The Nature Conservancy Staff Contributors to the DEIR/EIS

Name	Title	Qualifications	Years of Experience	Role
Ryan Luster	Project Director-Sacramento River Project	B.A. Environmental Biology; M.S. Rangeland Ecology	17	Document Review: Sac EFT Report

38.5.8 URS

Table 38-11 lists the staff from URS who contributed to the preparation of this DEIR/EIS.

Table 38-11
URS Staff Contributors to the DEIR/EIS

Name	Title	Qualifications	Years of Experience	Role
Joseph Barnes	Water Resources Engineer	B.S. Civil Engineering; P.E.	41	Engineering
Nik Carlson	Senior Economist	M.A. Philosophy, Politics and Economics; M.P.P. Public Policy.	21	Socioeconomics
Janis Offermann	Senior Cultural Resources Specialist	B.A. Anthropology; M.A. Anthropology	36	Cultural Resources

39. EIR/EIS Distribution List

39.1 Document Availability

This chapter provides an overview of the locations where this Draft EIR/EIS is available for review, and lists the agencies and organizations that received copies of it. The public distribution of this Draft EIR/EIS emphasizes the use of electronic media to ensure cost-effective and broad availability to the public and interested parties. This Draft EIR/EIS is available on the internet on the U.S. Bureau of Reclamation's (Reclamation's) website: http://www.usbr.gov/mp/nodos/, and on the California Department of Water Resources' (DWR's) website: http://www.water.ca.gov/storage/northdelta/. The Draft EIR/EIS is also available for review at the following locations:

Mr. Sean Sou
California Department of Water Resources
901 P Street
Sacramento, CA. 95814
sean.sou@water.ca.gov
Fax: (916) 651-9292

Ms. Sharon McHale
U.S. Bureau of Reclamation
2800 Cottage Way, MP-700
Sacramento CA. 95825
smchale@usbr.gov
Fax: (916) 978-5094

39.2 Agencies and Organizations Receiving a Copy of the Draft EIR/EIS

This list includes agencies and organizations that were involved in the scoping process for the Project, requested a copy of the Draft EIR/EIS, and/or that may use the Draft EIR/EIS for discretionary or informational purposes. DWR and Reclamation continue to solicit input from these entities regarding the Project by encouraging review of this Draft EIR/EIS.

39.2.1 Federal Agencies

- National Marine Fisheries Service
- NOAA Fisheries
- Six Rivers National Forest
- United States House of Representatives
- United States Senate
- U.S. Army Corps of Engineers
- U.S. Bureau of Indian Affairs
- U.S. Bureau of Land Management
- U.S. Bureau of Reclamation
- U.S. Department of the Interior, Office of the Solicitor
- U.S. Department of the Interior
- U.S. Department of Justice
- U.S. Environmental Protection Agency
- U.S. Fish and Wildlife Service

39.2.2 State Agencies

- Arizona Department of Environmental Quality
- Assembly Republican Caucus
- CALFED Bay-Delta Program
- California Bay-Delta Authority
- California Department of Fish and Game
- California Department of Food and Agriculture
- California Department of Justice
- California Department of Parks and Recreation
- California Department of Transportation

- California Department of Water Resources
- California Regional Water Quality Control Board
- California State Assembly
- California State Clearinghouse
- California State Senate
- Colorado Department of Natural Resources
- Colorado Division of Water Resources
- Congressman Dennis Cardoza
- Congressman George Miller
- Congressman Jerry McNerney
- Congressman Michael Thompson
- Congresswoman Nancy Pelosi
- Idaho Department of Environmental Quality
- Idaho Department of Water Resources
- Kansas Department of Health & Environment
- Montana Department of Environmental Quality
- Montana Department of Fish Wildlife and Parks
- Montana Department of Natural Resources & Conservation
- Nebraska Department of Environmental Quality
- Nevada Department of Administration, Budget and Planning
- Nevada State Clearinghouse
- New Mexico Energy Minerals and Natural Resources Department
- New Mexico Environment Department
- North Dakota Department of Health, Environmental Health Section
- Northern California Power Agency
- Office of Assemblyman Dickerson
- Office of Assemblyman Roger Niello
- Office of Assemblymember Alan Nakanishi
- Office of Assemblymember Anna Caballero
- Office of Assemblymember Anthony Rendon
- Office of Assemblymember Cathleen Galgiani
- Office of Assemblymember Douglas La Malfa
- Office of Assemblymember Joel Anderson
- Office of Assemblymember Juan Vargas
- Office of Assemblymember Patty Berg
- Office of Assemblymember Paul Cook
- Office of Assemblymember Tom Berryhill
- Office of Congressman George Radanovich
- Office of Congressman Sam Farr
- Office of Congressman Tom McClintock
- Office of Congressman Wally Herger
- Office of Congresswoman Doris Matsui
- Office of Representative Wes Chesbro
- Office of Senator Dianne Feinstein
- Office of State Senator Abel Maldonado
- Office of State Senator Charles Calderon
- Office of State Senator Dean Florez
- Office of State Senator Elaine Alquist
- Office of State Senator Joseph Simitian
- Office of State Senator Patricia Wiggins
- Office of State Senator Robert Dutton
- Office of U.S. Senator Barbara Boxer
- Oklahoma Department of Environmental Quality
- Oregon Department of Environmental Quality
- Oregon Water Resources Congress
- Reclamation District No. 70
- Reclamation District No. 108
- Reclamation District No. 1004
- State of California Resources Agency
- State Water Resources Control Board
- Texas Commission on Environmental Quality
- Texas General Lands Office
- Texas Historical Commission
- Texas Office of Budget, Planning and Policy
- Utah Public Lands Policy Coordination Office
- Washington State Department of Natural Resources
- Wyoming Department of Environmental Quality

39.2.3 Regional and Local Entities

- Alameda County Assessor's Office
- Alpine County Board of Supervisors
- Anderson-Cottonwood Irrigation District
- Arvin-Edison Water Storage District
- Association of California Water Agencies
- Bella Vista Water District
- Board of Supervisors, Red Bluff
- Browns Valley Irrigation District
- Butte County Board of Supervisors
- Carter Mutual Water Company
- Centerville Community Services District
- City of Redding
- City of Shasta Lake
- City of West Sacramento
- City of Yuba
- Clear Creek Community Services District
- Colusa Basin Drainage District
- Colusa County
- Colusa County Board of Supervisors
- Colusa County Farm Bureau
- Colusa County Water District
- Colusa Drain Mutual Water Company
- Colusa Indian Community Council
- Colusa Rancheria
- Contra Costa County Board of Supervisors
- Contra Costa Water District
- Cortina Indian Rancheria
- Cortina Water District
- Davis Water District
- Del Norte County Board of Supervisors
- Delta Diablo Sanitation District
- Delta Stewardship Council
- Diablo Sanitation District
- Dunnigan Water District
- East Bay Municipal Utility District
- El Dorado County Board of Supervisors
- Feather Water District
- Fresno County
- Fresno County Board of Supervisors
- Fresno County Farm Bureau
- Friant Water Authority
- Glenn County
- Glenn County Board of Supervisors
- Glenn Valley Water District
- Glenn-Colusa Irrigation District
- Grasslands Water District
- Grindstone Rancheria
- Hoopa Valley Tribal Fisheries Department
- Hoopa Valley Tribe
- Humboldt County Board of Supervisors
- Imperial County Board of Supervisors
- Jackson Rancheria
- Kanawha Water District; Glide Water District
- Kern County Board of Supervisors
- Kern County Water Agency
- Kings County Board of Supervisors
- La Grande Water District
- Lassen County Board of Supervisors
- Madera County Board of Supervisors
- Madera Irrigation District
- Maxwell Irrigation District
- Maxwell Unified School District
- Metropolitan Water District of Southern California
- Modesto Irrigation District
- Modoc County Board of Supervisors
- Mountain Gate Community Services District
- Napa County Board of Supervisors
- Natomas Central Mutual Water Company
- Nevada County Board of Supervisors
- Northern California Water Association
- Orland Unit Water Users' Association
- Pacheco Water District
- Paskenta Band of Nomelaki Indians
- Placer County Board of Supervisors
- Pleasant Grove-Verona Mutual Water Company
- Pleasant Valley Water District
- Plumas County Board of Supervisors
- Princeton-Cordora-Glenn Irrigation District
- Proberta Water District
- Provident Irrigation District
- Redding Rancheria
- Regional Council of Rural Counties
- Robinson Rancheria Band of Pomo Indians
- Ramsey Rancheria of Wintun Indians
- Sacramento Area Flood Control Agency

- Sacramento County
- Sacramento County Board of Supervisors
- Sacramento Municipal Utility District
- San Benito County Water District
- San Francisco Public Utilities Commission
- San Joaquin County Board of Supervisors
- San Juan Water District
- San Luis & Delta Mendota Water Authority
- San Luis Obispo County Board of Supervisors
- Santa Barbara County Board of Supervisors
- Santa Clara Valley Water District
- South Dakota Department of Environment & Natural Resources
- Shasta Community Services District
- Shasta County Board of Supervisors
- Shasta County Library
- Shasta County Water Agency
- Sierra County Board of Supervisors
- Siskiyou County Board of Supervisors
- Sites Project Joint Powers Authority
- Solano County Board of Supervisors
- South Delta Water Agency
- South San Joaquin Irrigation District
- Stockton East Water District
- Stony Creek Water District
- Sutter Mutual Water Company
- Swinford Tract Irrigation District
- Tehama County Board of Supervisors
- Tehama County Flood Control and Water Conservation District
- Tehama-Colusa Canal Authority
- Thomes Creek Water District
- Trinity County Board of Supervisors
- University of California Riverside
- Upper Lake Band of Pomo Indians
- Ventura County Board of Supervisors
- Western Area Power Administration
- Westlands Water District
- Yolo County
- Yolo County Board of Supervisors
- Yolo County Flood Control & Water Conservation District
