Runoff from 11 stream systems draining the foothill and valley floor watersheds contribute flow to the Colusa Basin Drain. This natural historic drainage system for the Colusa Basin has been almost entirely cut off from receiving floodwaters of the Sacramento River by an extensive levee system (except when flood flows on the Sacramento River exceed 300,000 cfs near Ord Ferry). In general, the Colusa Basin Drain conveys flood flows from November through March and agricultural irrigation and drainage flows from April through October. Its northern half is unleveed. Beginning south of Colusa, left bank levees extend southward to its confluence with the Sacramento River. Both Reclamation District 787 and Reclamation District 108 pump drainage from interior lands surrounded by levees to either the Sacramento River or the Colusa Basin Drain.

Both flood and drainage flows are regulated by the Knights Landing Outfall Gates. These gates prevent Sacramento River water from entering the basin. The magnitude of gravity flow from the Colusa Basin Drain is controlled by the water surface elevation in the Sacramento River and the gate openings.

The Knights Landing Ridge Cut provides flood relief to the Colusa Basin Drain by conveying flood and drainage water to the Yolo Bypass if discharge to the river cannot occur. The Knights Landing Ridge Cut design capacity is 20,000 cfs (DWR, 2010). The combined capacity of the Ridge Cut and the Outfall gates are insufficient at times to carry flood flows out of the basin, resulting in backwater conditions and inundation along the drain, especially in its lower reaches. Areas of 100-year flood inundation (Figure 9-4) reflect the limited capacity of the Knights Landing Ridge Cut and the Colusa Basin Drain’s 100-year flood flow at SR 20 of 34,500 cfs (FEMA, 2003). These problems have been the focus of ongoing studies by the Colusa Basin Drainage District to reduce damages to agricultural production.

9.3 Environmental Impacts/Environmental Consequences

9.3.1 Regulatory Setting

Flood hydrology and flood control are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

9.3.1.1 Federal Plans, Policies, and Regulations

- Executive Order 11988 (Floodplain Management)
- Clean Water Act, Section 408

- Federal Emergency Management Agency's National Flood Insurance Program
- Federal Emergency Management Agency Flood Zones and Flood Zone Regulations
- Federal Emergency Management Agency Levee Design and Maintenance Regulations
- Federal Emergency Management Agency 100-year Protection Standard
- Flood Control Act of 1936
- USACE Rehabilitation and Inspection Program
- Operations and Maintenance Controls, Flood Control Projects
- Rivers and Harbors Act of 1899

9.3.1.2 State Plans, Policies, and Regulations

- Central Valley Flood Protection Board Approval
- Assembly Bill 1200
- FloodSAFE California Initiative
- The State Plan of Flood Control Descriptive Document
- Senate Bill 5
- Assembly Bill 162
- California Water Code Section 8609
- California Water Code Division 3: Dams and Reservoirs
- Sacramento-San Joaquin River Basin Comprehensive Study
- Sacramento River Flood Control Project
- Sacramento River Bank Protection Project

9.3.1.3 Regional and Local Plans, Policies, and Regulations

- Colusa County General Plan
- Glenn County General Plan
- Colusa County Code, Chapter 33: Flood Damage Prevention
- Colusa County Flood Control and Conservation District
- Colusa County Floodplain Administrator

9.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for flood control and management:

Would the Project:

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?
- Place within a 100-year flood hazard area structures which would impede or redirect flood flows?
- Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?

- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?
- Place within a 100-year flood hazard area structures which would impede or redirect flood flows?
- Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?

9.3.3 Impact Assessment Assumptions and Methodology

9.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to flood control and management:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.

- All dams would be designed to be resistant to various failure modes. Dam safety at both Golden Gate and Sites dams would be monitored by instrumentation, measuring such parameters as seepage, settlement and earthquake-induced accelerations.
- Sites Reservoir would be designed to safely store the Probable Maximum Flood (PMF) without overtopping the dam. For both reservoir size options (i.e., 1.27-MAF and 1.81-MAF) included in the alternatives, the design includes a storage buffer more than 2.5 times larger than required to hold the PMF estimated inflow.
- All three proposed reservoirs (Sites, Holthouse, and TRR) would be designed with emergency spillways to prevent overtopping the dams.
- Sites Reservoir, given its proposed storage capacity, would be designed for a required maximum emergency drawdown release of 23,000 cfs, which would be released through the inlet/outlet works to quickly drain the reservoir, if needed. In addition, the Holthouse Reservoir design would require a spillway sufficient to pass the required Sites Reservoir maximum emergency drawdown release flow of 23,000 cfs.

9.3.3.2 Methodology

The SWP and CVP operations model (water resources simulation model known as CALSIM II) was used to simulate CVP and SWP operations to determine the surface water flows, storages, and deliveries associated with the baseline (i.e., Existing Conditions), No Project/No Action Alternative, and the three action alternatives (Alternatives A, B, and C). A detailed description of the assumptions used for modeling the baselines and the alternatives is included in Appendix 6A. The water resources system models used are described in Appendix 6B. The CALSIM II model was used to simulate system operations for an 82-year period using a monthly time-step. The model included assumptions regarding facilities, land use, water supply contracts, and regulatory requirements for Existing Conditions and the No Project/No Action Alternative. The historical 82-year flow record (1922 to 2003), adjusted for the influences of land use changes and upstream flow regulation, was used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities were represented by a network of arcs and nodes. CALSIM II used a mass balance approach to route water through this network. Simulated flows represented mean flows for the month; reservoir storage volumes corresponded to end-of-month storage.

CALSIM II modeled a complex and extensive set of regulatory standards and operations criteria. Descriptions of the modeling assumptions are contained in Appendix 6A. The analysis conducted used the best available tools to approximate systemwide changes in storage, flow, salinity, and reservoir system reoperation associated with the alternatives.

CALSIM II modeling followed all flood control operations rules for existing reservoirs and flood management facilities (i.e., encroachments into the flood control space of existing reservoirs was not allowed). However, CALSIM II's predictive capability is limited and cannot readily be applied to analyzing flood flows and hourly, daily, or weekly time steps for hydrologic conditions. Changes to the extents of the Sacramento River 100-year floodplain cannot be determined fully without operation criteria and model output for hourly, daily, or weekly time steps for hydrologic conditions. CALSIM II uses a monthly time step, which is inappropriate for flood control analysis. Thus, CALSIM II was not used to evaluate changes to the Sacramento River 100-year floodplain.

Of the five large reservoirs in the Secondary Study Area included in the CALSIM II operations modeling, only Shasta, Oroville, and Folsom reservoirs are operated officially with flood control as a primary objective.

9.3.4 Topics Eliminated from Further Analytical Consideration

The proposed Project facilities would all be located in rural and agricultural areas that are not serviced by existing or planned stormwater drainage systems. Therefore, the potential impact to a stormwater drainage system (**Impact Flood-4**) from Project implementation is not relevant to the Project, and is not discussed in this chapter.

In addition, no new housing is proposed as part of the Project. Therefore, potential impacts from placing housing within a flood hazard area (**Impact Flood-5**) from Project implementation is not relevant to the Project, and is not discussed in this chapter.

9.3.5 Impacts Associated with the No Project/No Action Alternative

9.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use, and San Luis Reservoir

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for altering existing drainage patterns, stream courses, or surface runoff has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could result in increased demand for water supplies within the Extended Study Area service areas. Changes in water supply deliveries and the possible associated changes in water elevation fluctuations at San Luis Reservoir would not alter existing drainage patterns and stream courses, or increase surface runoff. A larger population, with the expected increase in urban development, could be expected to alter existing drainage patterns and stream courses, and increase surface runoff. These impacts that would occur as a result of the increased population would be managed at the local level (e.g., cities and counties) in accordance with those agencies' regulations. Therefore, **there would not be a substantial adverse effect,** when compared to Existing Conditions.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Refer to the **Impact Flood-1** discussion. That discussion is also applicable to flood flows.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

Refer to the **Impact Flood-1** discussion. That discussion is also applicable to flooding as a result of the failure of a levee or dam.

9.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

Refer to the **Impact Flood-1** discussion for the Extended Study Area. That discussion is also applicable to the Secondary Study Area.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Refer to the **Impact Flood-1** discussion for the Extended Study Area. That discussion is also applicable to the Secondary Study Area.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

If the No Project/No Action Alternative is implemented, current levels of flooding within the Secondary Study Area would not increase, when compared to Existing Conditions. The 100-year flood flows and resulting flood levels within the greater Sacramento River Basin and its associated flood control features would remain unchanged. In turn, the 100-year discharge and inundation areas, as shown on the FEMA floodplain maps, would remain unchanged with the No Project/No Action Alternative.

No Project/No Action Alternative operations modeling results indicate minor changes in Sacramento River basin reservoir levels and flood flows as indicated by end of month storage/water surface elevation and river flow conditions provided in Appendix 6B.

Tables 9-4, 9-5, 9-6, and 9-7 indicate potential impacts to several flood control reservoirs in the Secondary Study Area as a measure of surface water elevation.

Percent Difference (%)	-0.5	-0.4	-0.4	-0.1	0.1	0.2	0.0	0.0	-0.2	-0.3	-0.7	-0.4

[a]Based on the 82-year simulation period.
[b]Relative difference of the monthly average.
[c]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Table 9-4 shows the average Shasta Lake end of the month water surface elevation for the No Project/No Action Alternative, when compared to Existing Conditions over the long-term and by water year type. The Wet and Above Normal year types are listed in the table because flooding is most likely to occur during these water year types. The long-term average water surface elevation changes would range between -0.1 and 0.1 percent. Changes for Wet and Above Normal years would range between 0.2 and 0.0 percent for both year types.

Tables 9-5, 9-6, and 9-7 indicate similar impacts at Trinity, Oroville, and Folsom reservoirs. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** to flood risks, including potential flooding due to a levee or dam failure, when compared to Existing Conditions.

9.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

Projects considered within the No Project/No Action Alternative are not located within the Primary Study Area. In addition, none of the proposed Project facilities would be constructed if this alternative is implemented. Local hydrology and drainage within the Primary Study Area would, therefore, be expected to remain substantially the same. Implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Refer to the **Impact Flood-1** discussion. That discussion is also applicable to the Primary Study Area.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

Refer to the **Flood-1** discussion. All existing facilities would be subject to current levels of flooding. The 100-year flood flows and resulting levels for Funks and Stone Corral creeks and the Colusa Basin Drain would remain unchanged. The 100-year discharge and inundation as shown on the FEMA floodplain maps would also likely remain unchanged with the No Project/No Action Alternative. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on flood risks, including potential flooding due to a levee or dam failure, when compared to Existing Conditions.

9.3.6 Impacts Associated with Alternative A

9.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use, and San Luis Reservoir

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

There would be no direct Project-related construction or maintenance occurring within the CVP and SWP service areas of the Extended Study Area; therefore, no Project-related flooding would occur, resulting in **no impact** in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

If Alternative A is implemented, changes in SWP and CVP service area water supply deliveries and surface water elevation fluctuations at San Luis Reservoir would not alter existing drainage patterns, stream courses, or surface runoff within the Extended Study Area. Therefore, operation of Alternative A would result in **no impact** on existing drainage patterns, stream courses, or surface runoff within the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

If Alternative A is implemented, no new Project-related structures would be constructed within the Extended Study Area, thus no 100-year flood flows would be impeded or redirected by their placement. Therefore, operation of Alternative A would result in **no impact** on 100-year flood flows within the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

San Luis Reservoir is operated entirely as a joint CVP and SWP supply storage reservoir and is not operated for flood control purposes. If Alternative A is implemented, water level fluctuations that would occur at San Luis Reservoir would fall within the historic range of operation and would not expose people or structures to any additional flooding risks related to dam failure. Thus, operation of Alternative A would result in **no impact** due to increased flooding risks, including potential flooding due a levee or dam failure, within the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

9.3.6.2 Secondary Study Area - Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

If Alternative A is implemented, no direct Project-related construction would occur at any of the above-listed facilities or areas within the Secondary Study Area other than the installation of one additional pump into an existing bay at the Red Bluff Pumping Plant. The additional pump would not alter the existing drainage pattern of the site, alter a stream course, or increase the amount of surface runoff. Therefore, the installation of a pump at the existing Red Bluff Pumping Plant would result in **no impact** on existing drainage patterns, stream courses, or surface runoff within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

If Alternative A is implemented, a new pump at the Red Bluff Pumping Plant would be installed in an existing pump bay. It would not impede or redirect 100-year flood flows. Therefore, construction, operation, and maintenance of Alternative A would result in **no impact** on 100-year flood flows within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

If Alternative A is implemented, the additional pump at the Red Bluff Pumping Plant would be installed in an existing bay and would not modify any existing levees. Therefore, installation of the additional pump would have no effect on existing dams or levees within the Secondary Study Area. When compared to Existing Conditions and the No Project/No Action Alternative, construction, operation and maintenance of Alternative A would result in **no impact** due to increased flooding risks, including potential flooding due a levee or dam failure**.**

Tables 9-8 through 9-15 indicate potential minor operational impacts to several flood control reservoirs in the Secondary Study Area if Alternative A is implemented as a measure of average surface water elevation.

Table 9-8 shows the average Shasta Lake end of the month water surface elevation for Alternative A, when compared to Existing Conditions over the long-term and by water year type. The Wet and Above Normal year types are shown because flooding is most likely to occur during these water year types. Long-term average water surface elevation changes would range between 0.1 and 0.6 percent. Changes during Wet years would range between 0.0 and 0.2 percent, and changes during Above Normal years would range between -0.2 and 0.3 percent.

Table 9-9 shows the same information for Shasta Lake, when compared to the No Project/No Action Alternative. Long-term average water surface elevation changes would range between 0.0 and 0.6 percent. Wet year changes would range between 0.0 and 0.3 percent, and Above Normal year changes would range between -0.1 and 0.5 percent.

Tables 9-10 through 9-15 indicate similar impacts at Trinity, Oroville, and Folsom reservoirs.

As indicated by the water surface elevation data, coordinated operation with Sites Reservoir would not increase flood risks due to significantly higher water surface elevations in flood control reservoirs in the Secondary Study Area during Wet and Above Normal water year types. Therefore, compared to both Existing Conditions and the No Project/No Action Alternative, construction, operation and maintenance of Alternative A would result in a **less-than-significant impact** due to increased flooding risks, including potential flooding due a levee or dam failure, within the Secondary Study Area.

Table 9-8

9.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area and Sites Reservoir Dams

Most reservoirs are designed as "on-stream" reservoirs. On-stream reservoirs are sited to directly dam up an active river channel or in a location where they would receive most of their inflow by capturing natural runoff. By comparison, off-stream reservoirs are not designed to dam up a natural river course and are not sited in a location where they receive the majority of their inflow naturally. Instead, off-stream reservoirs receive their inflow primarily via human-made diversions and are sited in ideal locations where they can store much-needed water for flexible distribution. Examples of California off-stream reservoirs are the SWP-CVP jointly-used San Luis Reservoir, Contra Costa Water District's Los Vaqueros Reservoir, and Metropolitan Water District's Eastside Reservoir (Diamond Valley Lake).

Sites Reservoir is also designed as an off-stream storage facility. Sites Reservoir would receive very little natural runoff from its 83-square mile watershed. Average annual natural inflow into the reservoir would be approximately 15,000 acre-feet which is little more than 1 percent of the Alternative A designed 1.27-MAF reservoir storage capacity. By comparison, the average annual inflow for Lake Oroville is approximately 4.2 MAF, or approximately 120 percent of Lake Oroville's approximately 3.5-MAF storage capacity. Sites Reservoir would be filled predominantly by diversions directly or indirectly from the Sacramento River using existing or new conveyances. Construction of the 1.27-MAF reservoir includes building two main dams and seven saddle dams. The crest elevation of all dams would be 500 feet, providing 20 feet of freeboard above the maximum operating level of 480 feet. The designed emergency spillway elevation would be at 486.5 feet.

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

Flows from Funks and Stone Corral creeks would be impounded and diverted during the construction of Golden Gate and Sites dams. Diversion of Funks and Stone Corral creeks would likely be accomplished by passing storm flows through buried corrugated metal pipe or concrete pipe around the construction areas.

During Project construction, a cofferdam would be installed upstream of the Sites and Golden Gate dams around the dams' construction work areas to retain storm flows entering the reservoir basin from Funks Creek and Stone Corral Creek and thereby keep the dam construction work area dry. These cofferdams would be designed to retain anticipated creek runoff in the reservoir basin during the construction period. During the construction period, storm flows would collect within the proposed reservoir basin behind the cofferdam and be released incrementally through a bypass around the Sites Dam area and discharged downstream. Storm flows would be managed during dam construction so as not to increase the downstream flood potential, resulting in a **less-than-significant impact** when compared to Existing Conditions and the No Project/No Action Alternative. Post-construction, Sites and Golden Gate dams would continue to alter existing flows on Funks and Stone Corral creeks; most water would be released through the reservoir inlet/outlet works. Thus, operation of Sites and Golden Gate dams would result in a **significant impact** due to alteration of a river or stream course, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of Sites Reservoir would decrease the magnitude of the 100-year peak flow event on Funks and Stone Corral creeks downstream of the dams by having the capacity to contain flood flows and control the release of water downstream. With implementation of Alternative A, of the 22,200 acres of land prone to flooding downstream of the proposed Sites and Golden Gate dam locations, approximately 21 percent (4,660 acres) would experience a reduction in flood-related damages. In addition to increasing the level of protection in the Funks Creek and Stone Corral Creek watersheds, a 100-year level of protection would be achieved for approximately 4,025 acres in the Colusa Basin. Based on a 100-year flood event, the flood risk would be reduced for a total of 8,685 acres (Reclamation, 2012). Therefore, operation of Sites Reservoir would result in a **potentially beneficial effect** by reducing the amount and rate of surface water runoff that has historically flooded areas downstream of the dams, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities associated with the reservoir (e.g., law enforcement and garbage removal) and dams (equipment, foundation, and embankment inspections and repairs; debris and vegetation removal) would not alter existing drainage patterns or the course of a stream and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Both Golden Gate and Sites dams would be located within 100-year flood hazard areas associated with Funks and Stone Corral creeks. Neither dam would impede or redirect flood flows in a manner that would increase potential downstream flood impacts. In contrast, both creeks would be impounded and diverted in a controlled manner during the construction of the dams, and operation of the dams would help to alleviate potential downstream flood flows on these creeks by capturing watershed runoff. Therefore, construction and operation of both dams would result in a **potentially beneficial effect** on 100-year flood flows downstream of the dam, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities associated with the dams, including equipment, foundation, and embankment inspections and repairs would not impede or redirect flood flows and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

DWR has prepared a potential dam break inundation map that reflects the inundation scenario associated with the future facility (Figure 9-5). The flood wave that would result from a hypothetical breach of Golden Gate Dam or Sites Dam has a small probability of occurring, but would present a significant hazard to both occupied and non-occupied structures downstream of Sites Reservoir. The peak outflow from a breach of Sites Reservoir is estimated at 2,078,000 cfs. The flood wave would flow east following the natural streambeds and would fan out to the relatively flat terrain of the Sacramento Valley before reaching the City of Maxwell and I-5. The estimated flow velocity at Maxwell and I-5 would be 4.5 feet per second and the maximum depth would be 10 feet. The flood wave would then continue approximately 13 miles east to the City of Colusa and the Sacramento River. The flood wave would then be impeded by the west levee of the Sacramento River. The flood would reach a depth of 22 feet (upslope of the Sacramento River levee) (DWR, 2005).

However, the Sites Reservoir dams would be designed and constructed pursuant to conservative guidelines and criteria designed to prevent failure. The designs would incorporate multiple lines of defense or design redundancy as required to meet both DWR's Division of Safety of Dams (DSOD) and Reclamation design standards. For example, the dam would be designed to withstand the largest and strongest earthquake (Maximum Credible Earthquake) as well as the largest possible flood (Probable Maximum Flood). These design standards would protect the dam from seismic or other catastrophic failure.

In addition, operation of Golden Gate and Sites dams would be monitored by instrumentation measuring such parameters as seepage, settlement, and earthquake-induced accelerations, which could provide early warning signs of potential dam failure. With modern design criteria, construction practices, and post-construction monitoring, the probability of dam failure and subsequent impacts is extremely small. Therefore, Sites Reservoir and Dams would result in a **less-than-significant impact** on the risk of loss, injury, or death due to flooding caused by dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Both DSOD and Reclamation dam safety guidelines establish criteria for handling the emergency evacuation of a reservoir and the design of related facilities, such as the Sites Dam emergency spillway and outlet structure, required to handle the evacuation flows. Although the NODOS Feasibility Study follows DSOD design standards, DSOD's emergency evacuation criteria are actually more conservative than Reclamation's evacuation criteria. Thus, Sites Dam and the associated facilities required to handle the emergency evacuation flows would meet both DSOD and Reclamation standards (Reclamation, 2012; Reclamation, 1990).

Based on DSOD guidelines, Sites Reservoir would include an emergency spillway to release flows with an elevation set to the potential PMF water surface elevation. The proposed emergency spillway design is a simple "morning glory" intake and outflow pipe structure located in Saddle Dam 6, which would allow for overflow spill if the water surface reaches the PMF elevation. However, as an offstream reservoir, Sites Reservoir would be filled by Project-controlled diversions and would receive little inflow from the local creeks. Generally, Sites Reservoir would fill to its highest operating levels by spring to early summer, and then the levels would be drawn down during summer for water supply uses. By the time of the rainy season, when a 100-year flood is generally anticipated, the reservoir would have more than enough capacity to handle large storm events from the local creeks, even at full operating capacity.

In addition, both DSOD and Reclamation require that large reservoirs, such as Sites Reservoir, have facilities capable of allowing rapid emergency drawdown of the water in the reservoir in the event of an unsafe condition at the dam. DSOD emergency drawdown (or "evacuation") guidelines for a large reservoir require that the dam facilities have the capability to lower the reservoir level by an amount equal to 10 percent of the hydraulic head[2] behind the dam in 10 days, and to evacuate the entire reservoir in 120 days. Sites Reservoir would accomplish this drawdown via the outlet tunnel in the inlet/outlet structure, which could discharge emergency release flows directly into Funks Creek; some of this drawdown could be attenuated by Holthouse Reservoir or released via the Delevan Pipeline, the T-C Canal, or the GCID Canal. The currently designed maximum discharge rate is 23,000 cfs, which exceeds the required 10-day average discharge rate. However, the risk of an event requiring such an emergency release remains very small. Because the probability of the emergency release event occurring is so remote, Sites Reservoir and Dams would have a

[2]The hydraulic head is the difference between the normal maximum water surface elevation and the dead pool (i.e., the water level below which water can no longer be discharged) elevation

less-than-significant impact on the risk of loss, injury, or death due to flooding caused by emergency reservoir releases, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Tunnel, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The Sites Pumping/Generating Plant, Tunnel, Electrical Switchyard, and Field Office Maintenance Yard would not be located directly on the Funks Creek channel alignment. Therefore, construction activities associated with these facilities would not alter existing drainage patterns or alter the course of Funks Creek. Post-construction, the footprint for these proposed facilities is not expected to substantially alter the existing drainage patterns in that area. In addition, the new impervious areas associated with these facilities would not be large enough to cause a significant increase in surface runoff. Maintenance activities, including washing and cleaning of equipment, inspections, and fence maintenance, would not alter drainage patterns or stream courses. Therefore, construction, operation, and maintenance of these facilities would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Most of the footprint of the Sites Reservoir Inlet/Outlet Structure would not be located directly on the Funks Creek channel alignment. However, the footprint of the outlet approach channel to Holthouse Reservoir would cross the Funks Creek channel and would permanently remove approximately 0.5 mile of Funks Creek immediately upstream of the existing Funks Reservoir. During construction, Funks Creek would be diverted. During operation, Funks Creek would flow into the approach channel upstream of the existing Funks Reservoir. Although slight alteration of the course of the creek would occur, it would not result in flooding because diverted flows would be controlled during construction, and upstream flows would be controlled by releases from Sites Reservoir during operation. Maintenance activities, such as inspections, would not alter drainage patterns or stream courses. Therefore, construction, operation, and maintenance of the inlet/outlet structure would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

The proposed Sites Pumping/Generating Plant, Tunnel, Reservoir Inlet/Outlet Structure, Electrical Switchyard, and Field Office Maintenance Yard would be constructed within the 100-year flood hazard area associated with Funks Creek. However, during construction, the flows from Funks Creek would be controlled with a diversion system. During operation, Sites Reservoir would substantially reduce flood flows associated with Funks Creek by capturing runoff from a large portion of the upstream watershed. The maintenance activities would not place structures within a flood hazard area. Therefore, these facilities are not expected to significantly impede or redirect 100-year flood flows. Construction, operation, and maintenance of these facilities would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

No dams or levees are associated with these proposed Project facilities. Therefore, construction, operation, and maintenance of these facilities would result in **no impact** due to increased flood risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The proposed Recreation Areas would encompass a total of approximately 1,205 acres, which is less than two square miles. Assuming the two square miles were completely covered by new impervious surface areas, such as asphalt parking lots, this would still account for only approximately 2 percent of the 83-square-mile Sites Reservoir watershed drainage area, which is too small to cause a significant difference in runoff from the runoff that currently occurs in that area (Reclamation, 2012). Therefore, construction, operation, and maintenance of the proposed Recreation Areas would not substantially alter the existing drainage patterns or a stream or river course, nor substantially increase surface runoff, resulting in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

If Alternative A is implemented, the proposed Recreation Areas would not be developed within a 100-year flood hazard area. Therefore, their construction, operation, and maintenance would result in **no impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

If Alternative A is implemented, there would be no dams or levees associated with the proposed Recreation Areas. Therefore, construction, operation, and maintenance of the proposed Recreation Areas would result in **no impact** due to increased flood risks, including potential flooding due to a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

If Alternative A is implemented, construction activities would include the relocation of portions of the existing Maxwell Sites Road and Sites Lodoga Road, and construction of the South Bridge across Sites Reservoir. This road relocation alignment, which includes the new South Bridge crossing, would be paved during construction and maintained as such during operation, but would not add significant new paved road area relative to the existing roadway alignment. In addition, this road relocation alignment would not cross any streams, and therefore, would not alter the course of a stream during construction or operation.

The temporary construction roads and additional permanent access roads, such as those to the proposed recreation areas and Project facilities, would be constructed and operated as unpaved (gravel) roads, and in turn, would not significantly contribute to surface runoff. In addition, these roads would not cross any streams, and therefore, would not alter the course of a stream during construction or operation. The only exception would be the proposed Eastside Road, which would be paved for approximately four miles at its southern end, and would cross Funks Creek approximately 0.4 mile downstream of the proposed Golden Gate Dam. The portion of the road that would be paved during construction and maintained as such during operation would not add significant new paved road area. The Funks Creek crossing would require the installation of a culvert; this activity would occur during the period that the creek is diverted. Although slight alteration of the course of the creek would occur during diversion, it would not result in flooding because bypass flows would be controlled during construction, and the course of the stream would be restored prior to operation. During operation, upstream flows would be controlled by releases from Sites Reservoir.

Road maintenance activities, such as chip sealing, patching, grading, vegetation control, and repair of damaged guardrails or fencing, and minor bridge or culvert maintenance, would consist of debris removal, and would not alter existing drainage patterns or alter the course of a stream. Therefore, construction, operation, and maintenance of the road relocations, new South Bridge, and new access roads combined would not substantially alter existing drainage patterns or stream courses and would not increase surface runoff, resulting in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

If Alternative A is implemented, the northeast end of the proposed Sulphur Gap Road, where it would connect with the existing Maxwell Sites Road, would be constructed within a portion of Stone Corral Creek's 100-year flood hazard area. However, only a small portion of flood hazard area would be affected by the proposed roadway during construction, and during operation, Sites Reservoir would substantially reduce flood flows associated with Stone Corral Creek by capturing runoff from a large portion of the upstream watershed. Road maintenance activities would not place additional structures within the flood hazard area. Therefore, construction, operation, and maintenance of the proposed road would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

If Alternative A is implemented, there would be no dams or levees associated with the proposed Road Relocations and South Bridge. Therefore, the construction, operation, and maintenance of the Road Relocations and the South Bridge would result in **no impact** due to increased flood risks including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The proposed GCID Canal Facilities modifications (including the new headgate structure, 200 feet of canal lining, and railroad siphon replacement) would not drastically alter the existing canal structure. In addition, operation and maintenance activities are expected to be similar to those of the existing canal. Construction, operation, and maintenance activities associated with the GCID Canal Facilities modifications would not alter the course of a natural stream or river and would not substantially alter existing drainage patterns or increase runoff. Therefore, construction, operation, and maintenance of the proposed GCID Canal Facilities modifications would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Most of the existing GCID Canal does not pass through a 100-year flood hazard area except for the north end, which passes through a 100-year flood hazard area associated with primarily Colusa Basin Drain flows. However, the proposed GCID Canal Facilities modifications that would occur during Project construction would be made to the existing canal and thus would not further impede or redirect 100-year flood flows more than the existing canal. In addition, operation and maintenance activities would be similar to those performed at the existing canal. Therefore, construction, operation, and maintenance of the proposed GCID Canal Facilities modifications would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

The existing GCID Canal Facilities are located on a non-leveed bypass channel that diverts Sacramento River flows. Because no levees or dams are associated with the GCID Canal Facilities, construction, operation, and maintenance the proposed modifications would have no impact on levees or dams, and therefore, no associated potential flood risk impacts due to levee or dam failure. Therefore, construction, operation, and maintenance of the proposed GCID Canal Facilities modifications would result in **no impact** due to increased flood risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Preliminary feasibility studies indicate that Holthouse Reservoir would need an active storage of approximately 6,500 acre-feet (approximately three times larger than the existing Funks Reservoir storage), covering a surface area of 530 acres (approximately 2.3 times larger than the existing Funks Reservoir surface area) and with maximum dam embankment heights of 45 feet above existing grade (Reclamation, 2012).

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

Dredging of the existing Funks Reservoir, as well as the construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard, would require the diversion of Funks Creek. Although alteration of the course of the creek would occur, it would not result in flooding because bypass flows would be controlled during construction.

The proposed Funks Reservoir enlargement that would result from construction of the adjacent Holthouse Reservoir would not be a large enough increase to substantially alter drainage patterns around the existing Funks Reservoir. In addition, during operation, the upstream Sites Reservoir would substantially reduce flood flows associated with Funks Creek by capturing runoff from a large portion of the upstream watershed. Operation and maintenance activities associated with the enlarged Holthouse Reservoir Complex are expected to be similar to those of the existing Funks Reservoir and would not increase the risk of flooding from existing conditions in the area. Maintenance of the existing Funks Reservoir would include road, vegetation, and fence maintenance, and debris removal. Funks Reservoir is also drained annually. These maintenance activities are expected to be the same for Holthouse Reservoir. Maintenance of the electrical switchyard may include annual washing and cleaning of insulating equipment, and landscape maintenance; these activities would not affect drainage patterns. Therefore, construction, operation, and maintenance of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard, and dredging of the existing Funks Reservoir, would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Funks Reservoir is an existing structure; an evaluation of **Impact Flood-2** is therefore not applicable to that Project feature. The Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would be constructed within a Special Flood Hazard Area associated with Funks Creek 100-year flood flows. However, during construction, the flows from Funks Creek would be controlled with a diversion system. During operation, the larger Holthouse Reservoir would likely not impede 100-year flood flows more so than the existing Funks Reservoir, which is located within the same Special Flood Hazard Area. The four-acre Holthouse Reservoir Electrical Switchyard would have a gravel base, and would not be expected to significantly impede 100-year flood flows. In addition, operation of Sites Reservoir would substantially reduce flood flows associated with Funks Creek by capturing runoff from a large portion of the upstream watershed. Maintenance activities are expected to be similar to those of the existing Funks Reservoir for Holthouse Reservoir, and would involve washing and vegetation control for the electrical switchyard; these activities would not place additional structures within the Special Flood Hazard Area.

Therefore, construction, operation, and maintenance of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

As designed, the 6,500-acre-foot Holthouse Reservoir, which is an expansion of the existing Funks Reservoir, would be a jurisdictional reservoir[3]. For jurisdictional reservoirs, DSOD oversees the dam design and permitting processes and usually requires a dam break analysis as part of the design and permitting process. The reservoir design is not detailed enough at this stage for a quantitative analysis. However, Holthouse Dam would be designed and constructed pursuant to the same conservative guidelines and criteria designed to prevent failure as described for Sites Reservoir. These design standards would protect the dam from seismic or other failure, and would, therefore, result in a **less-than-significant impact** on the risk of loss, injury, or death due to flooding caused by dam failure, when compared to Existing Conditions and the No Project/No Action Alternative. Holthouse Reservoir would also be constructed with a maximum emergency spillway discharge capacity of 23,000 cfs to pass the equivalent Sites Reservoir emergency drawdown flows required by DSOD, which would be discharged directly into Funks Creek via the inlet/outlet works (Reclamation, 2012). Some of this emergency drawdown could also be attenuated by the TRR, or could be released via the Delevan Pipeline, the T-C Canal, or the GCID Canal. However, the risk of an event requiring such an emergency release remains very small. Because the probability of the emergency release event occurring is so remote, the Holthouse Reservoir Complex would have a **less-than-significant impact** on the risk of loss, injury, or death due to flooding caused by emergency reservoir releases, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities associated with Holthouse Reservoir are expected to be similar to those of the existing Funks Reservoir and would not be expected to exposed people to increased flood risks. Therefore, maintenance of the Holthouse Reservoir Complex would result in a **less-than-significant impact** on the exposure of people to increased flood risks, including potential flooding due to a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pipeline, and Terminal Regulating Reservoir Pipeline Road

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The portion of these TRR facilities that would be constructed and operated above ground would not be located near a stream and do not have a large enough footprint to substantially alter existing drainage patterns. In addition, operation of the upstream Sites Reservoir would substantially reduce flood flows in this area associated with Funks Creek by capturing runoff from a large portion of the upstream watershed, as well as by limiting post-construction flows to Funks Creek downstream of Golden Gate Dam.

Maintenance activities, such as vegetation clearing and necessary repairs to the TRR Pipeline Road, would not substantially affect runoff in the area. However, the draining and dredging of the reservoir,

[3] A Jurisdictional Reservoir is a reservoir for which DSOD has design and construction permitting jurisdiction. A main threshold for DSOD jurisdiction is a minimum six foot height requirement.

which would occur every seven to 10 years depending on sediment accumulation, would require releases from the reservoir to Funks Creek via the TRR to Funks Creek Pipeline. Although these releases would increase creek flows, releases would be controlled with an energy dissipater and small concrete structure at the terminal end of the pipeline to avoid exceeding the capacity of the creek channel. Therefore, construction, operation, and maintenance of these TRR facilities would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

The TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, and TRR Pipeline Road would be constructed and operated within a 100-year flood hazard area associated with Funks Creek. These above-ground structures may impede 100-year flood flows; however, Sites Reservoir would substantially reduce these 100-year flood flows associated with Funks Creek by capturing runoff from a large portion of the upstream watershed. Maintenance activities associated with these facilities would not place additional structures within the flood hazard area. Therefore, construction, operation and maintenance of these TRR facilities would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

The TRR Pipeline and TRR to Funks Creek Pipeline would both be constructed within a 100-year flood hazard area associated with Funks Creek. Both pipelines would be buried a minimum of 10 feet (to top of pipe) below the ground surface. The only above-ground features associated with both pipelines would be blow off and air valves, each of which would occupy a small area of land. Once installed, surface grading would be restored above the pipelines such that operation of these pipelines would not significantly impede or redirect flood flows or increase flooding hazards in other areas. The pipelines would thus not impede 100-year flood flows. Therefore, construction, operation and maintenance of the TRR Pipeline and the TRR to Funks Creek Pipeline would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

Because of safety factors that are built into current engineering design practices, the probability of dam failure, in general, is extremely small. The TRR is expected to be considered jurisdictional by DSOD because the preliminary designed embankment height would be greater than six feet. A dam break analysis has not yet been performed, but the TRR would be designed and constructed pursuant to the same conservative guidelines and criteria designed to prevent failure as described for Sites Reservoir. These design standards would protect the dam from seismic or other failure, and would, therefore, result in a **less-than-significant impact** on the risk of loss, injury, or death due to flooding caused by dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Reservoir design would allow emergency releases during operation first to the GCID Canal, and then to Funks Creek via the TRR to Funks Creek Pipeline. Although these releases would increase creek flows, releases would be controlled with an energy dissipater and small concrete structure at the terminal end of the pipeline to avoid exceeding the capacity of the creek channel. In addition, the risk of an event requiring such an emergency release remains very small. Therefore, the TRR facilities would result in a

less-than-significant impact on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The Delevan Transmission Line would be operated as an entirely above-ground Project facility, except for its tower footings. Construction of the required footings for the 13-mile-long transmission line would create a total permanent ground disturbance of approximately 2.5 acres. However, given that the footings would not be a continuous strip of concrete (i.e., they would be spaced apart), this land area disturbance would not significantly alter the existing drainage area or runoff patterns of the transmission alignment area. In addition, tower footings would be sited to avoid stream crossings, and therefore, would not alter the course of a stream. Maintenance activities, including equipment inspections and vegetation maintenance, would not alter drainage patterns or alter the course of a stream. Therefore, construction, operation, and maintenance of the Delevan Transmission Line would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

Approximately half of the length of the above-ground Delevan Transmission Line would be located within the northern portion of a designated 100-year flood hazard area associated with primarily Colusa Basin Drain flows. Although the transmission line would be operated as an entirely above-ground facility, the construction of the required transmission line footings for the entire 13-mile length of the transmission line would create a total ground disturbance of approximately 2.5 acres. Approximately half of these footings would be located within a flood hazard area. However, the footings would be spaced apart, and their individual small footprint would not significantly impede 100-year flood flows. Maintenance activities would not place additional structures within the flood hazard area. Therefore, construction, operation, and maintenance of the Delevan Transmission Line would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

No dams or levees are associated with the Delevan Transmission Line. Therefore, construction, operation, and maintenance of the Delevan Transmission Line would result in **no impact** due to increased flooding risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Electrical Switchyard

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The Delevan Pipeline Electrical Switchyard would not be located directly on the Funks Creek channel alignment. Therefore, construction activities would not alter existing drainage patterns or alter the course of Funks Creek. During operation, the four-acre ground surface of the switchyard would have a gravel base and would not be expected to significantly alter the existing drainage area or runoff patterns of that area. Maintenance activities, including equipment washing and vegetation maintenance, would not alter drainage patterns or alter the course of a stream. Therefore, construction, operation, and maintenance of the Delevan Pipeline Electrical Switchyard would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

The Delevan Pipeline Electrical Switchyard would be constructed within a designated 100-year flood hazard area associated with Funks Creek. However, during construction, the flows from Funks Creek would be controlled with a diversion system. During operation, the four-acre switchyard would have a gravel base, and would not be expected to significantly impede 100-year flood flows. In addition, operation of Sites Reservoir would substantially reduce flood flows associated with Funks Creek by capturing runoff from a large portion of the upstream watershed. Maintenance activities would not place additional structures within the flood hazard area. Therefore, construction, operation, and maintenance of the Delevan Pipeline Electrical Switchyard would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

No dams or levees are associated with the Delevan Pipeline Electrical Switchyard. Therefore, construction, operation, and maintenance of the Delevan Pipeline Electrical Switchyard would result in **no impact** due to increased flooding risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The Delevan Pipeline would be constructed as an underground facility, generally buried 10 feet below the ground surface. The pipeline would cross the Colusa Basin Drain at the northern end of the drain. Construction at this crossing would likely occur during late fall after the irrigation season ends and before winter rains begin. Despite the timing, a portion of the CBD would likely need to be dewatered, with any existing flows bypassed around the construction site. This construction at the crossing would be accomplished by installing the pipeline in stages and bypassing flows on one side of the channel following the construction of a cofferdam. The slight alteration of the course of this waterway would not substantially alter drainage patterns. After installation of the pipeline, the CBD would be returned to a full channel and would be reconstructed to pre-project conditions. Once installed, surface grading would be restored above the pipeline such that it would not significantly alter the existing area drainage pattern. The only above-ground components associated with the operation of the Delevan Pipeline would be manholes and blow off and air valves, each of which would occupy a small area of land, and would, therefore, not impede or redirect flood flows. Maintenance activities, including periodic inspections, would not affect drainage patterns or runoff. Therefore, construction, operation, and maintenance of the Delevan Pipeline would result in a less-than-significant impact on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

The Delevan Pipeline would cross the northern portion of a designated 100-year flood hazard area associated with Funks Creek and Colusa Basin Drain flows. However, the Delevan Pipeline would be constructed as an underground facility, and therefore, would not impede or redirect flows.

Once the pipeline is installed, surface grading would be restored above the pipeline such that it would not significantly impede or redirect flood flows or increase flooding hazards in other areas. The only above-ground components associated with operation of the Delevan Pipeline would be manholes and blow off and air valves, each of which would occupy a small area of land. These above-ground components would not impede 100-year flood flows. In addition, Sites Reservoir would substantially reduce flood flows associated with Funks Creek by capturing runoff from a large portion of the upstream watershed. Maintenance activities would not place additional structures within the flood hazard area. Therefore, construction, operation, and maintenance of the Delevan Pipeline would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

No dams or levees are associated with the Delevan Pipeline. Therefore, construction, operation, and maintenance of the Delevan Pipeline would result in **no impact** due to increased flooding risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

The proposed Delevan Pipeline Intake Facilities would be constructed adjacent to the Sacramento River, where an existing flood protection levee separates the river from upland areas. The proposed footprint would not cover an area large enough to substantially alter existing drainage patterns or increase surface runoff. During construction and operation, the facility would be surrounded by a wide berm or ring levee that would have impacts on drainage patterns and surface runoff similar to those of the existing levee, and therefore, would not increase the risk of flooding. The proposed intake would require the construction of a large fish screen, which would be located on the west side of the river channel immediately downstream of the Maxwell ID Pumping Plant. During construction, a sheet-pile cofferdam that would extend approximately 40 feet into the river channel would be required to allow dewatering of the construction area. The cofferdam would be removed when construction is complete, but the operating fish screen would continue to extend into the river channel. In-channel structures have the potential to alter the course of the river. However, the preliminary fish screen was designed so as to not protrude into the river channel in a manner that would substantially alter the river channel. In addition, the upstream Maxwell ID Pumping Plant is located in a narrow section of the river and consequently acts as a local flow control point (Reclamation, 2012). Maintenance of the facilities would not alter drainage patterns or affect surface runoff.

Therefore, construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

The Delevan Pipeline Intake Facilities would be located adjacent to the Sacramento River within an area protected from the 100-year flood by existing levees along the Sacramento River. The Project includes improvements to the levee in the area of the intake to enhance the flood protection for this facility. An earthen setback levee (or ring levee around the site) would be installed for protection during construction and would remain a permanent structure to provide secondary containment of the Sacramento River in the event of a flood in the area. These above-ground structures would not impede 100-year flood flows during operation.

In addition, preliminary analysis shows that the proposed fish screen would not substantially impact the water surface elevation at high flows. Water surface elevations with the proposed fish screen are not expected to be significantly different than without the fish screen. The existing Maxwell ID Pumping Plant upstream from the proposed intake location would be the controlling structure, causing greater changes on Sacramento River water surface elevations at high flows than the proposed Delevan Pipeline Intake Facilities (Reclamation, 2012). Maintenance activities would not place additional structures within a flood hazard area. Therefore, construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would result in a **less-than-significant impact** on 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

Construction of the Delevan Pipeline Intake Facilities would require modification of the existing flood protection levee along the Sacramento River. Construction work along the existing levee has the potential to destabilize adjacent levee segments and, under worst-case conditions, cause their failure. DWR's and Reclamation's construction contractor would use standard geotechnical engineering practices related to the stabilization and compaction of soils during and after work around the levee for the Delevan Pipeline Intake Facilities to ensure that the integrity of the levee is not compromised. Such practices include soil densification of foundation soils to improve their stabilization and reduce potential liquefaction. Construction plans, specifications, and inspections would be coordinated with the CVFPB, as appropriate. It is unlikely that these facilities would significantly change the degree of protection of people and property behind the levee or result in an increased risk of levee failure.

Operation of the intake facilities would require the construction and operation of a forebay and afterbay. The forebay would be located on the river side of the existing Sacramento River levee, and would pass water to the concrete-lined afterbay through levee tubes that would pass under the existing levee. A new berm or ring levee would be constructed to enclose the afterbay. The remaining facilities would be constructed and operated on top of the berm. During extreme flood events on the river, the forebay and afterbay would be inundated, but these facilities and the levees would be designed to withstand these conditions. Maintenance activities would include the removal of sediment from the afterbay sediment spoil area. Sediment would be removed using a long arm excavator and suction dredge from within the afterbay and would not affect the levees. Therefore, construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would result in a **less-than-significant impact** due to increased flooding risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact Flood-1: Substantially alter the Existing Drainage Pattern of the Site or Project Area, Including through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner which would Result in Flooding On- or Off-site

If Alternative A is implemented, construction-related activities within the Project Buffer would include fence construction, demolition of several existing structures, and the creation of a fuelbreak. Ground disturbance associated with fence construction would consist of digging post holes. The existing structures to be demolished within the Project Buffer would include residences, sheds, shops, and barns. A fuelbreak would be created around the perimeter of the buffer. Fence construction, structure demolition, and the creation of a fuelbreak would not alter the course of a stream, and would not increase the rate of runoff in a manner that would result in flooding because the footprint of the fence posts and structures, as well as the area of the fuelbreak, represent a fraction of the acreage included in the Project Buffer. Therefore, construction activities within the Project Buffer would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff within the Primary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

Post-construction, Project operations and maintenance activities for the new fence and the fuelbreak within the Project Buffer would result in a **less-than-significant impact** on existing drainage patterns, stream courses, or surface runoff, when compared to Existing Conditions and the No Project/No Action Alternative, because the land would be managed as undeveloped open space that would buffer Project facilities from surrounding land uses.

Impact Flood-2: Place within a 100-year Flood Hazard Area Structures which Could Impede or Redirect Flood Flows

If Alternative A is implemented, the only new structures that would be installed within the Project Buffer would be fence posts. Fence construction, or the presence of the fence posts during operation, would not impede or redirect flood flows because the footprint of the fence posts represents a fraction of the acreage included in the Project Buffer. Maintenance activities would not place additional structures within the Project Buffer. Therefore, construction, operation, and maintenance of the Proposed Take Line would result in **no impact** to 100-year flood flows, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee* o*r Dam

If Alternative A is implemented, no dams or levees would be needed for the land acquisition or demarcation of the Project Buffer, and the Project Buffer would have no effect on an existing levee or dam. Therefore, construction, operation, and maintenance of the Project Buffer would result in **no impact** due to increased flooding risks, including potential flooding due a levee or dam failure, when compared to Existing Conditions and the No Project/No Action Alternative.

9.3.7 Impacts Associated with Alternative B

9.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to drainage patterns, stream courses, or surface runoff (**Impact Flood-1)**, 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3**), would be the same as described for Alternative A for the Extended Study Area.

9.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

Impacts due to the construction, operation, and maintenance of Alternative B, as they relate to drainage patterns, stream courses, or surface runoff (**Impact Flood-1)** and 100-year flood flows (**Impact Flood-2**) within the Secondary Study Area, would be the same as described for Alternative A. However, operational changes resulting from coordination with a 1.81-MAF Sites Reservoir with two conveyances for Alternative B, as opposed to the 1.27-MAF Sites Reservoir with three conveyances for Alternative A, have the potential to impact flood control reservoirs in the Secondary Study Area. The difference in average end of month elevation at the Secondary Study Area flood control reservoirs is described below.

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

Impacts due to the construction and maintenance of Alternative B due to increased flooding risks within the Secondary Study Area would be similar to those described for Alternative A.

Tables 9-16 through 9-23 indicate potential minor operational impacts to several flood control reservoirs in the Secondary Study Area. Table 9-16 provides the average Shasta Lake end of the month water surface elevation for Alternative B when compared to Existing Conditions over the long-term and by water year type. The Above Normal and Wet year types are shown because flooding is most likely to occur during these water year types. Long-term average changes to the water surface elevation would range from a 0.0 to 0.5 percent increase. Changes expected for Above Normal and Wet years would be less, at -0.1 to 0.1 percent and -0.2 to 0.1 percent, respectively.

Table 9-16
Shasta Lake End of Month Elevation, Long-Term Average, and Average by Water Year Type for Alternative B when Compared to Existing Conditions

[b]Relative difference of the monthly average.
[c]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Table 9-17 shows the same Shasta Lake information for Alternative B, when compared to the No Project/No Action Alternative. Long-term average changes would range from 0.0 to 0.5 percent increases. Wet year changes would range from -0.1 to 0.1 percent, and Above Normal year changes would range from -0.2 to 0.1 percent.

Modeling results indicate similar impacts at Trinity, Oroville, and Folsom reservoirs (Tables 9-18 through 9-23). Therefore, when compared to Existing Conditions and the No Project/No Action Alternative, construction, operation and maintenance of Alternative B would result in a **less-than-significant impact** due to increased flooding risks, including potential flooding due a levee or dam failure.

9.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to flood control and management:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex

- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The proposed 1.81-MAF Sites Reservoir associated with implementation of Alternative B would require the construction of two main dams and nine saddle dams. The crest elevation of all dams would be 540 feet, providing 20 feet of freeboard above the maximum operating elevation of 520 feet. The emergency spillway elevation would be at 525.5 feet. The larger reservoir would be constructed pursuant to the same conservative guidelines and criteria designed to prevent failure as described for Alternative A. The larger Alternative B reservoir and associated dams would capture flood flows on Funks and Stone Corral creeks and control downstream releases to these creeks as described for Alternative A, and therefore, would have the same impacts on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3**) as described for Alternative A.

The additional saddle dams associated with implementation of Alternative B would require additional saddle dam access roads. However, the slight extension of the saddle dam access roads would result in the same impacts on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3**) as described for Alternative A.

If Alternative B is implemented, the proposed Delevan Transmission Line would extend from only the Inlet/Outlet Structure to the existing PG&E or WAPA transmission line and consequently would not cross the Special Flood Hazard Area. The shorter transmission line would require fewer concrete footings, thus creating a smaller land disturbance footprint than the Alternative A transmission line configuration. These reduced effects would result in the same level of significance of impacts to drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3**) as was described for Alternative A.

The Delevan Pipeline Intake Facilities would be replaced with the smaller Delevan Pipeline Discharge Facility, which would not extend into the river channel, and therefore, would not alter the course of a stream. The Discharge Facility would require similar levee modifications as the Intake Facilities. The smaller footprint would have similar impacts on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3)** as was described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impact on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3)** as was described for Alternative A.

9.3.8 Impacts Associated with Alternative C

9.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impact of Alternative C on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3)** would be the same as described for Alternative A for the Extended Study Area.

9.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impact of Alternative C on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**) and 100-year flood flows (**Impact Flood-2**) within the Secondary Study Area would be the same as described for Alternative A. However, operational changes resulting from coordination with a 1.81-MAF Sites Reservoir with three conveyances for Alternative C, as opposed to the 1.27-MAF Sites Reservoir with three conveyances for Alternative A, have the potential to impact flood control reservoirs in the Secondary Study Area. The difference in average end of month elevation at the Secondary Study Area flood control reservoirs is described below.

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact Flood-3: Expose People or Structures to a Significant Risk of Loss, Injury, or Death from Flooding, Including Flooding as a Result of the Failure of a Levee or Dam

The impacts due to construction and maintenance of Alternative C within the Secondary Study Area would be similar to those described for Alternative B.

Tables 9-24 through 9-31 indicate potential minor operational impacts to several flood control reservoirs in the Secondary Study Area. Table 9-24 provides the average Shasta Lake end of the month water surface elevation for Alternative C, when compared to Existing Conditions over the long-term and by water year type. The Above Normal and Wet year types are shown because flooding is most likely to occur during these water year types. Long-term average changes to the water surface elevation in Shasta Lake would range from a 0.1 to 0.6 percent increase. Changes in Above Normal and Wet years would be even less, at -0.1 to 0.1 percent and -0.1 to 0.3 percent, respectively.

Percent Difference (%)	0.2	0.1	-0.1	0.1	-0.1	0.0	0.0	0.0	0.1	0.1	0.2	0.3

[a]Based on the 82-year simulation period.
[b]Relative difference of the monthly average.
[c]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Table 9-25 shows the same Shasta Lake information for Alternative C, when compared to the No Project/No Action Alternative. Long-term average changes would range from 0.1 to 0.6 percent. Wet year changes would range from -0.1 to 0.1 percent, and Above Normal year changes would range from -0.1 to 0.3 percent.

Modeling results indicate similar impacts at Trinity, Oroville, and Folsom reservoirs (Tables 9-26 through 9-31).

Therefore, when compared to Existing Conditions and the No Project/No Action Alternative, construction, operation and maintenance of Alternative C would result in a **less–than-significant impact** due to increased flooding risks, including potential flooding due a levee or dam failure.

9.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to flood control and management:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR

- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3)** as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Areas, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3)** as described for Alternative B.

The boundary of the Project Buffer would be the same for all alternatives, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on drainage patterns, stream courses, or surface runoff (**Impact Flood-1**), 100-year flood flows (**Impact Flood-2**), and flooding risks (**Impact Flood-3)** as described for Alternative A.

9.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 9-32 for the impacts that have been identified as significant or potentially significant.

Table 9-32
Summary of Mitigation Measures for
NODOS Project Impacts to Flood Control and Management

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Flood-1: Substantially Alter the Existing Drainage Pattern of the Site or Project Area, Including Through the Alteration of the Course of a Stream or River, or Substantially Increase the Rate or Amount of Surface Runoff in a Manner Which Would Result in Flooding On- or Off-site	Sites Reservoir, Sites Dams	Significant	Mitigation Measure Flood-1: Maintain Permanent Low Flow Releases into Stone Corral and Funks Creeks Downstream of Sites and Golden Gate Dams	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Flood-1: Maintain Permanent Low Flow Releases into Stone Corral and Funks Creeks Downstream of Sites and Golden Gate Dams

To mitigate for **Impact Flood-1** and pursuant to DFG Code 5937 related to maintaining flows downstream of dams, post-construction fish flows into Funks and Stone Corral creeks shall be maintained by DWR and Reclamation by means of low-flow release valves at Golden Gate and Sites dams. Flows shall be maintained at 10 cfs from October through May in both creeks to mimic the seasonal nature of the creeks while avoiding historic flooding.

Implementation of **Mitigation Measure Flood-1** would reduce the level of significance of Project impacts to flood control and management to **less than significant**.

Figures

Facilities

- **Approximately 1,600 miles of levees**
- **Five major weirs spilling floodwaters from the Sacramento River to bypass channels**
- **Five control structures directing flow in bypass channels along the San Joaquin River**
- **Six major pumping plants**
- **Channel improvements**
- **Bank protection**
- **Associated facilities, such as stream gages and drainage facilities**

Lands

- Fee title, easements, and agreements for project works and mitigation areas
- Approximately 18,000 parcels

Operations and Maintenance

- Two standard O&M manuals
- 118 unit-specific manuals
- Maintenance by State and local maintaining agencies

Conditions (terms)

- Assurances
- Flood Control Regulations, Part 208.10 of 33, Code of Federal Regulations
- Requirements of standard and unit-specific O&M manuals
- Design profiles (1955 and 1957)
- Project Cooperation Agreements

Programs and Plans

- Historical documents and processes
- As-constructed drawings
- Oversight and management

10. Groundwater Resources

10.1 Introduction

This chapter provides a description of the groundwater resources setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Groundwater resources refer to the groundwater aquifer system(s) including groundwater infrastructure (i.e., existing groundwater wells and their distribution facilities in the vicinity of the Project).

The regulatory setting for groundwater resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

10.2 Environmental Setting/Affected Environment

Throughout the State, the availability and predictability of groundwater for withdrawal is influenced by the geology and topography of the region, because groundwater may occur in alluvial sediment or fractured rock aquifers. The characteristics of these aquifers are described below.

Alluvial sediment aquifers occur primarily in valley areas where the lower elevation of the ground surface has provided a location for eroded sediment to collect and accumulate. Groundwater is collected and stored in the pore spaces between the pieces of eroded material. For example, groundwater is found between the stones in a gravel bed. The groundwater production associated with alluvial sediment aquifers varies from very little to large quantities based on the composition of the sediment and availability of recharge water. Wells in alluvial sediment aquifers provide water for many uses including domestic, irrigation, industrial, environmental, and public water supply.

Fractured rock aquifers are found primarily in mountainous regions where topography prevents the accumulation of significant amounts of eroded material. Groundwater collects and is stored in the fractures of the solid rock formations. Fractured rock aquifers are generally considered to produce less groundwater and to be less predictable water sources than alluvial aquifers. Wells in fractured rock aquifers provide water for many of the same uses as the wells in alluvial sediment aquifers.

10.2.1 Extended Study Area

10.2.1.1 Hydrogeology and Groundwater Resources

California is divided into 10 hydrologic regions based on surface water hydrology. Brief descriptions of the groundwater hydrogeology and resources within the hydrologic regions where changes in water supply distribution may occur as a result of Project implementation are provided below.

North Coast Hydrologic Region

Groundwater development in the North Coast Hydrologic Region occurs in areas of lower ground surface elevation and slope where eroded material can be deposited and accumulate. These include areas along the coast, near the mouths of or adjacent to major rivers, and in the inland valleys. Groundwater reliability varies significantly from area to area (DWR, 2003).

San Francisco Bay Hydrologic Region

Groundwater development in the San Francisco Bay Hydrologic Region is limited because coarse alluvial sediments where fresh groundwater is stored are thin in many areas. In more heavily used basins, fresh groundwater sediments are moderately thick. Groundwater availability varies significantly from area to area (DWR, 2003).

Central Coast Hydrologic Region

Groundwater development in the Central Coast Hydrologic Region is extensive. Aquifer reliability and storage vary greatly, ranging from large alluvial valleys with thick aquifer systems to small inland valleys and coastal terraces where large-scale groundwater production is not possible (DWR, 2003).

South Coast Hydrologic Region

Groundwater development in the South Coast Hydrologic Region is extensive. Groundwater is produced almost exclusively from alluvial aquifer systems. Aquifer production can be as high as thousands of gallons per minute (gpm) in large municipal wells (DWR, 2003).

Sacramento River Hydrologic Region

Groundwater development in the Sacramento River Hydrologic Region is widespread. The Sacramento Valley is considered to be one of the most productive aquifer systems in the state. Extensive deposition of alluvial material in the Sacramento Valley has created large, reliable, and productive aquifer systems. Groundwater production and reliability are less predictable from the alluvial sediments in mountain basins, but many produce significant amounts of groundwater. Small scale production is achieved from fractured rock aquifer systems outside of and along the edges of the alluvial basins (DWR, 2003).

San Joaquin River Hydrologic Region

Groundwater development in the San Joaquin River Hydrologic Region is extensive. Groundwater is produced from thick beds of alluvium and consolidated rocks. Groundwater production is generally high, ranging between 300 and 5,000 gpm (DWR, 2003).

Tulare Lake Hydrologic Region

Groundwater development in the Tulare Lake Hydrologic Region is extensive. Groundwater is produced from thick beds of alluvium in the San Joaquin Valley subbasins. The maximum thickness of freshwater aquifer deposits is approximately 4,400 feet. Groundwater production in these areas generally ranges from 300 to 4,000 gpm. Aquifer deposits in the smaller basins surrounding the San Joaquin Valley are thinner and generally produce less groundwater, averaging less than 500 gpm (DWR, 2003).

South Lahontan Hydrologic Region

Groundwater development in the South Lahontan Hydrologic Region is limited to populated areas. Groundwater is produced almost exclusively from alluvial sediments, and production varies greatly from basin to basin (DWR, 2003).

Colorado River Hydrologic Region

Groundwater is produced from alluvial aquifer systems in many of the region's subbasins. The thickness and production associated with the various aquifers varies greatly from basin to basin. Some aquifers can produce thousands of gallons per minute to properly designed wells (DWR, 2003).

10.2.2 Secondary Study Area

10.2.2.1 Hydrogeology and Groundwater Resources

The Secondary Study Area includes small portions of the North Coast and San Francisco Bay hydrologic regions and most of the Sacramento River Hydrologic Region. More detailed descriptions of the geologic setting and formations for the Secondary Study Area are included in Chapter 16 Geology, Minerals, Soils, and Paleontology.

North Coast Hydrologic Region

The portion of the North Coast Hydrologic Region that is included in the Secondary Study Area consists of areas surrounding Trinity Lake, Lewiston Lake, the Clear Creek Tunnel, the Trinity River, and the Klamath River downstream of the Trinity River. North and northeast of Redding, the valley meets the base of the Klamath Mountain Range.

In general, the geologic setting for this area consists of ancient marine-type sedimentary rocks uplifted by massive granitic intrusions. Groundwater is produced from eroded and redeposited material that often collects along stream and river channels and in valley areas within the mountain region. Some groundwater is also produced from fractured hard rock aquifers. Groundwater production in the mountain region is less predictable and usually less productive than in most parts of the valley because the geologic material storing the groundwater is much more limited.

San Francisco Bay Hydrologic Region

The portion of the San Francisco Bay Hydrologic Region that is included in the Secondary Study Area consists of areas surrounding the Sacramento-San Joaquin Delta (Delta), Suisun Bay, San Pablo Bay, and San Francisco Bay.

In general, the geologic setting for these areas consists of alluvial deposits of material eroded from rocks higher in the watersheds that were transported and deposited by rivers and streams feeding into the Region. Groundwater is produced from these alluvial sediments. Groundwater production varies from area to area because coarse sediments that store groundwater vary in thickness.

Sacramento River Hydrologic Region

The northern Sacramento Valley is bordered by the Klamath Mountain on the north, a portion of the Northern Coast Ranges to the west, and bordered on the east by the southern part of the Cascade Range and northern part of the Sierra Nevada. The valley is approximately 12 miles wide near the City of Red Bluff and approximately 38 miles wide south of the Sutter Buttes. The length of the valley is roughly

60 miles. Included in the Sacramento River Hydrologic Region are Shasta Lake, Keswick Reservoir, the Sacramento River, Spring Creek, Clear Creek, Whiskeytown Lake, Lake Oroville, the Thermalito Complex, the Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, and the American River.

The northern Sacramento Valley is underlain by an extensive alluvial aquifer system. Along the edges of the basin, near the base of the mountains, groundwater is also produced from limited fractured rock aquifers. In areas outside of the Sacramento Valley, groundwater occurs in alluvium deposited in smaller valleys and along stream and river channels. Groundwater is also produced from fractured rock areas and in the Cascade Range from sand and gravel aquifers found between ancient lava flows.

The boundaries of the part of the groundwater basin within the Secondary Study Area are formed by the foothills of the Sierra and Cascade mountain ranges to the east, the Coast Range to the west, and Klamath Mountains to the northwest. The region extends south from the Modoc Plateau and Cascade Range at the Oregon border, to the Sacramento-San Joaquin Delta (DWR, 2003).

The primary fresh groundwater-bearing geologic formations in the northern Sacramento Valley are the Tuscan, Tehama, and Laguna Formations. The valley stratigraphy is oriented approximately west to east between the cities of Willows and Oroville. The relationship between the geologic formations is depicted on this cross-section and this relationship is basically consistent through much of the valley.

The Tuscan Formation is derived primarily from mud flow and reworked volcanic deposits. The origin is near Lassen Peak, north and east of the Secondary Study Area. The mud flows of the Tuscan can be seen in outcrops on the eastern side of the valley from north of Oroville to Redding. The flows continued into the valley as far west as where Interstate 5 (I-5) is located in some locations, but were buried with more recent alluvial material. The composition of the Tuscan Formation in the valley consists of layers of gravel, sand, silt, and clay.

The Tehama Formation is derived from material eroded from the Coast Range and Klamath Mountains. The rolling hills formed by the Tehama Formation can be seen nearly uninterrupted from Cottonwood in the north to well beyond the southern end of the Secondary Study Area. North of Cottonwood, the Tehama Formation is exposed across the valley floor from Palo Cedro in the east to the Coast Range foothills in the west. Similar to the Tuscan Formation, the Tehama Formation is present in both surface exposures and in the subsurface of the valley where it is overlain by more recent alluvial material. In the subsurface, the Tehama Formation extends east beyond the Sacramento River in most locations within the Secondary Study Area. The composition of the Tehama Formation in the valley consists of layers of gravel, sand, silt, and clay.

The Laguna Formation is composed of material eroded from the Sierra Nevada. Similar to the Tehama Formation, the Laguna Formation is exposed at the surface in rolling hills. Exposures of the Laguna Formation can be seen at the base of the Sierra Nevada on the east side of the valley between Oroville and Sacramento. In the subsurface, the Laguna Formation extends west to approximately the Sacramento River. The Laguna Formation consists of primarily layers of gravel, sand, and silt.

Recent alluvial formations including the Red Bluff, Riverbank, Modesto, and Basin deposits cover the Tuscan, Tehama, and Laguna formations throughout much of the valley with up to 200 feet of gravel, silt, and clay. In localized areas, the recent alluvium can be a significant source of groundwater for domestic, agricultural, and public use, but generally these units provide a modest amount of water to primarily domestic users (DWR, 2003).

10.2.3 Primary Study Area

10.2.3.1 Hydrogeology and Groundwater Resources

Sites Reservoir Inundation Area, Dams, Recreation Areas, Roads and South Bridge, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Site Reservoir Inlet/Outlet Structure, and Sites Electrical Switchyard

Local Hydrogeology

The proposed location for the Sites Reservoir Inundation Area would completely inundate both the Funks and Antelope Creek groundwater basins. These groundwater basins consist primarily of shallow (generally less than 100 feet) alluvial deposits (DWR, 2003). These alluvial deposits are Late Quaternary (8,000 years ago) in age and occur within the reservoir footprint, primarily along the valleys of Stone Corral, Antelope, Funks, and Grapevine creeks. The deposits consist of fine-grained sands, silts, and clays occurring as stream channel and localized floodplain deposits.

Most of the wells in these groundwater basins are designed to produce water from the underlying rock formation (the Great Valley Sequence). The Great Valley Sequence is comprised of marine, clastic sedimentary rock consisting of siltstone, shale, sandstone, and conglomerate. The sequence has a maximum thickness of 15,000 feet. Groundwater resources from this formation are limited due to poor water bearing and water quality characteristics. More detailed descriptions of the geologic setting and formations are included in Chapter 16 Geology, Minerals, Soils, and Paleontology.

Local Groundwater Infrastructure

As of 2009, there are approximately 26 wells that have been constructed within an approximate one-mile radius of the Sites Reservoir footprint. Table 10-1 presents a summary of well data for these wells including the number of wells, well depth, well use, depth to water, and well yield, for the appropriate Township, Range, and Section. The data presented here are from the California Department of Water Resources (DWR) well completion report data set. All data are reported as it was submitted by the well driller at the time of drilling and development. None of this data was verified by DWR staff and conditions may have changed since the time of drilling. Additional wells may be present in the study area that were not reported to DWR by the driller.

As shown in Table 10-1, 10 wells are constructed to a depth of 100 feet or greater, the deepest well being 201 feet deep. Well yields in the area are low, ranging from a high of 60 gpm to a low of zero or no measurable yield, and averaging 14 gpm. The depth to water in the area, based on well completion reports, ranges from one foot to 30 feet below ground surface, with an average depth of approximately 17 feet (DWR, 2011).

Table 10-2 provides a summary of well data for each type of well (e.g., domestic or irrigation), as reported on well completion reports submitted to DWR. As shown, half of the wells in the area are domestic wells constructed to depths of approximately 77 feet with yields averaging approximately 15 gpm.

Stock wells are the second most common well type in the area constructed to depths of approximately 85 feet. Well yields from stock wells average approximately 18 gpm.

Table 10-1

Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, Tehama-Colusa Canal, Field Office Maintenance Yard, Terminal Regulating Reservoir Pipeline, and Terminal Regulating Reservoir Pipeline Road

Local Hydrogeology

The Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard (proposed location), T-C Canal (proposed modifications), and the Field Office Maintenance Yard, TRR Pipeline, and TRR Pipeline Road would overlie Great Valley Sequence and Holocene basin deposits. The Great Valley Sequence is comprised of marine clastic sedimentary rock consisting of siltstone, shale, sandstone, and conglomerate. The sequence has a maximum thickness of 15,000 feet. Groundwater resources in this area are limited due to the poor water bearing and water quality characteristics.

The basin deposits consist of silt and clay deposited in low-lying floodplain areas adjacent to major streams. Permeability of basin deposits is generally low and groundwater occurs in limited quantities.

Local Groundwater Infrastructure

As of 2009, there are approximately three wells that have been constructed and one test hole drilled within an approximate one-mile radius of the proposed Holthouse Reservoir Complex. Table 10-3 presents a summary of well data for these wells including the number of wells, well depth, well use, depth to water, and well yield, for the appropriate township, range, and section. The data presented here are from the DWR well completion report data set. All data are reported as it was submitted by the well driller at the time of drilling and development. None of this data was verified by DWR staff and conditions may have changed since the time of drilling. Additional wells may be present in the study area that were not reported to DWR by the driller.

The constructed well depths ranged from 124 feet to 240 feet and the reported well yields were low at 12 and 14 gpm. A depth to water measurement was only reported on the well completion report for two wells, and those measurements were 20 and 41 feet below ground surface. One well was drilled for industrial uses, and the other two for domestic water supplies (DWR, 2011).

Table 10-3
Wells Located Within a One-Mile Radius of the Proposed Holthouse Reservoir Complex and TRR Pipeline

Section Number	Number of Wells within Section	Well Depth (feet)	Well Use	Depth to Water (Feet)*	Well Yield (gpm)*
T17N R04W Sec 11	1	240	Industrial	20	14
T17N R04W Sec 12	2	80	Domestic	41	11
		240	Test Hole	NA	NA
T17N R04W Sec 16	1	124	Domestic	NA	12

*Depth to water and well yield values are based on estimates provided by the driller at the time of drilling in well completion reports.

Notes:

Further evaluation of well completion report data thru 2011 indicates no additional well drilling between 2009 and 2011. DWR well completion report data set may not include all wells.

Glenn-Colusa Irrigation District Canal

Local Hydrogeology

The GCID Canal (proposed modifications) crosses deposits of the Riverbank Formation and basin deposits. The Riverbank Formation is composed of terrace deposits that consist of poorly consolidated gravel, sand, and silt. These deposits are found along the Sacramento River and adjacent tributaries and are up to 200 feet thick. Permeability of the Riverbank Formation is moderate to high, and yields of domestic wells are moderate.

Basin deposits consist of silt and clay deposited in low-lying floodplain areas adjacent to major streams. Permeability of basin deposits is generally low, and groundwater occurs in limited amounts.

Delevan Pipeline, Delevan Transmission Line, Delevan Pipeline Electrical Switchyard, Delevan Pipeline Intake Facilities, and Delevan Discharge Facility

Local Hydrogeology

The Delevan Pipeline, Delevan Transmission Line, Delevan Pipeline Electrical Switchyard, Delevan Pipeline Intake Facilities, and Delevan Discharge Facility would overlie the Great Valley Sequence, Riverbank Formation, and basin deposits.

The Great Valley Sequence is comprised of marine, clastic sedimentary rock consisting of siltstone, shale, sandstone, and conglomerate. The sequence has a maximum thickness of 15,000 feet. Groundwater resources from this formation are limited due to poor water bearing and water quality characteristics.

The Riverbank Formation is composed of terrace deposits that consist of poorly consolidated gravel, sand, and silt. These deposits are found along the Sacramento River and adjacent tributaries and are up to 200 feet thick. Permeability of the Riverbank Formation is moderate to high, and yields of domestic wells are moderate.

Basin deposits consist of silt and clay deposited in low-lying floodplain areas adjacent to major streams. Permeability of basin deposits is generally low, and groundwater occurs in limited amounts.

Local Groundwater Infrastructure

As of 2009, there are approximately 35 wells that have been constructed within approximately one mile of the Delevan Pipeline construction area. Table 10-4 presents a summary of well data for these wells including the number of wells, well depth, well use, depth to water, and well yield, for the appropriate township, range, and section. The data presented here are from the DWR well completion report data set. All data are reported as it was submitted by the well driller at the time of drilling and development. None of this data was verified by DWR staff and conditions may have changed since the time of drilling. Additional wells may be present in the study area that were not reported to DWR by the driller.

Notes:

Further evaluation of well completion report data thru 2011 indicates no additional well drilling between 2009 and 2011. DWR well completion report data set may not include all wells.

gpm = gallons per minute
NA = Not Available

Source: DWR, 2011.

The well depths ranged from 13 feet to 863 feet. The reported data for well yields were limited, but ranged between 60 and 8,300 gpm. The depth to water measurements ranged between five and 30 feet below ground surface, with an average depth of 17 feet. The intended use of the wells reported on the well completion reports is as follows: 20 domestic, seven irrigation, four unknown, three monitoring, and one other (DWR, 2011).

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Local Hydrogeology

The TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and GCID Canal Connection to the TRR would overlie Riverbank Formation and basin deposits.

The Riverbank Formation is composed of terrace deposits that consist of poorly consolidated gravel, sand, and silt. These deposits are found along the Sacramento River and adjacent tributaries and are up to 200 feet thick. Permeability of the Riverbank Formation is moderate to high, and yields of domestic wells are moderate.

Basin deposits consist of silt and clay deposited in low-lying floodplain areas adjacent to major streams. Permeability of basin deposits is generally low, and groundwater occurs in limited amounts.

Local Groundwater Infrastructure

As of 2009, there are approximately 10 wells that have been constructed within an approximate one-mile radius of the proposed TRR. Table 10-5 presents a summary of well data for these wells including the number of wells, well depth, well use, depth to water, and well yield, for the appropriate township, range, and section. The data presented here are from the DWR well completion report data set. All data are reported as it was submitted by the well driller at the time of drilling and development. None of this data was verified by DWR staff and conditions may have changed since the time of drilling. Additional wells may be present in the study area that were not reported to DWR by the driller.

Table 10-5

*Depth to water and well yield values are based on estimates provided by the driller at the time of drilling in well completion reports.

Notes:

Further evaluation of well completion report data thru 2011 indicates no additional well drilling between 2009 and 2011. DWR well completion report data set may not include all wells.

gpm = gallons per minute
NA = Not Available

Source: DWR, 2011.

The well depths ranged from 70 feet to 400 feet. The reported data for well yields were limited, but ranged between 50 and 200 gpm. The depth to water measurements ranged between four and 20 feet below ground surface with an average depth of 12.5 feet. Nine of the 10 wells were drilled for domestic water supply. The intended use of the tenth well is unknown (DWR, 2011).

Project Buffer

Local Hydrogeology

The Project Buffer would surround groupings of Project facilities. The Project Buffer, therefore, would overlie the same formations and deposits as described for each of the Project facilities that are surrounded by the Project Buffer.

Local Groundwater Infrastructure

The Project Buffer extends from the Project facility footprints to the edge of the nearest land parcel; the distance of the Project Buffer boundary from any facility footprint is less than one mile. The well data presented for the Project facilities includes all wells located within one mile of the facilities and, therefore, includes wells that are located within the buffer boundary.

10.3 Environmental Impacts/Environmental Consequences

10.3.1 Regulatory Setting

Groundwater resources are regulated at the federal, State, and local levels. Management of groundwater resources occurs at the local level. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

10.3.1.1 Federal Plans, Policies, and Regulations

- National Environmental Policy Act
- Federal Safe Drinking Water Act
- Federal Antidegradation Policy
- Clean Water Act

10.3.1.2 State Plans, Policies, and Regulations

- California Environmental Quality Act

10.3.1.3 Regional and Local Plans, Policies, and Regulations

The State of California does not have a statewide regulatory permit process for groundwater extraction. Groundwater management has remained primarily a local responsibility with relatively little control exerted by the California Legislature. The authority to implement some sort of groundwater management practice has been provided to established local water agencies, special act districts, and counties. The authority of these districts varies greatly with the specific authorization that established the district – from granting the authority to establish a groundwater management plan to (in a few cases) monitoring and limiting extraction during overdraft conditions (DWR 2003).

Many of the counties within the Extended Study Area, and the majority of the counties in the Secondary Study Area, have established groundwater ordinances. Within the Primary Study Area, Colusa and Glenn counties require permits for pumping groundwater for export or for substituting groundwater for surface water that was exported. However, these groundwater ordinances do not pertain to activities related to the Project because no groundwater would be extracted as part of the Project.

10.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criterion for hydrology and water quality that is relevant to groundwater resources:

Would the Project:

- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Substantial depletion of groundwater supplies or substantial interference with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted).

- Increases in groundwater levels such that there would be adverse effects to environmental conditions, existing land uses, or planned uses for which permits have been granted.

10.3.3 Impact Assessment Assumptions and Methodology

10.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to groundwater resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation, increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge Facilities would be required.

10.3.3.2 Methodology

A combination of data, published reports, and professional experience with activities similar to those proposed was used to evaluate the potential impacts to groundwater resources from the alternatives. The data (detailed below) were used to determine the existing groundwater infrastructure, identify and estimate the aquifer properties of the underlying geologic material, and anticipate potential impacts that could result from Project-related activities in the three study areas.

The Extended and Secondary study area impact assessments relied on hydrologic and operational modeling performed using CALSIM II, which provided monthly river flows, and reservoir water surface elevations derived from monthly river flows and end-of-month reservoir storages, for the period of simulation extending from water year 1922 through 2003 (82-year simulation period). Detailed discussion of the CALSIM II model is provided in Appendix 6B. These modeling results were used in combination with professional judgment to assess the potential impacts of operation of the alternatives on groundwater resources.

DWR Bulletin 118-03 (DWR, 2003) was referenced to identify the groundwater basins within the Extended, Secondary, and Primary study areas, and to determine in more detail the aquifer properties of the geologic material within those basins.

A survey of DWR well completion report records (DWR, 2011) was conducted to determine the number, use, and depth of wells in the Primary Study Area. The well completion reports also provided general information regarding the geology and aquifer properties of the geologic formations encountered by the well drilling activities.

Previously completed projects, including the Thermalito Afterbay, and their resulting impacts were evaluated to determine the type and severity of impacts that might result in the Primary Study Area from proposed Project-related activities that would impound water.

10.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

10.3.5 Impacts Associated with the No Project/No Action Alternative

10.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to groundwater levels (either decrease or increase) has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** resulting in the depletion of groundwater resources, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger human population could be expected to cause increased demand for groundwater resources. Groundwater extraction has exceeded groundwater recharge in several areas of the Sacramento and San Joaquin hydrologic regions. Continued groundwater extraction at rates that exceed groundwater recharge **could have a substantial adverse effect** on groundwater resources, when compared to Existing Conditions.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion.

San Luis Reservoir

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

With implementation of the No Project/No Action Alternative, San Luis Reservoir would continue to experience water level fluctuations similar to Existing Conditions. Groundwater recharge would not be expected to be substantially adversely affected by continued fluctuations. Therefore, continued fluctuations in water levels at San Luis Reservoir **would not have a substantial adverse effect** on groundwater resources, when compared to Existing Conditions.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion.

10.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion for the Extended Study Area. Population growth could result in increased use of existing aquifers. Groundwater level data indicate that groundwater extraction has likely exceeded groundwater recharge in several areas of the Sacramento River Hydrologic Region. These areas are scattered throughout the region; there are areas with higher groundwater overdraft rates in Glenn County, and south of the city of Williams in Colusa County. These areas are located in the Sacramento Valley floor groundwater basins. If the No Project/No Action Alternative is implemented, the overdraft rates would likely continue and possibly increase. Continued groundwater extraction at rates that exceed groundwater recharge **could have a substantial adverse effect** on groundwater resources, when compared to Existing Conditions.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion for the Extended Study Area.

10.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion for the Extended Study Area. In addition, projects considered within the No Project/No Action Alternative are not located within the Primary Study Area, and therefore, **would not have a substantial adverse effect** on groundwater resources, when compared to Existing Conditions. With implementation of the No Project/No Action Alternative, local landowners and tenants would continue to use groundwater for domestic use and for crop irrigation. Because population growth is projected to be minimal in this area, groundwater extraction would not be expected to increase substantially. Therefore, continued groundwater use in the Primary Study Area with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on groundwater resources, when compared to Existing Conditions.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion for the Extended Study Area. In addition, projects considered within the No Project/No Action Alternative are not located within the Primary Study Area, and therefore, **would not have a substantial adverse effect** on groundwater resources, when compared to Existing Conditions.

10.3.6 Impacts Associated with Alternative A

10.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

There would be no Project construction or maintenance activities in the Extended Study Area; therefore, there would be **no impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative. There would be no proposed Project operational activities or results from those activities that would result in a substantial depletion of groundwater supplies in the Extended Study Area. Improvement in surface water supply reliability for agricultural, municipal, and industrial water users as a result of the Project would reduce the need for extracting groundwater and/or provide some additional applied water for deep percolation recharge of the aquifer system; groundwater supplies would, therefore, not be depleted or reduced. Therefore, increased surface water supply reliability would have a **less-than-significant impact** on groundwater resources in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

The provision of an alternate source of refuge water supply would not affect rates of groundwater use, and would, therefore, have **no impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion for the Extended Study Area. Improvement in surface water supply reliability for agricultural, municipal, and industrial water users as a result of the Project could result in stabilization or modest increases in groundwater resources in CVP/SWP areas due to slightly increased recharge rates or a reduced need for groundwater extraction, but not at significant levels. Therefore, increased surface water supply reliability would have a **less-than-significant impact** on groundwater resources in the Extended Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

San Luis Reservoir

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Operational modeling for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates that there would be continued water level fluctuations at San Luis Reservoir, but the fluctuations would occur more often and could be more severe. Severe reservoir level drawdowns could result in reduced seepage, which could reduce local groundwater recharge. However, San Luis Reservoir currently experiences severe water level fluctuations, and historic groundwater levels should not be substantially affected by continued fluctuations at an increased rate. Therefore, the increased fluctuations in water levels at San Luis Reservoir would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Increased fluctuations in water levels at San Luis Reservoir would not increase groundwater levels, and would, therefore, have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

10.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

There are no Project-related construction, operation, or maintenance activities that would result in a substantial depletion of groundwater supplies in the Secondary Study Area. Project operational activities would result in improved surface water storage in reservoir facilities within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative, which could increase infiltration that recharges groundwater in that area. Changes to the flow regime of the rivers, creeks, and bypasses could result in changes in the rate of groundwater recharge, but the amount of change is likely to be proportional to the change in flow, which is variable throughout the system. These changes are not expected to substantially affect groundwater recharge. Project diversions would not be expected to adversely affect groundwater recharge rates in areas where groundwater extraction has likely exceeded groundwater recharge because Project diversions would occur during periods of excess surface flows and storm events. Therefore, changes in reservoir storage and flow regime would have a **less-than-significant impact** on groundwater resources within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative. Construction, operation, and maintenance of an additional pump at the Red Bluff Pumping Plant would have **no impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative, because it would not extract groundwater.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Potential increased infiltration resulting from improved surface water storage could increase groundwater recharge rates. However, seepage is not expected to increase at a rate that would have a significant effect on groundwater resources. Therefore, changes in reservoir storage and flow regime would have a **less-than-significant impact** on groundwater resources within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative. Construction, operation, and maintenance of an additional pump at the Red Bluff Pumping Plant would have **no impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative, because it would not increase groundwater recharge.

10.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction and the initial filling of Sites Reservoir would completely inundate both the Funks and Antelope Creek groundwater basins. Approximately 26 groundwater wells that are located in the inundation area would no longer be functional, but there would no longer be any use for the wells after the reservoir is inundated.

Operation and maintenance activities would result in a wide fluctuation of water stored in the Sites Reservoir during the year, when compared to Existing Conditions and the No Project/No Action Alternative. Similar to the impacts discussed in the construction section, this fluctuation would likely result in localized changes in groundwater recharge. Because of the limited groundwater use and infrastructure in the area surrounding the reservoir, the resulting impact would likely be undetectable. Therefore, construction, operation, and maintenance of Sites Reservoir would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. In addition, it is likely that, despite the grouting of the underlying rock formations, minimal amounts of water would leak from the reservoir and could increase groundwater recharge in nearby areas outside of the inundation area. However, groundwater use and infrastructure in the area surrounding the reservoir is very limited, and the permeability of the geologic material is generally low, so the impact to groundwater users and land use would likely be undetectable. Therefore, construction, operation, and maintenance of Sites Reservoir would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Reservoir Dams

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Golden Gate Dam, Sites Dam, and the seven saddle dams would be located outside of the Funks and Antelope Creek groundwater basins. Sites and Golden Gate dams would be constructed on Stone Corral and Funks creeks, respectively; flows to those creeks would be maintained during construction. Some redirection of creek flows and stormwater management during construction may result in very minor redirection of groundwater recharge, when compared to Existing Conditions and the No Project/No Action Alternative. Operation and maintenance activities of the dam structures would not impede groundwater recharge. Therefore, the construction, operation, and maintenance activities associated with these dams would have **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Operation and maintenance activities of the dam structures would not significantly increase groundwater recharge. Therefore, the construction, operation, and maintenance activities associated with these dams would have **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

The recreation areas would be located outside of the Funks and Antelope Creek groundwater basins, and no deep subsurface construction would be required; therefore, their development would result in **no impact** to groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative. Groundwater would not be used during the construction and maintenance of, or as a potable water source for, the recreation areas. Therefore, the construction, operation, and maintenance activities associated with the recreation areas would have **no impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion.

Road Relocations and South Bridge

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

The construction, operation, and maintenance of these facilities would not require the use of groundwater and would not diminish groundwater recharge. Project construction may require temporary localized lowering of the shallow groundwater. However, the temporary lowering of groundwater levels would not impact current groundwater uses in the area because the groundwater levels would not be lowered enough or over a wide enough area to impact local groundwater users. These activities would, therefore, have **no impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Temporary localized lowering of the groundwater would not increase groundwater levels. The construction, operation, and maintenance of these facilities would therefore have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Electrical Switchyard, Tunnel, Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard may require temporary localized lowering of the shallow groundwater. However, the temporary lowering of groundwater levels would not impact current groundwater uses in the area because the groundwater levels would not be lowered enough or over a wide enough area to impact local groundwater users. Therefore, the construction, operation, and maintenance of these facilities would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Temporary localized lowering of the groundwater would not increase groundwater levels. Therefore, the construction, operation, and maintenance of these facilities would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, Terminal Regulating Reservoir Pipeline, and Terminal Regulating Reservoir Pipeline Road

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction of the Holthouse Reservoir Complex would require the dredging of the existing Funks Reservoir. Dredging activities would require the dewatering of Funks Reservoir for two years, which would likely result in a short-term reduction in groundwater recharge in the local area. The reduction would be small because permeability of the underlying material is low. It is unlikely that it would affect groundwater users because groundwater quantity is low. DWR records only indicate two wells within a mile radius of Funks Reservoir. Therefore, there would be a **less-than-significant impact** on groundwater resources from the dredging of Funks Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

Construction of the Holthouse Reservoir Complex facilities, Holthouse Reservoir Electrical Switchyard, TRR Pipeline, and TRR Pipeline Road may require temporary localized lowering of the shallow groundwater in the construction area. However, the temporary lowering of groundwater levels would not impact current groundwater uses in the area because the groundwater levels would not be lowered enough or over a wide enough area to impact local groundwater users. Construction of the Holthouse Reservoir Complex would, therefore, result in a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Dewatering Funks Reservoir would not increase groundwater levels. Therefore, there would be a **less-than-significant impact** on groundwater resources from the dredging of Funks Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

Inundation of Holthouse Reservoir would likely lead to higher groundwater levels in a localized area around the reservoir. There are three constructed wells within an approximately one-mile radius of the proposed Holthouse Reservoir. They are located to the north and northeast of the reservoir area. There is limited groundwater flow direction data for the area, but regional trends indicate groundwater flow is in an easterly to southeasterly direction. This trend indicates that it is unlikely that higher groundwater levels would be experienced in the three wells.

It is likely that groundwater levels would increase in the areas immediately south and southeast of the proposed Holthouse Reservoir during Project operation. There are identified sensitive wetlands and orchard crops in the areas that would likely experience an increase in groundwater levels. The groundwater levels could be increased enough to adversely impact wetland hydrology and water chemistry and agricultural operations in these areas. Construction, operation, and maintenance of the Holthouse Reservoir Complex would result in a **potentially significant impact** on groundwater resources south and southeast of Holthouse Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction of the new GCID Canal headgate structure may require temporary localized lowering of the shallow groundwater to allow for the installation of underground equipment in the construction area. The temporary lowering of groundwater levels would not impact current groundwater uses in the area because the groundwater levels would not be lowered enough or over a wide enough area to impact local groundwater users. Construction, operation, and maintenance of the GCID Canal headgate structure would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Temporary localized lowering of the groundwater would not increase groundwater levels. Therefore, the construction, operation, and maintenance of the GCID Canal headgate would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and the Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction of the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and the GCID Canal Connection to the TRR (an energy dissipation bay and inlet channel) may require temporary localized lowering of the shallow groundwater to allow for the installation of underground equipment in the construction area. Temporary lowering of groundwater levels would not impact current groundwater uses in the area because the groundwater levels would not be lowered enough or over a wide enough area to impact local groundwater users. Inundation of the reservoir would likely increase groundwater recharge and lead to higher groundwater levels in a localized area around the reservoir, and therefore, would not result in reduced groundwater supplies. Construction, operation, and maintenance of these facilities would, therefore, have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Filling of the reservoir would likely increase groundwater recharge and lead to higher groundwater levels in a localized area around the reservoir. There are three constructed wells within an approximately one-mile radius of the proposed TRR. They are located in sections north and northeast of the reservoir area. There is limited groundwater flow direction data for the area, but regional trends indicate groundwater flow is in an easterly to southeasterly direction. This trend indicates that it is unlikely that higher groundwater levels would be experienced in the three wells.

It is likely that groundwater levels would increase in the areas immediately south and southeast of the TRR. There are rice, grain, and orchard crops in the areas that would likely experience the increase in groundwater levels. The groundwater levels could be increased enough to adversely impact the agricultural operations in these areas. Construction, operation, and maintenance of the TRR would result in a **potentially significant impact** on groundwater resources surrounding the TRR (especially along the south and southeast sides), when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline, Delevan Transmission Line, and Delevan Pipeline Electrical Switchyard

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction of the Delevan Pipeline, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line tower footings may require temporary localized lowering of the shallow groundwater to allow for the installation of underground equipment in the construction area. The temporary lowering of groundwater would not impact current groundwater uses in the area because the groundwater levels would not be lowered enough or over a wide enough area to impact local groundwater users. Construction, operation, and maintenance of the Delevan Pipeline, Delevan Transmission Line, and Delevan Pipeline Electrical Switchyard would, therefore, have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. Temporary localized lowering of the groundwater would not increase water levels, and therefore, would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would include construction of a forebay facility at the proposed intake location. It is likely that groundwater levels would increase in the areas around the forebay after it is filled. Consequently, groundwater resources would not be reduced or depleted. Construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would result in a **less-than-significant impact** to groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. There are orchard crops located in the areas that would likely experience the increase in groundwater levels. Groundwater levels could be increased enough to adversely impact the agricultural operations in this area.

Construction, operation, and maintenance of the Delevan Pipeline Intake Facilities would, therefore, result in a **potentially significant impact** to groundwater resources in the areas directly surrounding the forebay facility, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact GW Res-1: Substantial Depletion of Groundwater Supplies or Substantial Interference with Groundwater Recharge Resulting in a Net Deficit in Aquifer Volume or a Lowering of the Local Groundwater Table Level, Causing Effects on Existing Land Uses or Planned Uses

Within the Project Buffer, some structures would be demolished, and any agricultural fields that are currently irrigated may not continue to receive irrigation. Any wells associated with those structures or used as irrigation sources may, therefore, no longer be used. The discontinued use of any wells could increase, rather than decrease, groundwater supplies. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses

Refer to the **Impact GW Res-1** discussion. The potential reduction in groundwater extraction rates related to the discontinued use of wells could increase groundwater supplies, but not by enough or over a wide enough area to impact local groundwater levels. Therefore, the acquisition of land within the Project Buffer would have a **less-than-significant impact** on groundwater resources, when compared to Existing Conditions and the No Project/No Action Alternative.

10.3.7 Impacts Associated with Alternative B

10.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) would be the same as described for Alternative A for the Extended Study Area.

10.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) would be the same as described for Alternative A for the Secondary Study Area.

10.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater resources:

- Recreation Areas
- Sites Pumping/Generating Plant

- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprint and construction disturbance area of Sites Reservoir and Dams, the Road Relocations and South Bridge, and the Delevan Transmission Line would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility. The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) as described for Alternative A, with the exclusion of the potential impacts associated with the Delevan Pipeline Intake Facility forebay and afterbay that are included in Alternative A, but not Alternative B.

10.3.8 Impacts Associated with Alternative C

10.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) would be the same as described for Alternative A for the Extended Study Area.

10.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) would be the same as described for Alternative A for the Secondary Study Area.

10.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Areas, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) as described for Alternative B.

The boundary of the Project Buffer would be the same for all three alternatives, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on groundwater supplies and recharge (**Impact GW Res-1**) and groundwater levels (**Impact GW Res-2**) as described for Alternative A.

10.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 10-6 for the impacts that have been identified as significant or potentially significant.

Table 10-6
Summary of Mitigation Measures for
NODOS Project Impacts to Groundwater Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact GW Res-2: Increases in Groundwater Levels Resulting in Adverse Effects to Environmental Conditions and/or Existing Land Uses or Planned Uses	Holthouse Reservoir Complex, TRR, Delevan Pipeline Intake Facilities	Potentially Significant	Mitigation Measure GW Res-2: Monitor and Lower Groundwater Levels as Necessary	Less than Significant
	Holthouse Reservoir	Potentially Significant	Mitigation Measure Bot-1e: Minimize Impacts by Siting Facilities Away from Drainage Swales and using BMPs; Conduct Hydrological Studies and Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant or Potentially Significant and Unavoidable

Note:
LOS = Level of Significance

Mitigation Measure GW Res-2: Monitor and Lower Groundwater Levels as Necessary

To minimize impacts to existing land uses from the expected increase in groundwater levels from the development of the Holthouse Reservoir Complex, the TRR, and the Delevan Pipeline Intake Facilities, groundwater level monitoring wells shall be installed around these facilities prior to filling of the reservoirs and forebay to provide existing groundwater level data for these areas. The wells shall be monitored throughout Project operation to determine changes in groundwater levels. Shallow groundwater return wells or French Drains with pumps shall be installed to pump groundwater and return it to the reservoirs and forebay if it is determined necessary to lower the groundwater levels.

Mitigation Measure Bot-1e: Minimize Impacts by Siting Facilities Away from Drainage Swales and using BMPs; Conduct Hydrological Studies and Implement Vegetation Community Mitigation Measures Recommended by USFWS

- DWR and Reclamation shall implement measures that mitigate impacts to alkaline wetland vegetation in the on-site swale to avoid sedimentation of the swale during Project construction, according to recommendations received during consultation with USFWS. DWR and Reclamation shall conduct studies to determine the importance of the headwaters of the swale to the health of the swale and the downstream alkaline marsh.

- DWR and Reclamation shall conduct studies to determine the effects of groundwater pressure on the health of the swale and the marsh. Measures may include protection of nearby similar vegetation communities, or USFWS may determine the effects are unavoidable and there may be no means of mitigation if there are no equivalent nearby vegetation communities that are feasible to protect or enhance.

Implementation of **Mitigation Measure GW Res-2** would reduce the level of significance of Project impacts to groundwater resources to **less than significant**.

Implementation of **Mitigation Measure Bot-1e** would reduce the level of significance of Project impacts to groundwater resources to **less than significant,** or they would remain **potentially significant and unavoidable.**

11. Groundwater Quality

11.1 Introduction

This chapter describes the groundwater quality setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Groundwater quality can be affected by both natural and human-caused activities. In natural systems, the quality of groundwater results from geochemical reactions between the water and rock as the water flows from areas of recharge. Typically, the longer that groundwater remains in contact with soluble materials, the greater the concentrations of dissolved materials in the water (in addition to the effects of temperature, pressure, and solubility). The quality of groundwater can also change as a result of the mixing of waters from different aquifers. Human-caused effects on groundwater quality can occur directly by the infiltration of compounds, or indirectly by alteration of flow or geochemical conditions. Groundwater chemistry may be influenced by irrigation water, wastewater from human activities, and by-products from industrial activities.

The regulatory setting for ground water resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

11.2 Environmental Setting/Affected Environment

11.2.1 Extended Study Area

11.2.1.1 Methodology

For the Extended Study Area, the existing groundwater quality conditions were evaluated using hydrologic regions as boundaries. There are 10 hydrologic regions in California; they consider varying climates, geography, and hydrology (See Figure 6-2 in Chapter 6 Surface Water Resources). These regions correspond to the state's major water drainage basins. Using the drainage basins as planning boundaries allows logical tracking of natural water runoff and accounting of surface and groundwater supplies. The CVP and SWP service areas of the Extended Study Area are located within nine of California's 10 hydrologic regions. San Luis Reservoir falls within the San Joaquin River hydrologic region.

<u>North Coast Hydrologic Region</u>

Overall, groundwater quality in the North Coast Hydrologic Region is very good. Groundwater quality problems in this region include contamination from seawater intrusion and nitrates in shallow coastal groundwater aquifers; high total dissolved solids (TDS) and alkalinity in groundwater associated with the lake sediments of the Modoc Plateau basins; and iron, boron, and manganese in the inland groundwater basins of Mendocino and Sonoma counties. Septic tank failures in western Sonoma County, at Monte Rio and Camp Meeker, and along the Trinity River downstream of Lewiston Dam, are a concern because of potential impacts to groundwater wells and recreational water quality (DWR, 2005).

From 1994 through 2000, samples were taken from 584 public supply wells in 32 of the 63 basins and subbasins in this region. Of these wells, 95 percent met the state primary MCLs for drinking water, and the remaining five percent of wells sampled exceeded one or more MCL (DWR, 2003).

San Francisco Bay Hydrologic Region

Groundwater quality throughout much of the San Francisco Bay Hydrologic Region is of good quality and suitable for most urban and agricultural uses with only local impairments, such as leaking underground storage tanks. Primary constituents of concern are high TDS, nitrate, boron, and organic compounds. The areas of high TDS (and chloride) concentrations are typically found in the region's groundwater basins that are situated close to the San Francisco Bay, such as the northern Santa Clara, southern Sonoma, Petaluma, and Napa valleys. Elevated levels of nitrate have been detected in a large percentage of private wells tested within the Coyote Subbasin and Llagas Subbasin of the Gilroy-Hollister Valley Groundwater Basin (in the Central Coast Hydrologic Region,) located to the south of the Santa Clara Valley (SCVWD, 2001). The shallow aquifer zone within the Petaluma Valley also shows persistent nitrate contamination. Groundwater with high TDS, iron, and boron levels were present in the Calistoga area of Napa Valley, and elevated boron levels in other parts of Napa Valley make the water unfit for agricultural uses. Releases of fuel hydrocarbons from leaking underground storage tanks and spills/leaks of organic solvents at industrial sites have caused minor to significant groundwater impacts in many basins throughout the region. Methyl tertiary-butyl ether (MTBE) and chlorinated solvent releases to soil and groundwater continue to be problems (DWR, 2003).

From 1994 through 2000, samples were taken from 485 public supply water wells in 18 of the 33 basins and subbasins in this region. Analyzed samples indicate that 410 wells, or 85 percent, met the state primary MCLs for drinking water standards, and 75 wells, or 15 percent, have constituents that exceed one or more MCL (DWR, 2003).

Central Coast Hydrologic Region

Much of the groundwater in the Central Coast Hydrologic Region is impaired due to high mineralization. It is characterized by calcium sulfate to calcium sodium bicarbonate sulfate water types resulting from marine sedimentary rock in the watersheds. Water character is determined from chemical analyses by the dominant positively charged cation (e.g., sodium, calcium, or magnesium) with the dominantly negatively charged anion (e.g., chloride, sulfate, or bicarbonate). Where dominant cations and anions are not present there may be a combination of several compositions. Water quality problems most frequently encountered in the Central Coastal Basin pertain to excessive salinity or hardness of local ground waters. In some of the coastal groundwater basins, groundwater is pumped at a higher rate than the underground supply is replenished, such that seawater has pushed into some coastal freshwater aquifers and is degrading groundwater quality. Aquifers intruded by seawater are typically characterized by sodium chloride to calcium chloride, and have chloride concentrations greater than 500 mg/L. Groundwater basins that are affected by salinity include the Hollister area, the Carrizo Plain, the Santa Maria and Cuyama valleys, San Antonio Creek Valley, portions of the Santa Ynez Valley, and the Goleta and Santa Barbara areas. In several areas, groundwater exceeds the MCL for nitrate.

In the southern portion of Santa Clara County, elevated concentrations of nitrate and perchlorate have been detected. In late 2002, perchlorate emerged as a significant groundwater contaminant in the southern end of Santa Clara County. The known extent of this groundwater chemical plume extends 10 miles, and more than 800 water supply wells have been affected (DWR, 2005).

From 1994 through 2000, samples were taken from 711 public supply water wells in 38 of the 60 basins and subbasins in this region. Analyzed samples indicate that 587 wells, or 83 percent, met the state primary MCLs for drinking water, and 124 wells, or 17 percent, have constituents that exceed one or more MCL (DWR, 2003).

South Coast Hydrologic Region

The South Coast Hydrologic Region is divided into three subregions: Los Angeles, Santa Ana and San Diego. Groundwater in basins of the Los Angeles subregion is mainly calcium sulfate and calcium bicarbonate in character. Nitrate content is elevated in some parts of the subregion. Volatile organic compounds (VOCs) have created groundwater impairments in some of the industrialized portions of the region. The San Gabriel Valley and San Fernando Valley groundwater basins both have multiple sites of contamination from VOCs. The main constituents in the contamination plumes are trichloroethylene (TCE) and tetrachloroethylene (PCE). Some of the locations have been declared federal Superfund sites. Contamination plumes containing high concentrations of TCE and PCE also occur in the Bunker Hill Subbasin of the Upper Santa Ana Valley Groundwater Basin. Some of these plumes are also designated as Superfund sites. Perchlorate is emerging as an important contaminant in several areas in this region.

Groundwater in basins of the Santa Ana subregion is primarily calcium and sodium bicarbonate in character. Local impairments from excess nitrate or VOCs have been recognized. Groundwater and surface water in the Chino Subbasin of the Santa Ana River Valley Groundwater Basin have elevated nitrate concentrations, partly derived from a large dairy industry in that area. In Orange County, water from the Santa Ana River provides a large part of the groundwater replenishment. The primary groundwater character in the San Diego subregion includes a combination of calcium and/or sodium cation, and bicarbonate and/or sulfate anions. Localized groundwater quality impairments by nitrate, sulfate, and TDS are found in this subregion. Camp Pendleton Marine Base, in the northwestern part of this subregion, is on the USEPA National Priorities List for soil and groundwater contamination by many constituents.

From 1994 through 2000, samples were taken from 2,342 public supply water wells in 47 of the 73 basins and subbasins in this region. Analyzed samples indicate that 1,360 wells, or 58 percent, met the state primary MCLs for drinking water, and 982 wells, or 42 percent, have constituents that exceed one or more MCL (DWR, 2003).

Sacramento River Hydrologic Region

Overall, groundwater quality in the Sacramento River Hydrologic Region is good, although there are local groundwater quality impairments. Natural water quality impairments occur at the northern end of the Sacramento Valley in the Redding subbasin, and along the margins of the valley and around the Sutter Buttes, where Cretaceous age marine sedimentary rocks containing brackish to saline water are near the surface. Groundwater near the Sutter Buttes is impaired because of local volcanic geology, and hydrogen sulfide is a problem in wells in the geothermal areas in the western part of the region. Human-induced impairments are usually associated with individual septic system development in shallow unconfined portions of aquifers, or in fractured hard rock areas where insufficient soil depths are available to properly leach effluent before it reaches the local groundwater supply. Some groundwater sources in this region do not meet State secondary MCLs for iron and manganese, and heavy metals from historical burn dumps also contaminate groundwater locally. In the Sierra foothills there is potential for encountering uranium and radon-bearing rock or sulfide mineral deposits containing heavy metals. Perchlorate, previously used as an oxidizer or booster for solid rocket fuel and now a human health concern in domestic water, has contaminated wells in Rancho Cordova, near Sacramento (DWR, 2005).

In the mountainous portions of this region, groundwater is of fairly good quality, but it may be contaminated by naturally occurring radon, uranium, or sulfide mineral deposits containing heavy metals. In particular, radon contamination is associated with granite, such as the granite batholith of the Sierra Nevada. Some groundwater sources do not meet State secondary MCLs for iron and magnesium. Also, because of the lack of community wastewater systems, individual septic tanks are prevalent for rural residential development in this region. The failure of septic tank systems can create sewage flows that have the potential to adversely affect nearby wells and groundwater quality.

From 1994 through 2000, samples were taken from 1,356 public supply water wells in 51 of the 88 basins and subbasins in the Sacramento River HR. Samples analyzed indicate that 1,282 wells, or 95 percent, met the state primary MCLs for drinking water, and 74 wells, or five percent, have constituents that exceed one or more MCL (DWR, 2003).

San Joaquin River Hydrologic Region

Groundwater quality throughout the San Joaquin River Hydrologic Region is adequate for most urban and agricultural uses. However, there are approximately 1,000 square miles overlying groundwater along the western edge of the valley floor that are contaminated with high salinity from naturally occurring marine sediments of the Coast Range. The salinity of groundwater in the region can increase as a result of agricultural practices in which the evapotranspiration of crops and wetlands leaves behind the majority of salts contained in the imported water (either imported surface water or groundwater). In addition, high water-table conditions underlying marginal lands along the west side of the San Joaquin River region contribute to subsurface drainage problems. To maintain a salt balance in the root zone, much of this salt is leached into the groundwater.

Nitrates that are generated from the disposal of human and animal wastes, or from the inefficient application of fertilizer and irrigation water, have contaminated 200 square miles of groundwater in the region, and threaten some domestic water supplies. Pesticides have contaminated 500 square miles of groundwater basins, primarily in agricultural areas on the east side of the San Joaquin Valley, where soil permeability is higher and the depth to groundwater is shallower. The entire Central Valley has approximately 500,000 single-family residential septic systems, each with leach fields that discharge to the groundwater. The most notable agricultural contaminant detected in groundwater samples from this region is dibromochloropropane (DBCP), which is a banned nematode pesticide that has been found mostly along the SR 99 corridor. There are also approximately 200 square miles of groundwater basins that are contaminated by naturally occurring selenium (DWR, 2005).

In the mountainous portions of this region, groundwater is of good quality, but it may be contaminated by naturally occurring radon, uranium, or sulfide mineral deposits containing heavy metals. In particular, radon contamination is associated with granite, such as the granite batholith of the Sierra Nevada. Some groundwater sources do not meet State secondary standards for both iron and magnesium. Also, because of the lack of community wastewater systems, individual septic tanks are prevalent for rural residential development in this region and have the potential to adversely affect nearby wells and groundwater quality.

From 1994 through 2000, samples were taken from 689 public supply water wells in 10 of the 11 basins and subbasins in this region. Samples analyzed indicate that 523 wells, or 76 percent, met the state primary MCLs for drinking water, and 166 wells, or 24 percent, have constituents that exceed one or more MCL (DWR, 2003).

Tulare Lake Hydrologic Region

Groundwater quality in the Tulare Lake Hydrologic Region is suitable for most beneficial uses; however, there are several areas with impairments to groundwater. On the region's west side, salinity, sulfate, boron, chloride, and selenium limit the uses of groundwater. Salinity is the primary water quality factor affecting use of groundwater for irrigation and native habitat. Where groundwater quality is marginal to unusable for agriculture, farmers use good quality surface water to irrigate crops or blend higher quality surface water with poor quality groundwater to create a larger supply. The inefficiency of some crop irrigation systems can increase percolation of irrigation water into the shallow unconfined aquifers, causing drainage problems and degrading groundwater quality. This marginal to poor quality groundwater has mounded up to reach crop root zones in that area and is threatens the viability of agriculture there.

Agricultural runoff and drainage are also the main sources of nitrate, pesticides, and selenium that endanger groundwater and surface water beneficial uses. The basin also has a relatively large concentration of dairies that contribute microbes, salinity, and nutrients to both surface water and groundwater.

Nitrate has contaminated more than 400 square miles of groundwater in the Tulare Lake Basin. In addition, oilfield waste has affected water quality. There are more than 800 oilfield waste dischargers, of which 250 are regulated pursuant to waste discharge requirements (CVRWQCB, 2002).

Naturally occurring arsenic, as well as pesticides and industrial chemicals, have contaminated some groundwater supplies that are used for domestic water in the region. With newer federal and State drinking water rules being implemented over the past few years, numerous community domestic water well sources are noncompliant and have had to implement treatment methods or plans to reduce arsenic levels in drinking water. The contamination of almost 50 wells in Fresno/Clovis area due to high levels of DBCP and/or TCE, and other organic compounds resulted in the installation of activated charcoal filtration systems to remove these contaminants from the well water.

For many years, portions of the Tulare Lake region have experienced significant drainage problems, exacerbated by the fact that it is a basin with no significant water outflow to remove salts. The poorly drained area is concentrated along the western side of the San Joaquin Valley from Kern County north into the San Joaquin River Hydrologic Region. Although the San Joaquin Valley has some of the most productive agricultural lands in the world, much of the west side of the valley is plagued by poor subsurface drainage that adversely affects crop productivity. Between 1977 and 1991, the area affected by saline shallow groundwater on the west side doubled to approximately 1,200 square miles. A substantial portion of the valley, approximately 4,000 square miles, is threatened by saline shallow groundwater resulting from the lack of proper drainage (DWR, 2005).

From 1994 through 2000, samples were taken from 1,476 public supply water wells in 14 of the 19 groundwater basins and subbasins in this region. Evaluation of analyzed samples shows that 1,049 of the wells, or 71 percent, met the state primary MCLs for drinking water, and 427 wells, or 29 percent, exceeded one or more MCL (DWR, 2003).

South Lahontan Hydrologic Region

Groundwater quality in the South Lahontan Hydrologic Region is of good quality, although there are local impairments. The chemical character of the groundwater varies throughout the region, but most often is of calcium- or sodium-bicarbonate. Near and beneath dry lakes, sodium chloride and sodium sulfate-chloride water is common. Groundwater near the edges of valleys contains lower TDS content than water beneath the central part of the valleys or near dry lakes where water pools and dissolved chemicals concentrate as water evaporates, and may percolate through soils into the groundwater. At the lower elevations in this region, groundwater can be degraded, both naturally from geothermal activity, and as a result of activities such as recreational uses and cattle grazing. Arsenic, a known human carcinogen, is a health concern in the basin, and therefore, in Los Angeles as well. The vast majority of public water supply wells do meet drinking water standards. However, in places where these standards are exceeded, it is most often because of elevated levels of TDS, fluoride, or boron. The USEPA lists 13 sites of contamination in this region. Several domestic water supply wells in the Barstow area have been closed due to historical contamination from industrial and domestic wastewater. Three military installations in the southwestern part of the region are on the federal Superfund National Priorities List because of volatile organic compounds and other hazardous contaminants. In addition, the PG&E chromium groundwater contamination site in Hinkley is also within this region (DWR, 2005).

From 1994 through 2000, samples were taken from 605 public supply water wells in 19 of the 77 basins and subbasins in this region. Analyzed samples indicate that 506 wells, or 84 percent, met the state primary MCLs for drinking water, and 99 wells, or 16 percent, have constituents that exceed one or more MCL (DWR, 2003).

Colorado River Hydrologic Region

The groundwater in the Colorado River Hydrologic Region is impaired in many cases primarily due to high mineral concentrations. The chemical character of groundwater in this region is variable. Cation concentration is dominated by sodium, with calcium common and magnesium appearing less often. Bicarbonate is usually the dominant anion, although sulfate and chloride waters are also common. In basins with closed drainages, water character often changes from calcium-sodium bicarbonate near the margins to sodium chloride or chloride-sulfate beneath a dry lake. It is not uncommon for concentrations of dissolved constituents to rise dramatically toward a dry lake where saturation of mineral salts is reached. An example of this is found in the Bristol Valley Groundwater Basin, where the mineral halite (sodium chloride) is formed and then mined by evaporation of groundwater in trenches in Bristol (dry) Lake. The TDS content of groundwater is high in many of the basins in this region. High fluoride content is common; sulfate content occasionally exceeds drinking water standards; and high nitrate content is common, especially in agricultural areas. Significant water quality concerns include nitrate pollution in Coachella Valley, Lucerne Valley, and Desert Hot Springs.

Two of the primary challenges in this region are overdraft in the Coachella Valley and leaking underground storage tanks. The USEPA has not yet placed any contamination sites in this region on the Superfund National Priorities List; however, one site is being considered because of high pesticide levels (DWR, 2005).

From 1994 through 2000, samples were taken from 314 public supply water wells in 23 of the 64 basins and subbasins in this region. Analyzed samples indicate that 270 wells, or 86 percent, met the state primary MCLs for drinking water standards, and 44 wells, or 14 percent, have constituents that exceed one or more MCL (DWR, 2003).

11.2.2 Secondary Study Area

11.2.2.1 Shasta Lake Area

The quality of water in underground basins and water-bearing soils is considered good throughout most of Shasta County. Little groundwater quality data are available from the vicinity of Shasta Lake because this area is not a designated groundwater basin. Potential hazards to groundwater quality involve nitrates and dissolved solids from agricultural and range practices, and septic tank failures. The ability of soils in Shasta County to support septic tanks and on-site wastewater treatment systems is for the most part severely limited, particularly on older valley terrace soils and certain loosely confined volcanic soils in the eastern portions of the county.

11.2.2.2 Sacramento River Downstream of Lake Shasta

The area of the Sacramento River downstream of Lake Shasta includes Keswick Reservoir, the RBPP, the Sutter Bypass, and the Yolo Bypass. In the Redding area downstream of Lake Shasta, groundwater composition varies. In some locations, it is characterized as magnesium-calcium bicarbonate and calcium-magnesium bicarbonate type water, some as magnesium-sodium bicarbonate and sodium-magnesium bicarbonate, some as sodium bicarbonate and sodium chloride type, and other areas as mixed cationic bicarbonate. TDS concentrations range from 70 to 360 mg/L (DWR, 2011a). Groundwater quality impairments include localized high boron, iron, manganese, and nitrate. High levels of total dissolved salts and chlorides are present in the lower Tehama and Tuscan formations. Sodium and boron is present at shallow depth where wells draw from the Chico Formation.

From the Shasta County line south, groundwater composition in the subbasins along the Sacramento River is characterized as calcium-magnesium bicarbonate and magnesium-calcium bicarbonate. TDS concentrations range from 120 to 558 mg/L (DWR, 2011a). Groundwater quality impairments are not widespread, are typically localized, and can include boron, chloride, high magnesium, TDS, calcium, and phosphorus. High nitrate concentrations have been noted in the Antelope area near Red Bluff (DWR, 1987) and in Chico (DWR, 1984). Also, in the Chico area, eight groundwater contamination plumes of PCE, trichloroethylene (TCE), pentachlorophenol (PCP), or chloroform were identified (DTSC, 2004).

The United States Geological Survey (USGS), in cooperation with the California State Water Resources Control Board (SWRCB), sampled 66 wells in 2007 to 2008 in the Shasta and Tehama County area as part of their Groundwater Ambient Monitoring and Assessment (GAMA) Program. The concentrations of most constituents detected in groundwater samples from these wells were below drinking water thresholds. Volatile organic compounds (VOC) and pesticides were detected in less than 25 percent of the samples, and were generally less than one hundredth of any health-based thresholds. N-nitrosodimethylamine (NDMA) was detected above the California Notification Level in one grid well. Concentrations of all nutrients and trace elements in samples from study unit wells were below the health based thresholds, with the exception of arsenic in three samples, which was above the California MCL A few samples contained iron, manganese, or pH at levels above the California secondary MCL or USEPA secondary MCL (USGS, 2009).

From Orland south, on the west side of the Sacramento River, calcium-magnesium bicarbonate and magnesium-calcium bicarbonate are the predominant groundwater types. Calcium bicarbonate waters occur locally from Orland to Artois, and near Stony Creek. Mixed character waters for different regions of the subbasin occur as follows: sodium bicarbonate waters from the Williams-Colusa area south to

Grimes; magnesium-sodium bicarbonate or sodium-magnesium bicarbonate waters near the Williams-Arbuckle area and locally near Zamora; and magnesium bicarbonate waters locally near Dunnigan. TDS values range from 120 to 1,220 mg/L, averaging 391 mg/L. Impairments in this range include high EC, TDS, nitrate; manganese impairments occur near Colusa. High TDS and boron occur near Knights Landing. High nitrates occur in Arbuckle, Knights Landing, and Willows. Localized areas have high manganese, fluoride, magnesium, sodium, iron, chloride, TDS, ammonia, and phosphorus (DWR, 2003).

In Sutter County, data collected by the California Department of Water Resources (DWR) from several wells indicate a TDS range of 133 to 1,660 mg/L. The primary groundwater chemistry in the subbasin is characterized by calcium, magnesium, sodium, chloride, sulfate and bicarbonate, which may occur in any combination. Groundwater containing calcium-magnesium bicarbonate or magnesium-calcium bicarbonate exists in the northwest portion of the subbasin. Some groundwater quality data collected indicates some wells drilled to various depths contain chemical elements and compounds in amounts that exceed drinking water quality safety and aesthetic standards. Groundwater quality impairments in some portions of the County have naturally occurring levels of minerals, which present some concerns (taste, economics) (DWR, 2003).

The USGS collected samples from 108 wells in Butte, Colusa, Glenn, Sutter, Tehama, Yolo, and Yuba counties as part of the GAMA program (it also covers portions east of the Sacramento River presented in the Feather River discussion in Section 11.2.2.5). Most constituents that were detected in groundwater samples were found at concentrations below drinking water thresholds. VOCs were detected in less than 33 percent of the wells, and pesticides and pesticide degredates in more than 50 percent of the wells. All detections of these constituents in samples from all wells of this study unit were below health-based thresholds. All detections of trace elements in samples from this study unit's wells were below health-based thresholds, with the exceptions of arsenic and boron. Arsenic concentrations were above the California MCL threshold in eight grid wells, and boron concentrations were above the California notification level in two wells. Although the USGS study was primarily designed to evaluate quality for drinking water wells, they did sample some other well types to add additional information to the study. Arsenic was detected above the California MCL in two of these wells, and arsenic, barium, boron, molybdenum, strontium, and vanadium were detected above health-based thresholds in a few rice irrigation wells; again these wells are not used to supply drinking water. Chloride and sulfate concentrations exceeded California secondary MCL thresholds in two wells and one well, respectively. Iron, manganese, and total dissolved solids concentrations were above the California secondary MCL thresholds in one, 12, and six wells, respectively. Nitrate (nitrite plus nitrate, as dissolved nitrogen) concentrations from two wells were above the California MCL (USGS, 2008).

South of Colusa County, the Sacramento River flows between Yolo and Solano counties to the west, and Sacramento County to the east. To the east, on the north side of the American River, the chemistry and quality of groundwater has been assessed for the American Basin. Many areas of good quality groundwater exist in the North American subbasin. In some portions of the basin, groundwater quality is marginal. The three major groundwater types are: magnesium-calcium bicarbonate or calcium-magnesium bicarbonate; magnesium-sodium bicarbonate or sodium-magnesium bicarbonate; and sodium-calcium bicarbonate or calcium-sodium bicarbonate (DWR, 1997).

Comparison of groundwater quality data with applicable water quality standards and guidelines for drinking and irrigation indicate elevated levels of some water quality parameters. This list includes TDS/specific conductance (measurements of dissolved substances in water), chloride, sodium, bicarbonate, boron, fluoride, nitrate, and iron, manganese. Arsenic may also be of concern in some locations within the subbasin (DWR, 1997).

High TDS levels exist in an area along the Sacramento River extending from Sacramento International Airport northward to the Bear River. The highest levels of TDS are found in an area extending just south of Nicholas to Verona, between Reclamation District 1001 and the Sutter Bypass. Some wells in this area have reported TDS concentrations exceeding 1,000 mg/L. This same area along the Sacramento River extending from Sacramento International Airport northward to the Bear River also contains high levels of chloride, sodium, bicarbonate, manganese, and arsenic. The groundwater in the southern part of the basin is characterized as of fairy good quality, low in disinfection by-product precursor materials, and moderate in mineral content, although some localized contamination issues exist.

Impairments include three sites within the subbasin with significant groundwater contamination issues: the former McClellan AFB, Union Pacific Railroad Rail Yard in Roseville, and the Aerojet Superfund Site. Although the Aerojet site is south of the North American subbasin, a contaminant plume (including TCE and PCE) extends north from Aerojet, under the American River, and into the North American subbasin as described in a 2000 study by Montgomery Watson (as cited in DWR, 2003). Other localized areas of contamination exist throughout the basin and are usually smaller in scope and extent of contamination (DWR, 2003).

On the south side of the American River, groundwater is typically characterized by calcium-magnesium bicarbonate or magnesium-calcium bicarbonate. Other minor groundwater types include sodium calcium bicarbonate or calcium sodium bicarbonate in the vicinity of Elk Grove, and a magnesium sodium bicarbonate or sodium magnesium bicarbonate near the confluence of the Sacramento and American rivers. TDS concentrations range from 24 to 581 mg/L, and average 221mg/L, based on 462 records from a 1991 report by Bertoldi and others (as cited in DWR, 2003).Impairments to the south of the American River include 7 sites within the subbasin with significant groundwater contamination have been identified in a 1997 report by Montgomery Watson (as cited in DWR, 2003). Included in the list are three USEPA Superfund sites: Aerojet, Mather Field, and the Sacramento Army Depot. Other sites are the Kiefer Boulevard Landfill, an abandoned PG&E site on Jiboom Street near Old Sacramento, and the Southern Pacific and Union Pacific rail yards in downtown Sacramento (DWR, 2003).

To the west of Sacramento County, groundwater in the Yolo region is characterized as a sodium magnesium, calcium magnesium, or magnesium bicarbonate type. The quality is considered well for both agricultural and municipal uses, even though the water is considered hard to very hard (typically over 180 mg/L $CaCO_3$). Selenium and boron are found in higher concentrations locally as noted in a 1985 report by KID. Evensong (as cited in DWR, 2003). TDS concentrations range from 107 to 1,300 mg/L, and average 574 mg/L noted in a 2000 report by California Department of Health Services (as cited in DWR, 2003). Localized impairments include elevated concentrations of boron (as high as two to three mg/L) in groundwater along Cache Creek and in the Cache Creek Settling Basin area (DWR, 2003). Woodland has experienced nitrate contamination in certain wells. The City of Davis has experienced selenium contamination and localized areas of nitrate contamination. The Central Valley Regional Water Quality Control Board reported several sites in Davis, Woodland, West Sacramento, and Dunnigan with MTBE contamination (YCFCWCD, 2000).

Groundwater within the Solano subbasin is considered to be of fairly good quality, and useable for beneficial uses. Groundwater characterization is primarily magnesium bicarbonate in the central and northern areas, sodium bicarbonate in the southern and eastern areas, and calcium magnesium or magnesium calcium bicarbonate around and west of Dixon. TDS values range from between 250 and 500 mg/L in the northwest and eastern portion of the basin, and are found at levels higher than 500 mg/L in the central and southern areas. Data from DHS show the TDS minimum of 150, maximum 880, and average of 427 mg/L. In general, most of the water within the subbasin is classified as hard to very hard. Chloride concentrations are found over 100 mg/L in the southern areas, while sulfate concentration is greater than 50 mg/L in the southern areas. Boron concentrations are less than 0.75 mg/L, except in the southern and southeastern basin where concentrations average between 0.75 and 2.0 mg/L. Iron concentrations increase toward the eastern side of the subbasin, from less than 0.02 mg/L to greater than 0.05 mg/L along the Sacramento River, and manganese concentrations also increase from west to east with concentrations from .01 to over 0.1 mg/L found north of Rio Vista and east of the Solano-Yolo County line. Groundwater in this area is rather hard. High concentrations of bicarbonate, which cause precipitation of Ca and Mg carbonates, are found in the southern portion of the basin. Other impairments to groundwater include arsenic, where concentrations are typically between 0.02 and 0.05 mg/L, with the highest concentrations found along the southeastern margin of the basin, and manganese, which is found at concentrations above the MCL of 0.05 mg/L along the Sacramento River along the eastern portion of the subbasin (DWR, 2003).

Groundwater quality within the Capay Valley Subbasin is derived almost exclusively from Cache Creek and its tributaries. Consequently, water quality samples taken from Cache Creek within the Capay Valley reflect the quality of the water within the groundwater basin. Water samples taken from a diversion dam near the lower end of the Capay Valley indicate principally good quality calcium-sodium bicarbonate-type with moderate to very high hardness. Highly mineralized water from Bear Creek and North Fork Cache Creek is a primary source of mineral constituents, especially boron, in groundwater in the Capay Valley Subbasin. Total dissolved solids measured in water taken from six wells in the Capay Valley range from approximately 300 to 500 mg/l, and are comparable to those found in water samples taken from Cache Creek (DWR, 2003).

11.2.2.3 Whiskeytown Area

The Whiskeytown area includes Whiskeytown Lake, Clear Creek, and Spring Creek. Little information is available from the mountainous portions of the Clear Creek and Spring Creek watersheds regarding groundwater quality because these creeks are not located within a defined groundwater basin, and as such, have not been assessed. Most groundwater in this area is high in iron and aluminum due to the minerals in the rock (NPS, 2004).

After Clear Creek enters the valley floor, it enters the Redding Groundwater Basin and Anderson Subbasin. Groundwater in the subbasin is characterized as magnesium-sodium bicarbonate and sodium-magnesium bicarbonate type waters. TDS concentrations range from 109 to 320 mg/L, averaging 194 mg/L. Localized areas with high iron, manganese, and nitrate occur in the subbasin (DWR, 2003).

11.2.2.4 Trinity River Watershed

The Trinity River watershed includes Trinity Lake, the Trinity River, Lewiston Lake, and the Klamath River downstream of the Trinity River. Nearly the entire length of the Trinity River watershed is outside of defined groundwater basins. Therefore, groundwater quality information is sparse. Septic tank failures along the Trinity River downstream from Lewiston Dam are a concern because of potential impacts to groundwater wells and recreational water quality (DWR, 2005).

In the Hoopa area, groundwater is predominantly calcium-magnesium bicarbonate in character. TDS concentrations range from 95 to 159 mg/L, and average 125 mg/L. The primary groundwater quality impairments in the basin are locally high iron concentrations, and low pH values (most ranging from 6.1 to 6.9) (DWR, 2011a).

In the Lower Klamath River Valley area, groundwater is predominantly calcium bicarbonate. TDS concentrations range from 49 to 508 mg/L, and average 196 mg/L. Localized areas with high aluminum, iron, manganese, and TDS occur in the basin (DWR, 2011a).

11.2.2.5 Feather River Area

The Feather River area includes Lake Oroville, the Feather River, and the Thermalito Complex. Groundwater in the area of the Feather River downstream of Lake Oroville, as it flows through Butte County, is predominantly calcium-magnesium bicarbonate and magnesium-calcium bicarbonate waters in the Sacramento River Hydrologic Region. Magnesium bicarbonate waters occur locally near the Biggs-Gridley area, south and east to the Feather River. TDS concentrations range from 75 to 801 mg/L, averaging 235 mg/L (DWR, 2004). Localized high concentrations of manganese, iron, magnesium, TDS, specific conductance, and calcium occur in this area (DWR, 2003).

As the Feather River flows through Yuba County, the good groundwater quality characteristics are apparent in the overall salinity of groundwater in the Secondary Study area. TDS concentrations in the area are typically below 500 mg/L throughout the entire basin. Data collected from wells indicate a TDS concentration range of 141 to 686 mg/L. The primary water chemistry in the area indicates calcium-magnesium bicarbonate or magnesium-calcium bicarbonate groundwater. Some magnesium bicarbonate exists in the northwest portion of the basin (DWR, 2003).

In the Sutter County area, the region includes both the Feather and Sacramento rivers as they near their confluence. Therefore, groundwater quality co increased levels of selenium present in the groundwater supplies for the City of Davis, conditions are similar to those discussed in the appropriate areas for the Sacramento River downstream of Lake Shasta (Section 11.2.2.2).

Also, the USGS did some water quality sampling in this area for the GAMA Program, as discussed previously in Section 11.2.2.2 (Sacramento River Downstream of Lake Shasta), because their sampling encompassed the entire mid portion of the Sacramento Valley.

11.2.2.6 American River Area

The American River area includes Folsom Lake, the American River, and Lake Natoma. In the area near Sacramento, the region includes both the American and Sacramento rivers as they near their confluence. Therefore, groundwater quality conditions are similar to those discussed in the appropriate areas for the Sacramento River downstream of Lake Shasta (Section 11.2.2.2).

11.2.2.7 Delta Region

The Delta region includes the Sacramento-San Joaquin Delta and Suisun Bay. Groundwater quality throughout most of the Delta region is suitable for some urban and agricultural uses, with only local impairments. The character of the groundwater varies in different portions of the Delta. The primary constituents of concern are high TDS, nitrate, boron, chloride, and organic compounds. Other constituents that may have local impairments include arsenic and manganese. As a result of declining water levels, poor quality water has been moving to the east in the Stockton area. Projections indicate that a saline front is moving to the east approximately 150 to 250 feet per year. Groundwater extraction in the Eastern San Joaquin Subbasin has increased the flow of saline water from the west. There is a concern that the eastward migration of saltwater will degrade portions of the basin, rendering the groundwater unsuitable for urban and agricultural purposes (SJCPWD, 2004).

11.2.2.8 San Francisco Bay Area

The San Francisco Bay area includes San Pablo Bay and San Francisco Bay. Groundwater quality throughout most of the region is suitable for urban and agricultural uses, with only local impairments, such as leaking underground storage tanks. Groundwater in the Livermore Valley and Niles Cone (southern Alameda County) basins has high levels of TDS, chloride, boron, and hardness, such that both Alameda County Flood Control and Water Conservation District-Zone 7 and Alameda County Water District (ACWD) are implementing wellhead demineralization projects to improve the quality of this groundwater supply. In the Santa Clara Valley region, some of the underlying groundwater supplies are threatened by pollutants from various industrial activities and historical agriculture. The Santa Clara Valley Water District (SCVWD) works to protect the quality of these supplies by aggressively responding to pollution threats, such as MTBE, PCE, TCE, and perchlorate. These pollution threats are individually identified and evaluated to prevent or mitigate for groundwater contamination. Elsewhere, groundwater in Petaluma Valley and the Gilroy-Hollister Valley has high levels of nitrate, which adversely impacts the ability to use domestic wells for drinking water purposes. Groundwater recharge projects and the use of imported water have effectively halted land subsidence in most areas, and have successfully stopped or reversed seawater intrusion into aquifers around the bay (DWR, 2005).

11.2.3 Primary Study Area

11.2.3.1 Sites Reservoir, Dams, and Recreation Areas

Groundwater quality data for the proposed Sites Reservoir area are limited[1]. Fifteen wells within the proposed Sites Reservoir footprint were sampled in 2005. Groundwater quality in the proposed Sites Reservoir footprint and adjacent area was fair, but high in mineral content. Salinity, measured as specific conductance, ranged from 680 to 2,190 μmhos/cm, and TDS values ranged from 375 to 1,291 mg/L. Sampling revealed that no Primary MCLs were exceeded. Of the 15 wells sampled, Secondary MCLs were exceeded for TDS in 14 wells, specific conductance in 12 wells, sulfate in four wells, pH in three wells, manganese and iron in two wells, and aluminum and chloride in one well each. Agricultural Water Quality Goals from the Food and Agriculture Organization of the United Nations (CVRWQCB, 2011) were exceeded for specific conductance and TDS in 14 wells each, sodium in 13 wells, chloride in eight wells, boron in six wells, pH in three wells, and selenium in one well (Appendix 11A).

11.2.3.2 Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

In the area of the proposed Holthouse Reservoir Electrical Switchyard and the Holthouse Reservoir Complex, which includes the existing Funks Reservoir, there are few wells. One well could be sampled that was near this area. Water from this well was extremely high in mineral content; for example, the specific conductance for this well was 38,200 μmhos/cm, and the TDS concentration was 27,400 mg/L.

---

[1] There are a limited number of well logs for wells in the proposed Sites Reservoir area. Several of these wells were not in use or were otherwise unable to be sampled. There are also several wells in this area for which no well log was available. Two of these wells were sampled to provide data in areas where no other wells were located and where adequate well construction data were provided by the owner/ranch manager.

The Primary MCL for arsenic was exceeded. Secondary MCLs were exceeded for chloride, specific conductance, manganese, and TDS Agricultural Water Quality Goals were exceeded for boron, chloride, and manganese (Appendix 11A).

11.2.3.3 Glenn-Colusa Irrigation District Canal

Groundwater data from 19 wells in the vicinity of the GCID Canal indicate good quality groundwater in this area. Impairments were not noted to be extensive, but some groundwaters had high mineral content. Specific conductance values ranged from 223 to 1,074 µmhos/cm, and TDS values ranged from 120 to 649 mg/L. Primary MCLs exceeded were for nitrite plus nitrate in two wells, and arsenic in one well. Secondary MCLs were exceeded for iron in four wells, TDS in three wells, and. aluminum and specific conductance in two wells each. Agricultural Water Quality Goals were exceeded for specific conductance in eight wells, TDS in five wells, sodium in six wells, and copper in one well (DWR, 2007).

11.2.3.4 Tehama-Colusa Canal

Groundwater data from 58 wells sampled along the length of the T-C Canal indicate that the quality of the groundwater along the canal is good, with a few impairments. Specific conductance ranged from 138 to 986 µmhos/cm, and TDS values ranged from 112 to 520 mg/L. Nitrate values exceeded the Primary MCL from one well. Secondary MCLs were exceeded for specific conductance, iron, and TDS in three wells each, and pH in one well. Agricultural Water Quality Goals were exceeded for specific conductance in five wells, boron and TDS in three wells each, copper and sodium in two wells each, and pH in one well (DWR, 2007).

11.2.3.5 Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Transmission Line, and Delevan Pipeline Electrical Switchyard

Data from 19 wells in the vicinity of the Delevan Pipeline, TRR Pipeline, TRR Pipeline Road, Delevan Transmission Line, and Delevan Pipeline Electrical Switchyard locations indicate that groundwater quality in this area is good; however, there are some impairments. This area had groundwater with a high mineral content, but concentrations were lower in proximity to the Sacramento River. Specific conductance values ranged from 324 to 2,245 µmhos/cm, and TDS ranged from 204 to 1,324 mg/L. The Primary MCL for arsenic was exceeded in four wells. Secondary MCLs were exceeded for manganese and specific conductance in nine wells each, TDS in eight wells, iron in five wells, and aluminum and sulfate in one well each. Recommended Agricultural Water Quality Limits were exceeded for sodium in 12 wells, specific conductance in 11 wells, TDS in nine wells, chloride and manganese in three wells each, and iron in one well (DWR, 2007).

11.2.3.6 Terminal Regulating Reservoir, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, and Terminal Regulating Reservoir Electrical Switchyard

Data from four wells near the locations of the proposed TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, and the TRR Electrical Switchyard indicate that groundwater quality in this area is fairly good, but high in mineral content. Specific conductance values ranged from 444 to 1,104 µmhos/cm, and TDS ranged from 259 to 608 mg/L. No Primary MCLs were exceeded. Secondary MCLs were exceeded for specific conductance and TDS in two wells each. Agricultural Water Quality

Limits were exceeded for sodium in three wells, specific conductance and TDS in two wells each, and chloride in one well (DWR, 2007).

11.2.3.7 Delevan Pipeline Intake/Discharge Facilities

Data from nine wells near the proposed Delevan Pipeline Intake/Discharge Facilities location indicate that groundwater quality is good, but high in mineral content. Specific conductance values ranged from 324 to 1,090 µmhos/cm, and TDS ranged from 204 to 622 mg/L. The Primary MCL for arsenic was exceeded in one well. Secondary MCLs were exceeded for manganese in six wells, specific conductance and iron in three wells each, and TDS in 2 wells. Recommended Agricultural Water Quality Limits were exceeded for specific conductance, sodium, and TDS in three wells each; manganese in two wells; and for arsenic, chloride and iron in one well each (DWR, 2007).

11.2.3.8 Road Relocations, South Bridge, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

Data from 21 wells near the locations of the proposed Road Relocations, South Bridge, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard were reviewed for groundwater quality in this area. The groundwater quality is fairly good, but impaired somewhat by high mineral content. Specific conductance values ranged from 290 to 2,190 µmhos/cm with 1 well at 38,200 µmhos/cm, and TDS ranged from 169 to 1,291 mg/L with 1 well at 27,400 mg/L. The Primary MCL for arsenic was exceeded from one well. Secondary MCLs were exceeded for TDS in 15 wells, specific conductance in 13 wells, manganese, pH, and sulfate each in three wells, and chloride and iron each in two wells. Agricultural Water Quality Goals were exceeded for specific conductance, sodium, and TDS in 14 wells each, chloride in eight wells, boron in six wells, pH in three wells, and selenium in one well (DWR, 2007).

11.2.3.9 Project Buffer

The Project Buffer would surround groupings of Project facilities. Groundwater quality within the Project Buffer would, therefore, be the same as described for each of the Project facilities that are surrounded by the Project Buffer.

11.3 Environmental Impacts/Environmental Consequences

11.3.1 Regulatory Setting

Groundwater quality is regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

11.3.1.1 Federal Plans, Policies, and Regulations

- Federal Safe Drinking Water Act
- Clean Water Act
- Federal Antidegradation Policy
- Porter-Cologne Water Quality Control Act

11.3.1.2 State Plans, Policies, and Regulations

- California Antidegradation Policy
- Water Quality Control Plan for the California Regional Water Quality Control Board Central Valley Region
- Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary
- Water Quality Control Plan for the Tulare Lake Basin
- Water Quality Control Plan for the North Coast Region

11.3.1.3 Water Quality Control Plan (Basin Plan)for the Sacramento/San Joaquin River Basins

- San Francisco Bay Basin Water Quality Control Plan
- California Code of Regulations – Underground Storage Tanks and Oil or Gas Wells

11.3.1.4 Regional and Local Plans, Policies, and Regulations

- Colusa County General Plan
- Glenn County General Plan
- Colusa County Groundwater Management Plan
- Glenn County Groundwater Ordinance and Management Plan

11.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for hydrology and water quality (no criteria are specifically directed at groundwater quality):

Would the Project:

- Violate any water quality standards or waste discharge requirements?
- Otherwise substantially degrade water quality?

These evaluation criteria used for this impact analysis represent a combination of Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact to groundwater quality if it would result in any of the following:

- A violation of any water quality standards or waste discharge requirements, a change in groundwater quality resulting in adverse effects to designated beneficial uses of groundwater, or otherwise substantially degrade groundwater quality

11.3.3 Impact Assessment Assumptions and Methodology

11.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to groundwater quality:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.

11.3.3.2 Methodology

A combination of data, published reports, modeling results, and professional experience with activities similar to those proposed was used to evaluate the potential impacts to groundwater quality from the alternatives. The data (detailed below) were used to assess existing groundwater quality and anticipate potential impacts that could result from Project-related activities in the three study areas.

The Extended and Secondary study area impact assessments relied on hydrologic and operational modeling performed using CALSIM II, which provided monthly river flows, and reservoir water surface elevations derived from monthly river flows and end-of-month reservoir storages, for the period of simulation extending from water year 1922 through 2003 (82-year simulation period). Detailed discussion of the CALSIM II model is provided in Appendix 6B. These modeling results were used in combination with professional judgment to assess the potential impacts of operation of the alternatives on groundwater quality.

DWR Bulletin 118-03 (DWR, 2003) was referenced to identify the groundwater basins within the Extended, Secondary, and Primary study areas, and to assess the groundwater quality within those basins from earlier assessments. In addition, DWR groundwater monitoring data (DWR, 2011a) were reviewed for the Primary and Secondary study areas.

A survey of DWR well completion report records (DWR, 2011b) was conducted to determine the number and location of wells in the Primary Study Area.

Previously completed studies of potential project effects to groundwater quality, including an Oroville Facilities FERC Relicensing groundwater study, were evaluated to determine the type and severity of impacts that might result in the Primary Study Area from proposed Project-related activities. Worst-case specific conductance (EC) conditions were simulated to assess the surface water quality of the proposed Sites Reservoir (refer to Appendix 7C for a detailed description of the EC Mass Balance Approach and modeling results). Expected surface water quality conditions were then compared to existing groundwater quality conditions to determine if an adverse impact could occur.

11.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above were eliminated from further consideration in this chapter.

11.3.5 Impacts Associated with the No Project/No Action Alternative

11.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Use

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to groundwater quality has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** to groundwater quality.

Groundwater extraction has exceeded groundwater recharge in several areas of the Sacramento and San Joaquin hydrologic regions. This has resulted in lower quality saline water infiltrating further into portions of the valley aquifer. Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. Population growth and/or increased agricultural demands could result in increased use of groundwater resources, adding additional stress to existing aquifers which could negatively affect groundwater quality. Continued groundwater extraction at rates that exceed groundwater recharge **could have a substantial adverse effect** on groundwater quality, when compared to Existing Conditions.

San Luis Reservoir

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

With implementation of the No Project/No Action Alternative, San Luis Reservoir would continue to experience water level fluctuations similar to Existing Conditions. Groundwater quality would not be expected to be substantially adversely affected by continued fluctuations. Therefore, continued fluctuations in water levels at San Luis Reservoir **would not have a substantial adverse effect** on groundwater quality, when compared to Existing Conditions.

11.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

As explained for the Extended Study Area, the No Project/No Action Alternative includes projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to groundwater quality has been addressed in those environmental documents. However, population growth could result in increased use of existing aquifers, which could result in a decline in groundwater quality. Groundwater level data indicate that groundwater extraction has likely exceeded groundwater recharge in several areas of the Sacramento River Hydrologic Region. These areas are scattered throughout the region, but there are areas with higher groundwater overdraft rates in Glenn County and south of the city of Williams in Colusa County. These areas are located in the Sacramento Valley floor groundwater basins. If the No Project/No Action Alternative is implemented, the overdraft rates would likely continue and possibly increase. Continued groundwater extraction at rates that exceed groundwater recharge **could have a substantial adverse effect** on groundwater quality, when compared to Existing Conditions.

11.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Use

Projects included in the No Project/No Action Alternative are not located within the Primary Study Area, and therefore **would not have a substantial adverse effect** on Primary Study Area groundwater quality. With implementation of the No Project/No Action Alternative, local landowners and tenants would continue to use groundwater for domestic use, manage crops with irrigation and pesticides, and raise cattle, which could degrade local groundwater quality. Population growth is projected to be minimal in this area, and **would not have a substantial adverse effect** on groundwater quality due to the small actual increase to the local population in this area, when compared to Existing Conditions.

11.3.6 Impacts Associated with Alternative A

11.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Use

Because there would not be any Project-related construction work or maintenance activities in the Extended Study Area, there would be **no impact** to groundwater quality associated with these activities.

The provision of an alternate source of wildlife refuge water supply would not affect rates of groundwater use, and would, therefore, have **no impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Project operation would have a beneficial, albeit limited, impact by increasing surface water supply reliability and consequently reducing reliance on groundwater in the CVP and SWP service areas within the Extended Study Area. Increased surface water supply reliability to agricultural, industrial, and municipal water users could result in decreased groundwater pumping. Decreased groundwater pumping would allow groundwater basins to recharge, resulting in improved groundwater quality. Additionally, irrigating with lower salinity water supplied from the Project, rather than groundwater, could alleviate existing increasing soil and groundwater salinity problems that result from evapotranspiration. Therefore, operational effects on groundwater quality within the Extended Study Area would be **potentially beneficial**, when compared to Existing Conditions and the No Project/No Action Alternative.

San Luis Reservoir

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Operational modeling for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates that operation of the Project would result in continued water level fluctuations at San Luis Reservoir, but the fluctuations would occur more often and could be more severe. Severe reservoir level drawdowns could result in reduced seepage, which could reduce local groundwater quality. However, San Luis Reservoir currently experiences severe water level fluctuations, and historic groundwater quality ranges should not be substantially adversely affected by continued fluctuations at an increased rate. Therefore, the increased fluctuations in water levels at San Luis Reservoir would have a **less-than-significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

11.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Project operation would result in improved surface water storage in reservoir facilities within the Secondary Study Area, which could increase seepage and soil percolation that recharges groundwater in these areas. However, this is not expected to increase at a rate that would have a significant beneficial effect on groundwater quality. Changes to the flow regime of the rivers, creeks, and bypasses could result in changes in the rate of groundwater recharge, but the amount of change is likely to be proportional to the change in flow, which would vary throughout the system. These changes are not expected to substantially affect groundwater quality. Project diversions would not be expected to adversely affect groundwater recharge rates in areas where groundwater extraction has likely exceeded groundwater recharge because Project diversions would occur during periods of excess surface flows and storm events. Therefore, changes in reservoir storage and flow regime would have a **less-than-significant impact** on groundwater quality within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative.

The installation, operation, and maintenance of an additional pump into an existing bay at the RBPP would have **no impact** on groundwater quality because it would neither extract groundwater nor increase groundwater recharge, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

The only direct Project-related maintenance activity that would occur within the Secondary Study Area is associated with the removal of sediment from the two existing canal intakes. This activity could result in the use of hazardous materials associated with heavy equipment. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. Contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

11.3.6.3 Primary Study Area – Alternative A

<u>Construction, Operation, and Maintenance Impacts</u>

Sites Reservoir Inundation Area

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

It is likely that, despite the grouting of the underlying rock formations, some water would leak from the reservoir and could increase groundwater recharge in nearby areas outside of the reservoir inundation area. Surface water quality modeling results indicate a worst-case long-term average EC of 190 to 192 µmhos/cm in Sites Reservoir (Appendix 7C), as compared to the range in EC of 680 to 2,190 µmhos/cm measured for existing groundwater quality conditions within the reservoir footprint. The weight of the reservoir could, therefore, force better quality surface water into the reservoir floor. There would also be additional percolation of surface water into the soils, and therefore, groundwater, beneath the reservoir. This surface water could beneficially alter shallow groundwater chemistry in and immediately around the reservoir. Therefore, reservoir inundation could have a potentially **beneficial effect** to shallow groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During construction in the Sites Reservoir Inundation Area it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There are approximately 26 wells and numerous septic systems located within the proposed reservoir inundation area. In addition to water wells, there may be current or historic oil and gas wells, test wells, and/or boreholes. All well types, boreholes, and septic systems would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality, or the potential for groundwater to contaminate reservoir surface water after inundation. The possible contamination resulting from the improper abandonment and consequent inundation of these wells, boreholes, and septic systems would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

There are not expected to be any underground storage tanks within the reservoir inundation area. However, if any are identified they would need to be located and abandoned pursuant to appropriate codes and regulations.

Sites Reservoir Dams

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Sites and Golden Gate dams would be constructed on Stone Corral and Funks creeks, respectively; flows to those creeks would be maintained during construction. Some redirection of creek flows and stormwater management during construction may result in very minor redirection of groundwater recharge, but not at a rate that would be expected to affect groundwater quality. Following completion of construction, flows would be maintained downstream of the dams. Therefore, the temporary dewatering of Funks and Stone Corral creeks during dam construction would have a **less-than-significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During construction in the Sites Reservoir Dams, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. In addition, during construction, an on-site concrete batch plant may be required. Storage of materials for production of concrete, waste products from this production, or other forms of contamination from associated equipment and construction vehicles could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There may be water wells, septic systems, or current or historic oil and gas wells, test wells, or boreholes at the damsites. All well types, boreholes, and septic systems would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality. The possible contamination resulting from the improper abandonment of any wells, boreholes, or septic systems would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Temporary dewatering of shallow groundwater may be required during construction. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface waters. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Hazardous Materials

During construction of the Recreation Areas, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. In addition, during operation and maintenance, increased vehicle traffic and use of the recreation areas by recreationists could introduce contaminants (such as fuels, oils, and herbicides) that could enter the environment and subsequently compromise groundwater quality. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There may be test wells or boreholes at the sites planned for Recreation Areas. All test wells and/or boreholes would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality. The possible contamination resulting from the improper abandonment of any test wells or boreholes would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Septic System, Leach Field, and Vault Toilet Construction

Vault toilets would be installed at all of the Recreation Areas. If they are improperly installed or not maintained correctly, they would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Hazardous Materials

During construction of the Road Relocations and South Bridge, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

In addition, on-site batch plants for asphalt or concrete may be required. Storage of materials for production of asphalt or concrete, waste products from this production, or other forms of contamination from associated equipment and construction vehicles could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation, vehicle traffic could have an adverse effect on groundwater quality resulting from spills or leaks. Runoff from materials used during road maintenance and repairs could also adversely affect groundwater quality. Careful management of ongoing road maintenance activities, together with habitat restoration and water quality pollution prevention projects in or adjacent to the road right-of-way, substantially contribute to the prevention of pollution. Combined, or individually, these would have a **less-than-significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There may be water wells, septic systems, or current or historic oil and gas wells, test wells, or boreholes along or adjacent to the road relocations. All well types, boreholes, and septic systems would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality. The possible contamination resulting from the improper abandonment of any wells, boreholes, or septic systems could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Temporary dewatering of shallow groundwater may be required during construction. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface waters. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Hazardous Materials

During construction of these facilities, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There may be water wells, septic systems, or current or historic oil and gas wells, test wells, or boreholes along or adjacent to these facilities. All well types, boreholes, and septic systems would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality. The possible contamination resulting from the improper abandonment of any wells, boreholes, or septic systems could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Construction of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard may require temporary localized lowering of the shallow groundwater. Construction of the tunnel from the Sites Pumping/Generating Plant to the Sites Reservoir Inlet/Outlet Structure would require dewatering. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface water. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Septic System and Leach Field Construction

Leach fields and a water treatment facility would be installed at the Field Office Maintenance Yard. Septic systems and associated leach fields must be properly sited, designed, installed, operated, and maintained to avoid harmful contamination from wastewater. Improper construction of these systems could result in a **potentially significant impact** to groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

During the construction of Holthouse Reservoir, Funks Reservoir would be drained and dredged to design capacity. The reservoir would be drained for up to two years. During this time, groundwater quality may be adversely affected due to reduced seepage and percolation from the drained reservoir. Because this is a temporary activity, and soil permeability is low in the area, the impact to groundwater quality would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Inundation of Holthouse Reservoir would likely lead to higher groundwater levels in a localized area around the reservoir from reservoir leakage and soil percolation. Holthouse Reservoir surface water quality is assumed to be the same as that modeled for Sites Reservoir. Surface water quality modeling results indicate a worst-case long-term average EC of 190 to 192 µmhos/cm for Sites Reservoir (Appendix 7C), as compared to the EC value of 38,200 µmhos/cm measured for existing groundwater quality conditions in the vicinity of Funks Reservoir. Therefore, this would a **beneficial effect** because shallow groundwater quality would be improved with better quality reservoir water, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During the dredging of Funks Reservoir, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

During the construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There are approximately three wells within a one-mile radius of these facilities. There may also be septic systems, current or historic oil and gas wells, test wells, or boreholes along or adjacent to the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard. All well types, boreholes, and septic systems would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality. The possible contamination resulting from the improper abandonment of any wells, boreholes, or septic systems could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard may require temporary localized lowering of the shallow groundwater. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface water. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Inundation of the TRR would likely lead to higher groundwater levels in a localized area around the reservoir from reservoir leakage and soil percolation. TRR surface water quality is assumed to be the same as that modeled for Sites Reservoir. Surface water quality modeling results indicate a worst-case long-term average EC of 190 to 192 µmhos/cm in Sites Reservoir (Appendix 7C), as compared to the range in EC of 444 to 1,104 µmhos/cm measured for existing groundwater quality conditions in the vicinity of the proposed TRR. Therefore, this would have a **beneficial effect** because shallow groundwater quality would be improved with better quality reservoir water, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During the construction of the TRR and associated facilities, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

There are approximately 10 wells within a one-mile radius of the proposed TRR. There may also be septic systems, or current or historic oil and gas wells, test wells, or boreholes along or adjacent to these TRR facilities. All well types, boreholes, and septic systems would need to be located, identified, and properly abandoned before or during construction; otherwise, they have the potential of creating a conduit for significant contaminant impacts to groundwater quality. The possible contamination resulting from the improper abandonment of any wells, boreholes, or septic systems could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Construction of these TRR facilities may require temporary localized lowering of the shallow groundwater. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface waters. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Underground Utilities

The proposed TRR Pipeline route would cross an existing PG&E gas line. It is possible that other gas lines exist along the pipeline route. All underground utilities would need to be located prior to construction to ensure that no damage is incurred during construction of the pipeline. If gas lines are damaged, they could allow gas to leak into groundwater, which would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

A portion of the earthen channel of the GCID Canal would be dewatered while 200 feet of the canal are lined with concrete. However, this construction is expected to occur during the regularly scheduled annual maintenance period for the canal, and would, therefore, not be expected to adversely affect groundwater recharge or quality. Once the canal is lined, there could be a reduction in the localized rate of groundwater recharge. However, because only 200 feet of canal would be lined, the potential subsequent loss of recharge in that small area would have a **less-than-significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During modifications of the GCID Canal facilities, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Hazardous Materials

During construction of the Delevan Transmission Line, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline and Delevan Pipeline Electrical Switchyard

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Hazardous Materials

During construction of the Delevan Pipeline and Delevan Pipeline Electrical Switchyard, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Temporary dewatering of shallow groundwater may be required during construction of these facilities. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface water. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Underground Utilities

The Delevan Pipeline route would cross an existing PG&E gas line. It is possible that other gas lines exist along the pipeline route. All underground utilities need to be located prior to construction to ensure that no damage is incurred during construction of the pipeline. If gas lines are damaged, they could allow gas to leak into groundwater, which would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Temporary dewatering of shallow groundwater may be required during construction. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Additionally, water from dewatering operations would need to be stored and properly handled and disposed of to avoid potentially contaminating surface water. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality.

Filling of the intake forebay would likely lead to higher groundwater levels in a localized area around the forebay from leakage and soil percolation. Forebay surface water quality is assumed to be the same as that modeled for Sites Reservoir. Surface water quality modeling results indicate a worst-case long-term average EC of 190 to 192 µmhos/cm in Sites Reservoir(Appendix 7C), as compared to the range in EC of 324 to 1,090 µmhos/cm measured for existing groundwater quality conditions in the vicinity of the facilities footprint. This would be a **potentially beneficial effect** because shallow groundwater quality would be improved with better quality surface water, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During construction of the Delevan Pipeline Intake Facilities, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Dewatering

Construction of the Delevan Pipeline Intake Facilities would require dewatering of shallow groundwater. Dewatering could expose soils and shallow groundwater to contamination from stormwater, construction materials, wastes, or other spilled materials. Contamination as a result of dewatering could have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Existing structures within the Project Buffer would be demolished, and any agricultural fields that are currently irrigated would not continue to receive irrigation. Any wells associated with those structures or used as irrigation sources may, therefore, no longer be used. The discontinued use of any wells could increase groundwater recharge, resulting in a **less-than-significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Hazardous Materials

During demolition of structures that are located within the Project Buffer, it is possible that the operation and maintenance of construction equipment could result in hazardous materials spills. These materials could pose a significant risk if misused or improperly handled and stored. Leaks and spills could enter the soil and potentially contaminate groundwater. The potential contamination of groundwater from hazardous materials would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

11.3.7 Impacts Associated with Alternative B

11.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to groundwater quality (**Impact GW Qual-1**), would be the same as described for Alternative A for the Extended Study Area.

11.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to groundwater quality (**Impact GW Qual-1**), would be the same as described for Alternative A for the Secondary Study Area.

11.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater quality:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline

- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprint or construction disturbance area of Sites Reservoir and Dams, the Road Relocations and South Bridge, and the Delevan Transmission Line would differ from Alternative A. In addition, the Delevan Pipeline Intake Facilities would be replaced by the Delevan Pipeline Discharge Facility. The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on groundwater quality (**Impact GW Qual-1**) as described for Alternative A, with the exclusion of the potential impacts associated with the Delevan Pipeline Intake Facility forebay and afterbay that are included in Alternative A, but not Alternative B.

The Sites Reservoir Inundation Area would increase from a 1.27-MAF capacity (with Alternative A) to a 1.81-MAF capacity (with Alternative B). The larger reservoir size associated with Alternative B would require the same type of construction, operation, and maintenance activities as for Alternative A, and would, therefore, have the same potential for impact from hazardous materials (**Impact GW Qual-1: Hazardous Materials**) as described for Alternative A. Potential impacts associated with a larger reservoir on rates of groundwater recharge and abandoned wells, septic systems, or underground storage tanks are described below.

Sites Reservoir Inundation Area

Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality

Changes in Rates of Groundwater Recharge

Refer to the **Impact GW Qual-1** discussion for the Alternative A Sites Reservoir Inundation Area. The greater volume of water in the Alternative B reservoir would not appreciably change the rate of groundwater forced into the soil from the weight of the reservoir water and from natural percolation from that described for Alternative A. It could, however, beneficially alter shallow groundwater chemistry in and immediately around the reservoir, as described for Alternative A. Therefore, the Sites Reservoir Inundation Area could have a **potentially beneficial effect** to shallow groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Abandoned Wells, Septic Systems, or Underground Storage Tanks

Refer to the **Impact GW Qual-1** discussion for the Alternative A Sites Reservoir Inundation Area. It is possible that the larger reservoir would inundate additional wells, septic systems, boreholes, or underground storage tanks than Alternative A, but the number of potential additional wells associated with Alternative B would be small relative to the total number affected. Regardless of whether additional impacts would occur in comparison to Alternative A, the possible contamination resulting from the improper abandonment and consequent inundation of these wells, boreholes, and septic systems would have a **potentially significant impact** on groundwater quality, when compared to Existing Conditions and the No Project/No Action Alternative.

11.3.8 Impacts Associated with Alternative C

11.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to groundwater quality (**Impact GW Qual-1**), would be the same as described for Alternative A for the Extended Study Area.

11.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to groundwater quality (**Impact GW Qual-1**), would be the same as described for Alternative A for the Secondary Study Area.

11.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater quality:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater quality (**Impact GW Qual-1**) as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Facilities, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to groundwater quality (**Impact GW Qual-1**) as described for Alternative B.

The boundary of the Project Buffer would be the same for all alternatives, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on groundwater quality (**Impact GW Qual-1**) as described for Alternative A.

11.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 11-1 for the impacts that have been identified as significant or potentially significant.

Table 11-1
Summary of Mitigation Measures for
NODOS Project Impacts to Groundwater Quality

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact GW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Groundwater Quality Resulting in Adverse Effects to Designated Beneficial Uses of Groundwater, or Otherwise Substantially Degrade Groundwater Quality				
Impact GW Qual-1a: Hazardous Materials	Sediment Removal at the T-C and GCID Canal Intakes; All Primary Study Area Project facilities	Potentially Significant	Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant
Impact GW Qual-1b: Abandoned Wells, Septic Systems, or Underground Storage Tanks	Sites Reservoir and Dams, Recreation Facilities, Road Relocations, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Holthouse Reservoir Complex, TRR, TRR Pipeline, TRR Pumping/Generating Plant, TRR to Funks Creek Pipeline, GCID Connection to TRR	Potentially Significant	Mitigation Measure GW Qual-1b: Implement DWR and County Standards for the Proper Abandonment of Wells, Boreholes, and Septic Systems	Less than Significant

Table 11-1
Summary of Mitigation Measures for
NODOS Project Impacts to Groundwater Quality

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact GW Qual-1c: Dewatering	Sites Reservoir Dams, Road Relocations, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Holthouse Reservoir Complex, TRR, TRR Pipeline, TRR Pumping/Generating Plant, TRR to Funks Creek Pipeline, GCID Connection to TRR, Delevan Pipeline, Delevan Pipeline Intake/Discharge Facilities	Potentially Significant	Mitigation Measure GW Qual-1c: Implement Caltrans Field Guide to Construction Site Dewatering	Less than Significant
Impact GW Qual-1d: Underground Utilities	TRR Pipeline, Delevan Pipeline	Potentially Significant	Mitigation Measure GW Qual-1d: Identify Underground Utilities Prior to Start of Construction	Less than Significant
Impact GW Qual-1e: Septic System, Leach Field, and Vault Toilet Construction	Recreation Facilities, Field Office Maintenance Yard	Potentially Significant	Mitigation Measure GW Qual-1e: Construct Septic Systems, Leach Fields, and Vault Toilets in Accordance with County Permit Specifications	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan

DWR and Reclamation shall prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) that emphasizes proper hazardous materials storage and handling procedures; shall outline spill containment, cleanup, and reporting procedures; and shall limit refueling and other hazardous activities to designated areas. Signs prohibiting refueling shall be posted in sensitive areas. Equipment shall be inspected prior to use each day to ensure that hydraulic hoses are tight and in good condition. Other appropriate BMPs, such as use of concrete washout basins and proper waste management, securely locating and maintaining portable toilets, combined with visual observation and water sample collection and analysis, shall be used to prevent discharge of possible contaminants and chemicals associated with construction, maintenance, or operations activities to reduce potentially significant contamination impacts to groundwater quality to a **less-than-significant level**. Details of these BMPs are described in Section WM-4 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure GW Qual-1b: Implement DWR and County Standards for the Proper Abandonment of Wells, Boreholes, and Septic Systems

According to DWR's Water Well Standards (DWR, 2012), a well that is no longer useful (including exploration and test holes) must be destroyed to assure that the existing groundwater quality and proposed Project water quality is protected and preserved for further use, and to eliminate any potential physical hazard. Destruction of a well shall consist of the complete filling of the well in accordance with the procedures described in DWR Water Well Standards Section 23. Permits for well destruction shall also be obtained from the appropriate County agency (Glenn or Colusa).

Any current or historic oil and gas wells detected within the Project facility footprints shall be addressed. Any well types that would be inundated shall be properly sealed and abandoned according to policies and procedures laid out in the California Code of Regulations Title 14 from the Department of Conservation. These wells shall be sealed to ensure that the existing groundwater quality is protected and preserved, and to eliminate any potential physical hazard. Permits for well destruction shall also be obtained from the appropriate County agency (Glenn or Colusa).

Any test holes, boreholes, other potential conduits to groundwater shall also be sealed and destroyed.

Existing septic systems, such as septic tanks, cesspools, and seepage pits, shall be identified and located. These septic systems shall then be properly abandoned and demolished, and, if necessary, removed and disposed of. Destruction of septic systems shall require:

- A licensed septic tank pumper to pump the septic tank. A copy of the receipt for this pumping shall be obtained.
- Abandonment of the tank in accordance with county ordinances, which may include methods such as:
  - Tank removed, then disposed of at a sanitary landfill
  - Tank top removed, tank crushed, then excavation filled with earthen materials to within 12 inches of native surface
  - Tank top removed, bottom perforated, then excavation filled with earthen materials to within 12 inches of native surface

Permits for abandonment and destruction shall also be obtained from the appropriate County (Glenn or Colusa) prior to work.

Mitigation Measure GW Qual-1c: Implement Caltrans Field Guide to Construction Site Dewatering

Effluent from dewatering activities shall be properly stored and disposed of to prevent contamination of surface water. This BMP is intended to prevent the discharge of pollutants from construction site dewatering operations associated with stormwater (accumulated rain) and non-stormwater (e.g., groundwater or water from a diversion or cofferdam). Dewatering effluent that is discharged from the construction site to a storm drain or receiving water is subject to the requirements of the applicable National Pollutant Discharge Elimination System (NPDES) permit. Refer to the *Caltrans Field Guide to Construction Site Dewatering* for detailed guidance for management of dewatering operations (Caltrans, 2001). The dewatering effluent shall be managed according to Central Valley RWQCB requirements and California Stormwater Quality Association BMPs.

Mitigation Measure GW Qual-1d: Identify Underground Utilities Prior to Start of Construction

Underground utilities in the vicinity of Project facility footprints, such as gas or sewer lines, must be identified and located prior to any excavation. This is to ensure excavation activities do not cause damage to the utilities, resulting in utility disruption and/or construction worker safety. Prior to the start of construction, utility providers shall be contacted to identify underground utilities in the vicinity of Project facility footprints.

Mitigation Measure GW Qual-1e: Construct Septic Systems, Leach Fields, and Vault Toilets in Accordance with County Permit Specifications

Septic systems, leach fields, and vault toilets shall be properly sited, designed, installed, operated, and maintained to ensure that wastewater is adequately treated and does not contaminate groundwater. Permits and approvals shall be obtained from Colusa County Environmental Health.

Implementation of **Mitigation Measures SW Qual-1e, GW Qual-1b, GW Qual-1c, GW Qual-1d, and GW Qual-1e** would reduce the level of significance of Project impacts to groundwater quality to **less than significant**.

12. Aquatic Biological Resources

12.1 Introduction

This chapter describes the aquatic habitat and fish resources found within the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Fish species of primary management concern include special-status species and species that have substantial commercial or recreation value. The biology and life history of these species are described in Appendix 12A.

The regulatory setting for aquatic biological resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas are evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives are described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

12.2 Environmental Setting/Affected Environment

12.2.1 Extended Study Area

12.2.1.1 Methodology

A county-level California Natural Diversity Database (CNDDB) (CDFG, 2009) search was conducted to determine the special-status fish species that may occur within the 39 counties included in the Extended Study Area. Documents specific to areas and species within the Extended Study Area were also reviewed to characterize aquatic biological resources.

12.2.1.2 Level 4 National Wildlife Refuges and Wildlife Areas

In addition to providing irrigation water to the Sacramento and San Joaquin valleys, and domestic water to cities and industries in Sacramento County and the east and south Bay areas, the CVP supplies water to wildlife refuges.

Fish species occur in the waterways that deliver CVP Level 4 wildlife refuge water supply[1] to the wetlands within the wildlife refuges. In the Sacramento River Basin, the refuges that receive Level 4 water include the Sacramento and Delevan national wildlife refuges (NWR). Waterways within these refuges include creeks, the Colusa Basin Drain (CBD), and many smaller water supply and drainage ditches. These waterways are part of the Sacramento River system. Most resident fish in the waterways that supply the refuge system are non-native warm-water species. Native anadromous fish include steelhead and four distinct runs of Chinook salmon.

---

[1] The Level 4 water deliveries that could be affected by Project operation are contracted to The Sacramento and Delevan National Wildlife Refuges (NWR), the West Bear Creek unit of the San Luis NWR Complex and the Merced unit of the Merced NWR, as well as the Los Banos, Volta, and Mendota WAs, the China Island and Salt Slough units of the North Grasslands Wildlife Area, and private wetlands of the Grassland Resource Conservation District within the San Joaquin River Basin; and to the Kern and Pixley NWRs within the Tulare Lake Basin.

The waterways of the NWRs and Wildlife Areas (WAs) within the San Joaquin River Basin and Tulare Lake Basin that receive Level 4 water supply support warm-water resident fish species. Sensitive species are not known to occur within the San Joaquin River Basin and the Tulare Lake Basin NWRs and WAs within the Extended Study Area (Reclamation et al., 2001; USFWS, 2004). Fish species commonly found in the San Joaquin River Basin NWR water conveyance ditches and canals include spotted bass (*Micropterus punctulatus*), largemouth bass (*M. salmoides*), channel catfish (*Ictalurus punctatus*), sunfish (*Lepomis* sp.), brown bullhead (*Ameiurus nebulosus*), and common carp (*Cuprinus carpio*). Flooding may occur, but is much less frequent than in the Sacramento River Basin. Sacramento splittail (*Pogonichthys macrolepidotus*) may occur within the San Joaquin River Basin NWRs during periods of spring flooding or high flows. Spawning populations of fall-run Chinook salmon (*Oncorhynchus tshawytscha*), Central Valley Steelhead (*Onchorynchus mykiss*), and lamprey (*Lampetra* sp.) are known to occur in the San Joaquin River Basin north and downstream of the NWRs (Reclamation et al., 2001). Fish passage upstream of the Merced River confluence is limited during the fall by a fish barrier that CDFG maintains in the San Joaquin River to prevent passage of adult fall-run Chinook salmon.

The fish species of primary management concern that may occur in the Extended Study Area are listed in Table 12-1.

Table 12-1
Fish Species of Primary Management Concern in the Extended Study Area

Common Name	Scientific Name	Listing Status Federal/State[a]
Central Valley Chinook salmon, winter-run[b]	*Oncorhynchus tshawytscha*	FE/SE
Central Valley Chinook salmon, spring-run[b]	*Onchorynchus tshawytscha*	FT/ST
Central Valley Chinook salmon, fall-/late fall-run	*Onchorynchus tshawytscha*	FSC/CSSC
Central Valley steelhead[b]	*Onchorynchus mykiss*	FT
Klamath Mountain Province ESU Steelhead	*Onchorynchus mykiss*	C
Central California Coast Steelhead	*Onchorynchus mykiss*	FT
South Central California Coast Steelhead	*Onchorynchus mykiss*	FT
Southern California Steelhead	*Onchorynchus mykiss*	FE
Coho Salmon Northern California/Southern Oregon ESU[c]	*Oncorhynchus kisutch*	FT
Central California Coast Coho Salmon ESU	*Oncorhynchus kisutch*	FE
Green sturgeon Southern DPS[d, b]	*Acipenser medirostris*	FT/CSSC
White sturgeon	*Acipenser transmontanus*	None
Delta smelt[b]	*Hypomesus transpacificus*	FT/ST
River lamprey	*Lampetra ayresi*	FSC/CSSC
Pacific lamprey	*Lampetra tridentata*	None
Sacramento splittail	*Pogonichthys macrolepidotus*	FT/CSSC
Hardhead	*Mylopharodon conocephalus*	CSSC
Longfin smelt	*Spirinchus thaleichthys*	FT/CSSC
Eulachon	*Thaleichthys pacificus*	FT
Largemouth bass	*Micropterus salmoides*	None
Resident Rainbow trout	*Oncorhynchus mykiss*	None
Brown trout	*Salmo trutta*	None
American shad	*Alosa sapidissima*	None
Striped bass	*Morone saxatilis*	None

[a]**Status Key**

FE = Federal Endangered
FT = Federal Threatened
FSC = Federal Species of Concern
C = Federal Candidate species
SE = State Endangered
ST = State Threatened
CSSC = California Species of Special Concern

[b]Critical Habitat has been designated for this species.
[c]ESU = Evolutionarily Significant Unit

12.2.1.3 Export Service Area Reservoirs

The CVP and SWP reservoirs (including San Luis Reservoir) that supply the service areas within the Extended Study Area support warmwater and coldwater sport fish, such as striped bass (*Morone saxatilis*), largemouth bass, and resident rainbow trout (*Oncorhynchus mykiss*). Fish species listed as sensitive, threatened, or endangered are found downstream of the major Central Valley reservoirs and in the Sacramento-San Joaquin Delta (Delta), but do not persist in the aqueduct and other constructed water conveyance and storage facilities. The fish species of management concern that are found in the Sacramento River Watershed and Delta are discussed in more detail in Section 12.2.2. Fish species of primary management concern that occur within and downstream of the CVP and SWP export service area reservoirs of the Extended Study Area are listed in Table 12-1 (NMFS, 1999).

12.2.2 Secondary Study Area

12.2.2.1 Methodology

A county-level CNDDB (CDFG, 2009) search was conducted to determine the special-status fish species that may occur within the 22 counties of the Secondary Study Area. For fish species listed pursuant to the Federal Endangered Species Act (FESA) that could occur within the Sacramento/San Joaquin River and Delta region, the Sacramento Fish and Wildlife Office's Endangered Species Program website (USFWS, 2010) was consulted. For species listed pursuant to the California Endangered Species Act (CESA) in this region, the January 2011 Endangered and Threatened Animal List maintained by CDFG was consulted (CDFG, 2011a). Documents or data specific to areas and species within the Secondary Study Area were also reviewed to characterize aquatic biological resources.

12.2.2.2 Sacramento River Watershed

The aquatic environments associated with the Sacramento River Watershed include Shasta Lake, Keswick Reservoir, Whiskeytown Reservoir, Spring Creek, Clear Creek, and the Sacramento River downstream of Keswick Dam. The Sacramento River Watershed drains an area of approximately 27,000 square miles and is the largest watershed in California (Figure 12-1). Its headwater streams upstream of Shasta Dam include the Fall, Upper Sacramento, Pit, and McCloud rivers. The watershed also includes the Feather River and American River watersheds.

The Sacramento River Watershed supports several fish species of primary management concern (Table 12-2), including green sturgeon (*Acipenser medirostris)*, Central Valley steelhead, and winter-, spring-, fall-, and late-fall-run Chinook salmon.

Table 12-2
Fish Species of Primary Management Concern in the Sacramento River Watershed Portion of the Secondary Study Area

Common Name	Range within Watershed	Federal/State Status[a]
Central Valley Chinook salmon, winter-run[b]	Sacramento River downstream of Keswick Dam	FE/SE
Central Valley Chinook salmon, spring-run[b]	Sacramento River downstream of Keswick Dam	FT/ST
Central Valley Chinook salmon, fall/late fall-run	Sacramento River downstream of Keswick Dam	FSC/CSSC
Central Valley steelhead[b]	Sacramento River downstream of Keswick Dam	FT

Table 12-2
Fish Species of Primary Management Concern in the Sacramento River Watershed Portion of the Secondary Study Area

Green sturgeon	Sacramento River downstream of Keswick Dam	FT/CSSC
White sturgeon	Sacramento River downstream of Keswick Dam and Shasta Lake	None
River lamprey	Sacramento River downstream of Keswick Dam	FSC/CSSC
Pacific lamprey	Sacramento River downstream of Keswick Dam	None
Sacramento splittail	Sacramento River downstream of Keswick Dam	FT/CSSC
California roach	Sacramento River and Streams Throughout Study Area	CSSC
Hardhead	Sacramento River downstream of Keswick Dam	CSSC
Largemouth bass	Throughout Study Area	None
Smallmouth bass	Throughout Study Area	None
Spotted bass	Throughout Study Area	None
Landlocked Chinook salmon	Shasta Lake and Whiskeytown Lake	None
Resident rainbow trout	Throughout Study Area	None
Brown trout	Throughout Study Area	None
American shad	Sacramento River downstream of Keswick Dam	None
Striped bass	Sacramento River downstream of Keswick Dam	None

Shasta Lake

Shasta Lake supports cold-water and warm-water fisheries. Thermal stratification, which occurs in Shasta Lake annually between April and November, establishes a warm surface water layer (epilimnion), a middle water layer characterized by decreasing temperature with increasing depth (metalimnion or thermocline), and a bottom cold-water layer (hypolimnion). The warm epilimnion of Shasta Lake provides habitat for warm-water fishes, whereas the reservoir's cold metalimnion and hypolimnion provides habitat for cold-water fish species throughout the summer and fall. Hence, Shasta Lake supports a "two-story" fishery during the stratified portion of the year (April through November).

Cold-water species in Shasta Lake include rainbow trout, brown trout (*Salmo trutta*), landlocked white sturgeon, and landlocked Chinook salmon. The lake's rainbow trout and Chinook salmon fishery are sustained through stocking of hatchery-raised fish. Shasta Lake warm-water species include smallmouth bass (*Micropterus dolomieu*), largemouth bass, spotted bass, black crappie (*Pomoxis nigromaculatus*), bluegill (*Lepomis macrochirus*), green sunfish (*Lepomis cyanellus*), channel catfish (*Ictalurus punctatus*), white catfish (*Ameiurus catus*), and brown bullhead (*Ameiurus nebulosus*). Non-game species in Shasta Lake include golden shiner (*Notemigonus crysoleucas*), threadfin shad (*Dorosoma petenense*), common carp, Sacramento sucker (*Catostomus occidentalis*), and Sacramento pikeminnow (*Ptychocheilus* *grandis*). The rainbow trout, Chinook salmon, smallmouth, largemouth, and spotted bass fisheries are important sport fisheries in the area.

Although developed primarily for irrigation, the multiple-purpose Shasta Lake also provides flood control, improves Sacramento River navigation, supplies domestic and industrial water, generates hydropower, provides fish and wildlife habitat, creates opportunities for recreation, and enhances water quality. Since construction, Shasta Dam has played a major role in meeting Bay-Delta water quality standards, and meeting temperature and spawning habitat requirements for the endangered winter-run Chinook salmon (Reclamation, 1999a). These uses of Shasta Lake water cause water surface elevations to fluctuate by approximately 55 feet over the course of a year, which disturbs the reservoir’s littoral (shallow, nearshore) habitats and influences the availability of cold- and warmwater habitats in the lake. Disruptions to littoral habitat also occur from shoreline wave action caused by wind and boating activity (Reclamation et. al., 2003). Littoral habitat supports spawning and rearing habitat for warm-water fish that are important for the sport fishery. These fish include smallmouth, largemouth, and spotted bass; black crappie; bluegill; and green sunfish. These fish species spawn in the spring between March and June. Surface water fluctuations during spring can dewater nests and reduce the amount of overhanging, emergent, and submerged vegetative cover, which can reduce the abundance of these fish species (DWR, 2002).

Keswick Reservoir

Cold-water fish species found in Keswick Reservoir include resident rainbow trout and brown trout. Warm-water species include the same species found in Shasta Lake. CDFG occasionally plants hatchery-reared fish in Keswick Reservoir. The reservoir is accessible from shore and by boat, but it is not heavily used for fishing. Keswick Dam is the uppermost barrier to anadromous fish migrating up the Sacramento River. Because of its small size, Keswick Reservoir does not stratify. Reservoir levels fluctuate daily by one to three feet. The reservoir can fluctuate as much as eight to nine feet on an annual basis. Releases to the Sacramento River have ranged from approximately 3,300 cfs (DWR, 2011) during drought periods and 79,000 cfs during flood events (DWR, 1974).

Whiskeytown Lake

Whiskeytown Lake supports cold-water and warm-water fisheries. Cold-water fish species include rainbow trout, brown trout, landlocked Chinook salmon, and kokanee salmon (*Oncorhynchus nerka*). The lake is well known for its kokanee salmon sport fishery. CDFG plants kokanee in Whiskeytown Lake, but kokanee also spawn in tributaries, such as Brandy and Whiskeytown creeks upstream of the reservoir. Warm-water fish species include largemouth bass, crappie, green sunfish, and various species of catfish.

The cold-water pool in Whiskeytown Lake is managed to provide cold water for release to the Sacramento River and Clear Creek. Temperature control curtains are operated on Whiskeytown Lake and on Lewiston Reservoir to improve the amount of cold-water pool available for release to the Sacramento River for winter-run Chinook salmon. The Whiskeytown Lake curtains are located at the Judge Francis Carr Powerhouse outlet and at the Spring Creek Tunnel inlet. The Carr Powerhouse curtain prevents the mixing of cold Trinity River water with warm surface water and directs it to the reservoir’s deep cold-water layer. The Spring Creek Tunnel curtain prevents the diversion of warm surface water while allowing the diversion of cold water from the reservoir’s bottom layer. Similar to Shasta Lake, fluctuations in surface water elevations disturb littoral habitat and warm-water fish species important to the sport fishery.

Sacramento River Downstream of Keswick Dam

The Sacramento River supports many resident and anadromous fish (Table 12-2). The Sacramento River supports a wide range of aquatic habitats, from fast-flowing gravel bedded reaches with alternating riffles and pools, to slow-moving off-channel sloughs and oxbows with fine sediments. From Keswick Dam to the City of Red Bluff, the river is relatively narrow and deep with some areas of broader alluvial floodplain. Most of the Chinook salmon spawning habitat in the Sacramento River is located in this reach.

Between the cities of Red Bluff and Colusa, the river meanders over a broad alluvial floodplain, and flow is significantly affected by tributaries during winter storms. From Colusa to the City of Sacramento, the river is constrained by levees. In this reach, high winter flows spill from the river into a system of weirs and bypasses, including the Sutter Bypass and Yolo Bypass. These bypasses can supply important floodplain rearing habitat for outmigrating Chinook salmon from the Sacramento River and its tributaries.

The variability and magnitude of natural seasonal flows on the Sacramento River have been significantly altered for the purposes of irrigation and flood control. The dams and diversions operated by the CVP and local irrigation districts control much of the flow in the Sacramento River. These dams and diversions include the Shasta, Keswick, Trinity, Lewiston, Whiskeytown, and Spring Creek Debris dams, the Anderson-Cottonwood Irrigation District diversion dam and canal, the Red Bluff Diversion Dam (RBDD), the Glenn-Colusa Irrigation District (GCID) pumping plant and canal, and the Tehama-Colusa (T-C) and Corning canals. Shasta Dam has the largest impact on Sacramento River flow. In addition to altering flows, the dam has substantially reduced the quality and availability of habitat for migratory and resident fish species by blocking passage, and reducing the delivery of coarse sediment and large wood debris. The effects of Shasta Dam on spawning habitat quality and flow are especially evident in the Redding area. Downstream of Redding, the tributaries to the Sacramento River, such as Cow Creek and Cottonwood Creek, influence flow and sediment supply and reduce the impacts of Shasta Dam on channel and floodplain habitat.

To protect holding and spawning winter-run Chinook salmon, Reclamation has been required to manage cold-water reservoir storage and releases to maintain daily average water temperatures at or below 56ºF between Keswick Dam and compliance locations between Balls Ferry and Bend Bridge from May 15 to September 30 since 1993. Cold-water releases from Shasta Dam mitigate for loss of habitat up-stream of Shasta Dam, by providing cooler water temperatures in the upper reaches of the river that are still accessible to anadromous fish. In drier years, when reservoir storage is low, the stretch of river in which cold-water temperatures are maintained is shortened by approximately nine miles, ending at Jelly’s Ferry Bridge. Water temperature control was improved in 1997 with the installation of the temperature control device at Shasta Dam. The device allowed greater control over cold-water reserves in Shasta Lake while continuing hydroelectric power generation. Before its installation, Reclamation had to forego power generation to make cold-water releases, especially during periods of low reservoir levels. Figure 12-2 shows average daily water temperatures at points along the Sacramento River from Balls Ferry to Colusa.

To mitigate for the loss of coarse sediment, Reclamation has managed an ongoing gravel augmentation program since 1997 on the Sacramento River, pursuant to the Central Valley Project Improvement Act (CVPIA), to improve Chinook salmon and steelhead spawning habitat in the Redding area upstream of Turtle Bay (RM 299). Prior to Shasta Dam, DWR estimates that the amount of gravel delivered to the river from the watershed above Shasta Dam was approximately 120,000 tons (75,000 cubic yards) per year (DWR, 1980).

A total of 174,670 tons (106,500 cubic yards) of gravel was added to the river by Reclamation, DWR, and CDFG between 1978 and 2005 (North State Resources, 2010). Reclamation continued this effort by adding a total of 54,000 tons of gravel to the river immediately downstream of Keswick Dam from 2006 through 2012(Hannon, pers. comm., 2012). Large in-channel gravel mining pits, which were created when gravel was mined for the construction of Shasta Dam, trap the gravel as it is transported downstream, limiting the amount of spawning habitat that is enhanced and reducing the time the gravel functions as spawning habitat. The gravel is placed upstream of these pits to enhance spawning habitat for winter-run Chinook salmon, which spawn primarily between Keswick Dam and Turtle Bay. Cottonwood Creek supplies an annual average of 65,000 tons of gravel to the Sacramento River, and as a result, the sediment conditions for spawning habitat improve and the effects from Shasta Dam are diminished at the confluence (RM 273) (DWR, 1994).

Blocked access to historical spawning grounds in the upper watershed causes spring-run Chinook salmon to spawn in the same lowland reaches of the Sacramento River that fall-run Chinook salmon use as spawning habitat. The overlap in spawning sites, combined with a slight overlap in spawning timing (Moyle, 2002), may be responsible for inter-breeding between spring and fall-run Chinook salmon. This inter-breeding has been observed in the Feather River (Hedgecock et al., 2001). Since 2008, very few spring-run spawned in the mainstem of the Sacramento River (CDFG, 2011b).

Diversions on the Sacramento River Downstream of Keswick Dam

Of the approximately 424 water diversions on the Sacramento River between Keswick Dam and the City of Sacramento at the I Street Bridge, approximately six percent have fish screens. Most of the diversions occur between the City of Colusa and the City of Sacramento. Diversions that are of significance to the aquatic environment and the proposed Project are the RBDD and the GCID Pumping Plant.

Diversions from the RBDD are made to the T-C and Corning canals at a maximum rate of approximately 2,500 cfs and a maximum annual diversion of about 600,000 acre-feet (TCCA and Reclamation, 2002). Closure of the RBDD gates affects passage of green sturgeon, steelhead, and winter-, spring- and fall-run Chinook salmon. Because of these concerns, the RBDD gates have been closed only from May 15 through September 15, and from June 15 to August 31 since 2009. The new period of gate closure is required in the June 2009 NMFS Operations Criteria and Plan Biological Opinion (NMFS, 2009). Although the gates are open at the beginning and end of the irrigation season, diversions are limited to what is available through pumps that have been installed at the headworks. The Tehama-Colusa Canal Authority (TCCA) constructed an interim pumping plant in 2009 to meet irrigation demands when the diversion dam gates are out. A new pumping plant and fish screen was constructed upstream of RBDD to replace the dam and improve passage for Chinook salmon, steelhead, and green sturgeon. Construction was completed in September 2012. The screen design allows diversion of up to 2500 cfs. The pumping plant has a diversion rate of 2,000 cfs and can be expanded to a rate of 2,500 cfs (Reclamation, 2009).

The GCID Pumping Plant provides water for primarily agricultural irrigation, but also supplies water for rice straw decomposition in the fall and maintenance of waterfowl habitat. The pumping plant is located on an oxbow channel west of the main Sacramento River channel. An interim flat plate fish screen was installed to replace a drum screen structure in 1993 to enhance fish protection at the pumping plant, and a permanent flat plate screen was installed in 2000. The flat plate screen has improved the protection for larval and juvenile anadromous fish at the GCID pumping plant, but investigations and monitoring have indicated that mortality caused by pumping operations is exceeding performance criteria for the facility. Mortality may be the result of predation in the oxbow channel.

To maintain appropriate sweeping and approach velocities at the screen, a "gradient facility" was constructed in the main channel of the Sacramento River upstream of the oxbow. Factors related to the GCID pumping plant and fish screen affecting juvenile fish are the approach and sweeping velocities, bypass position, and potential predations throughout the facility (Vogel, 2005).

Yolo Bypass and Sutter Bypass

Flow from the Sacramento River spills into the Sutter and Yolo bypasses during high flow events. The bypasses form a floodplain corridor that is an important part of the flood control system, but also serves an important floodplain function for juvenile salmonids and other native fish. Fish enter the bypasses through flood relief structures and weirs. The Sacramento River enters the Sutter Bypass at Moulton, Colusa, and Tisdale weirs, and enters the Yolo Bypass at the Freemont Weir. Downstream of the Freemont Weir, Cache Creek and Putah Creek enter the Yolo Bypass. Table 12-3 shows the approximate flow at which the flood relief structures are overtopped and the Sacramento River begins to flood the bypasses.

Table 12-3
Sacramento River flood relief structures and flood control weirs, and approximate flow at which water begins to enter the Sutter Bypass and Yolo Bypass.

Sacramento River Flood Relief Structure and Flood Control Weirs	Approximate Sacramento River Flow at which Structure is Overtopped (cfs)	Adjoining Basin or Bypass
Moulton Weir	65,000	Sutter Bypass
Colusa Weir	37,000	Sutter Bypass
Tisdale Weir	23,000	Sutter Bypass
Fremont Weir	56,000	Yolo Bypass

Note:
cfs = cubic feet per second
Source: NWS, 2011.

The floodplains of the bypasses are very important to rearing Chinook salmon (Sommer et al., 2001a). These areas can be much more productive than the main channel and provide a safe haven from predatory fish (Swenson et al., 2001; Sommer et al., 2001a). It remains unclear whether these spatial differences in feeding and growth result in improved survival. The use of low gradient floodplains does subject juveniles to stranding when high flows subside quickly (NMFS, 1997).

Splittail use floodplains and other shallow areas with emergent vegetation for spawning and rearing. Splittail spawning habitat is greatly increased during periods of floodplain inundation in the Sacramento and San Joaquin basins (Baxter, 1999b).

12.2.2.3 Feather River Watershed

The aquatic environments associated with the Feather River Watershed (Figure 12-3) within the Secondary Study Area include DWR's Oroville facilities (Lake Oroville, Thermalito Diversion Pool, Thermalito Forebay, Thermalito Afterbay, the fish barrier pool, and the Feather River). Issuance of the FERC license for the Oroville facilities is pending as of June 2012. The new license's requirements will affect aquatic habitat associated with and affected by the Oroville facilities, including the Feather River downstream of Oroville Dam.

Fish species of primary management concern found in the Feather River Watershed portion of the Secondary Study Area are shown in Table 12-4. The following information provided for the SWP Oroville Facilities and the Feather River is from DWR's *May 2007 Oroville Facilities Relicensing FERC Project No. 2100 Draft Environmental Impact Report*, unless otherwise noted.

Table 12-4
Fish Species of Primary Management Concern in the Feather River Watershed Portion of the Secondary Study Area

Common Name	Range within Watershed	Federal/State Status[a]
Central Valley Chinook salmon, spring-run[b]	Feather River downstream of Fish Barrier Dam	FT/CT
Central Valley Chinook salmon, fall- run	Feather River downstream of Fish Barrier Dam	FSC/CSSC
Central Valley steelhead[b]	Feather River downstream of Fish Barrier Dam	FT
Green sturgeon	Feather River downstream of Fish Barrier Dam	FT/CSSC
White sturgeon	Feather River downstream of Fish Barrier Dam	None
River lamprey	Feather River downstream of Fish Barrier Dam	FSC/CSSC
Pacific lamprey	Feather River downstream of Fish Barrier Dam	None
California roach	Feather River and Streams Throughout Study Area	CSSC
Sacramento splittail	Feather River below Fish Barrier Dam	FT/CSSC
Hardhead	Feather River downstream of Fish Barrier Dam	CSSC
Largemouth bass	Oroville Lake, Thermalito Forebay and Afterbay, Feather River downstream of Fish Barrier Dam	None
Smallmouth bass	Oroville Lake, Thermalito Forebay and Afterbay, Feather River downstream of Fish Barrier Dam	None
Spotted bass	Oroville Lake, Thermalito Forebay and Afterbay, Feather River downstream of Fish Barrier Dam	None
Rainbow trout	Lake Oroville, Diversion Pool, Thermalito Forebay	None
Brown trout	Lake Oroville, Diversion Pool, Thermalito Forebay	None
Landlocked Coho salmon	Lake Oroville	None
American shad	Feather River downstream of Fish Barrier Dam	None
Striped bass	Feather River downstream of Fish Barrier Dam	None

[a]Status designations:

FT = federally-listed as Threatened
FSC = federally-listed as Species of Concern
CT = California-listed as Threatened
CSSC = California-listed as Species of Special Concern

[b]Critical Habitat has been designated for this species within the study area.

Source: CDFG 2011a, Moyle 2002.

Lake Oroville

Lake Oroville typically thermally stratifies into three layers (epilimnion, metalimnion, and hypolimnion) beginning in the spring. The lake begins to de-stratify in the fall, and remains relatively uniform throughout the winter. Because of this stratification regime, Lake Oroville supports both cold-water and warm-water fisheries. The cold-water fish use the deeper cooler well-oxygenated hypolimnion, whereas the warm-water fish are found in the warmer shallower epilimnion and near-shore littoral zone. Once Lake Oroville de-stratifies in the fall, the two fishery components mix in their habitat use.

Oroville Dam is operated for water supply, power generation, flood control, and fish and wildlife habitat. Management for these uses causes fluctuations in surface water elevation and storage throughout the year, which affects the availability of cold- and warm-water habitat within layers. Cold-water hatchery-raised fish are stocked in Lake Oroville as yearlings, with the intent that they will grow in the lake before being caught by anglers. Hatchery stocking is necessary to sustain the cold-water fishery. Natural recruitment to the Lake Oroville cold-water fishery is very low because of a lack of spawning and rearing habitat in the reservoir and accessible tributaries, and natural and artificial barriers to migration into tributaries with sufficient spawning and rearing habitat. From 1993 through 2000, Chinook salmon and brown trout were the only salmonid species stocked in the lake. At the recommendations of CDFG, DWR began stocking Coho salmon instead of Chinook salmon and brown trout in 2002 to address an outbreak of Infectious Hematopoetic Necrosis (IHN) at the Feather River Hatchery (Coho salmon are less susceptible to IHN).

Cold water is taken from Lake Oroville's hypolimnion for releases to the Feather River for Chinook salmon and steelhead. Cold-water releases to the Feather River potentially limit the amount of cold water available for salmonids in Lake Oroville.

The Lake Oroville warm-water fishery is self-sustaining. Black bass are the most popular and important fishery, in terms of both popularity with anglers and economic effect on the area. Spotted bass are the most abundant bass species in Lake Oroville, followed by largemouth bass, redeye bass (*Micropterus coosae*), and smallmouth bass. Catfish are the next most popular warm-water sport fish sought by anglers at Lake Oroville; both channel and white catfish inhabit the lake. White and black crappie are also found in Lake Oroville; populations fluctuate widely from year to year. Bluegill and green sunfish are the most abundant sunfish species in Lake Oroville, and redear sunfish (*Lepomis microlophus*) and warmouth (*Lepomis gulosus*) exist in low numbers. Common carp, considered by many to be a nuisance species, are abundant in Lake Oroville. As described for Shasta Lake, fluctuations in surface water elevation affect littoral habitat, which can reduce the abundance of bass and sunfish (DWR, 2002).

The primary forage fish that occur in Lake Oroville are wakasagi (*Hypomesus nipponensis*) and threadfin shad. Threadfin shad were intentionally introduced in 1967 to provide forage for game fish, whereas wakasagi migrated down from an upstream reservoir in the mid-1970s. The population of threadfin shad has dwindled since the early 1990s, which may be a result of poor overwinter survival, or perhaps from competition with wakasagi for habitat and forage.

Thermalito Diversion Pool

The Feather River water temperature requirements create cold-water fishery habitat in the Thermalito Diversion Pool (Diversion Pool). The Diversion Pool is dominated by fish that have come out of Lake Oroville over the spillway or through the power plant, including rainbow trout, brown trout, and Coho salmon. With the exception of excess steelhead from the Feather River Hatchery, the Diversion Pool and the Thermalito Forebay (Forebay) are not stocked with fish by CDFG.

Thermalito Forebay

The Forebay provides habitat primarily for cold-water fish, although the same warm-water fish species found in Lake Oroville are believed to exist in the Forebay in low numbers (DWR, 2007).

Thermalito Afterbay

The Thermalito Afterbay (Afterbay) provides habitat for both cold-water and warm-water fish. Changes in flow rates, pumpback operation, and water surface elevations resulting from project operation affect water temperatures and the quality, quantity, and distribution of fish habitat in the Afterbay.

Fish species observed in the Afterbay include largemouth bass, smallmouth bass, rainbow trout, brown trout, bluegill, redear sunfish, black crappie, channel catfish, common carp, and large schools of wakasagi. Salmonids are not regularly stocked in the Afterbay, however, some years, when the Feather River Fish Hatchery has surplus steelhead (e.g., 2005, 2011, and 2012), they are put in the Afterbay. It is unlikely that any salmonids spawn in tributaries of Thermalito Afterbay. Therefore, rainbow trout and brown trout that occur in the Afterbay likely passed through the Thermalito pumping-generating plant from the Forebay. The Afterbay likely provides good habitat for largemouth, smallmouth, and spotted bass species, and large schools of wakasagi provide a good source of forage fish. Bass nest dewatering from reservoir fluctuations likely limits juvenile recruitment in the Afterbay (DWR, 2004a).

Feather River Downstream of Oroville Dam

Oroville facilities releases are primarily managed to benefit cold-water fisheries. There are several fish species of primary management concern in the Feather River downstream of Oroville Dam (Table 12-4, above), including spring- and fall-run Chinook salmon, Central Valley steelhead, and green sturgeon. The fish barrier weir at the Feather River Fish Hatchery is the most upstream barrier to fish passage on the Feather River downstream of Oroville Dam. The hatchery was constructed to mitigate for the loss of Chinook salmon and steelhead habitat upstream of Oroville Dam.

The Feather River below Oroville Dam, commences at the Low Flow Channel (LFC), which extends eight miles from the Fish Barrier Dam (RM 67) to the Thermalito Afterbay Outlet (RM 59). The LFC of the Feather River conveys releases from the Thermalito Diversion Dam to its confluence with the Afterbay outlet. Minimum flows and ramping criteria in the Feather River were established in an August 1983 agreement between DWR and DFG (DWR, 1983). The agreement specifies that DWR release a minimum of 600 cfs into the Feather River from the Thermalito Diversion Dam for fisheries purposes. Therefore, the LFC is operated at 600 cfs all year with variations in flow occurring rarely, only during flood control releases, or in the summer to meet downstream temperature requirements for salmonids. Water temperatures tend to be coldest in the uppermost portions of the Feather River near the fish barrier dam. Upon issuance of the FERC license, higher DWR releases will likely be required to maintain lower water temperatures in the LFC.

Flows in the high flow channel of the Feather River, which conveys the combined flows from the low flow channel and the Afterbay outlet, are maintained between the minimum flow and a flow no greater than 2,500 cfs from October 15 through November 30 to prevent Chinook salmon redd dewatering during the egg incubation period (DWR, 2007). The flow regime in the reach of the Feather River extending from the Thermalito Afterbay outlet (RM 59) to the confluence of the Feather and Sacramento rivers (RM 0) varies depending on runoff and month. The instream flow requirements below Thermalito Afterbay are 1,700 cfs from October through March, and 1,000 cfs from April through September. In Critical years, however, the minimum flow can be reduced to 1,200 cfs from October to February, and to 1,000 cfs in March (DWR, 2007). Small flow contributions from Honcut Creek and the Bear River, and larger flow contributions from the Yuba River, also influence flow in this segment. The Shanghai Bench between RM 26 and RM 25 and Sunset Pumps between RM 38 and 39 may impede sturgeon passage at lower flow ranges (DWR, 2007).

Oroville Dam, Thermalito Diversion Dam, and the fish barrier dam block gravel contribution to the Feather River. An estimated 97 percent of the sediment from the upstream watershed is trapped in Lake Oroville, resulting in sediment starvation downstream (DWR, 2007).

High flow releases from the Oroville facilities mobilize smaller substrate particle sizes. The smaller substrate sizes are not replaced by upstream gravel, resulting in a gradual coarsening of the particle size distribution of the substrate in the upper portions of the Feather River. Coarsening and armoring of the substrate size can affect the quality of spawning habitat and the distribution of spawning salmonids and other fishes. In general, the reach of river with the highest proportion of coarse substrate components is the low flow channel of the Feather River.

Blocked access to historical spawning grounds in the upper watershed causes spring-run Chinook salmon to spawn in the same lowland reaches of the Feather River as fall-run Chinook salmon. The overlap in spawning sites, combined with a slight overlap in spawning timing (Moyle, 2002) may be responsible for inter-breeding between spring-run and fall-run Chinook salmon in the Feather River (Hedgecock et al., 2001).

The majority of in-river spring-run Chinook salmon spawning is concentrated in the uppermost three miles of accessible habitat in the Feather River downstream of the Feather River Fish Hatchery, although spawning may extend to the downstream portion of the low flow channel upstream of the Thermalito Afterbay outlet (Sommer et al., 2001b).

Most of the natural steelhead spawning and rearing in the Feather River occurs in the low flow channel, particularly in the upper reaches near Hatchery Ditch, a side-channel located between RM 66 and 67 between the Table Mountain Bicycle Bridge and Lower Auditorium Riffle. Limited steelhead spawning also occurs downstream of the Thermalito Afterbay outlet. The smaller substrate size and greater amount of cover (compared to the main river channel) also make these side-channels more suitable for juvenile steelhead rearing (DWR, 2004b). This type of habitat comprises less than one percent of the available habitat in the low flow channel.

12.2.2.4 Trinity River Watershed

The aquatic environment associated with the Trinity River Watershed (Figure 12-4) within the Secondary Study Area includes Reclamation's Trinity River Division (TRD) facilities, which include Trinity Lake, Lewiston Lake, Whiskeytown Lake (which is described in the Sacramento River Watershed section), and the Trinity River downstream of Lewiston Dam.

Fish species of primary management concern found in the Trinity River Watershed portion of the Secondary Study Area are shown in Table 12-5.

Table 12-5
Fish Species of Primary Management Concern in the Trinity River Watershed Portion of the Secondary Study Area

Common Name	Range within Watershed	Federal/State Status[a]
Chinook salmon, spring-run	Trinity River downstream of Lewiston Dam	CSSC
Chinook salmon, fall- run	Trinity River downstream of Lewiston Dam	CSSC
Steelhead (Klamath Mountains Province DPS)	Trinity River downstream of Lewiston Dam, Klamath River	CSSC

Table 12-5
Fish Species of Primary Management Concern in the Trinity River Watershed Portion of the Secondary Study Area

Common Name	Range within Watershed	Federal/State Status[a]
Green sturgeon (Northern DPS)	Klamath River and Trinity River	CSSC
White sturgeon	Trinity River and Klamath River	None
River lamprey	Feather River downstream of Fish Barrier Dam, Klamath River	FSC/CSSC
Pacific lamprey	Feather River downstream of Fish Barrier Dam, Klamath River	None
Hardhead	Trinity River, Lewiston Reservoir, Trinity Lake, Klamath River	CSSC
Largemouth bass	Lewiston Reservoir, Trinity Lake	None
Smallmouth bass	Lewiston Reservoir, Trinity Lake	None
Spotted bass	Lewiston Reservoir, Trinity Lake	None
Resident rainbow trout	Trinity River, Lewiston Lake, Trinity Lake, Klamath River	None
Brown trout	Trinity River, Lewiston Lake, Trinity Lake, Klamath River	None

Trinity Lake and Lewiston Lake

Releases from Trinity Lake are re-regulated in Lewiston Lake prior to release downstream into the Trinity River. Lewiston Lake also acts as a forebay for the trans-basin export of water into Whiskeytown Lake via the Clear Creek Tunnel.

TRD operation is integrated with operation of the Shasta Division of the CVP. For example, TRD exports have been made in consideration of minimum flow and temperature requirements in the Trinity and Sacramento rivers, storage levels and cold-water pool in Trinity and Shasta lakes, and other CVP operating requirements (e.g., CVP deliveries, water quality requirements, and the OCAP BO). Trinity Lake is also operated to maximize power production during the summer and fall. The majority of TRD exports occur in the spring and summer. At the same time, temperature objectives to protect Trinity River salmon must be met. Addressing the temperature needs of the two systems is only one of the factors that influence operations.

Based on the Trinity River Mainstem Fishery Restoration ROD, dated December 19, 2000, a total of 368,600 to 815,000 AF is allocated annually for Trinity River flows. This amount is scheduled in coordination with the USFWS to best meet habitat, temperature, and sediment objectives in the Trinity River Basin (USBR, 2008).

Trinity River and Klamath River Downstream of the Trinity River

The Trinity River is the largest tributary to the Klamath River. Lewiston Dam releases are the major component of Trinity River flows until its confluence with the North Fork Trinity River. Downstream of the confluence, the accretion of tributary inflows, such as Willow Creek, reduces the dampening effects of the TRD.

The Klamath River flows from its confluence with the Trinity River to the Pacific Ocean. Species of management concern in the Trinity and Klamath rivers (Table 12-5) include Coho salmon, steelhead, spring- and fall-run Chinook salmon, and green sturgeon. The reach of the Klamath River within the Secondary Study Area is a migration route for these species to spawning habitat in the Trinity River and farther up in the Klamath River Watershed.

12.2.2.5 American River Watershed

The aquatic environments associated with the American River Watershed (Figure 12-5) within the Secondary Study Area include Folsom Lake, Lake Natoma, and the American River downstream of Nimbus Dam.

Fish species of primary management concern found in the American River Watershed portion of the Secondary Study Area are shown in Table 12-6.

Folsom Lake and Lake Natoma

Similar to the other large Central Valley reservoirs, strong thermal stratification occurs within Folsom Lake annually between November and April. Largemouth bass, smallmouth bass, spotted bass, bluegill, crappie, and catfish constitute the primary warm-water sport fisheries of Folsom Lake. The lake's cold-water sport species include rainbow and brown trout, kokanee salmon, and Chinook salmon, all of which are currently or have been stocked by DFG. Although brown trout are no longer stocked, a population still remains in the lake. These species are stream spawners and, therefore, do not reproduce within the lake. However, some spawning by one or more of these species may occur in the American River upstream of Folsom Lake. Other species that occur in the lake include hardhead and Sacramento pikeminnow.

Folsom Lake's cold-water pool is important not only to the lake's cold-water fish species, but also to lower American River fall-run Chinook salmon and steelhead. Seasonal releases from the lake's cold-water pool provide thermal conditions in the lower American River that support annual in-river production of these salmonid species. The cold-water pool in Folsom is primarily managed to sustain releases during October and November to maximally benefit fall-run Chinook salmon immigration, spawning, and incubation, but is not large enough to allow for cold-water releases during the warmest months (July through September) to provide maximum thermal benefits to lower American River steelhead.

Folsom Reservoir, because of its proximity to the Delta, is also often used by Reclamation to make releases when additional Delta outflow is required to meet Delta salinity standards. Consequently, Folsom Reservoir storage can be reduced, resulting in reduced cold-water pool volume. A reduced cold-water pool in Folsom Reservoir may result in releases from Nimbus Dam that are warmer and have the potential to exceed suitable water temperature ranges for fish species of focused evaluation in the American River. Nimbus Dam and Powerplant are located downstream from Folsom Dam. The dam forms Lake Natoma, which re-regulates water released from Folsom Dam and diverts water into the Folsom South Canal. Water not diverted is released into the American River through radial gates. Nimbus Dam is the most upstream barrier to fish passage on the American River.

American River Downstream of Nimbus Dam

The lower American River provides a diversity of aquatic habitats, including shallow fast-water riffles, runs, pools, and off-channel backwater habitats.

At least 40 species of fish have been reported to occur in the lower American River system, including numerous resident native and introduced species, as well as several anadromous species (SWRI, 2004).

With more than 125 miles of available upstream salmonid spawning habitat, the American River historically served as a regionally vital component for the health of fall- and spring-run Chinook salmon populations (Water Forum, 2001). Although dam construction eliminated the spring-run fishery, the lower American River continues to function as spawning and rearing habitat for large numbers of fall-run Chinook salmon. The river supports a mixed run of hatchery and naturally produced fish. During the period of 1967 through 1991 (the Anadromous Fish Restoration Program restoration goal baseline period), lower American River fall-run Chinook salmon spawning comprised on average approximately 21 percent (41,040 fish) of total fall-run Chinook salmon escapement (197,740 fish) in the Sacramento Valley river system, including the Sacramento River and its tributary rivers and creeks (DFG, 2011b). Recent escapement estimates (1992 to 2002) for the Central Valley suggest that American River fall-run Chinook salmon comprise approximately 22 percent of the total fall-run Chinook salmon escapement in the Sacramento River and its major tributaries (68,373 of 311,746) (PFMC, 2003).

The lower American River also provides spawning and rearing habitat for Central Valley steelhead. The majority of the steelhead run is believed to be of hatchery origin.

The primary factor potentially limiting fall-run Chinook salmon and steelhead production within the lower American River is believed to be high water temperatures during portions of their residency in the river. High water temperatures during the fall can delay the onset of spawning by Chinook salmon, and river water temperatures can become unsuitably high for juvenile salmon rearing during spring and for steelhead rearing during summer. In addition, relatively low October and November flows tend to increase the amount of fall-run Chinook salmon redd superimposition (occurs when females dig up the fertilized eggs of other females), thereby potentially reducing the number of juveniles produced per female.

12.2.2.6 Sacramento-San Joaquin Delta

The Delta is a unique aquatic ecosystem that provides complex habitat for a diverse assemblage of fish and macroinvertebrates. Table 12-7 identifies the fish species of primary management concern found within the Delta.

There are many fish species within the Delta that have experienced a general decline in abundance (Moyle et al., 1995). Therefore, many of these species require special management strategies, including winter-run and spring-run Chinook salmon, steelhead, delta smelt, longfin smelt, green sturgeon, and Sacramento splittail. These species are either listed for protection pursuant to FESA or CESA or listed by CDFG as a Species of Special Concern.

Several fish and macroinvertebrate species inhabiting the Delta also support recreational and commercial fisheries, such as fall-run Chinook salmon, northern anchovy, Pacific sardine, starry flounder, striped bass, largemouth bass, and white sturgeon. The Delta has been identified as Essential Fish habitat (EFH) for the commercially managed species (northern anchovy, Pacific sardine, starry flounder, and Chinook salmon) (NMFS, 2011).

USFWS and NMFS have designated all or part of the Delta within the Secondary Study Area as critical habitat or essential fish habitat for delta smelt, Central Valley steelhead, winter- and spring-run Chinook salmon, and green sturgeon.

The listing status, life history, and factors affecting population abundance for the special-status fish species that inhabit the Delta and may be affected by construction or operation of the proposed project are discussed in Appendix 12-A.

Table 12-7
Fish Species of Primary Management Concern in the Sacramento-San Joaquin Delta

Species	Scientific Name	Listing Status[a]		Life History[b]	Designated Habitat[c]

Many of the fish and macroinvertebrate species inhabit the Delta year-round; other species inhabit the system on a seasonal basis as a migratory corridor between upstream freshwater riverine habitat and coastal marine waters, as seasonal foraging habitat, or for reproduction and juvenile rearing habitat (Table 12-8).

The geographic distribution of fish species within the Delta is determined, in part, by salinity gradients, which range from fresh water within the Sacramento and San Joaquin river systems, to marine conditions near the Golden Gate Bridge (Moyle et-. al., 1982). The majority of fish species in the Delta use the Tidal

Perennial Aquatic community (see Affected Environment and the CALFED Ecosystem Restoration Program Plan for detailed description of the aquatic communities in the Delta).

The abundance, distribution, and habitat use by these fish and macroinvertebrates has been monitored for many years through investigations conducted by CDFG, NMFS, USFWS, DWR, and several other investigators. Results of these monitoring programs have shown evidence of long-term declines and sharper declines since the early 2000s in some of the Delta pelagic fish species (Baxter et al., 2010).

Table 12-8
Seasonal Occurrence of Different Life Stages of Migratory Fish Species of Primary Management Concern within the Sacramento-San Joaquin Delta

Species	Adult Migration (peak)	Spawning (peak)	Juvenile Freshwater Residency (all freshwater residency, not Delta residency)	Outmigration (peak)	Source
River lamprey	Fall	N/A	3-5 years	Spring	Moyle, 2002
Pacific lamprey	Jan-June (Mar-May)	N/A	5-7 years	Spring	Moyle, 2002
Green sturgeon	Feb-July	N/A	1-4 years	Aug-Oct	Federal Register, 2005; Moyle, 2002
Chinook salmon (Sacramento winter-run)	Dec-July (Mar)	N/A	5-10 months	Oct-May	Moyle, 2002; CDFG, 2010
Chinook salmon (Sacramento spring-run)	Mar-Sep (May-June)	N/A	3-15 months	Nov-Jun	Moyle, 2002; CDFG, 2010
Chinook salmon (Sacramento fall-run)	June-Dec (Sep-Oct)	N/A	1-7 months	Jan-Jun	Moyle, 2002; CDFG, 2010
Chinook salmon (Sacramento late fall-run)	Oct-Apr (Dec)	N/A	7-13 months	Apr-Sep	Moyle, 2002; CDFG, 2010
Central Valley steelhead	Aug-Mar (Sep-Oct)	N/A	1-3 years	Jan-Jun	Moyle, 2002; CDFG, 2010
Delta smelt	Dec-Mar (Jan)	Feb-July (Apr-May)	4-5 months	N/A	Moyle, 2002; Bennett, 2005
Longfin smelt	Winter	Nov-June (Feb-Apr)	0-2 months	Jan-Aug (Apr-June)	Moyle, 2002
Sacramento splittail	Dec-Mar	Feb-July (Mar-May)	All Year	N/A	Moyle, et al., 1995; Moyle, 2002
Striped bass	Apr-June	Apr-May	All Year	N/A	SWRI, 2003

Note:
N/A = not applicable because these species do not spawn in the Delta

Stressors Affecting Delta Fish Species

Pelagic organisms (organisms that live at or near the water's surface) live in the ocean or in estuaries like the Delta. Many pelagic organisms provide a resource base in the Delta food web, and can be considered key indicator species of the overall health and condition of the system they inhabit.

Since approximately 2005, there has been a significant effort to study the declining native fish populations in the Delta. The Interagency Ecological Program (IEP), consisting of scientists and managers representing six federal and three state agencies, is evaluating the possible causes of pelagic organism decline

(Baxter et al., 2010). In June 2006, the Legislature directed the Resources Agency to report on proposed actions to address the pelagic organism decline, and to stabilize the ecosystem in the Delta.

Since approximately 2002, the abundance indices calculated by the IEP fall Midwater Trawl survey demonstrated significant declines in numerous pelagic fishes within the Delta including the delta smelt, longfin smelt, age-0 striped bass, and threadfin shad (Baxter et al., 2010). The declines of these four species appeared to occur simultaneously despite the differences in their life histories and how these species utilize Delta habitats, suggesting that one of more Delta-wide factors contributed to the decline (Baxter et al., 2010).

The basic conceptual model for the pelagic organism decline contains four major components based on the following hypotheses: (1) prior fish abundance - continued low abundance of adults leads to low juvenile production (i.e., stock-recruitment effects); (2) habitat - the amount of water (volume or surface area) with suitable conditions for a species has changed because changes in estuarine water quality variables, disease, and toxic algal blooms in the estuary affect survival and reproduction; (3) top-down effects - predation and water project entrainment affect mortality rates; and (4) bottom-up effects - consumable resources and food web interactions affect survival and reproduction (Baxter et al., 2010). Stressors affecting the fish species of primary management concern within the Delta are discussed below.

Delta Agricultural Diversions

There are approximately 2,200 water diversions within the Delta (Herren and Kawasaki, 2001; Reclamation, 2008). Although entrainment by agricultural diversions is not frequently identified as a factor in the decline of Delta fish species, most of these small diversions are not screened (Herren and Kawasaki, 2001). The majority of the diversions divert water to agricultural fields between April and August. The early part of this irrigation season coincides with the timing of spawning and larval development of fish species of primary management concern in the Delta. Because spawning and larval development are likely to occur in shallow shoreline locations and movement is limited, entrainment of these life stages by agricultural diversions may be more substantial (Reclamation, 2008).

Reverse Flows

The CVP and SWP both divert water from Old River, a tidal slough that intersects the lower San Joaquin River. CVP and SWP diversions can cause the tidally averaged flow in the Old River, Middle River, and other adjacent channels in the southern Delta to reverse flow toward the diversions. These reverse flows contribute to the entrainment of numerous fish species, including migrating and spawning delta smelt. Patterns of entrainment vary with life history and season, as well as food availability and water quality (Grimaldo et al., 2009).

Reverse flows also affect downstream migrating juvenile Chinook salmon and steelhead. Pilot studies of the effect of Delta Cross Channel (DCC) operations on the movement of juvenile Chinook salmon in the Delta indicate that yearlings will move into the Delta Cross Channel during flood tides, and can be drawn into the channel after initially migrating past the channel gates (CALFED, 2000).

Non-Native Species

The Delta is one of the most biologically invaded estuaries in the world. Non-native species have been introduced intentionally and unintentionally. Many introduced species are considered undesirable, and some of these species are believed to adversely affect the ecosystem within the Delta. For example, since the introduction of the overbite clam (*Corbula amurensis*), there has been a reduction of the phytoplankton, thereby affecting the productivity of the estuary with a corresponding reduction in zooplankton and pelagic fish production. Historic relationships between Delta outflow and the populations of longfin smelt and striped bass have shifted since the introduction of this clam (Baxter et al., 2010).

The Delta also has experienced successive invasions of copepod species. Copepods are zooplankton that form the food base for many pelagic fishes. The most recently introduced copepod, *Limnoithona tetraspina*, displaced the previously dominant copepod species (*Psuedodiaptomus forbesi*) in the early 1990s. The abundance of other copepods has decreased continuously since its introduction. *Limnoithona* is a less suitable food item than the previous species (Baxter et al., 2010).

Toxins

Anthropogenic and environmental toxins could also have adversely affected fish populations (DWR and CDFG, 2007). Although initial data on striped bass and delta smelt indicated high frequencies of liver lesions and other signs of disease indicative of toxic poisoning (Armor et al., 2005), subsequent studies have shown that acute contaminant toxicity is not likely the cause for population declines, but could be a contributor (Baxter et al., 2010). Two toxins have received special attention: pyrethroid pesticides and *Microcystis* hepatotoxins (toxins that damage the liver).

Pyrethroid pesticides have received special attention in pelagic organism decline studies because of their increased use in recent years and their high toxicity to aquatic organisms. Although pyrethroids are readily absorbed into sediment, they can be mobilized during high flow events and are highly toxic to zooplankton and fish (Werner et al., 2006). Although it has been shown that these pesticides have the capacity to affect pelagic fish populations, a direct link to pelagic organism decline has yet to be demonstrated (Armor et al., 2005).

Microcystis is a colonial cyanobacteria that produces hepatotoxins that can affect both fish and humans. Blooms of *Microcystis* have become larger and more widespread during the summer. Reduced stream flow in the Delta seems to promote the growth of *Microcystis* and is more abundant in dry years (Baxter et al., 2010). *Microcystis* blooms have not yet been identified as a primary cause of the pelagic organism decline (Baxter et al., 2010).

Water Exports

CVP and SWP exports can influence the magnitude of flows into the Delta and the outflow from the Delta into Suisun Bay. Along with Delta inflow, Delta outflow is an important regulator of habitat quality and availability, and fish distribution, survival, and abundance (Baxter et al., 2010). Delta inflow and outflow are important for species residing primarily in the Delta (e.g., delta smelt and longfin smelt) (USFWS, 2008), and juveniles of anadromous species (e.g., Chinook salmon, steelhead, and green sturgeon) that rear in the Delta prior to ocean entry. CVP and SWP operations can increase fish entrainment, redirect fish into areas with higher risks of mortality, affect salinity, and degrade essential habitat conditions. The rate and location that water is diverted from the Delta affects the residence time of water in Delta channels, which affects primary and secondary production. High residence time allow phytoplankton to accumulate in the Delta (Kimmerer, 2004).

Water exports indirectly affect pelagic fish by changing the hydrology and salinity of the estuary. Hydrologic changes caused by water exports include changes in flow magnitude and direction (especially in the south Delta), movement of water from the Sacramento River into and through the central Delta, and changes in the amount of low salinity habitat available for fish that depend on this type of habitat.

Assessment of the indirect effects of exports has been focused largely on the position of the two parts per thousand (ppt) salinity isopleth (i.e., the “X2” location) and the relative abundance of low salinity habitat (USFWS, 2008; NMFS, 2009).

Most of the fish species of special concern are affected by Delta Cross Channel operation, including all races of Chinook salmon, steelhead, American shad, striped bass, and green and white sturgeon. The Delta Cross Channel is not screened. However, the gates of the Delta Cross Channel can be operated to reduce flow from the Sacramento River into the central Delta.

Efforts have been made to reduce water diversions in the spring, when diversions are believed to have the greatest impacts on fish in the Delta. However, during these years, the total amount of water exported from the Delta annually has increased substantially. The most notable changes have included a slight increase in flow down the Sacramento River since 2001, a reduction in peak San Joaquin River outflows since 1999, and increased exports during June through December (DWR and CDFG, 2007).

Delta smelt are affected by Delta Cross Channel operation, both during upstream migrations by spawning adults and during downstream transport of larvae (Reclamation et. al., 2003). Increased winter exports entrain early spawning delta smelt. The early spawners tend to be the largest and most robust individuals. Increased entrainment of the most robust members of the delta smelt population may be weakening the population when combined with other factors, such as increased predation (Bennett, 2005; DWR and CDFG, 2007).

In general, the majority of juvenile Chinook salmon (primarily fall-run Chinook salmon) are primarily observed in salvage operations during the late winter and early spring. The juveniles may include yearling spring-run and fall-run salmon, late fall-run salmon smolts, and pre-smolt winter-run juvenile salmon. Steelhead are primarily observed in salvage during the spring months.

Striped bass are primarily observed in salvage operation during late spring and summer. Delta smelt are primarily observed in salvage operation during the winter and spring months. Longfin smelt are primarily observed in the salvage operation during the spring (Grimaldo et al., 2009). A variety of other resident and migratory fish species are also collected as part of both SWP and CVP salvage operations (Reclamation et. al., 2003). Fish that are not bypassed by the salvage facility may survive passage through the pumps and enter the aqueduct. Fish, including striped bass and resident species, may rear in the canals and downstream reservoirs. These fish support recreational fisheries both in the aqueduct and in downstream reservoirs (Reclamation et al., 2003).

Operation of the SWP, in combination with CVP export operations, influences the hydrology within south Delta channels. Several management actions, including seasonal reductions in SWP and CVP export rates relative to Delta inflow (export/inflow ratio), have been implemented to reduce or avoid adverse effects of changes in hydrology and the vulnerability of species to salvage operations (Reclamation et al., 2003).

Reduced Habitat Quality

Habitat quality is directly related to fish abundance; an overall reduction in habitat quality tends to coincide with long-term declines in delta smelt, striped bass, and threadfin shad (Feyrer et al., 2007). The factors relating to fish abundance are water clarity and specific conductance[2] for delta smelt and striped bass, and specific conductance and temperature for threadfin shad. In addition, several other water quality, physical,

[2] Specific conductance is a measure of how well water can conduct an electrical current; it is an indicator of salinity levels.

and biological parameters, including dissolved oxygen, geomorphology, vegetation, predation, and food availability, could also result in changes in the abundance of these species (Baxter et al., 2010).

The purpose of the South Delta Temporary Barriers Project is to benefit local agricultural diversions by increasing water levels and circulation, and to improve fishery conditions for up-migrating adult salmon and out-migrating smolts (Reclamation et al., 2003). This program was initiated to assess the effects of temporary barriers on water quality, fisheries, and vegetation as a basis for predicting the effects of installing permanent barriers in the southern Delta.

The additional flow in the San Joaquin River helps maintain adequate dissolved oxygen concentrations for adult salmon migrating upstream (Reclamation et al., 2003). The barrier is notched at the top in the fall to allow passage of salmon migrating up Old River to enter the San Joaquin River. During spring, the barrier remains fully closed to prevent downstream migrating salmon smolts in the San Joaquin River from entering Old River, which avoids subsequent exposure to SWP, CVP, and agricultural diversions. In recent years, however, culverts have been installed in the barrier to improve water levels in the south Delta that allow some fish movement from the San Joaquin River into Old River. The other three temporary barriers are traversed by several buried 48-inch pipes, with flap gates on one end that allow unidirectional flow. These barriers operate by allowing water to flow through the pipes and flap gates during flood tides to fill the upstream channels. During ebb tides, the flap gates close to retain water in the channels.

Low Salinity Habitat and X2 Location

The Delta's low salinity habitat (LSH) is an area of the estuary characterized by higher levels of particulates, higher abundances of several types of organisms, and maximum turbidity. As a consequence of higher levels of particulates, the LSH may be biologically significant to some species. It is commonly associated with the location of the 2 ppt salinity isopleth (X2), but actually occurs over a broader range of salinities from 1 to 6 ppt. Historically, mixing and circulation in this area concentrated plankton and other organic material, thus increasing food biomass availability. Since approximately 1987, however, the introduced Asian clam population has reduced much of the primary production in the estuary, and there has been virtually no enhancement of phytoplankton production or biomass in the LSH (Reclamation et al., 2003).

Over the course of a year, X2 location can vary between San Pablo Bay during high Delta outflow (high river flow periods) and Rio Vista during low Delta outflow (summer). In recent years, it has typically been located between approximately Honker Bay and Sherman Island. X2 location is controlled directly by the volume of Delta outflow, although changes in X2 location lag behind changes in outflow. Although recent evidence indicates that X2 location and LSH are not as closely related as previously believed (Reclamation et al., 2003), X2 location continues to be used as an index of the location of LSH.

Predation

Fish (juvenile salmon, juvenile striped bass, and other species) that enter Clifton Court Forebay may reside in the forebay. Once in the forebay, fish may be eaten by other fish or taken by anglers (pre-screening losses); entrained by the pumps at the Banks Pumping Plant (direct loss); impinged on the fish screens at the Skinner Fish Protection Facility (direct loss); or bypassed and salvaged at the Skinner Fish Protection Facility (salvage). CDFG views predation on fish entrained in the forebay as a concern because it may exceed natural predation rates in Delta channels (Reclamation et al., 2003).

The existing intake structure and gates are believed to provide cover and a feeding station for predators. Predation losses are believed to be very high (Reclamation et al., 2003).

Survival of young striped bass in Clifton Court Forebay is also low. Six percent of young-of-the-year striped bass released at the radial gates survived passage across the forebay (Reclamation et al., 2003). The losses for both striped bass and salmon are attributed to predation. Sub-adult striped bass are the major predatory fish in Clifton Court Forebay (Reclamation et al., 2003). These fish are most abundant near the radial gates during winter and spring, when small fish may be particularly vulnerable. Predators have been periodically removed from the Forebay and released in the Delta. In 1993, striped bass made up 96 percent of the predators removed, followed by white catfish and channel catfish (Reclamation et al., 2003).

12.2.2.7 San Francisco Bay Estuary (including San Pablo Bay and Suisun Bay)

The San Francisco Bay Estuary is located at the terminus of the San Joaquin and Sacramento River network, where water draining from the Sacramento Valley enters the Pacific Ocean. It is the largest estuary on the west coast, encompassing roughly 1,600 square miles of central California (NOAA, 2012).

The estuary is surrounded by a contiguous urbanized region and has been greatly modified by 150 years of intensifying human activity (Nichols et al., 1986). Ninety percent of California's remaining coastal wetlands are located in the region. San Francisco Bay is recognized for protection by the California Bays and Estuaries Policy.

The San Francisco Bay Estuary is commonly divided into four different sub-regions: Suisun Bay, North Bay/San Pablo Bay, Central Bay, and South Bay. Each region has a distinct ecological structure defined by the local tidal datum, amount of fresh water influx, sediment input, and the underlying geology (NOAA, 2012). Water passes through the Delta, via the Sacramento-San Joaquin Rivers, and enters Suisun Bay which flows through the Carquinez Straight into San Pablo Bay. San Pablo Bay connects at its south end to Central and South Bays that together form what is known as the "San Francisco Bay".

Suisun Bay is a shallow embayment between Chipps Island at the western boundary of the Delta and the Benicia-Martinez Bridge at the eastern end of Carquinez Strait. Adjacent to Suisun Bay is Suisun Marsh, the largest brackish marsh in the United States. The narrow, 12-mile-long Suisun Bay is a large area of open water that is transitional between the freshwaters of the Delta and the saltwaters of San Francisco Bay; it is a shallow region of wind-stirred, brackish water, lined with tidal marshes (Moyle, 2008). Suisun Marsh is an approximately 74,130-acre marsh that is largely managed as freshwater wetlands to support waterfowl hunting (Moyle, 2008). Suisun Marsh maintains its freshwater character because of inflow from the Sacramento River via Montezuma Slough (Moyle, 2008). Large tidal gates on the upper end of Montezuma Slough control salinity in the marsh by allowing freshwater to flow in but preventing the tides from pushing it back out again (Moyle, 2008).

The estuary's aquatic and wetland habitats range from the brackish water of the lower delta and Suisun Bay to the dilute salt water of San Pablo Bay, and the highly saline waters of South San Francisco Bay (NOAA, 2012). Delta outflow interacts with tides to determine how far salt water intrudes from the ocean into the estuary. Delta outflow varies with hydrology, reservoir releases, and diversions upstream (DWR, 2009).

Fish species that are found in the estuary are virtually the same as those in Delta, although the estuary is more likely to contain euryhaline[3] marine species and early life history stages of estuarine-dependant species such as striped bass, delta smelt, and longfin smelt (Moyle, 2002). Fish species abundance and distribution in the estuary are influenced by seasonal and annual variability in hydrologic conditions,

[3] Capable of tolerating a wide range of salt water concentrations.

including the magnitude of flows into the Delta from the Sacramento and San Joaquin Rivers and other tributaries, outflow from the Delta into San Francisco Bay, and the salinity gradient which varies by region and fluctuates with outflow and tidal actions from the Pacific Ocean (Moyle, 2008).

Table 12-9 lists the species of management concern that are found in estuary. A county-level CNDDB (CDFG, 2009) search was conducted to determine the special-status fish species that may occur within the 22 counties of the Secondary Study Area. For fish species listed pursuant to FESA that could occur within the Delta region and San Francisco Bay Estuary, the Sacramento Fish and Wildlife Office's Endangered Species Program website (USFWS, 2010) was consulted. For species listed pursuant to CESA in this region, the January 2011 Endangered and Threatened Animal List maintained by DFG was consulted (CDFG, 2011a). Documents or data specific to areas and species within the Secondary Study Area were also reviewed to characterize aquatic biological resources.

Table 12-9
Fish Species of Primary Management Concern in the San Francisco Bay Estuary

Species	Scientific Name	Listing Status[a]		Designated Habitat[b]
		Federal	State	
Chinook salmon (Sacramento winter-run)	Oncorhynchus tshawytscha	*FE*	SE	EFH
Chinook salmon (Sacramento spring-run)	Oncorhynchus tshawytscha	*FT*	ST	EFH
Chinook salmon (Sacramento fall/late fall-run)	Oncorhynchus tshawytscha	*C*	CSC	EFH
Central Valley steelhead	Onorhynchus mykiss	*FT*	—	CH
Green sturgeon-southern DPS	Acipenser medirostris	*FT*	CSC	CH
Longfin smelt	Spirinchus thaleichthys	*FSC*	ST	—
Delta smelt	*Hypomesus transpacificus*	*FT*	ST	
Pacific smelt	Thalechthys pacificus	*FT*	CSC	—
River lamprey	Lampetra ayresii	—	CSC	—
Hardhead	Mylopharodon conocephalus	—	CSC	—
Striped bass	*Morone saxatilis*			
Sacramento perch	Archoplites inrerruptus		CSC	—
Tidewater goby	Eucyclogobius newberri	*FE*	CSC	—
Rough sculpin	Cottus asperrimus	—	ST; FP	—
Northern anchovy	Engraulis mordax	—	—	EFH
Pacific sardine	Sardinops sagax caerulea	—	—	EFH
Starry flounder	Platichthys stellatus	—	—	EFH

[a] Listing Status:

FE = Federal endangered
FT = Federal threatened
FSC = Federal species of concern
SE = State endangered
ST = State threatened
FP = State fully-protected species
CSC = state species of special concern

[b]Designated habitat:

CH = Critical habitat
EFH = Essential fish habitat

Note:
DPS = distinct population segment

Source: DFG, 2009, DFG, 2011a, Moyle, 2002, NMFS, 2011.

The San Francisco Bay Estuary supports a spectrum of diverse habitats that are important to the species that inhabit them. Tidal perennial aquatic habitat is one natural community that occurs within greater

San Francisco Bay ecological zones that many fish species of management concern are highly dependent on. Tidal perennial habitat includes deep water aquatic (greater than 10 feet deep from mean lower low tide [the lowest of the low tides in a day]), shallow aquatic (less than or equal to 10 feet deep from mean lower low tide), and unvegetated intertidal (i.e., tideflats) zones of estuarine bays, river channels, and sloughs (Moyle, 2008).

Many fish spend their entire lives in the tidal perennial aquatic community and use it for foraging, spawning, rearing, resting, and migration. Resident and migratory fish use tidal perennial aquatic habitat for spawning, rearing, foraging, and escape cover. Striped bass, delta smelt, Sacramento splittail, and many resident Bay-Delta fish use this habitat for rearing and as adults (CALFED, 2000). Young steelhead and Chinook salmon forage in these productive waters as fry and juveniles to put on weight before entering the ocean. Changes in physical attributes of the water column, such as flow, salinity and water temperature, provide environmental cues for some species to trigger the timing of biological events, such as migration and spawning.

Fish species that currently depend on these tidal marshes and adjoining sloughs, mudflats, and embayments include delta smelt, longfin smelt, Chinook salmon, green sturgeon, white sturgeon, pacific herring, starry. However, many new species of plants and animals have been introduced. These exotic and invasive species, such as the Chinese mitten crab and Asian clam, threaten to undermine the estuary’s food web and alter its ecosystem (DWR, 2009).

12.2.3 Primary Study Area

12.2.3.1 Methodology

A CNDDB (CDFG, 2009) search was conducted for Colusa and Glenn counties to determine the special-status fish species that may occur in the Primary Study Area. For fish species listed pursuant to FESA that could occur within the Primary Study Area, the Sacramento Fish and Wildlife Office’s Endangered Species Program website (USFWS, 2010) was consulted. For species listed pursuant to CESA in this region, the January 2011 Endangered and Threatened Animal List maintained by DFG was consulted (CDFG, 2011a). Documents or data specific to areas and species within the Primary Study Area were also reviewed to characterize aquatic biological resources. References are cited in the text. In Additionally, DFG conducted fisheries surveys and monitoring within the Primary Study Area (CDFG, 2003; CDFG, 2011c).

12.2.3.2 Waterways that Could be Affected by Project Facilities

The Primary Study Area includes the Sacramento River, Grapevine Creek, Antelope Creek, Funks Creek, Stone Corral Creek, Hunters Creek, Colusa Basin Drain, T-C Canal, GCID Canal, and Funks Reservoir. Fish species of primary management concern found in the Primary Study Area are shown in Table 12-10.

Table 12-10
Fish Species of Primary Management Concern in the Primary Study Area

Common Name	Range within Watershed	Federal/State Status[a]
Central Valley Chinook salmon, winter-run[b]	Sacramento River	FE/CE
Central Valley Chinook salmon, spring-run[b]	Sacramento River	FT/CT
Central Valley Chinook salmon, fall/late fall-run	Sacramento River	FSC/CSSC
Central Valley steelhead[b]	Sacramento River	FT
Green sturgeon	Sacramento River	FT/CSSC
White sturgeon	Sacramento River	None

Table 12-10
Fish Species of Primary Management Concern in the Primary Study Area

Common Name	Range within Watershed	Federal/State Status[a]
River lamprey	Sacramento River and streams throughout Primary Study Area	FSC/CSSC
Pacific lamprey	Sacramento River and streams throughout Primary Study Area	None
California roach	Sacramento River and streams throughout Primary Study Area	CSSC
Sacramento splittail	Sacramento River and Colusa Basin Drain	FT/CSSC
Largemouth bass[c]	Sacramento River, Funks Reservoir, streams throughout Primary Study Area	None
Rainbow trout	Sacramento River	None
Hardhead	Sacramento River	None
American shad	Sacramento River	None
Striped bass	Sacramento River	None

[a]Status designations:
FE = federally-listed as endangered
FT = federally-listed as Threatened
FSC = federally-listed as Species of Concern
CE = California-listed as Endangered
CT = California-listed as Threatened
CSSC = California-listed as Species of Special Concern

Source: DFG, 2009, DFG, 2011a, Moyle, 2002, NMFS, 2011.

[b]Critical Habitat has been designated for this species within the study area.
[c]Includes largemouth bass, smallmouth bass, spotted bass.

Proposed Project facilities within the Primary Study Area, and the waterways that those facilities could affect, are shown in Table 12-11 and in Figure 12-6. The proposed Project Buffer would have the potential to affect the same waterways as the facilities that it would surround.

Table 12-11
Proposed Project Facilities in the Primary Study Area and the Potentially Affected Waterways

Project Facilities	Potentially Affected Waterway
Sites Reservoir Inundation Area	Grapevine Creek, Funks Creek, Stone Corral Creek, Antelope Creek
Sites Reservoir Dams	Stone Corral Creek, Funks Creek
Recreation Areas	None
Roads Relocations and South Bridge	Antelope Creek, Grapevine Creek, Stone Corral Creek, Funks Creek
Delevan Pipeline	Hunters Creek, Colusa Basin Drain
Delevan Transmission Line	None
Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility	Sacramento River
TRR (including the TRR to Funks Creek Pipeline)	Funks Creek
TRR Pipeline, TRR Pipeline Road, TRR Pumping/Generating Plant, TRR Electrical Switchyard, GCID Canal Connection to the TRR, and Delevan Pipeline Electrical Switchyard	None
GCID Canal Facilities Modifications	Sacramento River
Holthouse Reservoir Complex (including Funks Reservoir Dredging)	Funks Creek
Holthouse Reservoir Electrical Switchyard	None
Sites Reservoir Inlet/Outlet Structure	Funks Creek
Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, and Field Office Maintenance Yard	None

Funks Creek, Stone Corral Creek, Grapevine Creek, and Antelope Creek

The portions of Funks, Stone Corral, Grapevine, and Antelope creeks within the Sites Reservoir footprint are characterized by deeply incised channels that are largely devoid of riparian cover as a result of heavy cattle use. On the valley floor, Funks Creek and Stone Corral Creek flow through irrigated pasture, rice fields, and row crop agriculture until they flow into the Colusa Basin Drain. They are incised and riveted in some areas, and have been straightened and probably excavated to facilitate farming. During summer, much of the streambed of all of the Primary Study Area creeks is dry, except for occasional pools or when receiving agricultural drainage or runoff.

Table 12-12 identifies fish species found in Funks Creek, Stone Corral Creek, Grapevine Creek, and Antelope Creek in the proposed Sites Reservoir Inundation Area. These species were observed during sampling conducted between January 1998 and July 1999 (CDFG, 2003). Most of the fish sampled were less than six inches long, suggesting that juveniles rear in these creeks and move downstream to larger bodies of water as adults. Many of the native minnow species found in these creeks typically ascend seasonal creeks in winter and spawn there in early spring (Moyle, 2002). Most adults migrate downstream after spawning. One spring-run Chinook salmon carcass was observed in Antelope Creek during sampling (CDFG, 2003). Live Chinook salmon and Chinook salmon carcasses were also observed in Funks Creek downstream of Funks Reservoir. These fish likely strayed from the Sacramento River during high flows or migrated up the Yolo Bypass and through the Ridge Cut. Suitable Chinook salmon spawning habitat does not exist downstream of Funks Reservoir, and spawning habitat is not known to exist on Antelope Creek as water quality and hydraulic conditions are not suitable to support a population.

Table 12-12
Fish species observed by CDFG during sampling efforts in the Colusa Basin Drain

Common Name	Scientific Name
Central Valley Chinook salmon,	*Oncorhynchus tshawytscha*
White Catfish	*Ictalurus catus*
Brown Bullhead	*Ameiurus nebulosus*
Black Bullhead	*Ameiurus melas*
Channel Catfish	*Ictalurus punctatus*
Bluegill	*Lepomis macrochirus*
Green Sunfish	*Lepomis cyanellus*
Largemouth Bass	*Micropterus salmoides*
Black Crappie	*Pomoxis nigromaculatus*
White Crappie	*Pomoxis annularis*
Pacific Lamprey	*Lampetra ayresi*
Threadfin Sad	*Dorosoma petenense*
California roach	*Hesperoleucus symmetricus*
Hitch	*Lavinia exilicauda*
Fathead Minnow	*Pimephales promelas*
Common Carp	*Cyprinus carpio*
Goldfish	*Carassius auratus*
Sacramento Pikeminnow	*Ptychocheilus grandis*
Sacramento Blackfish	*Orthodon microlepidotus*
Sacramento Splittail	*Pogonichthys macrolepidotus*
Hardhead	*Mylopharodon conocephalus*
Sacramento Sucker	*Catostomus occidentalis*
Inland Silverside	*Menidia beryllina*

Table 12-12
Fish species observed by CDFG during sampling efforts in the Colusa Basin Drain

Common Name	Scientific Name
Mosquitofish	*Gambusia affinis*
Sculpin sp.	*Cottus sp.*
Tule Perch	*Hysterocarpus traski*
Big scale logperch	*Percina macrolepida*

Hunters Creek and the Colusa Basin Drain

The Delevan Pipeline would cross Hunters Creek near its confluence with the Colusa Basin Drain. This stream has not been sampled to determine which fish species are found there. Due to the similar hydrology, channel form, and riparian habitat, Hunters Creek likely has a species composition similar to the streams found in the Sites Reservoir footprint.

The Delevan Pipeline would also cross the Colusa Basin Drain. Historically, the Colusa Basin Drain was a natural channel that transported water from westside tributaries, such as Willow, Funks, Stone Corral, and Freshwater creeks, to the Sacramento River. It also carried floodwater from the Sacramento River. When agricultural operations began in the Sacramento Valley, the Colusa Basin Drain was channelized and dredged to carry agricultural runoff in addition to natural flows. Table 6 identifies the fish species observed during sampling efforts in the drain conducted between January and July 1999 (CDFG, 2003). Fall-, late-fall-, and spring-run Chinook salmon have also been observed in the Colusa Basin Drain. Steelhead may also be present, with potential spawning habitat existing upstream of the Primary Study Area in Willow Creek and Freshwater Creek, but none were captured during sampling efforts (CDFG, 2003).

T-C Canal and GCID Canal

The T-C Canal and the GCID Canal provide habitat for native and non-native fish species. Native fish that are common in the canals are Sacramento sucker, Sacramento pike minnow, hardhead, and hitch. Non-native fish species include striped bass, black bass, sunfish, and common carp. Many of the native fish that occur in the canals likely enter through the intakes as larvae (Reclamation, 2001). Existing screens at the pumping plants are designed to keep Chinook salmon and steelhead from entrainment in the pumps and canals.

Sacramento River at the Delevan Pipeline Intake Facilities, Red Bluff Pumping Plant, and GCID Pumping Plant

The reach of the Sacramento River at the proposed Delevan Pipeline Intake/Discharge Facilities, the existing Red Bluff Pumping Plant, and the existing GCID Pumping Plant provides habitat for migrating adult and juvenile Central Valley steelhead, and winter-, spring-, late-fall-, and fall-run Chinook salmon. Fall- and late-fall-run also spawn in the river near the Red Bluff Pumping Plant and have spawned as far down as the GCID Pumping Plant.

Adult, larval, and juvenile white and green sturgeon also migrate and hold in the vicinity of the proposed pumping plant and the existing Red Bluff and GCID pumping plants. White sturgeon likely spawn in the vicinity of the GCID Pumping Plant and proposed Delevan Pipeline Intake Facilities. Green sturgeon are known to spawn in the vicinity of the Red Bluff and GCID pumping plants (Poytress et al., 2011). It is not known if green sturgeon spawn farther downstream at the proposed Delevan Pipeline Intake/Discharge Facilities site, but tracking data indicates that green sturgeon do not hold in this area during the spawning period. Sturgeon egg and larva surveys have been conducted on the Sacramento River downstream of Jelly's Ferry Bridge (RM 266.5) to upstream of the GCID Pumping Plant (RM 206.5). Spawning has been confirmed (eggs have been collected) as far upstream as RM 264.5 (near Inks Creek) and as far downstream as RM 206.5 upstream of GCID Pumping Plant) (Poytress et al., 2009, 2011). DFG conducted juvenile salmonid monitoring at the location of the proposed Delevan Pipeline Intake Facilities and approximately one mile upstream of the Tisdale Weir (DFG, 2011c). Sampling showed that juvenile Chinook salmon do migrate past the site in the summer (August), but are most abundant during the winter months (December to February). Chinook salmon juveniles were most abundant during periods of high flow. Abundance decreased as flows receded. The abundance of fish passing the site also appeared to increase during periods of high turbidity (associated with relatively small increases in flow).

12.3 Environmental Impacts/Environmental Consequences

12.3.1 Regulatory Setting

Aquatic biological resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable aquatic resource laws and regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this DEIR/EIS.

12.3.1.1 Federal Plans, Policies, and Regulations

- Federal Endangered Species Act
- U.S. Fish and Wildlife Service Operations Criteria and Plan Biological Opinion
- National Marine Fisheries Service Operations Criteria and Plan Biological Opinion
- Clean Water Act
- Rivers and Harbors Act of 1899
- Central Valley Project Improvement Act
- National Environmental Policy Act
- Magnuson-Stevens Fishery Conservation and Management Act
- USFWS Recovery Plan for the Sacramento/San Joaquin Delta Native Fishes
- National Marine Fisheries Service Recovery Planning for Salmon and Steelhead in California
- Fish and Wildlife Coordination Act
- Anadromous Fish Restoration Program
- CALFED Bay Delta Program
- National Invasive Species Act of 1996
- Trinity River Restoration Program
- Central Valley Project Long-term Water Service Contracts

12.3.1.2 State Plans, Policies, and Regulations

- California Endangered Species Act
- California Environmental Quality Act
- Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary
- California Fish and Game Code Section 1602 - Streambed Alteration
- The Salmon, Steelhead Trout, and Anadromous Fisheries Program Act
- Natural Community Conservation Planning Act
- California Fish and Game Code Sections 5937 and 5980-5993
- California Aquatic Invasive Species Management Plan

12.3.1.3 Regional and Local Plans, Policies, and Regulations

- Interagency Ecological Program Pelagic Organism Decline Studies
- Delta Vision Strategic Plan
- State Water Resources Control Board and California Environmental Protection Agency Draft Development of Flow Criteria for the Sacramento-San Joaquin Delta Ecosystem

12.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for biological resources:

Would the Project:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?

The evaluation criteria used for impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the aquatic biological resources impact assessment, indicators (e.g., water temperatures, flows) were used to evaluate whether the Project would have an impact on a species’ habitat. The impact indicators and evaluation guidelines were developed based on an extensive review of fisheries literature, with special emphasis on research conducted in the Central Valley. Impact determinations were based on consideration of all evaluated impact indicators for all life stages for a particular species in a particular river or geographic region (e.g., the Delta, the Export Service Area). For the purposes of this analysis, an alternative would result in a significant impact if it would result in the following:

- A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

A detailed description of each of the species and location-specific impact indicators is provided in Appendix 12B.

12.3.3 Impact Assessment Assumptions and Methodology

12.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to aquatic biological resources:

- Direct Project-related construction and maintenance activities would occur in the Primary Study Area
- The only direct project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump in an existing bay at the Red Bluff Pumping Plant

- The only direct project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant)
- No direct project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct project-related operational effects would occur in both the Primary Study Area and the Secondary Study Area
- Direct project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation, increased reliability of water supply to agricultural, municipal, and industrial water users, and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.

12.3.3.2 Methodology

Detailed discussion of the impact assessment methodology, impact indicators, and significance criteria used to evaluate potential impacts of the alternatives on aquatic biological resources, relative to Existing Conditions and the No Project/No Action Alternative for regulatory compliance purposes, is provided in Appendix 12B.

For each of the study areas (i.e., Extended, Secondary, and Primary), the impact assessment identifies fish species of primary management concern. Species of primary management concern include special-status fish species (federal- and State- listed threatened and endangered, federal candidate species and species of concern, and State species of special concern), as well as other recreationally important species (e.g., striped bass and American shad).

Potential impacts on fish species of primary management concern were assessed by evaluating hydrologic and water temperature model outputs to identify changes in aquatic habitat that could potentially impact fish species of primary management concern. The impact assessments relied on model output data, including:

- Simulated riverine, reservoir, and Delta hydrology, and X2 location:
  - Appendix 6B – CALSIM II Modeling (includes overview of modeling framework)
  - Appendix 6C – River Flow Modeling (USRDOM)
  - Appendix 7D – Delta Modeling (DSM2)
- Simulated water temperatures:
  - Appendix 7E – River Temperature Modeling
  - Appendix 7F – Sites Reservoir Discharge Temperature Modeling
- Summarized simulated hydrology and water temperature data (Appendix 12E and Appendix 12F)

- Simulated fisheries habitat and population parameters:
  - Appendix 12G – Sacramento Splittail Usable Flooded Area Analyses
  - Appendix 12I – Delta Pumping Salvage and Entrainment Analysis
  - Appendix 12J – Early Life-Stage Salmon Mortality Modeling
  - Appendix 12K – Salmonid Population Modeling (SALMOD)
  - Appendix 12L – Winter Run Chinook Salmon Life Cycle Modeling (IOS)
  - Appendix 12M – Delta Passage Modeling (DPM)
  - Appendix 12N – Weighted Useable Area Analysis

Not every model output node location or output variable was evaluated. Specific model outputs and output locations evaluated varied by species based on individual species life history periodicities, habitat requirements, and geographic distributions.

A detailed description of the general and species-specific analytical methodologies, model output types, and model output locations used to assess potential impacts on fish species of primary management concern are provided in Appendix 12B. Potential impacts on aquatic biological resources in the Secondary Study Area are discussed in detail in Appendix 12C.

Although operation of the Project facilities is conceptually simple (see Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives), implementation of the action alternatives would alter reservoir operations throughout the SWP and CVP system in ways not necessarily observed historically or evaluated in previous environmental documents. Specifically, simulated average monthly flows and water temperatures frequently increase and decrease by small and large amounts within the same month and among months over the 82-year simulation period. These hydrologic and water temperature changes are easily observed in the model output data, but are difficult to evaluate with respect to fish species of primary management concern.

Mass balance hydrologic and water temperature modeling was performed to provide a quantitative basis from which to assess potential operations-related impacts of the alternatives on fish species of primary management concern and aquatic habitats within the Extended (e.g., San Luis Reservoir) and Secondary (e.g., Trinity, Clear Creek, Sacramento, Feather and American rivers, and the Delta) study areas, relative to the CEQA and NEPA bases of comparison (i.e., Existing Conditions and the No Project/No Action Alternative). Specifically, the hydrological modeling analyses were utilized to simulate data representing Central Valley Project/State Water Project (SWP/CVP) operational conditions that would occur with implementation of the alternatives, as compared to modeled data representing operational conditions for the CEQA and NEPA bases of comparison. Assessment of fish species of primary management concern in the Primary Study Area (e.g., Sites and Funks reservoirs) consisted primarily of evaluation of construction, operation, and maintenance impacts. Both quantitative and qualitative assessments were conducted to evaluate potential impacts to aquatic biological resources that could occur as a result of implementation of the proposed Project. The methodologies used to simulate comparative operational scenarios, and assumptions associated with the alternatives and bases of comparison are described in Appendix 6A and Appendix 6B.

The impact assessment of aquatic biological resources consisted of three primary elements, including: (1) temporary and localized impacts associated with construction of the proposed Project infrastructure facility components; (2) ongoing impacts associated with operation and maintenance of the proposed Project facilities; and (3) ongoing hydrologic changes associated with operation of each of the alternatives. The detailed analytical approaches used to assess the potential impacts of each of these primary elements of the alternatives are described in Appendix 12B.

12.3.3.3 Extended Study Area

The Extended Study Area consists of the SWP/CVP water service areas, San Luis Reservoir, and the Level 4 wildlife refuges located throughout the water distribution system.

For fisheries impact evaluation purposes, the focus of the analyses was placed on the National Wildlife Refuges (NWR) and San Luis Reservoir.

Level 4 National Wildlife Refuges

Changes to Level 4 water supply reliability could potentially affect fisheries resources in the wildlife refuges or in the water distribution systems within the refuges. Potential changes in water deliveries to individual refuges are not provided as part of the CALSIM II model output. However, implementation of the action alternatives would result in the provision of an alternate source of Level 4 water supply and would not affect supply reliability. Therefore, Level 4 water supply to these refuges was evaluated qualitatively under the alternatives, relative to the bases of comparison.

San Luis Reservoir

Coldwater and warmwater fisheries in San Luis Reservoir were evaluated using the same methodology that was used for the reservoirs included in the Secondary Study Area, as described below.

12.3.3.4 Secondary Study Area

The Secondary Study Area consists of the SWP and CVP water bodies and the waterways within the Sacramento River, Feather River, Trinity River, and American River watersheds that lie outside of the Primary Study Area described above. For fisheries impact evaluation purposes, the Secondary Study Area includes Trinity Lake, the Trinity River, Clear Creek, Shasta Lake, the Sacramento River downstream of Keswick Dam, Lake Oroville, the Feather River, Folsom Lake, Sutter Bypass, the American River, the Yolo Bypass, and the Sacramento-San Joaquin Delta.

General Assessment Approach

Because the alternatives may result in changes in water temperatures and river flows, as well as Delta habitat parameters (e.g., salinity) in the Secondary Study Area, the impact assessment focused on these and other habitat-based elements. Specifically, the analysis of potential impacts was conducted using an ecologically scaled hierarchy. Changes to aquatic ecosystem-level functions (e.g., flow, water temperature) that are relevant to multiple fish species were evaluated first. The results of these analyses were then used to conduct individual fish species evaluations using species-specific habitat requirements and species-specific evaluation tools to identify potential impacts on fish species of primary management concern.

Analytical Tools

The aquatic biological resources impact assessment relied on hydrologic modeling to provide a quantitative basis from which to assess the potential impacts of the alternatives on fish species of primary management concern and their associated habitats within the SWP/CVP system. Specifically, the hydrological modeling and post-processing applications were utilized to simulate operations expected to occur in SWP/CVP reservoirs and rivers, and the Delta, as a result of implementation of the alternatives.

Hydrologic simulation results of monthly river flows and end-of-month reservoir storages from CALSIM II provided a quantitative basis to assess the potential impacts of operations on fish species, relative to the CEQA and NEPA bases of comparison, for the period of simulation extending from water year 1922 through 2003 (82-year simulation period). These simulated results were then used as inputs to Reclamation's Water Temperature Models (Appendix 7E), which simulate monthly water temperature of the main river systems (Trinity, Sacramento, Feather, and American rivers) for the same simulation period. The Upper Sacramento River Daily Operations Model (USRDOM) and the Sacramento River Water Quality Model (SRWQM) were used to simulate daily flows and water temperatures in the upper Sacramento River. The Reclamation Water Temperature model results were used as inputs to Reclamation's Early Life Stage Chinook Salmon Mortality Model (Salmon Mortality Model) to estimate annual mortality rates for the embryonic life stage of Chinook salmon. Flows and water temperatures were also utilized as inputs to other analytical tools including IOS, SALMOD, and the SacEFT to estimate potential population-level impacts on various life stages and habitat for some Sacramento River fishes. Electrical conductivity (EC) in the Delta was simulated using the DSM 2.

Specific nodes (i.e.; model output locations representing generalized geographic locations) from hydrologic and water temperature model output for fisheries impact assessment purposes, as well as the types of model outputs for flows and water temperatures (e.g., cumulative probability exceedance distributions) are identified by river and species in Appendix 12B. Additionally, detailed discussion of specific modeling tools, the modeling assumptions used to characterize the NODOS Project Alternatives' operations, and the appropriate use of model output results is presented in Appendix 6A and Appendix 6B.

Model Output Parameters Evaluated

Several quantitative model output parameters were evaluated by simulating CVP and SWP operations for each of the alternatives and the bases of comparison, then comparing those outputs to one another to identify differences between each of the alternative outputs. These differences in model output parameters are indicative of habitat or fish population changes that could occur with implementation of each of the alternatives.

Raw model output data included:

- Monthly flow, end-of-month storage, end-of-month reservoir water surface elevation, X2 location, and Old and Middle River (OMR) reverse flows
- Daily flow in the upper Sacramento River
- Monthly water temperature
- Daily water temperature
- Spawning habitat availability (expressed as weighted useable area)

Raw model outputs listed above were conditioned to aggregate data in meaningful ways for aquatic biological resources evaluation purposes. Additionally, raw model outputs were utilized as inputs to Reclamation's Early Life Stage Chinook Salmon Mortality Model, other fish population models (IOS, SacEFT, and SALMOD), and other additional analytical tools (e.g., spreadsheet tools) that allowed for examination of specific habitat or fish population variables (e.g., spawning flow-dependent habitat availability, south Delta pumping facility fish salvage).

The following types of data products (i.e., conditioned raw model output data) were utilized for evaluating hydrologic and fisheries data:

- Long-term average flow, water temperature, end-of-month reservoir storage, Delta outflow, X2 location, and OMR reverse flows. These output parameters were evaluated by month over the entire period of record and by water year type.
- Exceedance probability distributions (exceedance curves) for flow, water temperature, storage, Delta outflow, X2 location, OMR reverse flows, and IOS production estimates by month. These exceedance probability distributions were developed from ranked and sorted data, and show the percentage of time (probability) that a given value is exceeded. Exceedance probability distributions were evaluated by month over the entire period of record and by water year type.
- Monthly flow-dependent habitat availability curves expressed as weighted useable area for evaluating Chinook salmon and steelhead spawning habitat availability. Flow-dependent habitat is expressed as weighted useable area (WUA) and was evaluated during the spawning months for the entire period of record.
- Monthly salvage density. This estimate of fish taken at the CVP and SWP pumping facilities is calculated by utilizing existing historical salvage densities and applying them to simulated exports at the facilities. Monthly salvage density was evaluated for the entire period of record and by water year type.
- Reclamation's Early Life Stage Chinook Salmon Mortality Model. Early life stage mortality was evaluated over the entire period of record and by water year type.
- SALMOD. Estimates of juvenile production for each run of Chinook salmon in the Sacramento River were evaluated over the entire period of record and by water year type.
- IOS, Delta Passage Model (DPM) and SacEFT. Outputs from IOS and SacEFT were evaluated over the entire period of record and by water year type.

Detailed discussion of models and data products utilized for the aquatic biological resources analyses is provided in Appendix 12B.

Quantitative Evaluation Criteria

Evaluation of potential impacts on fisheries resources included evaluating the net difference in a habitat variable for each of the alternatives, relative to a baseline condition. The habitat variables were evaluated over the entire model period of record (e.g., 82 years for CALSIM II), by water year type (e.g., wet years, above normal years, below normal years), and during the lowest 25 percent of years as defined by the exceedance probability distributions. However, individual model output parameters and data products were also evaluated quantitatively based on the type of parameter examined and the existence in scientific literature of biologically relevant relationships to the parameter. For example, flow is important to maintain aquatic life, but no identified quantitative relationship between flow during Chinook salmon immigration and spawning success exists for the Sacramento River. However, the body of literature does contain information about biological effects that occur to individuals (e.g., stress response) or groups of individuals (e.g., 50 percent mortality) associated with exposure to specific water temperatures. Thus, some model output parameters were evaluated using specific index values as impact indicators, while other parameters were evaluated utilizing criteria that were not necessarily empirically derived or reported in scientific literature as being associated with a specific biological effect. Detailed discussion of evaluation criteria is provided in Appendix 12B. Evaluation methods and assumptions for each of the model output parameters are described briefly below.

Flow, Storage, Delta Outflow

- Evaluate the net difference in the number of years when flows, storage, or Delta outflow are greater or less than 10 percent different with implementation of the alternatives, relative to a baseline condition
  - Changes of less than 1 percent are considered “noise” in the model
  - Changes between 1 and 10 percent are considered real, but not substantial
  - Changes greater than 10 percent are considered substantial

Water Temperature

- Evaluate the net difference in the number of years that specific index values are exceeded with implementation of the alternatives, relative to a baseline condition by comparing life stage specific water temperature index values to model output for each alternative
  - Changes less than 0.3°F are considered noise in the model

WUA Curves

- Evaluate differences between the percentage of maximum WUA between the alternatives and a baseline condition
  - Differences in percentage of maximum WUA of 1 percent or greater are considered meaningful

Early Life Stage Mortality, SALMOD, IOS, Delta Passage Model

- Evaluate absolute differences and relative differences (in percentage) with implementation of the alternatives, relative to a baseline condition over the period of record and by water year type
  - A substantial change in any of the model output metrics is considered to be a change of 10 percent or more

X2 Location

- Evaluate changes in X2 location of 1 km or more under an alternative, relative to a baseline condition (for species that don’t have specific X2 evaluations)
- Evaluate changes in X2 location between river kilometer (RKm) 65 and RKm 80 of 10 percent or more during September through December
- Fall X2 location is evaluated as an indicator of habitat suitability in this region of the Delta. However, because of the controversy surrounding the Fall X2 delta smelt rearing habitat suitability index described by Feyrer et al. (2010), the habitat suitability index was not used.
- Evaluate the frequency with which average monthly X2 location is maintained at or downstream of 75 km during April through June to evaluate potential effects on American shad eggs and larvae.

Water Surface Elevation

- Evaluate reductions in water surface elevation of six feet or more per month during the March through June warm water fish spawning period.

Old and Middle River (OMR) Reverse Flows

- Evaluate exceedance probability distributions to identify the percentage of time from March through June when OMR flows are less than -1,500 cfs[4] during dry and critical years to evaluate entrainment potential for delta smelt larvae.
- Evaluate the percentage of time from December through February when OMR flows are less than -5,000 cfs to evaluate entrainment potential for delta smelt adults and straying potential for San Joaquin River fall-run Chinook salmon adults.
- Evaluate the percentage of time from December through March when OMR flows are less than -5,000 cfs to evaluate entrainment potential for longfin smelt juveniles and adults.
- Evaluate changes in the frequency with which mean monthly OMR flows are greater than -1,500 cfs during April and May of dry and critical water years to evaluate entrainment potential for longfin smelt larvae.
- Evaluate percentage of time from November through June when OMR flows are less than 2,500 cfs to evaluate entrainment potential into the Central Delta for juvenile Chinook salmon.
- Evaluate percentage of time from October through July when OMR flows are reduced to evaluate entrainment potential into the Central Delta for juvenile steelhead.

Reservoir- and River-Specific Assessment Approach

Changes in SWP/CVP operations resulting from implementation of the alternatives could potentially alter seasonal flows and water temperatures in the Trinity River, Clear Creek, the Sacramento River, the Feather River, the American River, and the Delta.

The river-specific fisheries impact assessment focused on the hydrologic changes, including reservoir water surface elevation, storage, and instream flows and water temperatures associated with implementation of the alternatives. Taking into account species-specific habitat requirements, operational components of the alternatives were assessed to evaluate potential impacts on identified fish species of primary management concern and associated aquatic habitat.

Because the fish species that inhabit, traverse, or utilize these areas could differ among regions, the fisheries impact assessment approach varied among geographic areas. Further, information available from modeling efforts differed among rivers. Therefore, the river-specific impact assessment included identification of fish species of primary management concern, model output and node locations, and species and life stage-specific evaluation methodologies for the alternatives.

Where specific flow requirements have not been developed for species evaluated in a specific river, potential flow-related impact determinations were based on an evaluation of the frequency and magnitude of change in modeled monthly mean flow for the alternatives, relative to the bases of comparison (Existing Conditions and the No Project/No Action Alternative). Impact determinations related to water temperature were based on species and life stage-specific water temperature impact indicator values

[4] Negative Old and Middle river flows imply that the average flow in Old and Middle Rivers is reversed and the flow is towards the south Delta pumps.

(presented in Appendix 12B and with detailed description of literature describing index value selection criteria presented in Appendix 12D).

Trinity, Shasta, Oroville, and Folsom Reservoirs

Implementation of the alternatives could potentially result in alterations to storage volumes and water surface elevations in Trinity, Shasta, Oroville, and Folsom reservoirs, which could potentially affect reservoir fish species. Model output parameters derived from CALSIM II used to determine potential impacts included:

- End-of-month (average annual monthly) reservoir storage volume
- End-of-month (average annual monthly) water surface elevations.

During the period when these reservoirs are thermally stratified (generally April through November), coldwater fish within the reservoir reside primarily within the reservoir's metalimnion[5] and hypolimnion[6] where water temperatures remain suitable. Reduced reservoir storage during this period could reduce the reservoir's coldwater pool volume, thereby reducing the quantity of habitat available to coldwater fish species during these months. Reservoir coldwater pool size generally decreases as reservoir storage decreases, although not always in direct proportion because of the influence of reservoir basin shape. Therefore, to assess potential storage-related impacts on coldwater fish habitat availability in Trinity, Shasta, Oroville, and Folsom reservoirs, end-of-month storage simulated for the alternatives were compared to end-of-month storage simulated for the bases of comparison for each month of the April through November period.

Because reservoir warmwater fish species[7] use the warm upper layer of the reservoir and nearshore littoral habitats, seasonal changes in reservoir storage, as it affects reservoir water surface elevation, and the rates at which water surface elevation change during specific periods of the year, can directly affect warmwater fish nesting and spawning success. To assess the impacts of potential reservoir water surface elevation changes on warmwater fish, the following approach was used. The magnitude of change, as measured in feet with reference to mean sea level (feet msl), in reservoir water surface elevation occurring each month of the primary spawning period for nest-building fish (March through June) simulated for the alternatives was determined and compared to the bases of comparison. Specifically, the number of times that reservoir reductions of six feet or more per month could occur with implementation of the alternatives was compared to the number of occurrences of the same modeled for the bases of comparison.

A detailed description of the specific methods utilized to evaluate coldwater and warmwater fish species in each of the existing reservoirs potentially affected by implementation of the alternatives is provided in Appendix 12B.

Trinity River

Project operations are not expected to substantially alter instream flows, water temperatures, or habitat conditions for fish inhabiting the Trinity River. However, as part of the impact assessment, modeling

[5] thermocline; thin, distinct layer that separates regions differing in temperature
[6] below thermocline; dense, bottom layer of water
[7] Largemouth bass are evaluated as an indicator species in this EIR/EIS analysis to reflect potential impacts on warmwater game fishes.

results were reviewed and an analysis conducted on seasonal flows, water temperatures, and habitat availability in the Trinity River.

Changes in SWP/CVP operations associated with implementation of the alternatives could potentially alter instream flow and seasonal water temperatures in the Trinity River below Lewiston Reservoir and adversely affect Trinity River fish species. CALSIM II was used to evaluate potential impacts associated with changes in flow, and Reclamation's Water Temperature Model was used to assess water temperatures in the Trinity River. Additionally, Reclamation's early life stage mortality model was used to evaluate water temperature-related mortality on fall-run Chinook salmon in the Trinity River.

A detailed description of the specific methods, including life stage periodicity and model output node locations utilized to evaluate species of primary management concern in the Trinity River, is provided in Appendix 12B.

Clear Creek

Water operations in Clear Creek, including diversions to Clear Creek from the Trinity River, are components of the integrated operations of the Trinity River Division CVP system. From Whiskeytown Lake, water is released through the Spring Creek Power Conduit to the Spring Creek Powerplant and into Keswick Reservoir (up to 2,000 cfs). As part of the CVP system, implementation of one of the alternatives has the potential to affect Clear Creek flows and water temperatures, thereby potentially affecting habitat for species of primary management concern.

Changes in SWP/CVP operations associated with the alternatives could potentially alter instream flow and seasonal water temperatures in the Clear Creek below Whiskeytown Dam and adversely affect Clear Creek fish species. Therefore, CALSIM II was used to evaluate potential impacts associated with changes in flow, and Reclamation's Water Temperature Model was used to assess water temperatures.

Detailed description of the specific methods, including life stage periodicity and model output node locations utilized to evaluate species of primary management concern in Clear Creek, is provided in Appendix 12B.

Sacramento River

Shasta Reservoir releases, and therefore, Sacramento River flow, often are governed by water temperature requirements below Keswick Dam for April through October, and an end-of-September minimum carryover storage for Shasta Reservoir of 1.9 million acre feet (MAF) to protect Sacramento River winter-run Chinook salmon. To meet the temperature objectives, a dynamic evaluation of ambient air temperature, weather forecasts, water temperature at the release point, and release rate occurs. Determination of the appropriate release rate is often made based on the temperature of the water released rather than on the rate needed to support CVP operations.

While water temperature and carryover storage targets for winter-run Chinook salmon generally govern Shasta Reservoir releases, the Sacramento River below Keswick Dam is utilized by a number of fish species of management concern, either as habitat during one or more of their life stages, or as a migration corridor to available habitat in Sacramento River tributaries. Changes in SWP/CVP operations resulting from implementation of the alternatives could potentially alter seasonal flows and water temperatures in the Sacramento River, which in turn could affect the relative habitat availability for fish species that are present in the Sacramento River.

The potential for changes in flows and water temperatures resulting from implementation of one of the alternatives to impact fish resources of the Sacramento River are dependent on the species-specific habitat and physiological requirements. Therefore, species-specific flow and water temperature methodologies for the Sacramento River fisheries assessment are discussed in detail in Appendix 12B. The following tools were utilized for analyses of specific habitat variables:

- CALSIM II – Flow
- Reclamation Water Temperature Model – Water Temperature
- Reclamation Early Life Stage Mortality Model – Chinook salmon early life stage mortality
- Flow-Habitat Relationships – Chinook salmon spawning WUA
- SALMOD – Chinook salmon population mortality and production potential
- IOS/DPM – Winter-run Chinook salmon population survival and female spawner abundance
- SacEFT – Steelhead spawning habitat availability, egg-to-fry survival, nest (redd) dewatering, redd scour, juvenile stranding, and juvenile rearing habitat; green sturgeon water temperature-related egg mortality

A detailed description of the specific methods, including life stage periodicity and model output node locations utilized to evaluate species of primary management concern in the Sacramento River, is provided in Appendix 12B.

Feather River

Because implementation of the alternatives may result in changes to Feather River flows and water temperatures, the impact assessment focuses on these and other habitat-based elements. Taking into account species-specific habitat requirements, operational components of the alternatives were assessed to evaluate potential impacts on identified fish species of primary management concern and associated aquatic habitat.

The potential for changes in flows and water temperatures resulting from implementation of the alternatives to impact fish resources of the Feather River are dependent on the species-specific habitat and physiological requirements. Therefore, species-specific flow and water temperature methodologies for the Feather River fisheries assessment are discussed in detail in Appendix 12B. The following tools were utilized for analyses of specific habitat variables:

- CALSIM II – Flow
- Reclamation Water Temperature Model – Water Temperature
- Reclamation Early Life Stage Mortality Model – Chinook salmon early life stage mortality
- Flow-Habitat Relationships – Chinook salmon and steelhead spawning WUA

A detailed description of the specific methods, including life stage periodicity and model output node locations utilized to evaluate species of primary management concern in the Feather River, is provided in Appendix 12B.

Sutter Bypass

To determine potential impacts on fish species of primary management concern potentially utilizing the Sutter Bypass, flows available from USRDOM were evaluated at Ord Ferry and Moulton, Colusa, and Tisdale weirs.

Detailed description of the specific methods utilized to evaluate species of primary management concern in the Sutter Bypass is provided in Appendix 12B.

American River

Because implementation of the alternatives may result in changes to American River flows and water temperatures, the impact assessment focused on the hydrologic changes associated with implementation of the alternatives.

Flows and water temperatures in the American River are controlled by operations of Folsom Reservoir. The impact evaluation on fishery resources requires an understanding of fish species' life histories and life stage-specific environmental requirements (see Affected Environment discussion), and the ability to meet them in the American River.

The potential for changes in flows and water temperatures resulting from implementation of one of the alternatives to impact fish resources of the American River are dependent on the species-specific habitat and physiological requirements. Therefore, species-specific flow and water temperature assessment methodologies for the American River fisheries assessment are discussed in detail in Appendix 12B. The following tools were utilized for analyses of specific habitat variables:

- CALSIM II – Flow
- Reclamation Water Temperature Model – Water Temperature
- Reclamation Early Life Stage Mortality Model – Fall-run Chinook salmon early life stage mortality
- Flow-Habitat Relationships – Fall-run Chinook salmon and steelhead spawning WUA

A detailed description of the specific methods, including life stage periodicity and model output node locations utilized to evaluate species of primary management concern in the American River, is provided in Appendix 12B.

Sacramento-San Joaquin Delta and Yolo Bypass

The alternatives have the potential to influence aquatic habitat conditions by potentially altering Delta inflow and water export operations. Therefore, aquatic habitat conditions and export operations (e.g., fish salvage operations) were evaluated to identify potential impacts on Delta species of primary management concern.

Because the alternatives have the potential to influence aquatic habitat conditions by potentially altering Delta inflow and water export operations, the following were evaluated:

- Water temperature
  - Water temperatures derived from Reclamation's Water Temperature Model in the lower reaches of the Sacramento River were used because Delta water temperatures from the DSM2 model were not available.
- Delta outflow
- X2 location
- Old and Middle River reverse flows
- Fish salvage and entrainment loss

Detailed description of the specific methods, including life stage periodicity and model output node locations utilized to evaluate species of primary management concern in the Sacramento-San Joaquin Delta, is provided in Appendix 12B. A detailed description of the methods and results of the fish salvage and entrainment loss modeling are provided in Appendix 12I.

In addition to the variables described above, the Delta Passage Model (DPM) was utilized to evaluate survival of Chinook salmon through the Yolo Bypass and the Delta. Additional detail regarding the DPM is provided in Appendix 12M.

The Yolo Bypass also was evaluated using CALSIM II flows for those species potentially utilizing the Yolo Bypass for spawning and rearing.

12.3.3.5 Primary Study Area

The Primary Study Area is comprised of the locations where the following proposed facilities would be constructed, modified, and/or operated: (1) the Sites Reservoir and associated facilities including the Holthouse Reservoir Complex, the TRR and associated facilities, and the Delevan Pipeline and associated facilities; (2) the Delevan Pipeline intake and discharge facilities on the Sacramento River; (3) the T-C Canal and Red Bluff Pumping Plant intake facility on the Sacramento River; and (4) the GCID Canal and intake facility on the Sacramento River.

Construction-Related Impacts

Construction-related impacts were evaluated for the new intake structure and pipeline, for infrastructure modifications at the existing points of diversion and conveyance, as well as for potentially affected water bodies in the immediate project vicinity of the proposed Sites Reservoir. The impact mechanisms evaluated for construction-related impacts included:

- Erosion, sedimentation, and turbidity
- Hazardous materials and chemical spills
- Aquatic habitat modification
- Hydrostatic pressure waves, noise, and vibration
- Stranding and entrainment potential
- Entrainment risk
- Fish passage
- Direct physical injury and/or mortality.

Within the Primary Study Area, NODOS Project construction-related impacts could potentially occur through direct contact of construction personnel, equipment, and/or debris, and generally would be limited to the area in the immediate vicinity of the construction footprint, and short distances downstream.

Potential construction-related impacts to resident and anadromous fisheries resources and aquatic habitat would depend on:

1. Location and type of infrastructure component to be constructed
2. Proximity of construction access routes, staging areas, and storage and disposal areas to waterways
3. Timing of construction activities
4. Specific techniques used

5. Potential for construction-related activities to directly harm individuals and/or remove, damage, or alter onsite habitat conditions within and adjacent to the construction footprint
6. Specific minimization and avoidance measures implemented before, during, and after construction

For each proposed project infrastructure component, the assessment was based on several considerations, including the duration and extent of construction-related activities, as well as the proximity of construction-related activities to waterways. Construction-related impacts could include: (1) changes in aquatic habitat quantity and quality; (2) changes in aquatic and riparian vegetation; and (3) changes in the composition of predator and prey fish community interactions within the immediate NODOS facility footprint area.

Detailed discussion of assessment methodology for the Primary Study Area is provided in Appendix 12B.

Operations- and Maintenance-related Impacts

The impact assessment methodology for the Primary Study Area addressed the operations and maintenance of Sites Reservoir facilities, Holthouse Reservoir Complex facilities, and the three points of diversion on the Sacramento River. The impact mechanisms evaluated for operations-related impacts included fish screen impingement and entrainment associated with water diversions, and temperature effects to the Sacramento River, resulting from Sites Reservoir releases. A detailed description of the assessment methodologies utilized to evaluate potential operations and maintenance impacts on aquatic biological resources is provided in Appendix 12B.

12.3.4 Topics Eliminated From Further Analytical Consideration

Several SWP/CVP re-regulating reservoirs that are located within the Secondary Study Area, including Lewiston Lake downstream of Trinity Dam, Whiskeytown Lake downstream of Lewiston Dam, Keswick Reservoir downstream of Shasta Dam, the Thermalito Complex downstream of Oroville Dam, and Lake Natoma downstream of Folsom Dam, have been eliminated from consideration for these analyses. No storage- or elevation-related impacts on fishery resources in these reservoirs are expected to occur with implementation of the alternatives, relative to the bases of comparison. As regulating afterbays, the re-regulating reservoirs are operated to receive highly variable flows and, as a result, monthly storage and elevation fluctuate significantly on a daily and hourly basis. Therefore, changes in releases from upstream reservoirs under the alternatives would not affect monthly mean storage or elevation, relative to the CEQA or NEPA baseline conditions. Consequently, no assessment of potential storage- or elevation-related impacts on biological aquatic resources in re-regulating reservoirs is warranted.

The following facilities within the Primary Study Area were not evaluated in detail because they would not be located within or adjacent to a waterway; therefore construction, operation, or maintenance of these facilities would not be anticipated to affect aquatic biological resources:.

- Recreation Areas
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Terminal Regulating Reservoir (TRR)
- GCID Canal Connection to the TRR
- TRR Pumping/Generating Plant

- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Transmission Line
- Delevan Pipeline Electrical Switchyard

12.3.5 Impacts Associated with the No Project/No Action Alternative Relative to Existing Conditions

The fourteen proposed projects that are included in the No Project/No Action Alternative and their associated potential impacts to aquatic biological resources within the three study areas are summarized below.

12.3.5.1 DWR - Mayberry Farms Subsidence Reversal and Carbon Sequestration Project

The creation of permanently flooded wetlands on Sherman Island associated with the Mayberry Farms Subsidence Reversal and Carbon Sequestration Project could increase local food availability, which could benefit aquatic species.

12.3.5.2 CCWD - Contra Costa Canal Fish Screen Project

Installation of fish screens at the Rock Slough diversion associated with the Contra Costa Canal Fish Screen Project is expected to minimize the entrainment losses of fish species in the Delta, which could benefit fisheries resources. Improvements at the diversion site also would potentially reduce predation on fish species.

12.3.5.3 CCWD, Reclamation, and DWR - Middle River Intake and Pump Station

Construction of the Alternative Intake Project would result in the installation of a new intake in the Delta, which could result in changes to local hydrodynamics and entrain or impinge fish species, as well as increase susceptibility of fish species to predation near the intake.

12.3.5.4 DWR – Federal Energy Regulatory Commission License Renewal for Oroville Project

Relicensing of the Oroville Facilities could result in operational changes in hydrology of Oroville Reservoir, Thermalito Afterbay, and the Feather River, which could affect aquatic biological resources in these locations. Effects of relicensing activities on reservoir storage and surface elevations, as well as Feather River flows and temperatures, are included in the assumptions associated with the hydrologic model simulations of the No Project/No Action Alternative. Therefore, operations-related effects on aquatic biological resources resulting from Oroville Facilities Relicensing efforts are evaluated below in conjunction with other No Project/No Action Alternative operations-related effects.

12.3.5.5 Freeport Regional Water Authority and Reclamation - Freeport Regional Water Project

Construction of both a new water intake facility/pumping plant on the Sacramento River and a 17-mile underground water pipeline within Sacramento County in association with the Freeport Regional Water Project could result in entrainment and impingement of fish species and result in changes in flow-dependent habitat availability downstream of the intake facility. Operation of the facility is included in the hydrologic model assumptions and potential effects on aquatic habitat are evaluated using hydrologic model results.

12.3.5.6 Reclamation District 2093 - Liberty Island Conservation Bank

Conservation and restoration of aquatic habitat at Liberty Island associated with the Liberty Island Conservation Bank is expected to provide additional habitat for native Delta fish species and anadromous fish species, which could provide for increased foraging and rearing habitat availability, and potentially result in increased survival of Delta and anadromous fish species.

12.3.5.7 City of Stockton - Delta Water Supply Project

Diversion of water from the Delta associated with the Delta Water Supply Project could result in changes in local hydrodynamics causing an increase in susceptibility of fish species to predation, and the possibility of entrainment or impingement of fish species.

12.3.5.8 Reclamation and SWRCB - Battle Creek Salmon and Steelhead Restoration Project

Restoration of salmonid habitat along Battle Creek and its tributaries due to changes in instream flows, removal of diversion dams, and construction of fish ladders and fish screens at other diversion dams associated with the Battle Creek Salmon and Steelhead Restoration Project is anticipated to improve and expand salmonid spawning, rearing, and migration habitat. This may result in increased abundance, productivity, and diversity, as well as improved spatial structure, of anadromous salmonid populations in Battle Creek.

12.3.5.9 Tehama Colusa Canal Authority and Reclamation - Red Bluff Diversion Dam Fish Passage Improvement Project

Modification of the Red Bluff Diversion Dam associated with the Red Bluff Diversion Dam Fish Passage Improvement Project is anticipated to reduce or minimize impacts on migration of anadromous fish species. The four-month “gates in” operation (May 15 through September 15) is expected to be discontinued once the new pumping plant is completed in 2012.

12.3.5.10 Reclamation, CDFG, and Natomas Central Mutual Water Company - American Basin Fish Screen and Habitat Improvement Project

This project involves modifications to the Natomas Central Mutual Water Company and other private water diversions on the Sacramento River and Natomas Cross Canal associated with the American Basin Fish Screen and Habitat Improvement Project, including installation of one or two positive-barrier fish screen diversion facilities; decommissioning and removal of the Verona Diversion Dam and lift pumps; removal of five pumping plants and one small private diversion; and modification of the existing distribution system. These activities are anticipated to reduce or minimize entrainment of juvenile fishes at these water diversions.

12.3.5.11 Reclamation – Delta-Mendota Canal/California Aqueduct Intertie

Construction of an intertie between the Delta-Mendota Canal and the California Aqueduct is anticipated to provide greater operational flexibility for the SWP and CVP, which could benefit Delta fish species.

12.3.5.12 Reclamation, USACE, SAFCA, and CVFPB - Folsom Dam Safety and Flood Damage Reduction Project

Dam safety and flood control improvements at Folsom Dam associated with the Folsom Dam Safety and Flood Damage Reduction Project are not anticipated to substantially affect fisheries resources.

12.3.5.13 Yolo County - Yolo County General Plan Update

Additional residential and commercial growth in Yolo County (within the Central Valley and along the Sacramento River within the Delta) is provided for under the Yolo County General Plan. This growth could result in indirect water quality-related effects on aquatic biological resources, due to potential increases in stormwater runoff into the Sacramento River and the Delta from new development. Effects associated with discrete development projects will be evaluated individually during the environmental review process for each of those potential development projects.

12.3.5.14 Zone 7 Water Agency and DWR - South Bay Aqueduct Improvement and Enlargement Project

Improvement and expansion of the South Bay Aqueduct associated with the South Bay Aqueduct Improvement and Enlargement Project is not anticipated to substantially affect aquatic biological resources.

A summary of changes in aquatic habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the export service area resulting from implementation of the No Project/No Action Alternative, relative to Existing Conditions, is presented in Table 12-13. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas resulting from implementation of the No Project/No Action Alternative, relative to Existing Conditions, is presented in Table 12-14. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.5.15 Extended and Secondary Study Areas – No Project/No Action Alternative

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Potential impacts on reservoir coldwater fish species associated with implementation of the No Project/No Action Alternative were evaluated in Trinity, Shasta, Oroville, and Folsom reservoirs in the Secondary Study Area; and in San Luis Reservoir and other export service area reservoirs in the Extended Study Area. Within the Secondary Study Area and San Luis Reservoir in the Extended Study Area, reservoir storage was evaluated. Within the Extended Study Area, SWP and CVP exports were evaluated as an indicator of potential changes to export service area reservoirs.

Reservoir coldwater fish species habitat conditions for the No Project/No Action Alternative would be similar to Existing Conditions in Shasta and San Luis reservoirs. In Trinity Reservoir, the expected slightly increased end-of-month storages indicate improved coldwater reservoir fish species habitat conditions. However, habitat conditions in Oroville and Folsom reservoirs would be slightly less suitable as a result of slightly decreased reservoir storages. Similarly, export service area reservoir habitat conditions are anticipated to be slightly less suitable because patterns of Delta exports would change and would be reduced more frequently, and would be reduced by 10 percent or more during some months of critical years. Additionally, although exports would increase slightly most of the time during six months of the year, and decrease slightly during the remaining six months of the year, large decreases in exports would also occur, which could potentially result in large reductions in storage during some years.

Reservoir coldwater fish species are not considered state or federal special status species, but are evaluated for their recreational importance. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, potential impacts on reservoir coldwater fish species in Trinity, Shasta, Oroville, Folsom, and San Luis and other export service area reservoirs are considered **less than significant**.

Reservoir Warmwater Fish Species

Potential impacts on reservoir warmwater fish species associated with implementation of the No Project/No Action Alternative were evaluated in Trinity, Shasta, Oroville, and Folsom reservoirs in the Secondary Study Area; and in San Luis Reservoir and other export service area reservoirs in the Extended Study Area. Within the Secondary Study Area and San Luis Reservoir in the Extended Study Area, net changes in water surface elevation reductions of 6-feet or more during the warmwater fish nesting season were evaluated. Within the Extended Study Area, SWP and CVP exports were evaluated as an indicator of potential changes to export service area reservoirs.

Reservoir warmwater fish species habitat conditions for the No Project/No Action Alternative would be similar to Existing Conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs. However, export service area reservoir habitat conditions are anticipated to be slightly less suitable for reasons described for coldwater reservoir fish species, above.

Reservoir warmwater fish species are not considered state or federal special status species, but are evaluated for their recreational importance. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on reservoir warmwater fish species in Trinity, Shasta, Oroville, Folsom, and San Luis and other export service area reservoirs.

Southern Oregon/Northern California Coho Salmon

Potential impacts associated with implementation of the No Project/No Action Alternative on Southern Oregon/Northern California Coho salmon were evaluated only in the Trinity River. Flows and water temperatures were evaluated to identify potential changes in Trinity River habitat conditions that could potentially impact Coho salmon.

In general, habitat conditions in the Trinity River would be similar under the No Project/No Action Alternative, relative to Existing Conditions.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on Coho salmon in the Trinity River.

Upper Klamath-Trinity River Fall-Run and Spring-Run Chinook Salmon

Potential impacts associated with implementation of the No Project/No Action Alternative on Upper Klamath-Trinity River fall-run and spring-run Chinook salmon were evaluated only in the Trinity River. Flows and water temperatures were evaluated to identify potential changes in Trinity River habitat conditions that could potentially impact Upper Klamath-Trinity River fall-run and spring-run Chinook salmon. Additionally, water temperature-related early life stage mortality was evaluated using Reclamation's Early Life Stage Mortality Model.

In general, during the periods when Chinook salmon are present in the Trinity River, habitat conditions, as well as early life stage mortality, would be similar under the No Project/No Action Alternative, relative to Existing Conditions.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on spring-run and fall-run Chinook salmon in the Trinity River.

Klamath Mountains Province Steelhead

Potential impacts associated with implementation of the No Project/No Action Alternative on Klamath Mountains Province steelhead were evaluated only in the Trinity River. Flows and water temperatures were evaluated to identify potential changes in Trinity River habitat conditions that could potentially impact steelhead.

In general, during the periods when steelhead are present in the Trinity River, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on steelhead salmon in the Trinity River.

Sacramento River Winter-Run Chinook Salmon

Potential impacts associated with implementation of the No Project/No Action Alternative on Sacramento River winter-run Chinook salmon were evaluated in the Sacramento River, Sutter Bypass, Delta, and Suisun, San Pablo, and San Francisco bays (bays). Flows, water temperatures, and spawning habitat availability were evaluated to identify potential changes in habitat conditions at various locations. Additionally, water temperature-related early life stage mortality, population mortality, production potential, population survival, and female spawner abundance were evaluated using various modeling tools. Through-Delta survival was evaluated using the Delta Passage Model component of IOS.

In general, during periods when winter-run Chinook salmon are present in the Sutter Bypass, Delta, and bays downstream of the Delta, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. Habitat conditions in the Sacramento River would be similar but slightly less suitable as a result of slightly less suitable spawning and embryo incubation conditions more often. However, slightly less suitable conditions in the Sacramento River would not result in substantial effects because reductions in habitat suitability would be small in magnitude and occur relatively infrequently (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on winter-run Chinook salmon in the Sacramento River, Sutter Bypass, Delta, and the bays.

Central Valley Spring-Run Chinook Salmon

Potential impacts associated with implementation of the No Project/No Action Alternative on Central Valley spring-run Chinook salmon were evaluated in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Delta, and bays. Flows, water temperatures, and spawning habitat availability were evaluated to identify potential changes in habitat conditions at various locations. Additionally, water temperature-related early life stage mortality, and population mortality and production potential, were evaluated using various modeling tools. Through-Delta survival was evaluated using the Delta Passage Model.

In general, during periods when spring-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in Clear Creek would be slightly improved during all life stages due to increased flows and decreased water temperatures occurring more frequently under the No Project/No Action Alternative, relative to Existing Conditions (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on spring-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Delta, and the bays.

Central Valley Fall-Run Chinook Salmon

Potential impacts associated with implementation of the No Project/No Action Alternative on Central Valley fall-run Chinook salmon were evaluated in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Delta, and bays. Flows, water temperatures, spawning habitat availability, and OMR reverse flows were evaluated to identify potential changes in habitat conditions at various locations. Additionally, water temperature-related early life stage mortality, and population mortality and production potential, were evaluated using various modeling tools. Through Delta survival was evaluated using the Delta Passage Model.

In general, during periods when fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in Clear Creek would be slightly improved during all life stages due to increased flows and decreased water temperatures occurring more frequently. Additionally, habitat conditions in the American River would be substantially less suitable during all life stages (see Appendix 12C for a detailed discussion). Specifically, decreased flows and increased water temperatures, as well as increased early life stage mortality would occur more frequently, as a result of implementation of the No Project/No Action Alternative.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on fall-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, Sutter Bypass, Delta, and bays**,** but **there would be a potentially substantial adverse effect** on fall-run Chinook salmon in the American River.

Central Valley Late Fall-Run Chinook Salmon

Potential impacts associated with implementation of the No Project/No Action Alternative on Central Valley late fall-run Chinook salmon were evaluated in the Sacramento River, Clear Creek, Sutter Bypass, Delta, and bays. Flows, water temperatures, and OMR reverse flows were evaluated to identify potential changes in habitat conditions at various locations. Additionally, water temperature-related early life stage mortality, and population mortality and production potential, were evaluated using various modeling tools. Through-Delta survival was evaluated using the Delta Passage Model.

In general, during periods when late fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. Additionally, habitat conditions in Clear Creek would be generally similar or improved during all life stages due to increased flows and decreased water temperatures occurring more frequently (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on late fall-run Chinook salmon in the Sacramento River, Clear Creek, Sutter Bypass, Delta, and bays.

Central Valley Steelhead

Potential impacts associated with implementation of the No Project/No Action Alternative on Central Valley steelhead were evaluated in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays. Flows, water temperatures, Delta outflow, and OMR flows were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated. Additionally, spawning, embryo incubation, and juvenile rearing and emigration conditions in the Sacramento River were evaluated using SacEFT, and spawning habitat availability in the Feather River was evaluated using flow-habitat relationships.

In general, during periods when steelhead are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in Clear Creek would be similar during most years, but would be more suitable for all life stages during low flow conditions as a result of increased flows and decreased water temperatures occurring more frequently. Additionally, habitat conditions in the American River would be substantially less suitable for juvenile rearing and emigration, and smolt emigration, as a result of decreased flows and increased water temperatures occurring more frequently, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on steelhead in the Sacramento River, Clear Creek, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays**,** but **there would be a potentially substantial adverse effect** on steelhead in the American River.

Green Sturgeon

Potential impacts associated with implementation of the No Project/No Action Alternative on green sturgeon were evaluated in the Trinity River, Sacramento River, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays. Flows and water temperatures were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated. Additionally, water temperature-related egg survival in the Sacramento River was evaluated using SacEFT.

In general, during periods when green sturgeon are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in the American River would be substantially less suitable during all life stages due to decreased flows and increased water temperatures occurring more frequently, particularly during low flow conditions (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on green sturgeon in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays, but **there would be a potentially substantial adverse effect** on green sturgeon in the American River.

White Sturgeon

Potential impacts associated with implementation of the No Project/No Action Alternative on white sturgeon were evaluated in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays. Flows and water temperatures were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when white sturgeon are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions.

White sturgeon are not considered State or federal special status species, but are evaluated for their recreational importance. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on white sturgeon in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays**.**

Pacific Lamprey

Potential impacts associated with implementation of the No Project/No Action Alternative on Pacific lamprey were evaluated in the Trinity River, Sacramento River, Clear Creek, Feather River, American River, Delta, and bays. Flows and water temperatures were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when Pacific lamprey are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in Clear Creek would be similar during most years, but would be more suitable for all life stages during low flow conditions as a result of increased flows occurring more often. Additionally, habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows and increased water temperatures occurring more frequently, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Pacific lamprey are not considered special status species in California, but are evaluated because the USFWS in Oregon and Washington considers Pacific lamprey to be a species of concern. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse**

effect on Pacific lamprey in the Trinity River, Sacramento River, Clear Creek Feather River, Delta, and bays**,** but **there would be a potentially substantial adverse effect** on Pacific lamprey in the American River**.**

River Lamprey

Potential impacts associated with implementation of the No Project/No Action Alternative on river lamprey were evaluated in the Sacramento River, Clear Creek, Feather River, American River, Delta, and bays. Flows and water temperatures were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when river lamprey are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in Clear Creek would be similar during most years, but would be more suitable for all life stages during low flow conditions as a result of increased flows occurring more often. Additionally, habitat conditions in the American River would be substantially less suitable for all life stages, due to decreased flows and increased water temperatures occurring more frequently, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on river lamprey in the Sacramento River, Clear Creek, Feather River, Delta, and bays are considered **less than significant,** but **there would be a potentially substantial adverse effect** on river lamprey in the American River.

Hardhead

Potential impacts associated with implementation of the No Project/No Action Alternative on hardhead were evaluated in the Sacramento River, Clear Creek, Feather River, and American River. Flows and water temperatures were evaluated to identify potential changes in habitat conditions at various locations.

In general, during periods when hardhead are present in the Sacramento and Feather rivers, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. Habitat conditions in Clear Creek would be similar during most years, but would be more suitable for all life stages during low flow conditions due to increased flows occurring more often. Additionally, habitat conditions in the American River would be similar during spawning but less suitable for other life stages due to decreased flows occurring more frequently (see Appendix 12C for a detailed discussion). However, because habitat conditions during spawning would be similar, and reduced habitat suitability for other life stages would be a result of decreased flows occurring more frequently while water temperatures remain within the range considered suitable, reduced flows alone would not be anticipated to result in a substantial effect on the population.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on hardhead in the Sacramento River, Clear Creek, Feather River, and American River.

California Roach

Potential impacts associated with implementation of the No Project/No Action Alternative on roach were evaluated in the Sacramento River, Clear Creek, Feather River, and American River in the Secondary Study Area, and in Level 4 wildlife refuges in the Extended Study Area. Within the Extended Study Area, habitat conditions were evaluated based on anticipated conditions resulting from implementation of the

No Project/No Action Alternative. Within the Secondary Study Area, simulated flows and water temperatures were evaluated to identify potential changes in habitat conditions at various locations.

Within the Secondary Study Area, during periods when roach are present in the Sacramento and Feather rivers, habitat conditions generally would be similar under the No Project/No Action Alternative, relative to Existing Conditions. Habitat conditions in Clear Creek would be similar during most years, but would be more suitable for spawning during low flow conditions as a result of increased flows occurring more often. Additionally, habitat conditions in the American River would be similar during spawning but less suitable for other life stages due to decreased flows occurring more often (see Appendix 12C for a detailed discussion). However, because habitat conditions during spawning would be similar, and reduced habitat suitability for other life stages would be a result of decreased flows occurring more frequently while water temperatures remain within the range considered suitable, reduced flows alone would not be anticipated to result in a substantial effect on the population. Habitat conditions within the Extended Study Area are anticipated to be similar under the No Project/No Action Alternative, relative to Existing Conditions.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on California roach in the Sacramento River, Clear Creek, Feather River, American River, and Level 4 wildlife refuges.

Delta Smelt

Potential impacts associated with implementation of the No Project/No Action Alternative on delta smelt were evaluated in the Yolo Bypass, Delta (some analyses included model nodes in the lower reaches of the Sacramento River), and bays. Flows, water temperatures, X2 location, Delta outflow, salvage and entrainment, and OMR flows were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when delta smelt are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on delta smelt in the Yolo Bypass, Delta, and bays.

Longfin Smelt

Potential impacts associated with implementation of the No Project/No Action Alternative on longfin smelt were evaluated in the Delta (some analyses included model nodes in the lower reaches of the Sacramento River), and bays. Flows, water temperatures, X2 location, Delta outflow, salvage and entrainment, and OMR flows were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when longfin smelt are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions.

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on longfin smelt in the Delta and bays.

Sacramento Splittail

Potential impacts associated with implementation of the No Project/No Action Alternative on splittail were evaluated in the Feather River, American River, Sutter Bypass, Yolo Bypass, and Delta in the

Secondary Study Area; and in Level 4 wildlife refuges in the Extended Study Area. Extended Study Area habitat conditions were evaluated based on anticipated conditions resulting from implementation of the No Project/No Action Alternative. Within the Secondary Study Area, simulated flows, water temperatures, and useable flooded area were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when splittail are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in the American River would be substantially less suitable for spawning, as a result of decreased flows and reduced useable flooded area occurring more often, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on Sacramento splittail in the Feather River, Sutter Bypass, Yolo Bypass, Delta, and Level 4 wildlife refuges, but **there would be a potentially substantial adverse effect** on Sacramento splittail in the American River.

Striped Bass

Potential impacts associated with implementation of the No Project/No Action Alternative on striped bass were evaluated in the Sacramento River, Feather River, American River, Delta, and bays. Flows, water temperatures, and X2 location were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when striped bass are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows occurring more often, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Striped bass are not considered State or federal special status species, but are evaluated for their recreational importance. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on striped bass in the Sacramento River, Feather River, Delta, and bays, but **there would be a potentially substantial adverse effect** on striped bass in the American River.

American Shad

Potential impacts associated with implementation of the No Project/No Action Alternative on American shad were evaluated in the Sacramento River, Feather River, American River, Delta, and bays. Flows, water temperatures, and X2 location were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when American shad are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows occurring more often, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

American shad are not considered State or federal special status species, but are evaluated for their recreational importance. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on American shad in the Sacramento River, Feather River, Delta, and bays, but **there would be a potentially substantial adverse effect** on American shad in the American River.

Largemouth Bass

While largemouth bass are evaluated as a species of recreational importance, they also are evaluated as an indicator of potential impacts on other warmwater game fishes.

Potential impacts associated with implementation of the No Project/No Action Alternative on largemouth bass were evaluated in the Sacramento River, Feather River, American River, Yolo Bypass, and Delta. Flows, water temperatures, X2 location, and monthly Electrical Conductivity (EC) in the Delta were evaluated to identify potential changes in habitat conditions at various locations. Salvage at the SWP and CVP Delta pumping facilities also was evaluated.

In general, during periods when largemouth bass are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to Existing Conditions. However, while flows in the American River would be reduced and water temperatures would be increased, these changes would not be likely to adversely affect largemouth bass or other warmwater game fishes. In fact, the expected reduced flows and more frequently increased water temperatures could potentially benefit largemouth bass by reducing habitat suitability for coldwater fish species, thereby making them more susceptible to predation.

Largemouth bass are not considered State or federal special status species, but are evaluated for their recreational importance. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on largemouth bass in the Sacramento River, Feather River, American River, Yolo Bypass, and Delta.

12.3.5.16 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

No construction, operations, or maintenance activities would occur in the Primary Study Area under the No Project/No Action Alternative. Habitat conditions in Funks and Stone Corral creeks are not anticipated to change with implementation of the No Project/No Action Alternative. However, existing agricultural land use activities in the Primary Study Area are assumed to continue as they do under Existing Conditions. These activities would likely include unrestricted cattle movement within some of the local creeks and continued disturbance to riparian areas. Ongoing land uses and agricultural practices in the Primary Study could result in degraded habitat conditions within Funks and Stone Corral creeks. Therefore, under the No Project/No Action Alternative, relative to Existing Conditions, **there would not be a substantial adverse effect** on fish species and aquatic habitat in Funks and Stone Corral creeks.

12.3.6 Impacts Associated with Alternative A Relative to Existing Conditions

Potential impacts on fish species of primary management concern associated with implementation of Alternative A, relative to Existing Conditions, were evaluated in an identical manner to those described for the No Project/No Action Alternative, relative to Existing Conditions. Specifically, model results and locations evaluated were identical among alternatives.

A summary of changes in habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the Export Service Area under Alternative A, relative to Existing Conditions, is presented in Table 12-15. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas under Alternative A, relative to Existing Conditions, is presented in Table 12-16. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.6.1 Extended and Secondary Study Areas - Alternative A Relative to Existing Conditions

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Reservoir coldwater fish species habitat conditions would be similar or more suitable in Trinity, Shasta, Oroville, and Folsom reservoirs under Alternative A, relative to Existing Conditions. Specifically, within the Secondary Study Area, end-of-month storage generally would be greater more often under Alternative A, relative to Existing Conditions, in Trinity, Shasta and Folsom reservoirs, and would be generally similar in Lake Oroville. Reservoir coldwater fish species habitat conditions would be similar or less suitable in San Luis Reservoir, and similar or generally more suitable in export service area reservoirs due to reduced storage more often in San Luis Reservoir, and potentially increased storage in other export service area reservoirs due to increased SWP/CVP exports.

Therefore, for Alternative A, relative to Existing Conditions, potential impacts on reservoir coldwater fish species in Oroville and San Luis reservoirs are considered **less than significant,** and impacts to coldwater fish species in Trinity, Shasta, Folsom, and other export service area reservoirs are considered **potentially beneficial**.

Reservoir Warmwater Fish Species

Reservoir warmwater fish species habitat conditions would be similar or more suitable under Alternative A, relative to Existing Conditions, in Trinity and Shasta reservoirs because fewer water surface elevation reductions of six feet or more would occur during the warmwater fish nesting season. Therefore, fewer nest dewatering events would be anticipated. Water surface elevation reductions of six feet or more would occur with similar frequency in Oroville Reservoir, and slightly more often in Folsom Reservoir. Therefore, habitat conditions for warmwater fish species are anticipated to be similar in Oroville Reservoir and potentially slightly less suitable in Folsom Reservoir. Habitat conditions in San Luis Reservoir are anticipated to be slightly less suitable because of increased frequencies of water surface elevation reductions of six feet or more, while expected increases in exports more often are anticipated to increase habitat suitability for warmwater fish species inhabiting other export service area reservoirs.

Therefore, for Alternative A, relative to Existing Conditions, potential impacts on reservoir warmwater fish species in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs are considered **less than significant,** and impacts to warmwater fish species in other export service area reservoirs are considered **potentially beneficial**.

Southern Oregon/Northern California Coho Salmon

Construction activities would not impact Southern Oregon/Northern California Coho salmon because they are not found in the Sacramento River.

In general, habitat conditions in the Trinity River would be similar under Alternative A, relative to Existing Conditions because flows would be similar during most life stages, while water temperature index values would be exceeded with similar frequencies during most life stages (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to Existing Conditions, potential operational impacts on Coho salmon in the Trinity River are considered **less than significant**.

Upper Klamath-Trinity River Fall-Run and Spring-Run Chinook Salmon

Construction activities would not impact Upper Klamath-Trinity River fall-run and spring-run Chinook salmon because they are not found in the Sacramento River.

In general, during the periods when Chinook salmon are present in the Trinity River, habitat conditions, as well as early life stage mortality, would be similar or more suitable under Alternative A, relative to Existing Conditions because flows would be similar, but slightly higher during some life stages while water temperature index values would be exceeded with similar or lower frequencies during all life stages (see Appendix 12C for detailed discussion).

Therefore, under Alternative A, relative to Existing Conditions, potential operational impacts on spring-run and fall-run Chinook salmon in the Trinity River are considered **less than significant**.

Klamath Mountains Province Steelhead

Construction activities would not impact Upper Klamath-Trinity River fall-run and spring-run Chinook salmon because they are not found in the Sacramento River.

In general, during the periods when steelhead are present in the Trinity River, habitat conditions would be similar under Alternative A, relative to Existing Conditions, with flows being lower slightly more often and water temperatures being slightly more suitable more often.

Therefore, under Alternative A, relative to the Existing Condition, potential operational impacts on steelhead in the Trinity River are considered **less than significant**.

Sacramento River Winter-Run Chinook Salmon

Construction in the Secondary Study Area would consist of the installation of additional pump into an existing bay at the Red Bluff Pumping Plant during the annual maintenance period for the T-C Canal. Although the canal would be dry during construction, construction activities would occur near the Sacramento River and therefore could potentially impact winter-run Chinook salmon in the Sacramento River as they migrate upstream (adults) or downstream (emigrating juveniles). Potential impact mechanisms include: (1) increases in sedimentation and turbidity; and (2) hazardous materials and chemical spills. These potential impacts could result in reduced habitat suitability, physiological stress and sub-lethal effects, as well as direct mortality to individual fish, which could result in population-level impacts (e.g., reduced spawning activity and subsequent initial year class strength).

Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on winter-run Chinook salmon in the Sacramento River are considered **potentially significant**.

In general, during periods when winter-run Chinook salmon are present in the Sutter Bypass, Delta, and bays downstream of the Delta, habitat conditions would be similar or more suitable under Alternative A, relative to Existing Conditions. Habitat conditions in the Sacramento River would be generally more suitable as a result of more suitable spawning and embryo incubation conditions more often, while habitat conditions in the Delta would be similar or more suitable due to generally higher juvenile survival through the Delta (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on winter-run Chinook salmon in the Sutter Bypass, Delta, and the bays are considered **less than significant,** and operational impacts on winter-run Chinook salmon in the Sacramento River are considered **potentially beneficial**.

Central Valley Spring-Run Chinook Salmon

Construction-related impacts on spring-run Chinook salmon would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on spring-run Chinook salmon in the Sacramento River are considered **potentially significant**.

In general, during periods when spring-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative A, relative to Existing Conditions, due to more frequently increased flows and reduced water temperatures. Habitat conditions in the American River for non-natal juvenile spring-run Chinook salmon would be generally similar or slightly less suitable due to reduced flows occurring more frequently under Alternative A, relative to Existing Conditions. However, it is not anticipated that these habitat conditions would substantially affect spring-run Chinook salmon, particularly because the American River only supports non-natal juvenile rearing (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to Existing Conditions, potential operational- impacts on spring-run Chinook salmon in Clear Creek, Feather River, American River, Sutter Bypass, Delta, and bays are considered **less than significant,** and impacts on spring-run Chinook salmon in the Sacramento River are considered **potentially beneficial**.

Central Valley Fall-Run Chinook Salmon

Construction-related impacts on fall-run Chinook salmon would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on fall-run Chinook salmon in the Sacramento River are considered **potentially significant**.

In general, during periods when fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative A, relative to Existing Conditions. However, habitat conditions in the American River would be substantially less suitable during all life stages (see Appendix 12C for a detailed discussion). Specifically, decreased flows and increased water temperatures, as well as increased early life stage mortality would occur more frequently, as a result of implementation of Alternative A.

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on fall-run Chinook salmon in the Sacramento River, Feather River, Sutter Bypass, Delta, and bays are considered **less than significant.**

On the American River under Alternative A relative to Existing Conditions, impacts on fall-run Chinook salmon would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on fall-run Chinook salmon are considered to be **less than significant**.

Central Valley Late Fall-Run Chinook Salmon

Construction-related impacts on late fall-run Chinook salmon would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on late fall-run Chinook salmon in the Sacramento River are considered **potentially significant**.

In general, during periods when late fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative A, relative to the Existing Condition (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on late fall-run Chinook salmon in the Sacramento River, Clear Creek, Sutter Bypass, Delta, and bays are considered **less than significant**.

Central Valley Steelhead

Construction-related impacts on steelhead would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on steelhead in the Sacramento River are considered **potentially significant**.

In general, during periods when steelhead are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions. However, habitat conditions in Clear Creek would be similar during most years, but would be generally more suitable for all life stages during low flow conditions as a result of increased flows and decreased water temperatures occurring more frequently. Habitat conditions in the American River would be substantially less suitable for adult immigration and holding, juvenile rearing and emigration, and smolt emigration, as a result of decreased flows and increased water temperatures occurring more frequently, particularly during low flow conditions when habitat may be limited. Habitat conditions in the Yolo Bypass would also be less suitable for juvenile rearing and emigration, as a result of decreased frequency of inundation (as identified by reduced Yolo Bypass outflow more often), and potentially reduced Delta productivity as a result of decreased Yolo Bypass inundation frequency (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on steelhead in the Sacramento River, Clear Creek, Feather River, Sutter Bypass, Delta, and bays are considered **less than significant,** and impacts on steelhead in the Yolo Bypass are considered **potentially significant**.

On the American River under Alternative A relative to Existing Conditions, impacts on steelhead would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on steelhead are considered to be **less than significant**.

Green Sturgeon

Construction-related impacts on green sturgeon would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on green sturgeon in the Sacramento River are considered **potentially significant**.

In general, during periods when green sturgeon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative A, relative to Existing Conditions. However, habitat conditions in the American River would be substantially less suitable during all green sturgeon life stages due to decreased flows more often and increased water temperatures occurring with similar or higher frequencies, particularly during low flow conditions. Habitat conditions in the Yolo Bypass would also be less suitable for juvenile rearing and emigration as a result of decreased frequency of inundation (as identified by reduced Yolo Bypass outflow more often), and potentially reduced Delta productivity as a result of decreased Yolo Bypass inundation frequency (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on green sturgeon in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on green sturgeon in the Yolo Bypass are considered **potentially significant**.

On the American River under Alternative A relative to Existing Conditions, impacts on green sturgeon would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on green sturgeon are considered to be **less than significant**.

White Sturgeon

Construction-related impacts on white sturgeon would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on white sturgeon in the Sacramento River are considered **potentially significant**.

In general, during periods when white sturgeon are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions in the Trinity River, Sutter Bypass, Delta and Bays, but would be similar or less suitable in the Sacramento and Feather rivers. Habitat conditions would be less suitable in the Sacramento River due to reduced flows more often during the spawning and embryo incubation lifestage, but water temperatures would not be increased substantially more often. Habitat conditions would be less suitable in the Feather River due to reduced flows more often during all lifestage periodicities, but water temperatures would be generally similar. Additionally, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing due to a decreased frequency of floodplain activation, which results in reduced floodplain rearing opportunities and reduced nutrient inflow to the Delta and bays (see Appendix 12C for a detailed discussion).

Therefore, for Alternative A, relative to Existing Conditions, potential impacts on white sturgeon in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Delta, and bays are considered **less than significant,** and impacts to white sturgeon in the Yolo Bypass are considered **potentially significant**.

Pacific Lamprey

Construction-related impacts on Pacific lamprey would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on Pacific lamprey in the Sacramento River are considered **potentially significant**.

In general, during periods when Pacific lamprey are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions in the Trinity and Sacramento rivers, the Delta and bays, would be similar or more suitable in Clear Creek, would be similar or less suitable in the Feather River, and would be substantially less suitable in the American River. Habitat conditions in Clear Creek would be similar during most years, but would be more suitable for all life stages during low flow conditions as a result of increased flows occurring more often. Habitat conditions in the Feather would be slightly less suitable due to generally reduced flows slightly more often for all life stages. Habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows and similar or increased probabilities of higher water temperatures, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, for Alternative A, relative to Existing Conditions, potential impacts on Pacific lamprey in the Trinity River, Sacramento River, Clear Creek, Feather River, Delta, and bays are considered **less than significant**. On the American River under Alternative A relative to Existing Conditions, impacts on Pacific lamprey would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on Pacific lamprey are considered to be **less than significant**.

River Lamprey

Construction-related impacts on river lamprey would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on river lamprey in the Sacramento River are considered **potentially significant**.

In general, during periods when river lamprey are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions in the Sacramento River, the Delta and bays, would be similar or more suitable in Clear Creek, would be similar or less suitable in the Feather River, and would be substantially less suitable in the American River. Simulated habitat conditions in Clear Creek would be similar during most years, but would be more suitable for all life stages during low flow conditions as a result of increased flows occurring more often. Habitat conditions in the Feather River would be slightly less suitable due to generally reduced flows occurring slightly more often for all life stages. Habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows and similar or increased probabilities of higher water temperatures, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to Existing Conditions, potential operational impacts on river lamprey in the Sacramento River, Clear Creek, Feather River, Delta, and bays are considered **less than significant**. On the American River under Alternative A relative to Existing Conditions, impacts on river lamprey would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on river lamprey are considered to be **less than significant**.

Hardhead

Construction-related impacts on hardhead would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on river lamprey in the Sacramento River are considered **potentially significant**.

In general, during periods when hardhead are present in the Sacramento and American rivers, habitat conditions would be similar under Alternative A, relative to Existing Conditions. Habitat conditions in Clear Creek would be similar during most years, but are more suitable for all life stages during low flow conditions due to increased flows occurring more often. Additionally, habitat conditions in the Feather River would be generally less suitable for all life stages due to decreased flows occurring more frequently (see Appendix 12C for a detailed discussion). However, because reduced habitat suitability would be a result of decreased flows occurring more frequently while water temperatures generally remain within the range considered suitable, reduced flows alone would not be anticipated to result in a substantial impact on hardhead.

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on hardhead in the Sacramento River, Clear Creek, Feather River, and American River are considered **less than significant**.

California Roach

Construction-related impacts on roach in the Sacramento River would be identical to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on roach in the Sacramento River are considered **potentially significant**.

Within the Secondary Study Area, during periods when roach are present in the Sacramento, Feather and American rivers, habitat conditions generally would be similar under Alternative A, relative to Existing Conditions. Habitat conditions in Clear Creek would be similar during most years, but would be more suitable for spawning during low flow conditions as a result of increased flows occurring more often. Habitat conditions for roach within the wildlife refuges of the Extended Study Area are anticipated to be similar under Alternative A, relative to Existing Conditions.

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on California roach in the Sacramento River, Clear Creek, Feather River, American River, and Level 4 wildlife refuges are considered **less than significant**.

Delta Smelt

Construction activities would not impact delta smelt because they are not found in the Sacramento River near the construction location.

In general, during periods when delta smelt are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions.

Therefore, under Alternative A, relative to Existing Conditions, impacts on delta smelt in the Delta and bays are considered **less than significant**.

Longfin Smelt

Construction activities would not impact longfin smelt because they are not found in the Sacramento River near the construction location.

In general, during periods when longfin smelt are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions.

Therefore, under Alternative A, relative to Existing Conditions, impacts on longfin smelt in the Delta and bays are considered **less than significant**.

Sacramento Splittail

Construction-related impacts on splittail would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on splittail in the Sacramento River are considered **potentially significant**.

In general, during periods when splittail are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions in the Feather River and the Sutter Bypass. Habitat conditions in the American River would be slightly less suitable for spawning due to decreased flows and reduced useable flooded area occurring slightly more often. The reduction in usable flooded area slightly more often is not anticipated to result in a substantial impact to splittail in the American River. Habitat conditions for splittail within the wildlife refuges of the Extended Study Area are anticipated to be similar under Alternative A, relative to Existing Conditions. Additionally, reduced flows into and out of the Yolo Bypass would result in less suitable habitat conditions for splittail spawning. Because of the importance of the Yolo Bypass to splittail population abundance, reduced floodplain inundation in the Yolo Bypass constitutes a substantial impact (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to Existing Conditions, potential operational impacts on splittail in the Feather River, American River, Sutter Bypass, Delta, and Level 4 wildlife refuges are considered **less than significant**, and impacts on splittail in the Yolo Bypass are considered **potentially significant**.

Striped Bass

Construction-related impacts on striped bass would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on striped bass in the Sacramento River are considered **potentially significant**.

In general, during periods when striped bass are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions. However, habitat conditions in the Feather River would be similar or less suitable due to lower flows more often during the spawning and early life stage period. Habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows occurring more often, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to Existing Conditions, potential operational impacts on striped bass in the Sacramento River, Feather River, Delta, and bays are considered **less than significant**. On the American River under Alternative A relative to Existing Conditions, impacts on striped bass would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on striped bass are considered to be **less than significant**.

American Shad

Construction-related impacts on American shad would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on American shad in the Sacramento River are considered **potentially significant**.

In general, during periods when striped bass are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions. However, habitat conditions in the Feather River would be similar or less suitable due to lower flows more often during the spawning and early life stage period. Habitat conditions in the American River would be substantially less suitable for all life stages, as a result of decreased flows occurring more often, particularly during low flow conditions when habitat may be limited (see Appendix 12C for a detailed discussion).

Therefore, for Alternative A, relative to Existing Conditions, potential impacts on American shad in the Sacramento River, Feather River, Delta, and bays are considered **less than significant**. On the American River under Alternative A relative to Existing Conditions, impacts on American shad would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative A, the potential operational impacts on American shad are considered to be **less than significant**.

Largemouth Bass

While largemouth bass are evaluated as a species of recreational importance, they also are evaluated as an indicator of potential impacts on other warmwater game fishes.

Construction-related impacts on largemouth bass would be similar to those described for winter-run Chinook salmon. Therefore potential construction-related impacts associated with implementation of Alternative A, relative to Existing Conditions, on largemouth bass in the Sacramento River are considered **potentially significant**.

In general, during periods when largemouth bass are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to Existing Conditions. Habitat conditions in the Delta and Yolo Bypass would be similar or less suitable due to reduced flows into and out of the Yolo Bypass, resulting in reduced habitat availability for all life stages. However, reduced flows in the Yolo Bypass are not likely to adversely impact largemouth bass or other warmwater game fishes. In fact, reduced flows and increased water temperatures occurring more frequently could potentially benefit largemouth bass by reducing habitat suitability for coldwater fish species, thereby making them more susceptible to predation. Additionally, habitat availability in the Delta would be increased during the summer and fall due to reduced EC at various locations.

Therefore, for Alternative A, relative to Existing Conditions, potential impacts on largemouth bass in the Sacramento River, Feather River, American River, and Delta are considered **less than significant,** and impacts to largemouth bass in the Yolo Bypass are considered **potentially significant**.

Ecosystem Enhancement Storage Account – Operational Actions (Project-level Analysis – Alternatives A, B and C)

NODOS Project planners adopted a list of objectives that were incorporated into the operations strategy for the action alternative plans. The objectives, which are referred to as the Ecosystem Enhancement Storage Account (EESA), and their associated potential effects on fish species of primary management concern and aquatic habitat are described below:

- **Improve the reliability of coldwater pool storage in Shasta Lake to increase Reclamation's operational flexibility to provide suitable water temperatures for fish species in the Sacramento River.** This action would operationally translate into an increase in Shasta Lake May storage levels, and increased coldwater pool storage, with particular emphasis on Below Normal, Dry, and Critical water year types. Refer to species-specific SWP and CVP operations analyses for the Sacramento River for potential effects of this action on fish species of primary management concern.
- **Provide releases of appropriate water temperatures from Shasta Dam, and subsequently from Keswick Dam, to maintain mean daily water temperatures year-round at levels suitable for all species and life stages of anadromous salmonids in the Sacramento River between Keswick Dam and Red Bluff Diversion Dam.** Particular emphasis should be placed on the months of highest potential water temperature-related impacts (i.e., July through November) during Below Normal, Dry, and Critical water year types. Refer to species-specific SWP and CVP operations analyses for the Sacramento River for potential effects of this action on fish species of primary management concern.
- **Increase the availability of coldwater pool storage in Folsom Reservoir, by increasing May storage, to allow Reclamation additional operational flexibility to provide suitable water temperatures in the American River.** This action would utilize additional coldwater pool storage by

providing releases from Folsom Dam (and subsequently from Nimbus Dam) to maintain mean daily water temperatures at levels suitable for juvenile steelhead over-summer rearing and fall-run Chinook salmon spawning in the American River from May through November during all water year types. This action may potentially increase the suitability of water temperature conditions in the American River for fish species of primary management concern during May through November of all water year types.

- **Stabilize flows in the American River to minimize dewatering of fall-run Chinook salmon redds (i.e., October through March) and steelhead redds (i.e., January through May), and reduce isolation events (specifically, flow increases to ≥ 4,000-cfs with subsequent reduction to < 4,000 cfs) of juvenile anadromous salmonids, particularly from October through June. Reduce the reliance upon Folsom Reservoir as a "real-time, first response facility" to meet Delta objectives and demands, particularly from January through August, to reduce flow fluctuation and water temperature-related impacts to fall-run Chinook salmon and steelhead in the American River.** This action may potentially reduce fall-run Chinook salmon and steelhead redd dewatering and redd isolation events, and potentially improve water temperature conditions for fall-run Chinook salmon and steelhead in the American River.

- **Provide supplemental Delta outflow during summer and fall months (i.e., May through December) to improve X2 location (if possible, west of Collinsville, 81 km) and increase estuarine habitat, reduce entrainment, and improve food availability for anadromous fishes and other estuarine-dependent species (e.g., delta smelt, longfin smelt).** Refer to species-specific SWP and CVP operations analyses for the Delta for potential effects of this action on fish species of primary management concern. General changes in mean monthly Delta outflow under each modeled Alternative comparison are described below:

  - Alternative A relative to Existing Conditions: Delta outflow would be increased more often during October, December, and June through September, but would be reduced more often during November and January through May.
  - Alternative A relative to the No Project/No Action Alternative: Delta outflow would be increased more often during October, December, and June through September, and would be reduced more often during November and January through April.
  - Alternative B relative to Existing Conditions: Delta outflow would be increased more often during October, December, and June through September, and would be reduced more often during November and January through May.
  - Alternative B relative to the No Project/No Action Alternative: Delta outflow would be increased more often during October, December, and June through September, and would be reduced more often during November and January through May.
  - Alternative C relative to Existing Conditions: Delta outflow would be increased more often during October through December and June through September, and would be reduced more often during January through May.
  - Alternative C relative to the No Project/No Action Alternative: Delta outflow would be increased more often during October, December and June through September, and would be reduced more often during November and January through May

- **Improve the reliability of coldwater pool storage in Lake Oroville to improve water temperature suitability for juvenile steelhead and spring-run Chinook salmon over-summer rearing and fall-run Chinook salmon spawning in the Feather River from May through November during all water year types. Provide releases from Oroville Dam to maintain mean daily water temperatures at levels suitable for juvenile steelhead and spring-run Chinook salmon over-summer rearing, and fall-run Chinook salmon spawning in the Feather River. Stabilize flows in the Feather River to minimize redd dewatering, juvenile anadromous salmonid stranding, and isolation.** Refer to species-specific SWP and CVP operations analyses for the Feather River for potential effects of this action on fish species of primary management concern. In addition, this action may improve the suitability of daily water temperatures for fish species of primary management concern during May through November, and potentially reduce anadromous salmonid redd dewatering and juvenile stranding and isolation in the Feather River.
- **Stabilize flows in the Sacramento River between Keswick Dam and the Red Bluff Diversion Dam to minimize dewatering of fall-run Chinook salmon redds (for the spawning and embryo incubation life stage periods extending from October through March), particularly during fall months.** Refer to species-specific SWP and CVP operations analyses for the Sacramento River for potential effects of this action on fish species of primary management concern.
- **Provide increased flows from spring through fall in the lower Sacramento River by reducing diversions at Red Bluff Diversion Dam (into the Tehama-Colusa Canal) and at Hamilton City (into the Glenn-Colusa Irrigation District Canal), and by providing supplemental flows (at Delevan).** This action would provide multiple benefits to riverine and estuarine habitats, and to anadromous fishes and estuarine-dependent species (e.g., delta smelt, splittail, longfin smelt, and Sacramento splittail) by providing or augmenting transport flows, increasing habitat availability, increasing productivity, and improving nutrient transport and food availability. Refer to species-specific SWP and CVP operations analyses for the Sacramento River and the Delta for potential effects of this action on fish species of primary management concern. To address other aquatic biological resources potentially affected by changes in flows into and through the Delta, changes in modeled Delta outflow were evaluated for each alternative comparison below.

Ecosystem Enhancement Fund – Non-Operational Actions (Programmatic-level Analysis – Alternatives A, B and C)

The Ecosystem Enhancement Fund (EEF) would be established as an endowment to provide long-term funding for aquatic habitat restoration actions on the Sacramento River and its tributaries that do not necessarily require additional water. Projects implemented through the EEF would be in addition to any NODOS Project mitigation, CVPIA, or OCAP requirements.

A Governance Board would manage the fund, prioritize potential projects, and collaboratively determine funded actions, based upon habitat needs. The fund would support planning and implementation of priority non-operational actions. Projects eligible for EEF funding would include those that would directly benefit anadromous fish, with an emphasis on actions in the Sacramento River (e.g. spawning gravel augmentation; sidechannel, riparian, or floodplain restoration; and construction of instream aquatic habitat downstream from Keswick Dam).

These types of restoration projects would potentially result in beneficial effects to fish species of primary management concern, particularly anadromous salmonids and sturgeon. Project-specific environmental documentation would be completed prior to implementation of actions associated with the Ecosystem Enhancement Fund to identify any potential impacts or benefits to fish species of primary management concern.

12.3.6.2 Primary Study Area - Alternative A Relative to Existing Conditions

Construction, Operation, and Maintenance Impacts

The potential impacts of proposed Project facilities that would be located within or adjacent to waterways are described below.

Sites Reservoir Inundation Area and Sites Dams

Erosion, Sedimentation and Turbidity

Construction activities associated with the Sites Reservoir Inundation Area and Sites Dams, including clearing and grubbing vegetation, would have the potential to cause erosion and contribute sediment to Funks and Stone Corral creeks downstream of the construction activities. During Project operation and maintenance, stream maintenance flows discharged from Sites Reservoir into Funks and Stone Corral creeks, as well as debris and vegetation removal associated with maintenance of the dam embankments, could also result in increased erosion and turbidity. It has been reported that behavioral avoidance of turbid waters may be one of the most important effects on fishes from suspended sediments (Birtwell et al., 1984; DeVore et al., 1980; Scannell, 1988). Exposure duration is reportedly a critical determinant of the occurrence and magnitude of potential physical or behavioral effects on fishes associated with increased turbidity (Newcombe and MacDonald, 1991). While native fish species such as salmonids reportedly appear to be little affected by the high concentrations of suspended sediments that occur during storm and snowmelt runoff episodes (Bjornn and Reiser, 1991), chronic exposure to increased turbidity can cause physiological stress responses that can increase maintenance energy use and reduce feeding and growth (Lloyd, 1987; Redding et al., 1987; Servizi and Martens, 1991). Because increased turbidity and sedimentation could cause temporary changes in fish behavior, the potential for predation also may be increased. Increased erosion, turbidity, and predation resulting from construction, operation, and maintenance of Sites Reservoir and Dams could result in a **potentially significant impact** to fish species of primary management concern.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter Funks and Stone Corral creeks as a result of seepage or accidental spills. During maintenance activities, there is also the potential for chemical or hazardous spills or leakage in these creeks. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas. Hazardous materials and chemical spills associated with the construction and maintenance of Sites Reservoir and Dams could result in a **potentially significant impact** to fish species of primary management concern.

Hydrostatic Pressure Waves, Noise, and Vibration

Construction of Golden Gate and Sites dams on Funks and Stone Corral creeks, respectively, could potentially result in noise-related impacts to fish species in Funks and Stone Corral creeks, resulting in a potentially significant impact to fish species of primary management concern.

However, because Funks and Stone Corral creeks would be temporarily re-routed around the construction areas, potential impacts to fisheries resources would be minimized (see Section 12.4) and are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities also have some limited potential to "harm" juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because most equipment to be used during construction, operation, and maintenance activities would be located on land, the potential for direct physical harm would be minimal. Therefore, these activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Water Surface Elevation Fluctuations

Water surface elevation fluctuations may occur within Sites Reservoir once it is constructed and filled, potentially impacting any stocked fisheries that may occur within Sites Reservoir after it becomes operational. However, because no fishery exists in Sites Reservoir under Existing Conditions or the No Project/No Action Alternative, there are **no potential impacts** to aquatic biological resources in Sites Reservoir to evaluate.

Aquatic Habitat Modification

Construction of Sites Reservoir (1.27 MAF under Alternative A) would eliminate and inundate approximately 3.9 miles of Stone Corral Creek and approximately 6.5 miles of Funks Creek upstream of Sites and Golden Gate dams. Stone Corral and Funks creeks are characterized by deeply incised channels with little riparian vegetation or instream cover (Brown, 2000). In addition, water quality is reported to be poor and high in dissolved minerals (Brown, 2000). While the reaches of Funks Creek and Stone Corral Creek that would be inundated generally have little riparian habitat and are ephemeral (Figure 12-7), they have been found to support native and non-native fish species, including California roach, Sacramento blackfish, and Sacramento sucker (Brown, 2000). The reach of Funks Creek immediately downstream of the proposed Sites Dam appears to have more suitable aquatic and riparian habitat compared to other reaches of the creek (Figures 12-8 and 12-9). Adult, juvenile, and early life stages of fish species of primary management concern could be present within and downstream of construction, operation, and maintenance areas year-round. Aquatic habitat removal and modification, specifically the inundation of Funks and Stone Corral creeks associated with the construction of Sites Reservoir, would result in a **potentially significant impact** to fish species of primary management concern.

Operation and maintenance activities in the vicinity of Sites and Golden Gate dams are not anticipated to substantially modify aquatic habitat in Stone Corral or Funks creeks downstream of Sites Reservoir, and would be conducted such that any restored habitat would not be degraded, resulting in a **less than significant impact** to fish species of primary management concern.

Road Relocations and South Bridge

Erosion, Sedimentation and Turbidity

Construction activities associated with road relocations and construction of the South Bridge in the vicinity of Funks and Stone Corral creeks would have the potential to cause erosion and contribute sediment to the creeks downstream of the construction activities, particularly at the proposed Eastside

Road crossing at Funks Creek. It has been reported that behavioral avoidance of turbid waters may be one of the most important effects on fishes from suspended sediments (Birtwell et al., 1984; DeVore et al., 1980; Scannell, 1988). Because increased turbidity and sedimentation could cause temporary changes in fish behavior, the potential for predation also may be increased and could result in a **potentially significant impact** to fish species of primary management concern.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter Funks and Stone Corral creeks as a result of seepage or accidental spills. During road and bridge maintenance activities, there is also the potential for chemical or hazardous spills or leakage in these creeks. Accidental discharge of hazardous materials and chemicals could affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas, and could therefore result in a **potentially significant impact** to fish species of primary management concern.

Hydrostatic Pressure Waves, Noise, and Vibration

Construction of the Eastside Road Bridge over Funks Creek may include pile driving activities, potentially resulting in noise-related impacts to fisheries in Funks Creek, which could adversely affect fish species of primary management concern.

However, Funks Creeks would be re-routed away from the construction areas, minimizing any potential impacts to fisheries resources (see Section 12.4) and resulting in a **less than significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities have limited potential to “harm” juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because most equipment to be used during construction, operations, and maintenance activities would be located on land, the potential for direct physical harm would be minimal. Therefore, these activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Aquatic Habitat Modification

Construction activities associated with road relocations and bridges in the vicinity of Funks and Stone Corral creeks would have the potential to alter aquatic habitat conditions. Stone Corral and Funks creeks are characterized by deeply incised channels with little riparian vegetation or instream cover (Brown, 2000). The reaches of Funks Creek and Stone Corral Creek that may be affected generally have little riparian and aquatic habitat. It is not anticipated that riparian or aquatic habitat would be permanently removed or substantially impacted by road relocations or bridge construction. Operation and maintenance activities associated with new roads and bridges also are not anticipated to substantially modify aquatic habitat in the downstream reaches of Stone Corral or Funks creeks. Therefore, these activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Fish Passage

It is expected that activities associated with road relocation and bridge construction in the vicinity of Stone Corral and Funks creeks would occur when the creeks are ponded or dry, or when the creeks are re-routed away from the construction area. Therefore, construction of the Eastside Road Bridge over Funks Creek is not anticipated to substantially affect hydrologic or fish passage conditions within Funks Creek. Construction of any culverts on Funks and Stone Corral creeks would be designed to maintain existing fish passage conditions. Operation and maintenance activities associated with constructed roads and bridges would be conducted in a manner that would not substantially affect fish passage conditions. Therefore, these activities are anticipated to result in a **less than significant** impact to fish species of primary management concern.

Sites Reservoir Inlet/Outlet Structure and Sites Pumping/Generating Plant

Erosion, Sedimentation and Turbidity

Construction activities associated with the Sites Reservoir Inlet/Outlet Structure and the Sites Pumping/Generating Plant along Funks Creek would have the potential to cause erosion and contribute sediment to Funks Creek downstream of the construction activities. It has been reported that behavioral avoidance of turbid waters may be one of the most important effects on fishes from suspended sediments (Birtwell et al., 1984; DeVore et al., 1980; Scannell, 1988). Because increased turbidity and sedimentation could cause temporary changes in fish behavior, the potential for predation also may be increased and could result in a **potentially significant impact** to fish species of primary management concern.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter Funks Creek as a result of seepage or accidental spills. During construction activities there would also be the potential for chemical or hazardous spills or leakage into Funks Creek. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas and, therefore, could result in a **potentially significant impact** to fish species of primary management concern.

Hydrostatic Pressure Waves, Noise, and Vibration

Construction of the Sites Reservoir Inlet/Outlet Structure and Sites Pumping/Generating Plant may include construction activities that result in noise and vibration effects to fisheries resources in Funks Creek, potentially impacting fish species in Funks Creek.

However, Funks Creek would be re-routed away from the construction areas to minimize any potential impacts to fisheries resources. Construction activities are therefore anticipated to result in a **less than significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities have limited potential to “harm” juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because most equipment to be used during construction, operation, and maintenance activities would be located on land, the potential for direct physical harm would be minimal. Therefore, these activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Aquatic Habitat Modification

Construction of the Sites Reservoir Outlet Structure would permanently remove approximately 0.5 mile of Funks Creek immediately upstream of the existing Funks Reservoir. As previously discussed, Funks Creek is characterized by deeply incised channels with little riparian vegetation or instream cover (Brown, 2000). While the reach of Funks Creek that would be removed generally has little riparian habitat and is ephemeral, it has been found to support native and non-native fish species, including California roach, Sacramento blackfish and Sacramento sucker (Brown, 2000). The reach of Funks Creek immediately downstream of the proposed Holthouse Dam appears to have more suitable aquatic and riparian habitat compared to other reaches of the creek (Figures 12-8 and 12-9). Adult, juvenile, and early life stages of fish species of primary management concern could be present within and downstream of construction, operation, and maintenance areas year-round. Aquatic habitat removal and modification associated with the construction of the Sites Reservoir Inlet/Outlet Structure and Sites Pumping/Generating Plant would result in a **potentially significant impact** to fish species of primary management concern.

Fish Passage

As previously discussed, construction of the inlet/outlet structure would eliminate approximately 0.5 mile of Funks Creek immediately upstream of the existing Funks Reservoir. During construction activities, Funks Creek would be diverted upstream of the inlet/outlet structure construction area, preventing fish passage through the construction area. The extent to which fish species may currently move between Funks Reservoir and Funks Creek upstream of Funks Reservoir is unknown. However, Funks Creek would connect to the approach channel of the inlet/outlet structure to allow flows and fish passage between Funks Creek, the inlet/outlet structure, and Holthouse Reservoir. Operation and maintenance activities associated with the inlet/outlet structure would be conducted as to not substantially affect fish passage conditions. These activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Holthouse Reservoir Complex

The Holthouse Reservoir Complex includes the Holthouse Reservoir and Dam, Holthouse Spillway and Stilling Basin, Holthouse Pumping Plant, T-C Canal Discharge Dissipater, the T-C Canal Bypass Pipeline, and the Holthouse to T-C Canal Pipeline.

Erosion, Sedimentation and Turbidity

Construction of the Holthouse Reservoir Complex would occur adjacent to the existing Funks Reservoir, and thus would have the potential to increase erosion, sedimentation and turbidity in Funks Creek downstream of the construction area. Dredging activities at Funks Reservoir associated with removal of accumulated sediment would also have the potential to increase sedimentation and turbidity in Funks Creek downstream of Funks Reservoir, which could result in a **potentially significant impact** to fish species of primary management concern.

Maintenance activities at the Holthouse Reservoir Complex, such as periodic road, vegetation, and fence maintenance, as well as debris removal, would also have the potential to increase erosion and turbidity in Funks Creek downstream of the proposed Holthouse Reservoir. However, maintenance activities at Holthouse Reservoir are anticipated to be similar to existing maintenance activities at Funks Reservoir, and would be conducted to avoid impacting any aquatic habitat that may have been restored. Flows released into Funks Creek from Holthouse Reservoir are anticipated to be consistent with flow conditions under Existing Conditions, but have the potential for increasing sedimentation and turbidity in Funks Creek, resulting in a potentially significant impact to fish species of primary management concern. However, construction of a velocity dissipater on the inlet/outlet structure is anticipated to minimize sedimentation and turbidity and result in a **less than significant impact** to fish species of primary management concern (see Section 12.4).

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter Funks Creek as a result of seepage or accidental spills. During operation and maintenance activities, such as debris and sediment removal, dredging, equipment maintenance, and repairs, there would also be the potential for chemical or hazardous spills or leakage in the creek. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas, and could result in a **potentially significant impact** to fish species of primary management concern.

Hydrostatic Pressure Waves, Noise, and Vibration

Construction of the Holthouse Reservoir Complex may involve construction activities that could result in increased noise and vibration levels in local waterways, resulting in a potentially significant impact to fish species of primary management concern.

However, Funks Creek would be re-routed away from the construction area to minimize any potential impacts to fisheries resources and is anticipated to result in a **less than significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities have limited potential to directly “harm” juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because Funks Creek would be re-routed away from the construction area, the potential for direct physical harm would be minimal. Therefore, these activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Aquatic Habitat Modification

The construction of the dam and spillway stilling basin, and the consequent inundation of Holthouse Reservoir, would result in the permanent removal of the reach of Funks Creek immediately downstream of the existing Funks Reservoir (approximately 0.7 stream mile) (Figures 12-8 and 12-9). Adult, juvenile, and early life stages of fish species of primary management concern could be present within and downstream of construction, operation, and maintenance areas year-round. Aquatic habitat removal and modification within Funks Creek associated with the construction and inundation of Holthouse Reservoir would result in a **potentially significant impact** to fish species of primary management concern.

Operation and maintenance activities at Funks and Holthouse reservoirs, such as periodic road, vegetation, and fence maintenance, would not be anticipated to substantially affect aquatic habitat in Funks Creek, and would be conducted such that restored areas are not degraded. Operation and maintenance activities are therefore anticipated to result in a **less than significant impact** to fish species of primary management concern.

Fish Passage

Funks Creek would be diverted during construction activities, and Funks Reservoir would be drained during dredging activities. In-stream construction activities also could impede upstream passage of resident fishes due to altered hydrologic conditions. However, because fish passage is generally blocked at the outlet of the existing Funks Reservoir and the reservoir is drained annually under Existing Conditions, these activities are anticipated to result in a **less than significant impact** to fish species of primary management concern.

Following completion of construction of the Holthouse Reservoir Complex, it is anticipated that fish passage would be blocked downstream of Holthouse Reservoir. However, Flow releases from Holthouse Reservoir into Funks Creek are anticipated to be generally consistent with flow conditions in Funks Creek under Existing Conditions, resulting in a **less than significant impact** to fish species of primary management concern.

GCID Canal Facilities Modifications

Erosion, Sedimentation and Turbidity

Construction activities at the GCID Canal intake and headworks facilities, which involve installing a new headgate structure, lining 200 feet of the canal, and replacing a railroad siphon, have the potential to increase erosion, sedimentation, and turbidity within the GCID Canal and in the Sacramento River in the vicinity of the GCID Canal intake structure. Ongoing maintenance activities, such as sediment removal may also temporarily increase turbidity within the GCID Canal and in the Sacramento River in the vicinity of the GCID Canal intake structure. It has been reported that behavioral avoidance of turbid waters may be one of the most important effects on fishes from suspended sediments (Birtwell et al., 1984; DeVore et al., 1980; Scannell, 1988). Because increased turbidity and sedimentation could cause temporary changes in fish behavior, the potential for predation also may be increased. This could result in a **potentially significant impact** to fish species of primary management concern.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter the GCID Canal or the Sacramento River as a result of accidental spills. During operation and maintenance activities, such as debris and sediment removal, and equipment maintenance and repairs, there would also be the potential for chemical or hazardous spills or leakage into the canal and river. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas. This could result in a **potentially significant impact** to fish species of primary management concern.

TRR to Funks Creek Pipeline

Erosion, Sedimentation and Turbidity

Construction of the TRR to Funks Creek Pipeline has the potential to increase erosion, sedimentation, and turbidity within Funks Creek in the vicinity of the proposed pipeline and could therefore result in a **potentially significant impact** to fish species of primary management concern. Discharge operations of water from the TRR to Funks Creek also have the potential to increase turbidity in Funks Creek. However, a velocity dissipater at the outlet of the pipeline is anticipated to minimize potential increases in turbidity in Funks Creek (see Section 12.4), resulting in a **less-than-significant impact** to fish species of primary management concern.

Ongoing maintenance activities, such as sediment removal, could also temporarily increase turbidity within Funks Creek, resulting in a **potentially significant impact**.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter Funks Creek as a result of accidental spills. During operation and maintenance activities, such as debris and sediment removal, and equipment maintenance and repairs, there would also be the potential for chemical or hazardous spills or leakage into the canal and river. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas, and could result in a **potentially significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities have limited potential to directly “harm” juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because most equipment to be used during construction, operation, and maintenance activities would be located on land, the potential for direct physical harm would be minimal. Therefore, these activities are anticipated to result in a **less-than-significant impact** to fish species of primary management concern.

Delevan Pipeline

Erosion, Sedimentation and Turbidity

The Delevan Pipeline would be constructed to convey water from the Sacramento River to Holthouse Reservoir, and also to convey water from Holthouse Reservoir to the Sacramento River. The pipeline would cross the Colusa Basin Drain and Hunters Creek, a tributary to the Colusa Basin Drain. Construction activities at the creek crossings would have the potential to increase erosion, sedimentation, and turbidity within the Colusa Basin Drain and Hunters Creek. However, construction of the Colusa Basin Drain crossing would likely occur during late fall, after the irrigation season ends and before winter rains begin. Portions of the CBD would likely be dewatered so that the pipeline trench could be excavated and the pipeline could be installed. Trench dewatering would involve discharging water into local irrigation ditches and drainage canals after silt is allowed to settle out. Construction would be staged at this crossing and would occur within one half of the channel while an installed coffer dam bypasses flows on the other half of the channel. After installation, the CBD would be returned to service and would be reconstructed to pre-Project conditions. Construction of the Hunters Creek crossing would likely occur when the creek is dry. Construction and dewatering activities would have the potential to increase turbidity levels in adjacent waterways, potentially affecting fisheries resources that may be present and resulting in a **potentially significant impact** to fish species of primary management concern.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter the Colusa Basin Drain or Hunters Creek as a result of accidental spills. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction and maintenance areas and could result in a **potentially significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities have limited potential to "harm" juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because most equipment to be used during construction, operation, and maintenance activities would be located on land, the potential for direct physical harm would be minimal and is anticipated to result in **a less-than-significant impact** to fish species of management concern.

Aquatic Habitat Modifications

Construction activities required to install the Delevan Pipeline underneath the Colusa Basin Drain and Hunters Creek may require disturbance of aquatic habitat and removal of riparian vegetation, which could result in a **potentially significant impact** to fish species of primary management concern.

Fish Passage

It is not anticipated that the fish species potentially present in the Colusa Basin Drain or Hunters Creek (e.g., centrarchids, Sacramento sucker, Sacramento blackfish, hitch, and California roach) would be substantially affected by a partial and temporary blockage of these waterways. While a few anadromous salmonids are frequently observed in the Colusa Basin Drain during some years, they are not believed to represent a sustainable population and are likely strays from the Sacramento River. Therefore, partial and temporary blockage of the Colusa Basin Drain and Hunters Creek is anticipated to result in a **less-than-significant impact** to fish species of primary management concern.

Delevan Pipeline Intake Facilities

Erosion, Sedimentation and Turbidity

The proposed Delevan Pipeline Intake Facilities on the Sacramento River would include a system of structures to divert water from the Sacramento River, release water to the Sacramento River, and generate electricity when water is released to the Sacramento River. A fish screen structure also would be constructed at the point of diversion. In-river construction would be accommodated by constructing a cofferdam along the entire length of the intake structure (approximately 1,200 feet) and dewatering the area within the cofferdam.

Construction activities associated with construction of the intake facilities, including clearing and grading, transportation of materials, construction of the cofferdam, dewatering the cofferdam, excavation of the forebay and pumping plant site, construction of a berm/ring levee, construction of the facility structures and fish screen system, removal of the cofferdam, fill and re-grading activities, and restoration of disturbed areas after construction all have the potential to increase erosion, sedimentation and turbidity near and downstream of the construction site in the Sacramento River. This increased erosion, sedimentation, and turbidity could result in a **potentially significant impact** to fish species of primary management concern.

Operation of the intake facilities also has the potential to increase turbidity in the Sacramento River in the vicinity of the intake structure; however, the fish screen would act as a velocity dissipater when water is being released to the Sacramento River, minimizing potential increases in turbidity and resulting in **less-than-significant** impacts.

Maintenance activities, including periodic sediment removal within the forebay and dredging of the intake channel every few years, may result in increased turbidity within the Sacramento River, which would have a **potentially significant impact** on fish species of primary management concern. As discussed for the Secondary Study Area, increases in turbidity in the Sacramento River may temporarily disrupt normal behaviors of fish species that are essential to growth and survival such as feeding, sheltering, and migrating, resulting in a **potentially significant impact** to fish species of primary management concern.

Hazardous Materials and Chemical Spills

Hazardous materials and chemicals in the form of gasoline, engine oil, lubricants, or other fluids used during construction activities could potentially enter the Sacramento River as a result of seepage or accidental spills. During operations and maintenance activities, such as debris and sediment removal, dredging, equipment maintenance, and repairs, there would also be the potential for chemical or hazardous spills or leakage into the Sacramento River. Accidental discharge of hazardous materials and chemicals could potentially affect fishes that may be present in the immediate vicinity and downstream of the construction, operation, and maintenance areas by increasing physiological stress and altering their behavior, which could result in an increased susceptibility to predation. Accidental spills could therefore result in a **potentially significant impact** to fish species of primary management concern.

Direct Harm

In addition to the habitat alteration effects associated with construction, operation, and maintenance activities, these activities have some limited potential to directly “harm” juvenile and adult fishes by direct physical contact, including physical injury or mortality. However, because most equipment to be used during construction, operation, and maintenance activities would be located on land, the potential for direct physical harm would be minimal and is anticipated to result in a **less-than-significant impact** to fish species of primary management concern.

Hydrostatic Pressure Waves, Noise, and Vibration

A cofferdam would be constructed in the Sacramento River along the entire length of the intake structure (approximately 1,200 feet in length) and the isolated area would be subsequently dewatered to allow for construction of the Delevan Pipeline Intake Facilities. Because construction of the cofferdam would include vibratory pile driving in the Sacramento River, fishes in the vicinity could potentially be affected by underwater noise, pressure waves, and vibration. Vibration and pressure waves generated by construction, operation, and maintenance activities could potentially alter fish behavior in the Sacramento River, potentially leading to increased predation risk. Vibration and pressure could, therefore, result in a **potentially significant impact** to fish species of primary management concern.

During landside construction activities associated with the intake facilities, the potential would exist for vibration and pressure waves generated by construction and excavation activities to affect fish species in the Sacramento River. Operation and maintenance activities also may increase ambient underwater noise levels. However, the noise levels produced by both landside construction and excavation activities, and operation and maintenance activities, are not expected to reach a level that would harm juvenile or adult fishes. Because most construction and excavation activities are anticipated to occur above water, the noise levels under water would be much lower than those created in the air, and are anticipated to result in a **less-than-significant impact** to fish species of primary management concern.

Predation Risk

Construction of the intake facilities on the Sacramento River has the potential to provide habitat for non-native piscivorous predators, such as striped bass and centrarchids, which may result in increased predation risk for other fish species of primary management concern, including outmigrating juvenile salmonids. Increased predation risk associated with the construction of this facility could have a **potentially significant** impact on fish species of primary management concern.

Aquatic Habitat Modification

Activities such as river channel alteration, riparian vegetation and in-stream woody material (IWM) removal, and other in-stream work could potentially reduce biodiversity, macroinvertebrate production, and recolonization of disturbed substrate, as well as limit the exchange of nutrients between surface and subsurface waters and between aquatic and terrestrial ecosystems (USFWS, 2000).

Construction of the Delevan Pipeline Intake Facilities would include the modification and removal of shaded riverine aquatic (SRA) habitat (Figures 12-9 and 12-10). Preliminary estimates using GIS indicate that approximately 1.1 acres of Fremont Cottonwood riparian habitat that acts as SRA habitat, and an additional 0.5 acres of Valley Foothill Riparian habitat that may act as a source of IWM inputs to the Sacramento River, would be removed as a result of construction of the intake facilities. During a reconnaissance site visit conducted on February 23, 2011, available woody material was identified in the area. Examples include one piece of IWM (between six and eight inches in diameter and approximately 20 feet long) that was observed protruding from the river surface, and another piece of similar size that was identified immediately adjacent to the bank that could function as IWM at higher flows (Figure 12-10). The loss and degradation of SRA habitat within the construction footprints and within the access routes, staging areas, and storage and disposal areas could result in an impact to fish species through reduction in the quality of fish habitat and removal of important habitat elements.

Adult, juvenile, and early life stages of fish species of primary management concern could be present within and downstream of construction, operation, and maintenance areas year-round in the Sacramento River. Aquatic habitat removal and modification associated with construction of the intake facility on the Sacramento River would remove aquatic and riparian habitat, including SRA habitat, resulting in a **potentially significant impact** to fish species of primary management concern in the Sacramento River.

Maintenance activities may include replacement of existing riprap necessary to protect the conveyance features and facilities, which is anticipated to result in a **less-than-significant impact** to fish species of primary management concern because no additional habitat would be modified.

Fish Passage

Installation of a cofferdam to facilitate the construction of the intake facilities could potentially physically impede migrating adults, limiting their ability to reach spawning areas, and could hinder migration of juveniles, potentially exposing them to increased predation and unsuitable aquatic habitat conditions. In-stream construction activities also could impede upstream passage of fishes due to altered hydrologic conditions, such as temporarily increased velocities. However, because the cofferdam would only extend a short distance into the waterway (i.e., 40 feet), relative to the entire width of the Sacramento River, it is not anticipated that the movement or survival of juvenile or adult fish species of primary management concern would be substantially affected. Therefore, installation of a coffer dam is anticipated to result in a **less-than-significant impact** to fish species of primary management concern in the Sacramento River.

Stranding, Impingement and Entrainment

During installation of the cofferdam, any fish that are present potentially could be trapped behind the dam before closure. If individual fish do not exit through the partially enclosed cofferdam and return to the river, stranding of fishes could occur when the enclosed area is dewatered. Because some fish species of primary management concern may be in the vicinity of construction areas year-round, dewatering and in-river work during cofferdam placement and removal could result in fish impingement, entrainment, and stranding, which would result in a **potentially significant impact**.

Operation of the Delevan Pipeline Intake Facilities would also have the potential to entrain or impinge fish species of management concern, resulting in an adverse effect on fish species of primary management concern. However, the intakes would be designed to be protective of anadromous salmonids, and are anticipated to result in a **less-than-significant impact** to fish species of primary management concern.

Temperature Effects on the Sacramento River

Operation of the Delevan Pipeline Intake Facilities would include releases from Sites Reservoir to the Sacramento River. If release temperatures differ from the receiving waters of the Sacramento River, fish species of primary management concern could be adversely affected. However, preliminary modeling results indicate that in more than 98 percent of the months, Sites Reservoir releases would be within 0.5°F of the receiving Sacramento River water temperatures. Even though the model indicates a small number of months (<5%) with a likely cooling impact of 0.2°F or more, the Sites Reservoir temperature results show that it is possible to avoid such impacts by releasing from appropriate outlets. Only one month showed a cooling of more than 1°F in the 82 years. In a few years, mainly in an extended drought period when both Sites Reservoir storage and Sacramento River flow are low, releases from Sites Reservoir would be likely to cause warming of the receiving Sacramento River water. In less than one percent of the months the temperatures in the Sacramento River would increase by 1°F or more due to the releases from the Sites Reservoir. Approximately five percent of the months would likely have a warming impact of 0.2°F or more, although most of the months would be within the same year. The warming impact would mainly occur during September and October months. These slight changes to receiving water temperatures in the Sacramento River would not be expected to adversely affect fish species of primary management concern and are therefore considered to be **less than significant**.

Project Buffer

Erosion, Sedimentation and Turbidity

Ground-disturbing activities associated with the Project Buffer would include the construction of fences and the creation and maintenance of a fuelbreak around the perimeter of the buffer. These activities have the potential to cause erosion and contribute sediment to the creeks adjacent to the locations of these activities. It has been reported that behavioral avoidance of turbid waters may be one of the most important effects on fishes from suspended sediments (Birtwell et al., 1984; DeVore et al., 1980; Scannell, 1988). Because increased turbidity and sedimentation could cause temporary changes in fish behavior, the potential for predation also may be increased and could result in a **potentially significant impact** to fish species of primary management concern.

12.3.7 Impacts Associated with Alternative A Relative to the No Project/No Action Alternative

Potential impacts on fish species of primary management concern associated with implementation of Alternative A, relative to the No Project/No Action Alternative were evaluated in an identical manner to those described for the No Project/No Action Alternative, relative to Existing Conditions. Specifically, model results and locations evaluated were identical among alternatives.

A summary of changes in habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the export service area under Alternative A, relative to the No Project/No Action Alternative, is presented in Table 12-17. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas under Alternative A, relative to the No Project/No Action Alternative, is presented in Table 12-18. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.7.1 Extended and Secondary Study Areas - Alternative A Relative to the No Project/No Action Alternative

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C. Construction-related impacts associated with implementation of Alternative A relative to the No Project/ No Action Alternative would be the same as those described for Alternative A relative to Existing Conditions. Operational impacts associated with Alternative A relative to the No Project/No Action Alternative are described below.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Reservoir coldwater fish species habitat conditions would be more suitable in Trinity, Shasta, Oroville, and Folsom reservoirs under Alternative A, relative to the No Project/No Action Alternative. Specifically, within the Secondary Study Area, end-of-month storage generally would be greater more frequently under Alternative A, relative to the No Project/No Action Alternative in each of the SWP/CVP reservoirs evaluated. Reservoir coldwater fish species habitat conditions would be similar in San Luis Reservoir, and similar or slightly more suitable in export service area reservoirs due to generally increased SWP and

CVP exports occurring more often and resulting in increased storage in San Luis Reservoir and potentially increased storage in other export service area reservoirs.

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on reservoir coldwater fish species in San Luis and other export service area reservoirs are considered **less-than-significant**, and impacts on coldwater fish species in Trinity, Shasta, Oroville, and Folsom reservoirs are considered **potentially beneficial**.

Reservoir Warmwater Fish Species

Reservoir warmwater fish species habitat conditions would be similar or more suitable under Alternative A, relative to the No Project/No Action Alternative in Trinity and Shasta reservoirs because water surface elevation reductions of six feet or more during the warmwater fish nesting season would occur less frequently. Therefore, fewer nest dewatering events are anticipated. Water surface elevation reductions of six feet or more would be similar in Oroville and Folsom reservoirs. Therefore, impacts on reservoir warmwater fish species are anticipated to be similar. Habitat conditions in San Luis Reservoir are anticipated to be slightly less suitable because of increased frequency of water surface elevation reductions of six feet or more during March, while more frequent increases in exports are anticipated to increase habitat suitability for warmwater fish species inhabiting other export service area reservoirs.

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on reservoir warmwater fish species in Trinity, Shasta, Oroville, Folsom, San Luis, and other export service area reservoirs are considered **less than significant**.

Southern Oregon/Northern California Coho Salmon

In general, habitat conditions in the Trinity River would be similar or more suitable under Alternative A, relative to the No Project/No Action Alternative because flows would be generally similar during most life stages, while water temperature index values would be generally exceeded less frequently during all life stages (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to the No Project/No Action Alternative, potential impacts on Coho salmon in the Trinity River are considered **less than significant**.

Upper Klamath-Trinity River Fall-Run and Spring-Run Chinook Salmon

In general, during the periods when Chinook salmon are present in the Trinity River, habitat conditions, as well as early life stage mortality, would be similar or more suitable under Alternative A, relative to the No Project/No Action Alternative because flows would be generally similar but slightly higher during some life stages, while water temperature index values would be generally exceeded less frequently during all life stages (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to the No Project/No Action Alternative, potential impacts on spring-run and fall-run Chinook salmon in the Trinity River are considered **less than significant**.

Klamath Mountains Province Steelhead

In general, during the periods when steelhead are present in the Trinity River, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative (see Appendix 12C for a detailed discussion).

Therefore, under Alternative A, relative to the No Project/No Action Alternative, potential impacts on spring-run Chinook salmon in the Trinity River are considered **less than significant**.

Sacramento River Winter-Run Chinook Salmon

In general, during periods when winter-run Chinook salmon are present in the Sutter Bypass, Delta, and bays downstream of the Delta, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. Habitat conditions in the Sacramento River would be generally more suitable due to increased flows and decreased water temperatures during low flow conditions, increased spawning habitat availability and reduced water temperatures during spawning, reduced early life stage mortality, reduced population mortality and increased production potential, and increased spawner abundance (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on winter-run Chinook salmon in the Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**, and impacts on winter-run Chinook salmon in the Sacramento River are **potentially beneficial**.

Central Valley Spring-Run Chinook Salmon

In general, during periods when spring-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in the Sacramento River would be more suitable, and would be similar or more suitable in Clear Creek. Specifically, in the Sacramento River flows would be higher more frequently during low flow conditions, and water temperatures would be lower more frequently near Keswick Dam where spawning occurs. Additionally, these conditions would result in reduced early life stage mortality, reduced population mortality, and increased production potential. In Clear Creek, slightly lower water temperatures would occur more frequently (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on spring-run Chinook salmon in Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**, and impacts on spring-run Chinook salmon in the Sacramento River are considered **potentially beneficial**.

Central Valley Fall-Run Chinook Salmon

In general, during periods when fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in Clear Creek would be similar or more suitable due to slightly decreased water temperatures during spawning. Additionally, habitat conditions in the American River would be similar or more suitable due to slightly improved habitat conditions during some life stages (see Appendix 12C for a detailed discussion). Specifically, decreased flows and increased water temperatures, as well as increased early life stage mortality, would result from implementation of the No Project/No Action Alternative.

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on fall-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**.

Central Valley Late Fall-Run Chinook Salmon

In general, during periods when late fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on late fall-run Chinook salmon in the Sacramento River, Clear Creek, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**.

Central Valley Steelhead

In general, during periods when steelhead are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing and emigration, as a result of decreased frequency of inundation (as identified by reduced Yolo Bypass outflow), and potentially reduced Delta productivity as a result of decreased Yolo Bypass inundation frequency (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on steelhead in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on steelhead in the Yolo Bypass are considered **potentially significant**.

Green Sturgeon

In general, during periods when green sturgeon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative A, relative to the No Project/No Action Alternative. Specifically, habitat conditions in the Trinity River, Sacramento River, and American River would be generally more suitable, while conditions in the Feather River would be similar. In the Trinity River, flows would be higher more often during adult immigration, and water temperatures would be lower more often during spawning. In the Sacramento River, particularly in the lower reaches, habitat conditions would be more suitable due to generally higher flows occurring more often during low flow conditions, and generally lower water temperatures occurring more often. In the American River, flows would be higher slightly more often during most life stages, and water temperatures would be slightly lower more often during juvenile rearing and emigration. However, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing due to a decreased frequency of floodplain activation, which would result in reduced floodplain rearing opportunities and reduced nutrient inflow to the Delta and bays (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, potential operational impacts on green sturgeon in the Trinity River, Sacramento River, Feather River, American River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts to green sturgeon in the Yolo Bypass are considered **potentially significant**.

White Sturgeon

In general, during periods when white sturgeon are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, simulated habitat conditions would be similar or less suitable in the Feather River due to generally similar changes in flows and water temperatures during most life stages, but with lower flows occurring more frequently during the spawning and embryo incubation period. Additionally, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing due to a decreased frequency of floodplain activation, which would result in reduced floodplain rearing opportunities and reduced nutrient inflow to the Delta and bays (see Appendix 12C for a detailed discussion).

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on white sturgeon in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on white sturgeon in the Yolo Bypass are considered **potentially significant**.

Pacific Lamprey

In general, during periods when Pacific lamprey are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in American River would be similar during most years, but would be more suitable for all life stages due to increased flows and decreased water temperatures occurring more frequently. Additionally, habitat conditions in the Feather River would be similar or less suitable during spawning and egg incubation due to inconsistent conditions of increased and decreased flows occurring more frequently in the downstream reaches of the river, as well as increased water temperatures occurring more frequently (see Appendix 12C for a detailed discussion).

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on Pacific lamprey in the Trinity River, Sacramento River, Clear Creek, Feather River, Delta, and bays are considered **less than significant**, and impacts on Pacific lamprey in the American River are considered **potentially beneficial**.

River Lamprey

In general, during periods when river lamprey are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in American River would be similar during most years, but would be more suitable for all life stages due to increased flows and decreased water temperatures occurring more frequently. Additionally, habitat conditions in the Feather River would be similar or less suitable during adult immigration, and for spawning and egg incubation due decreased flows occurring slightly more frequently in the downstream reaches of the river, as well as increased water temperatures occurring slightly more frequently (see Appendix 12C for a detailed discussion). While Feather River conditions would be slightly less suitable for immigration and spawning life stages, these conditions would occur in the lower reaches of the river where spawning occurs infrequently, if it occurs downstream of the Thermalito Afterbay.

Overall, under Alternative A, relative to the No Project/No Action Alternative, potential operational impacts on river lamprey in the Sacramento River, Clear Creek, Feather River, Delta and bays are considered **less than significant**, and impacts on river lamprey in the American River are considered **potentially beneficial**.

Hardhead

In general, during periods when hardhead are present in the Sacramento River and Clear Creek, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative.

Habitat conditions in the Feather River would be similar or more suitable during spawning due to increased flows and suitable water temperatures occurring more often, particularly during low flow conditions. However, habitat conditions in the Feather River would be similar or less suitable due to lower flows occurring more often during portions of the spawning period (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on hardhead in the Sacramento River, Clear Creek, Feather River, and American River are considered **less than significant**.

California Roach

Within the Secondary Study Area and refuges in the Extended Study Area, during periods when roach are present in the water bodies evaluated, habitat conditions generally would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in the American River would be similar or more suitable for spawning due to increased flows and decreased water temperatures occurring more frequently (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, operational impacts on California roach in the Sacramento River, Clear Creek, Feather River, American River, and Level 4 refuges are considered **less than significant**.

Delta Smelt

In general, during periods when delta smelt are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative A, relative to the No Project/No Action Alternative. Specifically, most analyses indicate that habitat conditions would be similar, but downstream movement of X2 location indicates that more suitable habitat conditions would occur during wet, above normal, and below normal water years. Reductions in Yolo Bypass outflow could potentially reduce habitat suitability for delta smelt by reducing nutrient inflow to the Delta. However, improved X2 location during some years could improve juvenile conditions by allowing juveniles to rear in more suitable locations near Suisun and San Pablo bays.

Therefore, under Alternative A, relative to the No Project/No Action Alternative, impacts on delta smelt in the Delta and bays are considered **less than significant**.

Longfin Smelt

In general, during periods when longfin smelt are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative.

Therefore, under Alternative A, relative to the No Project/No Action Alternative, impacts on longfin smelt in the Delta and bays are considered **less than significant**.

Sacramento Splittail

Habitat conditions in the American River under Alternative A, relative to the No Action/No Project Alternative would be similar or more suitable during the splittail spawning period due to increased flows occurring more often, particularly during low flow years. In the Feather River, habitat conditions would be similar or slightly less suitable due to decreased flows occurring more often during portions of the spawning period. Additionally, reduced flows into and out of the Yolo Bypass would result in less suitable habitat conditions for splittail spawning. Because of the importance of the Yolo Bypass to splittail population abundance, reduced floodplain inundation in the Yolo Bypass would constitute a substantial impact (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, potential operational impacts on splittail in the Feather River, American River, Sutter Bypass, Delta, and Level 4 refuges are considered **less than significant**, and impacts on splittail in the Yolo Bypass are considered **potentially significant**.

Striped Bass

In general, during periods when striped bass are present in the evaluated water bodies, habitat conditions would be similar under Alternative A, relative to the No Project/No Action Alternative. However, habitat conditions in the American River would be more suitable due to increased flows and water temperatures within the evaluated range occurring more frequently for all life stages. Additionally, in the Feather River habitat conditions would be similar or less suitable due to reduced flows occurring more frequently during some months of the spawning period (see Appendix 12C for a detailed discussion).

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on striped bass in the Sacramento River, Feather River, Delta, and bays are considered **less than significant**, and impacts on striped bass in the American River are considered **potentially beneficial**.

American Shad

Operations-related impacts on American shad would be similar to those described for striped bass under Alternative A, relative to the No Project/No Action Alternative.

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on American shad in the Sacramento River, Feather River, Delta, and bays are considered **less than significant**, and impacts on American shad in the American River are considered **potentially beneficial**.

Largemouth Bass

In general, during periods when largemouth bass are present in the evaluated water bodies, habitat conditions would be similar under the No Project/No Action Alternative, relative to the Existing Condition. However, habitat conditions in the Yolo Bypass would be less suitable for adults feeding on rearing juvenile fishes in the bypass, as well as juvenile largemouth bass rearing, due to decreased frequency of inundation (as identified by reduced Yolo Bypass outflow), and potentially reduced Delta productivity as a result of decreased Yolo Bypass inundation frequency (see Appendix 12C for a detailed discussion). Additionally, habitat availability in the Delta would be increased during the summer and fall due to reduced EC at various locations.

Therefore, for Alternative A, relative to the No Project/No Action Alternative, potential impacts on largemouth bass in the Sacramento River, Feather River, American River, and Delta are considered **less than significant**, and impacts on largemouth bass in the Yolo Bypass are considered **potentially significant**.

12.3.7.2 Primary Study Area - Alternative A Relative to the No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Refer to the **Impact Fish-1** Primary Study Area discussion for Alternative A relative to Existing Conditions. That discussion also applies to Alternative A relative to the No Project/No Action Alternative.

12.3.8 Impacts Associated with Alternative B Relative to Existing Conditions

Potential impacts on fish species of primary management concern associated with implementation of Alternative B, relative to Existing Conditions, were evaluated in an identical manner to those described for Alternative A, relative to Existing Conditions. Specifically, model results and locations evaluated were identical among alternatives.

A summary of changes in habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the export service area under Alternative B, relative to Existing Conditions, is presented in Table 12-19. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas under Alternative B, relative to Existing Conditions, is presented in Table 12-20. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.8.1 Extended and Secondary Study Areas - Alternative B Relative to Existing Conditions

The impacts associated with Alternative B relative to Existing Conditions, as they relate to fish species of primary management concern (**Impact Fish-1**), would be the same as described for Alternative A relative to Existing Conditions for the following species within the Extended and Secondary study areas:

- Southern Oregon / Northern California Coho
- Upper Klamath / Trinity fall and spring-run Chinook salmon
- Klamath Mountains Province steelhead
- Sacramento River winter-run Chinook salmon
- Central Valley spring-run Chinook salmon
- Central Valley late fall-run Chinook salmon
- Central Valley steelhead
- White sturgeon
- Pacific lamprey
- River lamprey
- Hardhead
- Delta smelt
- Longfin smelt
- Striped bass
- American shad
- Largemouth bass

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C. Construction-related impacts associated with implementation of Alternative B, relative to Existing Conditions, on all fish species of primary management concern would be the same as those described for Alternative A relative to Existing Conditions. Operational impacts associated with Alternative B relative to Existing Conditions that would differ from those described for Alternative A, relative to Existing Conditions, are described below.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Reservoir coldwater fish species habitat conditions would be similar or more suitable in Trinity, Shasta and Oroville reservoirs under Alternative B, relative to Existing Conditions, due to generally higher reservoir storages occurring more often. Reservoir coldwater fish species habitat conditions would be similar in Folsom Reservoir due to generally similar reservoir storages. Simulated habitat conditions would be similar or less suitable in San Luis Reservoir, and similar or generally more suitable in export service area reservoirs due to reduced storage that would occur more often in San Luis Reservoir, and potentially increased storage in other export service area reservoirs due to increased SWP/CVP exports.

Therefore, for Alternative B, relative to Existing Conditions, potential impacts on reservoir coldwater fish species in Oroville, Folsom, and San Luis reservoirs are considered **less than significant,** and impacts to coldwater fish species in Trinity, Shasta, and other export service area reservoirs are considered **potentially beneficial**.

Reservoir Warmwater Fish Species

Reservoir warmwater fish species habitat conditions would be similar or more suitable under Alternative B, relative to Existing Conditions, in Trinity and Shasta reservoirs because fewer water surface elevation reductions of six feet or more would occur during the warmwater fish nesting season. Therefore, fewer nest dewatering events would be anticipated. Water surface elevation reductions of six feet or more would occur with similar frequencies in Oroville and Folsom reservoirs. Therefore, habitat conditions for warmwater fish species are anticipated to be similar in Oroville and Folsom reservoirs. Habitat conditions in San Luis Reservoir are anticipated to be slightly less suitable because of increased frequencies of water surface elevation reductions of six feet or more, while increases in exports more often are anticipated to increase habitat suitability for warmwater fish species inhabiting other export service area reservoirs.

Therefore, for Alternative B, relative to Existing Conditions, potential impacts on reservoir warmwater fish species in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs are considered less than significant, and impacts to warmwater fish species in other export service area reservoirs are considered **potentially beneficial**.

Central Valley Fall-Run Chinook Salmon

In general, during periods when fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative B, relative to Existing Conditions. Habitat conditions would be similar to those discussed under Alternative A, relative to Existing Conditions, except that conditions for fall-run Chinook salmon in the Sacramento River would be similar instead of similar/more suitable due to reduced spawning habitat availability. Habitat conditions in the American River would be substantially less suitable during all life stages (see Appendix 12C for a detailed discussion). Specifically, decreased flows and increased water temperatures, as well as increased early life stage mortality, would occur more frequently as a result of implementation of Alternative B.

Overall, under Alternative B, relative to Existing Conditions, potential operational impacts on fall-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**. On the American River under Alternative B relative to Existing Conditions, impacts on fall-run Chinook salmon would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative B, the potential operational impacts on fall-run Chinook salmon are considered to be **less than significant**.

Green Sturgeon

In general, during periods when green sturgeon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative B, relative to Existing Conditions. Habitat conditions would be generally similar to those described under Alternative A, relative to Existing Conditions, except that habitat conditions in the Trinity River would be considered similar instead of similar/more suitable due to similar flow and water temperature conditions. Habitat conditions in the American River would be substantially less suitable during all green sturgeon life stages due to decreased flows more often and increased water temperatures occurring with similar or higher frequencies, particularly during low flow conditions. Habitat conditions in the Yolo Bypass also would be less suitable for juvenile rearing and emigration as a result of decreased frequency of inundation (as identified by reduced Yolo Bypass outflow more often), and potentially reduced Delta productivity as a result of decreased Yolo Bypass inundation frequency (see Appendix 12C for a detailed discussion).

Overall, under Alternative B, relative to Existing Conditions, potential operational impacts on green sturgeon in the Trinity River, Sacramento River, Feather River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on green sturgeon in the Yolo Bypass are considered **potentially significant**. On the American River under Alternative B relative to Existing Conditions, impacts on green sturgeon would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative B, the potential operational impacts on green sturgeon are considered to be **less than significant**.

California Roach

Within the Secondary Study Area, during periods when roach are present in the Sacramento, Feather and American rivers, habitat conditions generally would be similar under Alternative B, relative to Existing Conditions. Habitat conditions would be generally similar to those discussed under Alternative A relative to Existing Conditions, except that habitat conditions in the Feather River would be similar or less suitable instead of similar, due to reduced flows more often during the spawning period. Habitat conditions in Clear Creek would be similar during most years, but would be more suitable for spawning during low flow conditions as a result of increased flows occurring more often. Habitat conditions for roach within the Level 4 refuges in the Extended Study Area are anticipated to be similar under Alternative B, relative to Existing Conditions.

Overall, under Alternative B, relative to Existing Conditions, potential operational impacts on California roach in the Sacramento River, Clear Creek, Feather River, and American River and Level 4 refuges are considered **less than significant**.

Sacramento Splittail

In general, during periods when splittail are present in the evaluated water bodies, habitat conditions would be similar under Alternative B, relative to the Existing Condition in the Sutter Bypass, and similar or less suitable in the Feather and American rivers. Habitat conditions in the Feather and American rivers would be slightly less suitable for spawning due to decreased flows and reduced useable flooded area occurring slightly more often. The reduction in usable flooded area slightly more often is not anticipated to result in a substantial impact to splittail in the Feather and American rivers. Habitat conditions for splittail within the Level 4 refuges in the Extended Study Area are anticipated to be similar under Alternative B, relative to Existing Conditions. However, reduced flows into and out of the Yolo Bypass would result in substantially less suitable habitat conditions for splittail spawning. Because of the importance of the Yolo Bypass to splittail population abundance, reduced floodplain inundation in the Yolo Bypass would constitute a substantial impact (see Appendix 12C for a detailed discussion).

Therefore, under Alternative B, relative to Existing Conditions, potential operational impacts on splittail in the Feather River, American River, Sutter Bypass, Delta, and Level 4 refuges are considered **less than significant**, and impacts on splittail in the Yolo Bypass are considered **potentially significant**.

Ecosystem Enhancement Storage Account and Ecosystem Enhancement Fund

Refer to the EESA and EEF discussions for Alternative A relative to Existing Conditions. That discussion applies to all three action alternatives.

12.3.8.2 Primary Study Area – Alternative B Relative to Existing Conditions

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to aquatic biological resources:

- Sites Reservoir Inlet/Outlet Structure
- Sites Pumping/Generating Plant
- Holthouse Reservoir Complex

- GCID Canal Facilities Modifications
- TRR to Funks Creek Pipeline
- Delevan Pipeline

The Alternative B saddle dam access roads included in the Road Relocations and South Bridge feature would differ from Alternative A, but Eastside Road would have the same alignment over Funks Creek and would require the same construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impacts on fish species of primary management concern (**Impact Fish-1**) as described for Alternative A.

The Alternative B Sites Reservoir would require the construction of two more saddle dams than the Alternative A reservoir. However, these additional saddle dams would not be located within or adjacent to a waterway. The Alternative B dams would therefore have the same impacts on fish species of primary management concern (**Impact Fish-1**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impacts on fish species of primary management concern (**Impact Fish-1**) as described for Alternative A.

The Alternative B Sites Reservoir would be larger than the Alternative A reservoir. In addition, Alternative B would replace the Delevan Pipeline Intake Facilities with the smaller Delevan Pipeline Discharge Facility. Potential impacts to aquatic biological resources associated with these proposed Project features that would differ from Alternative A are discussed below.

Sites Reservoir Inundation Area

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Aquatic Habitat Modification

Construction of a larger Sites Reservoir would have similar potential impacts to aquatic biological resources as discussed for Alternative A, except that construction of Sites Reservoir (1.81 MAF under Alternative B vs. 1.27 MAF under Alternative A) would eliminate and inundate approximately four miles of Stone Corral Creek and seven miles of Funks Creek upstream of the Sites Reservoir dams, compared to 3.9 miles of Stone Corral Creek and 6.5 miles of Funks Creek under Alternative A. Aquatic habitat removal and modification, specifically the inundation of Funks and Stone Corral creeks associated with the construction of Sites Reservoir, would result in a **potentially significant impact** to fish species of primary management concern.

Delevan Pipeline Discharge Facility

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified

as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Hydrostatic Pressure Waves, Noise and Vibration

Under Alternative B a cofferdam would be constructed in the Sacramento River along the entire length of the discharge facility (approximately 350 feet in length) and subsequently dewatered to allow for construction of the facility. Potential impacts to fisheries resources associated with the coffer dam construction would be similar to those discussed for the Delevan Pipeline Intake Facilities under Alternative A and could, therefore, result in a **potentially significant impact** to fish species of primary management concern.

Predation Risk

Potential impacts to fisheries resources associated with predation risk during construction, operation, and maintenance of the discharge facility would be similar to those discussed for the intake facilities under Alternative A. However, because Alternative B would only include a discharge facility without diversion capabilities, the facility footprint would be smaller than the intake facility under Alternative A. This smaller footprint would reduce the amount of riparian and aquatic habitat impacted, and therefore, reduce the potential for non-native predatory fish habitat creation. Despite the reduced potential in comparison to Alternative A, increased predation risk associated with the construction of this facility could have a **potentially significant** impact on fish species of primary management concern.

Aquatic Habitat Modification

The footprint of the smaller discharge facility is estimated to displace approximately 1.5 acres of Fremont Cottonwood riparian habitat that may act as SRA habitat, and approximately 0.1 acre of Valley Foothill Riparian habitat (compared to 1.1 acres and 0.5 acre of Fremont Cottonwood and Valley Foothill Riparian habitat types, respectively, under Alternative A), which may act as a source of IWM inputs to the Sacramento River. The removal of SRA habitat would result in a **potentially significant impact** to fish species of primary management concern in the Sacramento River.

Changes to Sacramento River Water Temperature

Water release temperatures from Sites Reservoir through the Delevan Pipeline Discharge Facility are expected to be the same as described for the Delevan Pipeline Intake Facilities and are therefore considered to be **less than significant**.

12.3.9 Impacts Associated with Alternative B Relative to the No Project/No Action Alternative

Potential impacts on fish species of primary management concern associated with implementation of Alternative B, relative to the No Project/No Action Alternative, were evaluated in an identical manner to those described for the No Project/No Action Alternative, relative to Existing Conditions. Specifically, model results and locations evaluated were identical among alternatives.

A summary of changes in habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the export service area under Alternative B, relative to the No Project/No Action Alternative, is presented in Table 12-21. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas under Alternative B, relative to the No Project/No Action Alternative, is presented in Table 12-22. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.9.1 Extended and Secondary Study Areas - Alternative B Relative to the No Project/No Action Alternative

The impacts associated with Alternative B relative to the No Project/No Action Alternative, as they relate to fish species of primary management concern (**Impact Fish-1**), would be the same as described for Alternative A relative to the No Project/No Action Alternative for the following species within the Extended and Secondary study areas:

- Klamath Mountains Province steelhead
- Sacramento River winter-run Chinook salmon
- Central Valley fall-run Chinook salmon
- Central Valley late fall-run Chinook salmon
- White sturgeon
- Pacific lamprey
- River lamprey
- Hardhead
- California roach
- Delta smelt
- Longfin smelt
- Sacramento splittail
- Largemouth bass

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C. Construction-related impacts associated with implementation of Alternative B, relative to the No Project/No Action Alternative, on all fish species of primary management concern would be the same as those described for Alternative A relative to Existing Conditions. Operational impacts associated with Alternative B relative to the No Project/No Action Alternative that would differ from those described for Alternative A relative to the No Project/No Action Alternative are described below.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Reservoir coldwater fish species habitat conditions would be more suitable in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs under Alternative B, relative to the No Project/No Action Alternative.

Specifically, within the Secondary Study Area, end-of-month storage generally would be greater under Alternative B, relative to the No Project/No Action Alternative in each of the SWP/CVP reservoirs evaluated. Reservoir coldwater fish species habitat conditions would also be anticipated to be more suitable in export service area reservoirs due to generally increased SWP and CVP exports occurring more frequently and potentially resulting in increased storage in export service area reservoirs.

Therefore, for Alternative B, relative to the No Project/No Action Alternative, potential impacts on reservoir coldwater fish species in Trinity, Shasta, Oroville, Folsom, San Luis, and other export service area reservoirs are considered **potentially beneficial**.

Reservoir Warmwater Fish Species

Reservoir warmwater species habitat conditions would be similar or more suitable under Alternative B, relative to the No Project/No Action Alternative in Trinity and Shasta reservoirs because water surface elevation reductions of six feet or more during the warmwater fish nesting season would occur less frequently. Therefore, fewer nest dewatering events are anticipated. Water surface elevation reductions of six feet or more would be similar in Oroville, Folsom, and San Luis reservoirs. Therefore, impacts on reservoir warmwater fish species are anticipated to be similar. Reservoir warmwater fish species habitat conditions are anticipated to be more suitable in export service area reservoirs due to generally increased SWP and CVP exports that would occur more frequently and potentially result in increased littoral habitat in export service area reservoirs.

Therefore, for Alternative B, relative to the No Project/No Action Alternative, potential impacts on reservoir warmwater fish species in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs are considered **less than significant**, and impacts on warmwater fish species in other export service area reservoirs are considered **potentially beneficial**.

Southern Oregon/Northern California Coho Salmon

In general, simulated habitat conditions in the Trinity River would be similar under Alternative B, relative to the No Project/No Action Alternative (see Appendix 12C for a detailed discussion).

Therefore, under Alternative B, relative to the No Project/No Action Alternative, potential impacts on Coho salmon in the Trinity River are considered **less than significant**.

Upper Klamath-Trinity River Fall-Run and Spring-Run Chinook Salmon

In general, during the periods when Chinook salmon are present in the Trinity River, habitat conditions, as well as early life stage mortality, would be similar under Alternative B, relative to the No Project/No Action Alternative (see Appendix 12C for a detailed discussion).

Therefore, under Alternative B, relative to the No Project/No Action Alternative, potential impacts on spring-run and fall-run Chinook salmon in the Trinity River are considered **less than significant**.

Central Valley Spring-Run Chinook Salmon

In general, during periods when spring-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under Alternative B, relative to the No Project/No Action Alternative. However, habitat conditions in the Sacramento River and Clear Creek would be similar or more suitable. Specifically, in the Sacramento River, habitat conditions would be generally similar during most life stages, but flows would be higher and water temperatures would be lower more frequently during spawning and embryo incubation. Additionally, these conditions would result in reduced early life stage mortality, reduced population mortality, and increased production potential. Habitat conditions in Clear Creek would be similar or more suitable because slightly lower water temperatures would occur more frequently (see Appendix 12C for a detailed discussion).

Overall, under Alternative B, relative to the No Action Alternative, potential operational impacts on spring-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**.

Central Valley Steelhead

In general, during periods when steelhead are present in the evaluated water bodies, habitat conditions would be similar under Alternative B, relative to the No Project/No Action Alternative. However, habitat conditions in the American River would be similar or more suitable because flows would be increased more frequently during most life stages. Additionally, spawning habitat availability would be greater in the American River under Alternative B, relative to the No Project/No Action Alternative. However, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing and emigration, as a result of decreased frequency of inundation (as identified by reduced Yolo Bypass outflow), and potentially reduced Delta productivity as a result of decreased Yolo Bypass inundation frequency (see Appendix 12C for a detailed discussion).

Overall, under Alternative B, relative to the No Action Alternative, potential operational impacts on steelhead in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on steelhead in the Yolo Bypass are considered **potentially significant**.

Green Sturgeon

In general, during periods when green sturgeon are present in the evaluated water bodies, habitat conditions would be similar under Alternative B, relative to the No Project/No Action Alternative. Additionally, habitat conditions in the Sacramento River would be generally similar or more suitable due to generally higher flows that would occur more often and occur more often during low flow conditions. However, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing due to a decreased frequency of floodplain activation, which results in reduced floodplain rearing opportunities and reduced nutrient inflow to the Delta and bays (see Appendix 12C for a detailed discussion).

Overall, under Alternative B, relative to the No Action Alternative, potential operational impacts on green sturgeon in the Trinity River, Sacramento River, Feather River, American River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on green sturgeon in the Yolo Bypass are considered **potentially significant**.

Striped Bass

In general, during periods when striped bass are present in the evaluated water bodies, habitat conditions would be similar under Alternative B, relative to the No Project/No Action Alternative. However, habitat conditions in the American River would be similar or more suitable due to increased flows that would occur more frequently during most months of all life stages, although reduced flows would occur more frequently (see Appendix 12C for a detailed discussion).

Therefore, for Alternative B, relative to the No Project/No Action Alternative, potential impacts on striped bass in the Sacramento River, Feather River, American River, Delta, and bays are considered **less than significant**.

American Shad

Operations-related impacts on American shad would be similar to those described for striped bass under Alternative B, relative to the No Project/No Action Alternative, and are considered **less than significant**.

12.3.9.2 Primary Study Area – Alternative B Relative to the No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Refer to the **Impact Fish-1** Primary Study Area discussion for Alternative B relative to Existing Conditions. That discussion also applies to Alternative B relative to the No Project/No Action Alternative.

12.3.10 Impacts Associated with Alternative C Relative to Existing Conditions

Potential impacts on fish species of primary management concern associated with implementation of Alternative C, relative to Existing Conditions, were evaluated in an identical manner to those described for Alternative A, relative to Existing Conditions. Specifically, model results and locations evaluated were identical among alternatives.

A summary of changes in habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the export service area under Alternative C, relative to Existing Conditions, is presented in Table 12-23. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas under Alternative C, relative to Existing Conditions, is presented in Table 12-24. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.10.1 Extended and Secondary Study Areas - Alternative C Relative to Existing Conditions

The impacts associated with Alternative C relative to Existing Conditions, as they relate to fish species of primary management concern (**Impact Fish-1**), would be the same as described for Alternative A relative to Existing Conditions for the following species within the Extended and Secondary study areas:

- Southern Oregon / Northern California Coho
- Upper Klamath / Trinity fall and spring-run Chinook salmon
- Klamath Mountains Province steelhead
- Central Valley steelhead
- Green sturgeon
- White sturgeon
- Pacific lamprey
- River lamprey
- Hardhead
- California Roach
- Delta smelt
- Longfin smelt

- Striped bass
- American shad
- Largemouth bass

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C**.** Construction-related impacts associated with implementation of Alternative C, relative to Existing Conditions, on all fish species of primary management concern would be the same as those described for Alternative A relative to Existing Conditions. Operational impacts associated with Alternative C relative to Existing Conditions that would differ from those described for Alternative A, relative to Existing Conditions, are described below.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Reservoir coldwater fish species habitat conditions would be similar or more suitable in Trinity, Shasta and Oroville reservoirs under Alternative C, relative to Existing Conditions, due to generally higher reservoir storages that would occur more often. Coldwater fisheries habitat conditions would be generally similar to conditions under Alternative A relative to Existing Conditions, except that conditions would be similar or more suitable in Folsom Reservoir instead of more suitable, due to more similar reservoir storages. Habitat conditions would be similar or less suitable in San Luis Reservoir, and more suitable in export service area reservoirs due to reduced storage that would occur more often in San Luis Reservoir and potentially increased storage in other export service area reservoirs due to increased SWP/CVP exports.

Therefore, for Alternative C, relative to Existing Conditions, potential impacts on reservoir coldwater fish species in Oroville, Folsom, and San Luis reservoirs are considered **less than significant**, and impacts on coldwater fish species in Trinity, Shasta, and other export service area reservoirs are considered **potentially beneficial**.

Reservoir Warmwater Fish Species

Reservoir warmwater species habitat conditions would be similar or more suitable under Alternative C, relative to Existing Conditions, in Trinity and Shasta reservoirs because fewer water surface elevation reductions of six feet or more would occur during the warmwater fish nesting season. Therefore, fewer nest dewatering events would be anticipated. Warmwater fisheries habitat conditions would be similar to conditions under Alternative A, relative to Existing Conditions, except that conditions in Shasta Lake would be more suitable instead of similar or more suitable, due to reduced water surface elevation reductions. Simulated water surface elevation reductions of six feet or more would occur with similar frequency in Oroville Reservoir, and would occur with slightly higher frequencies in Folsom Reservoir. Therefore, habitat conditions for warmwater species are anticipated to be similar in Oroville Reservoir and slightly less suitable in Folsom Reservoir. Habitat conditions in San Luis Reservoir are anticipated to be slightly less suitable because of expected increased frequencies of water surface elevation reductions of six feet or more, while increases in exports that would occur more often are anticipated to increase habitat suitability for warmwater species inhabiting other export service area reservoirs.

Therefore, for Alternative C, relative to Existing Conditions, potential impacts on reservoir warmwater fish species in Trinity, Oroville, Folsom, and San Luis reservoirs are considered **less than significant**, and impacts on warmwater fish species in Shasta and other export service area reservoirs are considered **potentially beneficial**.

Sacramento River Winter-Run Chinook Salmon

In general, during periods when winter-run Chinook salmon are present in the Sutter Bypass, Delta, and bays downstream of the Delta, habitat conditions would be similar or more suitable under Alternative A, relative to Existing Conditions. Habitat conditions in the Sacramento River would be generally more suitable as a result of more suitable spawning and embryo incubation conditions that would occur more often, while habitat conditions in the Delta would be more suitable due to generally higher juvenile survival that would occur more often through the Delta (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to Existing Conditions, potential operational impacts on winter-run Chinook salmon in the Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**, and impacts on winter-run Chinook salmon in the Sacramento River are considered **potentially beneficial**.

Central Valley Spring-Run Chinook Salmon

In general, during periods when spring-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar or more suitable under Alternative C, relative to Existing Conditions, due to increased flows that would occur more often and reduced water temperatures that would occur more often. Habitat conditions under Alternative C would be similar to conditions under Alternative A relative to Existing Conditions, except that conditions in the Sacramento River are considered similar or more suitable instead of more suitable, due to slightly less suitable flows and water temperatures during October. In addition, Delta habitat conditions are considered similar under Alternative C instead of similar or more suitable under Alternative A relative to Existing Conditions, due to generally similar through Delta survival. Habitat conditions in the American River for non-natal juvenile spring-run Chinook salmon would be generally similar or slightly less suitable due to reduced flows that would occur more frequently under Alternative C, relative to Existing Conditions. However, it is not anticipated that these habitat conditions would substantially affect spring-run Chinook salmon, particularly because the American River only supports non-natal juvenile rearing (see Appendix 12C for a detailed discussion).

Overall, under Alternative C, relative to Existing Conditions, potential operational impacts on spring-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**.

Central Valley Fall-Run Chinook Salmon

In general, during periods when fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be generally similar or more suitable under Alternative C, relative to Existing Conditions. Habitat conditions would be similar to those discussed under Alternative A relative to Existing Conditions, except that conditions for fall-run Chinook salmon in the Sacramento River would be considered similar instead of similar or more suitable due to reduced spawning habitat availability. Habitat conditions in the American River would be substantially less suitable during all life stages (see Appendix 12C for a detailed discussion). Specifically, decreased flows and increased water temperatures, as well as increased early life stage mortality, would occur more frequently as a result of implementation of Alternative C.

Overall, under Alternative C, relative to Existing Conditions, potential operational impacts on fall-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**. On the American River under Alternative C relative to Existing Conditions, impacts on fall-run Chinook salmon would be considered potentially significant. However, these impacts would occur with or without implementation of the proposed Project and are therefore not considered to be Project-related impacts. Because these adverse changes in flows and temperatures would not be caused by implementation of Alternative C, the potential operational impacts on fall-run Chinook salmon are considered to be **less than significant**.

Sacramento Splittail

In general, during periods when splittail are present in the evaluated water bodies, habitat conditions would be generally similar under Alternative C, relative to Existing Conditions in the Sutter Bypass, and would be similar or less suitable in the Feather and American rivers. Habitat conditions in the Feather and American rivers would be slightly less suitable for spawning due to decreased flows and reduced useable flooded area that would occur slightly more often. The reduction in usable flooded area that would occur slightly more often is not anticipated to result in a substantial impact to splittail in the Feather and American rivers. Habitat conditions for splittail within the Level 4 refuges in the Extended Study Area are anticipated to be similar under Alternative C, relative to Existing Conditions. However, reduced flows into and out of the Yolo Bypass would result in substantially less suitable habitat conditions for splittail spawning. Because of the importance of the Yolo Bypass to splittail population abundance, reduced floodplain inundation in the Yolo Bypass would constitute a substantial impact (see Appendix 12C for a detailed discussion).

Therefore, under Alternative C, relative to Existing Conditions, potential operational impacts on splittail in the Feather River, American River, Sutter Bypass, Delta, and Level 4 refuges are considered **less than significant**, and impacts on splittail in the Yolo Bypass are considered **potentially significant**.

Ecosystem Enhancement Storage Account and Ecosystem Enhancement Fund

Refer to the EESA and EEF discussions for Alternative A relative to Existing Conditions. That discussion applies to all three action alternatives.

12.3.10.2 Primary Study Area – Alternative C Relative to Existing Conditions

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to aquatic biological resources:

- Sites Reservoir Inlet/Outlet Structure
- Sites Pumping/Generating Plant
- Holthouse Reservoir Complex
- GCID Canal Facilities Modifications
- TRR to Funks Creek Pipeline
- Delevan Pipeline

The Alternative C Road Relocations and South Bridge feature would include the same alignment of Eastside Road over Funks Creek as Alternative A. Therefore, the impacts of the road relocations on fish species of primary management concern (**Impact Fish-1**) would be the same as described for Alternative A.

The Alternative C Sites Reservoir Inundation Area and Sites Dams would be the same as the Alternative B reservoir and dams. The Alternative C reservoir and dams would therefore have the same impacts on fish species of primary management concern (**Impact Fish-1**) as described for Alternative B.

The Delevan Pipeline Intake Facilities included in Alternative C would be the same as the Alternative A intake facilities. Therefore, the impacts of the intake facilities on fish species of primary management concern (**Impact Fish-1**) would be the same as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are surrounded by the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, this difference in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. It would, therefore, have the same impacts on fish species of primary management concern (**Impact Fish-1**) as described for Alternative A.

12.3.11 Impacts Associated with Alternative C Relative to the No Project/No Action Alternative

Potential impacts on fish species of primary management concern associated with implementation of Alternative C, relative to the No Project/No Action Alternative, were evaluated in an identical manner to those described for the No Project/No Action Alternative, relative to Existing Conditions. Specifically, model results and locations evaluated were identical among alternatives.

A summary of changes in habitat conditions in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs, as well as reservoirs in the export service area under Alternative C, relative to the No Project/No Action Alternative, is presented in Table 12-25. A summary of the changes in habitat conditions associated with riverine, estuarine, and floodplain habitats in the Extended and Secondary study areas under Alternative C, relative to the No Project/No Action Alternative, is presented in Table 12-26. Species-specific summary discussions of the information presented in these tables are provided below to support significance determinations.

12.3.11.1 Extended and Secondary Study Areas - Alternative C Relative to the No Project/No Action Alternative

The impacts associated with Alternative C relative to the No Project/No Action Alternative, as they relate to fish species of primary management concern (**Impact Fish-1**), would be the same as described for Alternative A relative to the No Project/No Action Alternative for the following species within the Extended and Secondary study areas:

- Southern Oregon/Northern California Coho salmon
- Upper Klamath-Trinity River fall-run and spring-run Chinook salmon
- Klamath Mountains Province steelhead
- Sacramento River winter-run Chinook salmon
- Central Valley late fall-run Chinook salmon
- White sturgeon
- Pacific lamprey
- River lamprey
- Hardhead
- California roach
- Delta smelt
- Longfin smelt
- Striped bass
- American shad
- Largemouth bass

Refer to the Alternative B discussion for Central Valley steelhead relative to the No Project/No Action Alternative. That discussion also applies to Central Valley steelhead under Alternative C, relative to the No Project/No Action Alternative.

Detailed discussion of potential impacts and aquatic habitat conditions in the Extended and Secondary study areas is provided in Appendix 12C. Construction-related impacts associated with implementation of Alternative C, relative to the No Project/No Action Alternative, on all species of primary management concern would be the same as those described for Alternative A relative to Existing Conditions. Operational impacts associated with Alternative C relative to the No Project/No Action Alternative that would differ from those described for Alternative A, relative to the No Project/No Action Alternative, are described below.

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use, San Luis Reservoir, Export Service Area Reservoirs, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Spring Creek, Shasta Lake, Sacramento River, Clear Creek, Lake Oroville, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish

nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.

Reservoir Coldwater Fish Species

Reservoir coldwater fish species habitat conditions would be more suitable in Trinity, Shasta, Folsom, and San Luis reservoirs, and similar or more suitable in Oroville Reservoir under Alternative C, relative to the No Project/No Action Alternative. Specifically, within the Secondary Study Area, end-of-month storage generally would be greater under Alternative C, relative to the No Project/No Action Alternative in each of the SWP/CVP reservoirs evaluated. Reservoir coldwater fish species habitat conditions also are anticipated to be more suitable in export service area reservoirs due to generally increased SWP and CVP exports that would occur more frequently and potentially result in increased storage in export service area reservoirs. However, reservoir coldwater fish species habitat in San Luis Reservoir would be less suitable as a result of net storage decreases of 10 percent or more that would occur more often under Alternative C, relative to the No Project/No Action Alternative.

Therefore, for Alternative C, relative to the No Project/No Action Alternative, potential impacts on reservoir coldwater fish species in Oroville Reservoir are considered **less than significant;** impacts on coldwater fish species in Trinity, Shasta, Folsom, and other export service area reservoirs are considered **potentially beneficial;** and impacts on coldwater fish species in San Luis Reservoir are considered **potentially significant**.

Reservoir Warmwater Fish Species

Reservoir warmwater fish species habitat conditions would be similar or more suitable under Alternative C, relative to the No Project/No Action Alternative in Trinity and Shasta reservoirs because water surface elevation reductions of six feet or more during the warmwater fish nesting season would occur less frequently. Therefore, fewer nest dewatering events are anticipated. Water surface elevation reductions of six feet or more would be similar in Oroville and Folsom reservoirs. Therefore, impacts on reservoir warmwater fish species are anticipated to be similar. Reservoir warmwater fish species habitat conditions are anticipated to be more suitable in export service area reservoirs due to generally increased SWP and CVP exports that would occur more frequently and potentially result in increased littoral habitat in export service area reservoirs. However, San Luis Reservoir warmwater fish species habitat would be similar or less suitable due to reservoir water surface elevation reductions of six feet or more that would occur more frequently.

Therefore, for Alternative C, relative to the No Project/No Action Alternative, potential impacts on reservoir warmwater fish species in Trinity, Shasta, Oroville, Folsom, and San Luis reservoirs are considered **less than significant,** and impacts on warmwater fish species in other export service area reservoirs are considered **potentially beneficial**.

Central Valley Spring-Run Chinook Salmon

In general, during periods when spring-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under Alternative C, relative to the No Project/No Action Alternative. However, habitat conditions in the Sacramento River and Clear Creek would be similar or more suitable. Specifically, in the Sacramento River, habitat conditions would be generally similar during most life stages, but flows would be higher and water temperatures would be lower more frequently during spawning and embryo incubation. Additionally, these conditions would result in reduced early life stage mortality, reduced population mortality, and increased production potential. Habitat conditions in the American River would be similar or more suitable because higher flows and lower temperatures generally would occur more frequently. Habitat conditions in Clear Creek would be similar or more suitable due to slightly lower water temperatures that would occur more frequently (see Appendix 12C for a detailed discussion).

Overall, under Alternative C, relative to the No Action Alternative, potential operational impacts on spring-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**.

Central Valley Fall-Run Chinook Salmon

In general, during periods when fall-run Chinook salmon are present in the evaluated water bodies, habitat conditions would be similar under Alternative C, relative to the No Project/No Action Alternative. However, simulated habitat conditions in Clear Creek would be similar or more suitable because slightly decreased water temperatures would occur during spawning. Habitat conditions in the American River would be more suitable because of higher flows and lower temperatures that would occur more frequently (see Appendix 12C for a detailed discussion).

Overall, under Alternative C, relative to the No Action Alternative, potential operational impacts on fall-run Chinook salmon in the Sacramento River, Clear Creek, Feather River, Sutter Bypass, Yolo Bypass, Delta, and bays are considered **less than significant**, and impacts on fall-run Chinook salmon in the American River are considered **potentially beneficial**.

Green Sturgeon

In general, during periods when green sturgeon are present in the evaluated water bodies, habitat conditions would be similar under Alternative C, relative to the No Project/No Action Alternative. Additionally, habitat conditions in the Sacramento River would be generally similar or more suitable due to generally similar spawning conditions, but higher flows would occur more often in the lower reaches of the river during adult immigration, and higher flows would occur more often during low flow conditions during juvenile emigration. However, habitat conditions in the Yolo Bypass would be less suitable for juvenile rearing due to a decreased frequency of floodplain activation, which would result in reduced floodplain rearing opportunities and reduced nutrient inflow to the Delta and bays (see Appendix 12C for a detailed discussion).

Overall, under Alternative C, relative to the No Action Alternative, potential operational impacts on green sturgeon in the Trinity River, Sacramento River, Feather River, American River, Sutter Bypass, Delta, and bays are considered **less than significant**, and impacts on green sturgeon in the Yolo Bypass are considered **potentially significant**.

Sacramento Splittail

In general, during periods when splittail are present in the evaluated water bodies, habitat conditions would be similar under Alternative C, relative to the No Project/No Action Alternative. However, reduced flows into and out of the Yolo Bypass would result in less suitable habitat conditions for splittail spawning. Because of the importance of the Yolo Bypass to splittail population abundance, reduced floodplain inundation in the Yolo Bypass would constitute a substantial impact (see Appendix 12C for a detailed discussion).

Overall, under Alternative A, relative to the No Project/No Action Alternative, potential operational impacts on splittail in the Feather River, American River, Sutter Bypass, Delta, and Level 4 wildlife refuges are considered **less than significant**, and impacts on splittail in the Yolo Bypass are considered **potentially significant**.

12.3.11.2 Primary Study Area – Alternative C Relative to the No Project Alternative

Construction, Operation, and Maintenance Impacts

Refer to the **Impact Fish-1** Primary Study Area discussion for Alternative C relative to Existing Conditions. That discussion also applies to Alternative C relative to the No Project/No Action Alternative.

12.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 12-27 for the impacts that have been identified as significant or potentially significant.

Table 12-27
Summary of Mitigation Measures for
NODOS Project Impacts to Aquatic Biological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Fish-1: A substantial adverse effect (either directly, through habitat modifications, by interfering with the movement of native fish species, or by impeding the use of native fish nursery/rearing sites) on any fish species of primary management concern, including species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by CDFG, NMFS or USFWS.				
Impact Fish-1a: Temperature Effects	San Luis Reservoir (Alternative C compared to the No Project/No Action Alternative for coldwater fish species)	Potentially Significant	Mitigation Measure Fish-1a: Increase stocking frequency of coldwater fish species.	Less than Significant
Impact Fish-1b: Reduced Flows	Yolo Bypass (all alternatives)	Potentially Significant	Mitigation Measure Fish-1b: Prepare and Implement a Mitigation Monitoring and Reporting Plan	Less than Significant

Table 12-27
Summary of Mitigation Measures for
NODOS Project Impacts to Aquatic Biological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Fish-1c: Erosion, Sedimentation and Turbidity	Sites Reservoir Inundation Area, Sites Dams, Road Relocations and South Bridge, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Holthouse Reservoir Complex, GCID Canal Facilities Modifications, TRR to Funks Creek Pipeline, Delevan Pipeline, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility, Project Buffer	Potentially Significant	Mitigation Measure Fish-1c: Prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) and an Erosion and Sediment Control Plan (ESCP) prior to the initiation of construction activities.	Less than Significant
Impact Fish-1d: Hazardous Materials and Chemical Spills	Sites Reservoir Inundation Area, Sites Dams, Road Relocations and South Bridge, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Holthouse Reservoir Complex, GCID Canal Facilities Modifications, TRR to Funks Creek Pipeline, Delevan Pipeline, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility	Potentially Significant	Mitigation Measure Fish-1c: Prepare and Implement a Stormwater Pollution Prevention Plan (SWPPP) and an Erosion and Sediment Control Plan (ESCP) Prior to the initiation of Construction Activities.	Less than Significant
			Mitigation Measure Fish-1d: Prepare and Implement a Spill Prevention and Hazardous Materials Management Plan Prior to the Initiation of Construction Activities.	

Table 12-27
Summary of Mitigation Measures for
NODOS Project Impacts to Aquatic Biological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Fish-1e: Aquatic Habitat Modification	Sites Reservoir Inundation Area, Sites Dams, Sites Reservoir Inlet/Outlet Structure, /Sites Pumping/Generating Plant, Holthouse Reservoir Complex, Delevan Pipeline, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility	Potentially Significant	Mitigation Measure Fish-1e: Implement Habitat Restoration Actions	Less than Significant
Impact Fish-1f: Hydrostatic Pressure Waves, Noise, and Vibration	Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility	Potentially Significant	Mitigation Measure Fish-1f: Perform In-Water Pile Driving July Through September During Daylight Hours.	Less than Significant
Impact Fish-1g: Predation Risk	Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility, Delevan Pipeline Discharge Facility	Potentially Significant	Mitigation Measure Fish-1g: Design Fish Screen in Compliance with NMFS and CDFG Criteria	Less than Significant
Impact Fish-1h: Stranding, Impingement, and Entrainment	Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility	Potentially Significant	Mitigation Measure Fish-1h: Prepare and Implement a Fish Salvage and Rescue Plan	Less than Significant

Mitigation Measure Fish-1a: Increase stocking frequency of coldwater fish species.

[Text to be developed]

Mitigation Measure Fish-1b: Prepare and Implement a Mitigation Monitoring and Reporting Plan

DWR and Reclamation shall prepare and implement a Mitigation Monitoring and Reporting Plan to mitigate for expected significant reduced flows through the Yolo Bypass (all alternatives), which could include the following mitigation measure:

- Modifications to the Fremont Weir to allow additional flow for inundation of the Yolo Bypass has been identified as a fisheries habitat improvement action by other projects or programs and may be implemented before the NODOS Project is authorized. If modifications occur before implementation of the NODOS Project, this impact would be reduced to less than significant and would not require mitigation. If the modifications are not yet implemented, mitigation measures for the NODOS Project could include modification of the weir to offset potentially reduced flows through the Yolo Bypass and associated habitat availability for splittail and other fish species of primary management concern.

Mitigation Measure Fish-1c: Prepare and Implement a Stormwater Pollution Prevention Plan (SWPPP) and an Erosion and Sediment Control Plan (ESCP) Prior to the Initiation of Construction Activities.

DWR and Reclamation shall prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) and an Erosion and Sediment Control Plan (ESCP) prior to the initiation of construction activities. The SWPPP and/or ESCP shall incorporate Central Valley Regional Water Quality Control Board's dewatering requirements and the California Storm Water Quality Association's best management practices for dewatering, and shall establish site-specific erosion- and sediment-control measures for construction, operation, and maintenance activities, such as:

- Minimizing traffic speeds on access roads to 10 miles per hour or less.
- Maintaining a minimum of two feet of freeboard on all haul trucks.
- Periodically applying water to disturbed areas, to control dust exposure as needed, depending on weather conditions.
- Applying soil stabilizers in accordance with manufacturers' specifications to all inactive construction areas.
- Installing erosion control wattles around all disturbed areas and ditches.
- Installing silt fencing.
- Utilizing drainage inlet protection.
- Utilizing sediment settling basins through which all water removed from any waterways will be pumped into prior to being discharged into any waterways.
- Utilizing concrete washout areas.
- Hydroseeding and mulching disturbed areas.

Mitigation Measure Fish-1d: Prepare and Implement a Spill Prevention and Hazardous Materials Management Plan Prior to the Initiation of Construction Activities.

DWR and Reclamation shall prepare a Spill Prevention and Hazardous Materials Management Plan (developed as part of the SWPPP) that would be designed to minimize the potential for chemical spills and seepage during construction, operation, and maintenance activities. Such a plan may include, but not be limited to, the following:

- On-site handling rules to keep construction and maintenance materials out of drainages and waterways;
- Prevention of any substances that could be hazardous to aquatic life from contaminating the soil or entering watercourses, including ditches and canals;
- Cleaning up all spills immediately according to the spill prevention and control plan, and notifying CDFG and the Central Valley Regional Water Quality Control Board (CVRWQCB) immediately of spills and associated cleanup procedures;

- Providing staging and storage areas away from watercourses and their watersheds for equipment, materials, fuels, lubricants, solvents, and other possible contaminants
- Publishing protocols for regular maintenance of construction vehicles and equipment to minimize the potential for leakage or spills.

Mitigation Measure Fish-1e: Implement Habitat Restoration Actions.

To minimize disturbance to aquatic habitat, construction personnel shall participate in an environmental awareness training program provided by a qualified biologist. Construction personnel shall be informed about any sensitive biological resources associated with the proposed Project and that disturbance of sensitive habitat or special-status species would be a violation of the Endangered Species Act and the Clean Water Act.

Mitigation specific to construction of the proposed Project facilities could include the following:

- **Construction of Sites Reservoir Inundation Area and Sites Dams**
  - Mitigation measures to offset inundation of Stone Corral and Funks creeks shall include habitat restoration of Stone Corral and Funks Creek at a ratio of 2:1 (i.e., two acres restored for every acre removed), such that twice as many linear stream miles would be restored along Stone Corral and Funks creeks as would be inundated by Sites Reservoir and displaced by Sites and Golden Gate dams. Habitat restoration actions may occur at other nearby creeks if feasible habitat restoration actions on Stone Corral and Funks creek are inadequate to meet mitigation requirements. Habitat restoration measures could include removal of non-native vegetation in the riparian area, planting of native riparian species, bank stabilization in areas with excessive erosion, and potentially active removal of non-native fish species. Monitoring of restoration actions shall be conducted for a minimum of five years to ensure that restored habitat is functioning as intended. Specific restoration actions and sites to be restored at each creek shall be included in the Mitigation Monitoring and Reporting Plan.
- **Construction of Holthouse Reservoir Complex, the Sites Reservoir Inlet/Outlet Structure, and the Sites Pumping/Generating Plant**
  - Mitigation measures shall include habitat restoration along Funks Creek at a ratio of 2:1, which shall be in addition to the number of stream miles restored associated with inundation of Funks Creek by Sites Reservoir. Habitat restoration actions may occur at other nearby creeks if feasible habitat restoration actions on Funks creek are inadequate to meet mitigation requirements. Monitoring of restoration actions shall be conducted for a minimum of five years to ensure that restored habitat is functioning as intended. Specific restoration actions and sites to be restored shall be included in the Mitigation Monitoring and Reporting Plan.
- **Construction of the Delevan Pipeline**
  - Construction activities associated with the Delevan Pipeline at Hunters Creek and the Colusa Basin Drain shall occur during the summer months when the water bodies generally are dry. If construction occurs during a particularly wet year when the water bodies do not cease flowing, construction shall occur in a manner that allows passage of native fishes past construction sites. Specifically, construction shall occur across only half of the water body at one time. Cofferdams shall be installed to isolate half of the total construction area, allowing the other half of the water body to remain flowing. After construction on one side of the water body is complete, the other half shall then be isolated and dewatered where construction shall continue.

- Measures to mitigate for the temporary loss of habitat on Hunters Creek and the Colusa Basin Drain shall include on-site habitat restoration following the completion of construction. Habitat restoration measures could include planting of native riparian species and removal of non-native vegetation. Monitoring of restoration actions shall be conducted for a minimum of five years to ensure that restored habitat is functioning as intended.

- **Construction of the Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility**
  - As mitigation for loss of riparian and SRA habitat on the Sacramento River, degraded habitat shall be restored to provide riparian and/or SRA habitat at or near the areas affected by construction of the intake/discharge facilities at a ratio of 2:1. Proposed restoration activities shall include the removal of non-native vegetation as necessary and re-vegetation with native riparian species to provide shaded riverine aquatic (SRA) and/or riparian habitat. As a component of SRA habitat, riparian tree species such as alders, cottonwoods and willows, shall be planted. In addition to habitat restoration actions, due to the importance of IWM to juvenile fishes in the Sacramento River, any IWM that is moved or altered by construction activities shall stay on-site and be returned to the river, or be replaced with a functional equivalent. Monitoring of restoration actions shall be conducted for a minimum of five years to ensure that restored habitat is functioning as intended. Specific restoration actions and sites to be restored on the Sacramento River shall be included in the Mitigation Monitoring and Reporting Plan.

Mitigation Measure Fish-1f: Perform In-Water Pile Driving July Through September During Daylight Hours.

In-water pile driving shall only occur during July through September during daylight hours. This time period takes into consideration the migratory patterns of salmonids; pile driving shall occur after the cessation of the outmigration of juvenile salmon and before the initiation of the upstream migration of adults returning to spawn. To avoid impacts to the majority of fish species of primary management concern, sheet pile installation and in-stream heavy equipment activity shall be coordinated with USFWS, USBR, CDFG, and NMFS to avoid and or minimize potential impacts. If feasible, a vibratory hammer shall be used, and pile driving shall commence at low energy levels and slowly build to impact force. In addition, underwater sound levels shall be monitored to ensure that pile driving activities do not create underwater sound levels that exceed NMFS’ noise thresholds (i.e., accumulated sound exposure level of 183 dB and a peak pressure of 206 dB).

Mitigation Measure Fish-1g: Design Fish Screen in Compliance with NMFS and CDFG Criteria.

Fish screen at the Delevan Pipeline Intake Facilities shall be designed to comply with NMFS and CDFG fish screening criteria. The Delevan Pipeline Intake Facilities or Discharge Facility shall be designed to minimize hydraulic and physical habitat that is suitable for non-native predatory fish species. The facility shall be designed in coordination with NMFS and CDFG to ensure incorporation of the best available scientific and engineering knowledge of fish screen design to minimize predation potential on fish species of primary management concern. These design criteria shall minimize or avoid increased habitat suitability for non-native predatory fish species. However, a monitoring and adaptive management program shall be implemented to ensure that losses resulting from predatory fish are minimized.

Mitigation Measure Fish-1h: Prepare and Implement a Fish Salvage and Rescue Plan.

The fish screen at the Delevan Pipeline Intake Facilities shall be designed to comply with NMFS and CDFG fish screening criteria. In addition, a Fish Salvage and Rescue Plan shall be developed and approved by NMFS and CDFG prior to initiation of construction activities, and could include the following measure:

- A qualified biologist shall provide construction monitoring throughout all phases of the project. If spawning activities for sensitive fish species are encountered during construction activities, the monitoring biologist shall be authorized to stop construction activities until appropriate corrective measures are completed or it is determined that the fish would not be harmed. If possible, all fish species shall be allowed to independently move away from the area. Fish that become entrapped in any side channel where construction work is taking place shall be netted, transported to the river, and released according to the Fish Salvage and Release Plan.

Implementation of **Mitigation Measures Fish-1a, Fish-1b, Fish-1c, Fish-1d, Fish-1e, Fish-1f, Fish-1g, and Fish-1f** would reduce the level of significance of Project impacts to aquatic biological resources to **less than significant**.

13. Botanical Resources

13.1 Introduction

This chapter describes the botanical resources setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Botanical resources include vegetation communities, non-native invasive weed species, and special-status plant species.

The regulatory setting for botanical resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

13.2 Environmental Setting/Affected Environment

13.2.1 Extended Study Area

13.2.1.1 Methodology

Vegetation Communities

Vegetation communities are broad categories that represent an assemblage of similar native vegetation associations that are typically defined by dominant or co-dominant species. Vegetation communities, as used in this section, are based on the broader and more general vegetation categories, sometimes referred to as “series” (Sawyer and Keeler-Wolf, 1995) or, more recently “alliance” or even more generally “group” (Sawyer et al., 2009).

No vegetation community type (alliance, group) for urban or agricultural land is designated in the above sources. Likewise, DFG’s Wildlife Habitat Relationships (WHR) System (DFG, 2008) urban and agricultural types do not have any corresponding vegetation communities in the National Vegetation Classification System (NVCS); these land cover types “do not meet the criteria for any wildland (native) habitat” (DFG, 2007). Because none of the categories of native plant communities normally used for California vegetation apply in this case, no native vegetation types are discussed for the urban or agricultural lands in the Extended Study Area.

The specified wildlife refuges contain perennial marsh native plant communities. The community name for perennial marshes (“temperate and subpolar grasslands”) found in Sawyer et al., (2009), Appendix 3 (National Vegetation Classification Hierarchy – groups and macrogroups) conveys little information. In the Manual of California Vegetation, perennial freshwater marsh is a collection of over 20 alliances, ranging from the Common Rush Riparian Grassland alliance to Bulrush-Cattail Wetland (Sawyer et al., 2009). To more appropriately describe the general perennial freshwater marsh or wetlands potentially affected, the WHR fresh emergent wetland habitat type is used in this analysis. This habitat type also encompasses other subtypes, such as alkaline marsh.

Invasive Plant Species

An invasive species is defined by the National Invasive Species Council pursuant to Executive Order 13112 as "a species that is (1) non-native (or alien) to the ecosystem under consideration, and (2) whose introduction causes or is likely to cause economic or environmental harm or harm to human health" (Center for Invasive Plant Management, 2011). A noxious weed, as defined by the California Department of Food and Agriculture (DFA), means any "species of plant that is, or is liable to be, troublesome, aggressive, intrusive, detrimental, or destructive to agriculture, silviculture, or important native species, and difficult to control or eradicate" (DFA, 2010a).

Many invasive non-native plant species occur within urban and agricultural lands in the Extended Study Area. A database of these species is not maintained by geographic area. The statewide inventories of the California Department of Food and Agriculture (DFA) and California Invasive Plant Council (Cal-IPC), as well as environmental documents covering some of the service areas, were reviewed for examples of invasive species likely to be affected by increased reliability of water supply in urban and agricultural areas of the Central Valley. A "wetland/marsh/aquatic" habitat query of the overall California Cal-IPC list was conducted for the perennial wetland habitats of the wildlife refuges in the Extended Study Area.

Special-Status Plant Species

Very few, if any, federally or State-listed plant species are expected to occur in urban and agricultural lands because appropriate habitat is lacking. The DFG Rarefind 4 was used to query the November 2009 CNDDB for all listed species in perennial wetland habitat categories in the 7 counties containing wildlife refuges that receive Level 4 water deliveries. The habitat categories included were Wetland, Swamp, Marsh/Swamp, Freshwater Marsh, and Alkali Marsh. The counties included were Merced, Fresno, Kern, Kings, Tulare, Glenn, and Colusa; an additional condition of elevational range lower than 2,700 feet was applied to exclude montane and sub-alpine species. Species occurring only in drying seasonal vernal pools were also omitted because they would most likely not benefit from more reliable water deliveries.

13.2.1.2 Vegetation Communities

Wildlife refuge perennial wetland or marshlands are classified as fresh emergent wetland in WHR (refer to Chapter 14 Terrestrial Biological Resources for descriptions). This habitat occurs in parts of affected National Wildlife Refuges (NWR) and Wildlife Areas (WA) from the Sacramento/Delevan NWRs in the north, to Kern and Pixley NWRs in the southern end of the San Joaquin Valley (Figure 1-7 in Chapter 1 Introduction). Fresh emergent wetland includes inland (non-coastal) alkaline wetlands, as well as completely freshwater wetland areas. Fresh emergent wetland habitats have greater than two percent cover by herbaceous species and less than 10 percent total cover by tree or shrub species. Because emergent wetlands are frequently flooded, their vegetation is adapted to being rooted in an anaerobic environment. Fresh emergent wetland habitats are characterized by erect, rooted water-dependent plants; dominant species are generally tall perennial grass-like plants such as cattails (*Typha*), bulrush (*Scirpus*), rushes (*Juncus*), sedges (*Carex*, *Cyperus*), arrowhead (*Sagittaria*), or saltgrass (*Distichlis*) if on more alkali sites. Freshwater wetlands are relatively stable over many thousands of years, but can accumulate sediments, and become replaced by upland communities over time. Soil substrates are generally silts and clays, or sometimes organic peats, in depressions or basins within a generally level to gently rolling landscape (Mayer and Laudenslayer, 1988). Freshwater emergent wetland or marsh does not include such seasonal wetlands as vernal pools or riparian (streamside) edges by moving waters.

13.2.1.3 Invasive Plant Species

Approximately 256 species of non-native weeds of varying degrees of invasiveness are known to occur throughout California (Cal-IPC, 2008). These occur in a wide range of habitats. Some (such as dandelion, bromes, thistles, mulleins, yellow star-thistle, and tumbleweeds) are well known from urban ruderal (i.e., weedy roadside) areas. Others, such as Johnson-grass, tall vervain, mustards, dock, or bindweed, are more common in agricultural areas, especially wet ditches and field margins. Others tend to invade riparian or wet habitats within urbanized areas, or spread into wildlands at the disturbed urban-wildland interface. One hundred thirty-four invasive species from the DFA 2008 list and 256 species from the Cal-IPC 2008 list are found in some part of the Extended Study Area, which includes much of California's Central Valley, but also extends into the Sierra foothills east of Oroville and Stockton, into the Bay Area, and also into southern coastal and desert lands.

The Cal-IPC query indicated that 33 invasive species are potentially present in wetland/marsh/aquatic habitats of the Extended Study Area. These species are listed in Table 13-1. This could be an underestimate because many water-tolerant riparian and upland invasive species can also occur in wetland edges.

Table 13-1
Invasive Weed Species Potentially Present in Wildlife Refuges Receiving Level 4 Water Supply in the Extended Study Area

Common Name	Scientific Name	Cal-IPC Wildland Impact Potential Rating	Habitats of Concern and Comments
Creeping bentgrass	*Agrostis stolonifera*	Limited	Wetlands, riparian; grown for domestic forage. Limited distribution.
Alligator weed	*Alternanthera philoxeroides*	High	Freshwater aquatic systems, including marshes.
Lens-podded white-top	*Cardaria chalepensis*	Moderate	Central Valley wetlands. Limited distribution in California. May not be as invasive as *C. draba*.
Hoary cress	*Cardaria draba*	Moderate	Riparian areas, marshes of central coast. More severely invasive in northern California.
Bull thistle	*Cirsium vulgare*	Moderate	Riparian areas, marshes, meadows. Widespread; can be a regional problem.
Pampasgrass	*Cortaderia selloana*	High	Coastal dunes, coastal scrub, Monterey pine, riparian, grasslands, wetlands, serpentine soils. Still spreading both coastal and inland.
Brazilian egeria	*Egeria densa*	High	Streams, ponds, sloughs, lakes, Sacramento-San Joaquin Delta.
Water hyacinth	*Eichhornia crassipes*	High	Aquatic systems in Sacramento-San Joaquin Delta.
Common velvet grass	*Holcus lanatus*	Moderate	Coastal grasslands, wetlands. Invasions can be more severe locally, especially in wetland areas.
Mediterranean barley, hare barley, wall barley	*Hordeum marinum, H. murinum*	Moderate	Grasslands; *H. marinum* invades drier habitats, and *H. murinum* invades wetlands. Widespread, but generally do not form dominant stands.
Yellowflag iris	*Iris pseudacorus*	Limited	Riparian, wetland areas, especially southern California. Limited distribution.
Perennial pepperweed, tall whitetop	*Lepidium latifolium*	High	Coastal and inland marshes, riparian areas, wetlands, grasslands; potential to invade montane wetlands.
Uruguay water-primrose	*Ludwigia hexapetala*	High	Freshwater aquatic systems.

Table 13-1
Invasive Weed Species Potentially Present in Wildlife Refuges Receiving Level 4 Water Supply in the Extended Study Area

Common Name	Scientific Name	Cal-IPC Wildland Impact Potential Rating	Habitats of Concern and Comments
Hyssop loosestrife	*Lythrum hyssopifolium*	Limited	Grasslands, wetlands, vernal pools. Widespread.
Purple loosestrife	*Lythrum salicaria*	High	Wetlands, marshes, riparian areas.
Pennyroyal	*Mentha pulegium*	Moderate	Vernal pools, wetlands. Poisonous to livestock. Spreading rapidly.
Parrotfeather	*Myriophyllum aquaticum*	High	Freshwater aquatic systems.
Hardinggrass	*Phalaris aquatica*	Moderate	Coastal sites, especially moist soils. Limited distribution. Can be highly invasive locally.
Japanese knotweed	*Polygonum cuspidatum*	Moderate	Riparian areas, wetlands, forest edges. Distribution limited in California.
Sakhalin knotweed	*Polygonum sachalinense*	Moderate	Riparian areas. Distribution limited in California.
Himalaya blackberry	*Rubus armeniacus*	High	Riparian areas, marshes, oak woodlands.
Red sorrel, sheep sorrel	*Rumex acetosella*	Moderate	Many habitats, riparian areas, forest, wetlands. Widespread.
Curly dock	*Rumex crispus*	Limited	Grasslands, vernal pool, meadows, riparian. Widespread. Impacts appear to be minor.
Ravennagrass	*Saccharum ravennae*	Moderate	Riparian scrub, marsh, and swamp.
Oppositeleaf Russian thistle	*Salsola soda*	Moderate	Marine systems, estuaries, vernal pool, marsh, and swamp.
Giant salvinia	*Salvinia molesta*	High	Freshwater aquatic systems. Population in San Diego River was eradicated.
Smooth cordgrass and hybrids, Atlantic cordgrass	*Spartina alterniflora* (and *S. alterniflora x foliosa* hybrids)	High	San Francisco Bay salt marshes and mudflats.
Common cordgrass	*Spartina anglica*	Moderate	San Francisco Bay salt marshes. Very severe impact in other countries. Limited distribution in California.
Dense-flowered cordgrass	*Spartina densiflora*	High	San Francisco and Humboldt Bay salt marshes.
Saltmeadow cord grass	*Spartina patens*	Limited	San Francisco Bay salt marshes. Very limited distribution. Invasion currently minor in California, but high in other countries.
Spanish broom	*Spartium junceum*	High	Coastal scrub, grasslands, wetlands, oak woodland, forests.
Tall vervain, seashore vervain	*Verbena bonariensis, Verbena litoralis*	Eval Not Listed	Often in disturbed areas of irrigation canals.
Calla lily	*Zantedeschia aethiopica*	Limited	Coastal prairie, wetlands. Invasion high in other countries, and may be locally high in California.

13.2.1.4 Special-Status Plant Species

Several special-status plant species are documented within fresh emergent wetland habitats within wildlife refuges receiving Level 4 water supply throughout the Central Valley. Twenty-five plant species on CNPS Lists 1, 2, and 3, including several State- or federally listed species, are known to occur in lower elevation marshy habitats in the 7 counties where wildlife refuges are located (DFG, 2010a). Species that are potentially present[1] in the affected wildlife refuges are listed in Table 13-2.

Table 13-2
Special-Status Species Potentially Present in the Extended Study Area

Common Name	Scientific Name	Federal Listing Status	State Listing Status	CNPS List[a]	Habitat
Henderson's bent grass	*Agrostis hendersonii*	None	None	3.2	Valley and foothill grassland, vernal pool, Wetland
Horn's milk-vetch	*Astragalus hornii* var. *hornii*	None	None	1B.1	Alkali playa, meadow and seep, wetland
Brittlescale	*Atriplex depressa*	None	None	1B.2	Alkali playa, chenopod scrub, meadow and seep, valley and foothill grassland, vernal pool, wetland

[a]California Native Plant Society (CNPS, 2010): List 1A= plants presumed extinct in California; List 1B = plants rare, threatened, or endangered in California and elsewhere; List 2 = plants rare, threatened, or endangered in California but common elsewhere; List 3 = plants about which more information is needed to determine current status. CNPS threat codes: 0.1: Seriously endangered in California. 0.2: Fairly endangered in California; 0.3: Not very endangered in California.

[b]Listing status being changed to List 1B.

[c]These vernal pool grasses may not be affected if in entirely seasonal wetlands rather than perennial wetland parts of a refuge.

Source: CNPS, 2010.

13.2.2 Secondary Study Area

13.2.2.1 Methodology

Vegetation Communities

The vegetation types that could be affected by fluctuations in reservoir levels and changes in stream flow volumes are those within and around the immediate borders of the facilities included in the Secondary Study Area. A crosswalk (i.e., a cross-referencing table) (DFG, 2007)) for DFG's Manual of California Vegetation (MCV) and WHR habitats was used to determine the current MCV vegetation alliances or groups equivalent to the affected WHR habitats in the Secondary Study Area, which are: lacustrine, riverine, estuarine, valley foothill riparian, fresh emergent wetland, montane riparian (Trinity-Klamath River only), saline emergent wetland, barren, rice, irrigated grain crops, and irrigated row and field crops.

The maps of each vegetation alliance (Sawyer et al., 2009) were consulted to verify that each alliance is found within the Secondary Study Area.

Invasive Plant Species

For land at margins of lakes, rivers, marshes, estuaries, and croplands, the overall Cal-IPC list was searched with a query that included Wetland/marsh/aquatic and Riparian habitats. Similar to that described for the wetland habitats, this list is likely an underestimate because many invasive species found in similar habitats may not have been specifically listed as “riparian”. Species listed as typical mostly of desert, coastal, or southern California areas were not included.

Special-Status Plant Species

CDFG’s Rarefind 4 program was used to query the November 2009 CNDDB for all listed species in riparian and perennial wetland habitat categories in the 22 counties where affected CVP and SWP facilities are located. The habitat categories included were Aquatic, Estuary, Marine Bay, Klamath/North Coast flowing waters, Mud shore/flats, Riparian woodland, Riparian scrub, Sacramento/San Joaquin flowing waters and standing waters, Wetland, Swamp, Marsh/swamp, Freshwater Marsh, Brackish Marsh, Salt Marsh, and Alkali Marsh. The counties included were Alameda, Butte, Colusa, Contra Costa, Del Norte, El Dorado, Glenn, Humboldt, Marin, Placer, Sacramento, San Francisco, San Mateo, Santa Clara, Shasta, Solano, Sonoma, Sutter, Tehama, Trinity, Yolo, and Yuba. An additional condition of elevational range lower than 2,700 feet was applied to exclude high montane and sub-alpine species. Species occurring only in drying seasonal vernal pools were also omitted because they would likely be located in upland landforms.

In addition, species not appearing in the Rarefind 4 query, but included in DWR’s rare plant survey search list for the 2009 Bay-Delta Conservation Plan (BDCP) surveys, were added to the list of potentially affected special-status plant species if they occurred within water-related habitats or on riparian or drainage banks.

13.2.2.2 Vegetation Communities

Table 13-3 lists the vegetation alliances identified in the Manual of California Vegetation (MCV) that are expected to be affected by the alternatives, and a correlation of vegetation types or groups of types with WHR and with Secondary Study Area Project features. Vegetation alliances listed in the MCV crosswalk (a cross-referencing table) (DFG, 2007) were listed only if their mapped distribution (Sawyer et al., 2009) included Project features in the Secondary Study Area.

Table 13-3

The central waterway of the Secondary Study Area is the Sacramento River. Historically, the edges and floodplain of the Sacramento River supported several riparian vegetation communities. At water's edge, willow riparian scrub and annual plants occupied the shifting gravel and sand bars and banks. Well-developed multiple-storied cottonwood and sycamore riparian forests lined inner terraces, transitioning into mixed species and then valley oak cathedral forests on the somewhat higher terraces. Currently, in most of the Secondary Study Area, less than 15 percent of this original riparian corridor remains along the Sacramento River. It is now represented by narrow strips in a pattern interrupted by agriculture (mostly orchards) down to the river's edge.

13.2.2.3 Invasive Plant Species

Approximately 73 species of non-native weeds of varying degrees of invasiveness are known to occur in riparian and aquatic habitats in the northern half of California (Cal-IPC, 2008). Adding the 32 species resulting from a Wetland/marsh/aquatic habitat query of the Cal-IPC list, and eliminating duplicates, a total of 77 weed species potentially exist in the water-edge habitats of the Secondary Study Area. These species are listed in Appendix 13A. This could be an underestimate because many facultative riparian and upland weed species can also occur in wetland edges. In addition, many additional invasive plant species may occur in the agricultural areas of the Yolo and Sutter Bypass portions of the Secondary Study Area.

Some examples of weedy species that could be affected by changes in water levels or timing of flows are stands of Poison hemlock (*Conium maculatum)* or fennel *(Foeniculum vulgare*), Pampas grass (*Cortaderia selloana*), Perennial pepperweed (*Lepidum latifolium*), Giant reed (*Arundo donax*), and Montevideo waterweed (*Ludwigia peploides* ssp. *montevidensis*) in Suisun Marsh, other locations around the edges of San Francisco Bay and the Delta, Bypass areas, and river and stream floodplains.

13.2.2.4 Special-Status Plant Species

In riparian, aquatic, and wetland habitats within affected SWP and CVP areas throughout northern California, including the Trinity/Klamath River and San Francisco Bay and Delta, numerous special-status plant species are documented. There are 114 plant species on CNPS lists 1, 2 and 3, including several State- or federally listed species that are known to occur in lower-elevation water-related habitats in the 22 counties containing affected SWP or CVP facilities (DFG, 2010a; CNPS, 2010). These species are summarized by listing status on Table 13-4 and are listed in greater detail in Appendix 13B. Some of these species may not occur at the specific Project features or facilities affected by changing Project operation flows, because they may occur in slightly different habitats or geographic areas. However, these species are potentially present in the affected Secondary Study Area streamside, wetland/marsh, or aquatic areas.

Five smaller geographic regions within the Secondary Study Area that are based on climatic and other biogeographic differences were defined for the discussion of potentially affected special-status plant species (Figure 13-1). The numbers of special-status plant species that are expected to occur in each of these geographic regions are listed in Table 13-5.

As indicated in Table 13-5, the Bay/Delta portion of the Secondary Study Area supports the greatest number of potentially affected special-status plant species. Some of these, such as Delta button celery (*Eryngium racemosum),* a State endangered species, or Suisun Marsh aster (*Symphyotrichum lentum)* and Carquinez goldenbush (*Isocoma arguta)*, both CNPS List 1B species, occur only in the Bay-Delta part of the Secondary Study Area.

Table 13-5
Number of Special-Status Plant Species by Region and Status

Status	Region				
	North Coast	**Shasta**	**Central Valley**	**Bay/Delta**	**Folsom**
Federal	1	0	5	9	3
State	0	1	1	3	2
CNPS 1A	0	0	0	2	0
CNPS 1B	8	6	18	33	5
CNPS 2	12	9	7	8	0
CNPS 3	0	0	1	1	0
CNPS 4	4	2	7	13	1
TOTAL	**25**	**18**	**39**	**69**	**11**

Note:

Totals for the regions add up to 162 rather than 114 because some of the 114 species are present in more than one region.

Source: DFG, 2010a; CNPS, 2010.

However, other portions of the Secondary Study Area also support special-status plant species not found in any other region. For example, several plant species are found only in the North Coast (Trinity-Klamath Rivers) portion of the Secondary Study area, such as Western lily *(Lilium occidentale)*, a federally endangered species, and Howell's miner's-lettuce (*Montia howellii)*, a CNPS List 1B species. This northwest coastal area is influenced by its unique proximity to the north coast, with Klamath region serpentine substrates and high rainfall.

Similarly, several species are known only from the Folsom area, such as federally endangered Sacramento orcutt grass (*Orcuttia viscida)*, or Myers' pincushionplant (*Navarretia myersii* ssp. *myersii),* a CNPS List 1B species. The Folsom area foothill-valley edge has vernal pool and gabbro/serpentine substrates that support unique sets of plant species.

Special-status plants unique to the cool mountainous Shasta area include Shasta snow wreath (*Neviusia cliftonii)* and Howell's alkali grass (*Puccinellia howellii),* both CNPS List 1B species.

Special-status plants occurring mainly in the Central Valley include vernal pool species such as federally listed Greene's tuctoria (*Tuctoria greenei)* and Colusa grass (*Neostapfia colusana)*, as well as highly localized foothill-valley edge species such as federally endangered Butte County meadowfoam (*Limanthes floccosa* ssp. *californica)* and Sacramento cryptantha (*Cryptantha crinita),* a CNPS 1B species. Several species such as Palmate-bracted bird's-beak (*Cordylanthus palmatus* [federally and State endangered]), Pappose tarweed (*Centromadia parryi* [CNPS List 1B]), and three saltbushes (*Atriplex* spp. [all CNPS List 1B]), are found in both the alkaline wetlands of the Central Valley and the brackish marsh edges of the Bay-Delta. The only potentially affected special-status plant species known from all parts of the Secondary Study Area is Sanford's arrowhead (*Sagittaria sanfordii),* a CNPS List 1B species that is found at pond edges.

13.2.3 Primary Study Area

13.2.3.1 Methodology

Vegetation Communities

CNPS and DFG have classified natural plant communities in California for broad scale resource inventory and assessment. This classification system defines characteristics for general vegetation types and for rare communities (Sawyer and Keeler-Wolf, 1995). These classifications were used as the first step to define the natural vegetation communities and associations in the Primary Study Area that may be affected by the proposed Project features (DWR, 2005). Associations or vegetation types were added to these classifications to encompass the variation of dominant species composition and vegetation structure (density of cover) that was found in the vicinity of proposed Project facilities, especially areas lying outside the confines of the reservoir footprints.

Vegetation within the proposed reservoir footprint was mapped in 1998 (DWR, 2005). Vegetation in and adjacent to other features, including proposed road relocation routes, conveyance routes, and recreation areas, were mapped in 2000 to 2001. Reservoir footprint vegetation types were delineated by hand on overlays over hard-copy true-color aerial photos (1:6,000; 1:12,000). The polygons were field-verified and then digitized using computer mapping software (AutoCad, converted to ArcView [ESRI, 1998]). Vegetation types in feature areas outside of the proposed reservoir footprint were delineated directly on-screen using "heads-up digitizing" in ArcView 3.x (ESRI, 2000) over geo-referenced true-color digital aerial photo images (1:7,200, 1:12,000 and 1:30,000) flown in 1997 for the proposed Project. Interpretation of vegetation composition was based on prior familiarity from 3 years of rare plant surveys. In addition, field verification of the proposed reservoir footprint occurred after initial mapping was completed.

In vegetation mapping for features outside of the proposed reservoir footprint, vegetation types were defined somewhat more finely for dominant woody species and vegetation density than in the earlier reservoir footprint mapping. However, all vegetation types used were easily convertible, and the resulting polygons for both were integrated into a single mapping coverage (shapefile). The 2001 vegetation mapping for the Primary Study Area was partially updated in 2004 based on field observations in selected sampling sites. This original vegetation mapping included lands surrounding all proposed Project features covered by aerial photography, a total of 104,331 acres. In addition, computer mapping software (ArcGIS v. 9.2) was used in 2010 to obtain acreages and percent cover for each vegetation type occurring within the Primary Study Area. Acres of each vegetation type were also mapped using similar methods for the "construction disturbance area," which represents the maximum potential ground disturbance area resulting from construction activity.

Invasive Plant Species

A list of weed species potentially occurring in and in the vicinity of the Primary Study Area was created by listing all species from the current Federal Noxious Weed List (USDA, 2005), DFA list (DFA, 2010b), and the Cal-IPC list (Cal-IPC, 2010) and adding those from the local Colusa-Glenn-Tehama Weed Management Area (CGT WMA, 2002). Also added were species of concern to the Mendocino National Forest (Ruhl, 2006). This original list contained 83 species. Likelihood of occurrence of these 83 species was evaluated based on documented occurrences for Colusa and/or Glenn counties in CalFlora, DFA, or local floras (Oswald, 2002), and whether the species was found during Project field surveys. Species known only from habitats, elevations, or geographical localities not extending into the Primary Study Area (e.g., montane species or those not known to occur west of the Sacramento River) were not included.

Invasive plant species found during Project surveys were assigned a high probability of occurrence. Species not found during surveys, but previously recorded from Glenn and Colusa counties, were assigned a medium probability of occurrence.

Special-Status Plant Species

Lists of special-status plant species potentially affected by the proposed Project were developed prior to conducting the 1998 to 2003 field surveys. The initial list of federal- and State-listed species, species of concern (CNPS lists 1, 2, and 3), and species of limited distribution (CNPS List 4) was compiled after consulting DFG, CNPS, and USFWS references and regional specialists (DWR, 2005) regarding known occurrences within the Primary Study Area. The list was then updated each year prior to continuation of surveys, using the current version of Rarefind, CNDDB, letter requests to USFWS and the updated CNPS Inventory (DWR, 2005).

To develop a June 2009 baseline for a list of potentially affected species for this document, DFG's October 2009 Special Plants List (DFG, 2010c) was used, along with the CNPS 3-month list of additions, deletions, name changes, and list or rank changes. There were no changes affecting the Primary Study Area. The October 2009 DFG Special Plants List was used as a cross-check to ensure that a list generated by a November 2009 CNDDB query was as close as possible to a summer 2009 list. CDFG's Rarefind 4 program was used to query the November 2009 CNDDB for all listed species in all habitats, in 16 USGS 7.5-minute quadrangle maps encompassing the Primary Study Area and nearest known special-status plant occurrence sites, including: Colusa, Gilmore Peak, Hough Springs, Lodoga, Leesville, Logan Ridge, Logandale, Manor Slough, Maxwell, Moulton Weir, Princeton, Rail Canyon, Salt Canyon, Sites, Stonyford, and Williams. An additional condition of elevational range lower than 3,000 feet was applied to exclude high montane and sub-alpine species. A GIS selection from the November 2009 CNDDB spatial files based on the same 16 quadrangle maps was consulted for additional species in the Primary Study Area known from less than 3,000 feet elevation. This 2009 list of potentially affected special-status plant species was used as a baseline in this report, although field surveys were conducted using earlier lists. This 2009 list is included in Tables 13-9 and 13-10.

A list was prepared of special-status plant species with limited distribution, on CNPS List 4, with potential to occur in the Primary Study Area as of the time of Project field surveys (1998 to 2003). This list was compiled from the original list developed in 1997 (DWR, 2005), and updated to reflect species present on the latest CNPS lists at the time (CNPS, 2001, 2002, 2003). This list is included in Table 13-11. The list has been updated again (May 2010) for this document (CNPS, 2010). The sole information source is the CNPS Inventory, which tracks List 4 species only at the county level.

Field surveys were conducted for special-status plant species within the proposed Sites Reservoir footprint in 1998 and 1999, and within potential routes for conveyances, recreation areas, and road relocations in 2000 through 2003. Additional proposed Project features (Eastside Road extension to Road 69, Holthouse Reservoir Complex, and the redesigned Delevan Pipeline Intake/Discharge facilities) were surveyed in 2010 and 2011. Survey corridors in 2000 and 2001 were 500 feet wide for road relocation routes, and 1,000 feet wide or more for conveyance routes. Survey corridors were 1,500 feet wide for all features surveyed in 2002 and 2003. The Eastside Road extension route was surveyed in a corridor of 100 feet to either side of a centerline; for the proposed Holthouse Reservoir Complex and the Delevan Pipeline Intake/Discharge facilities, entire footprints were surveyed. Botanical surveys were conducted according to established guidelines and protocols (Nelson, 1987; CNPS, 1994; DFG, 1984; DFG, 2000; DFG, 2009a; and USFWS, 1996). Pursuant to these guidelines, focused habitat-specific surveys were conducted, using wandering transect methodology, between February and October. These months coincided with the appropriate flowering and fruiting stages necessary for the identification of most plant species occurring in the area, including all special-status species (Tables 13-9 and 13-10).

Field survey activities and plant identifications were documented throughout the multiple-year study, including dates, location, authorized property access, and assigned personnel (DWR, 2005).

Land not surveyed included properties for which authorized access was not obtained, private residences and yards, cemeteries, agricultural fields, and some bedrock stream channels and vertical slopes. Also not surveyed were areas that do not support suitable habitat for the special-status species, such as impenetrable woodland, chaparral or scrub areas, and large solid stands of Yellow star-thistle (*Centaurea solstitialis*). Some creek channels and vertical slopes were examined with binoculars where habitat appeared potentially suitable for certain species. Also not surveyed were lands outside of defined proposed Project feature corridors. Within defined proposed Project feature areas, lands with degraded or otherwise marginal or unsuitable habitat not warranting further surveys were surveyed less thoroughly. Areas with high quality potential habitat were prioritized and surveyed throughout the flowering period with more complete transect coverage. Habitat parameters, including mapped soils, aspect, and plant associates, defined the number of return visits and the level of coverage. In each Project feature area, small areas of potential habitat remain unsurveyed due to field season time constraints or lack of access authorization. Within time constraints of each season, 100 percent survey coverage was attempted in potential habitat known to support the special-status plant species, with special emphasis on federal- or State-listed species and those on CNPS lists 1, 2, or 3. Habitat for CNPS List 4 species was also checked carefully as it was encountered during surveys for more seriously threatened species.

Plant species were identified and recorded in the field whenever possible, or preserved in a voucher collection for identification at a later date. The voucher collection consists of plant specimens that were collected and preserved as proof for species on the plant inventory lists. Data collected for each special-status species occurrence included habitat parameters, approximate number of individuals, phenological state (stage of maturity), full location description, plant community associates, existing site conditions, and present or possible threats to the population. Occurrence definitions in this analysis follow the CNDDB occurrence reporting standard of at least 0.25 mile separation between stands or colonies of a special-status species. Detailed descriptions of survey methodology, area surveyed, and documentation of findings are provided in the NODOS Botanical Resources Progress Report (DWR, 2005).

13.2.3.2 Plant Species Biology and Life History of Federal- or State-Listed Species

None of the species presented in Table 13-9 were found during Project field surveys in the Primary Study Area. Three of the species in Table 13-9 are not likely to be present in the Primary Study Area because of lack of suitable elevation, substrate, and other habitat elements. They are Milo Baker's lupine (*Lupinus milo-bakeri* [occurs above 1,300 feet elevation]), Indian Valley brodiaea (*Brodiaea coronaria* ssp. *rosea* [occurs on serpentine soils]), and Red Mountain catchfly (*Silene campanulata* ssp. *campanulata* [occurs over 1,300 feet on serpentine substrate]).

Hoover's spurge *(Chamaesyce hooveri)*, Hairy Orcutt grass (*Orcuttia pilosa)*, Palmate-bracted bird's-beak (*Cordylanthus palmatus)*, and Greene's tuctoria (*Tuctoria greenei)* may occur within the Primary Study Area. Palmate bracted bird's beak has been reported within a few miles of either side of the GCID Canal in habitats similar to some of those traversed by the GCID Canal (DFG, 2009b). However, Palmate-bracted bird's-beak is restricted to alkali wetland habitats, which have been mostly converted to intensive agriculture in the Primary Study Area. Colusa-grass *(Neostapfia colusana)* has been extirpated (locally extinct) from the Colusa County portion of its former range (DFG, 2009b; USFWS, 2006). Potential habitat for some of these species may exist in the footprint for the proposed Holthouse Reservoir southeast of the existing Funks Reservoir.

The remaining federally listed plant species, Keck's checkerbloom (*Sidalcea keckii*), may occur within the Primary Study Area, in grassy areas within open blue oak woodland in hills around the western side of the proposed Sites Reservoir footprint. This species was not thought to occur in the northern half of California during the time of Project surveys.

Indian Valley brodiaea (*Brodiaea coronaria* ssp. *rosea*)

Indian Valley brodiaea, a State Endangered species, is a perennial herb in the Lily family (Liliaceae) that flowers in May and June. Its habitat includes closed-cone coniferous forest, chaparral, cismontane woodland, and valley and foothill grasslands on serpentinite soils typically at elevations ranging from 1,100 to 4,760 feet (335 to 1,450 meters), but has been observed as low as 100 feet (30 meters) (Oswald, 2002). It has been found in gravelly creek bottoms, meadows and swales, and other vernally moist sites with serpentine substrates. Thirteen occurrences of Indian Valley brodiaea have been reported in Colusa, Glenn, Lake, and Tehama counties (two of which are possibly extirpated) (DFG, 2010a). These sites are on lands owned and managed by BLM, USFS, private parties, and unknown entities. Known populations occur within six miles of the Primary Study Area. Some plant species thought to occur only on serpentinite can sometimes be found downslope or downstream from serpentine areas on contiguous non-serpentine substrate. Therefore, potential habitat may exist, but is not likely, within the western portion of the Primary Study Area. Existing threats to these populations have been identified, including inundation by reservoir construction, mining, off-road recreational vehicle activity, road or trail construction, horticultural collecting, vandalism, and dumping. Populations are protected, in part, at a BLM Area of Critical Environmental Concern in Lake County.

Hoover's spurge (*Chamaesyce hooveri*)

Hoover's spurge, a federal Threatened species, is also listed on CNPS List 1B. It is an annual herb in the spurge family (Euphorbiaceae) that flowers in July and August. Its habitat is limited to vernal pools at elevations ranging from 80 to 820 feet (25 to 250 meters). Its preferred substrate is deeply cracking adobe clay. Hoover's spurge has been reported from 29 occurrences in California: 20 are clustered in Butte, Glenn, and Tehama counties; three are in Stanislaus and Merced counties, and six are in Tulare County. Of the 20 occurrences north of San Joaquin County, all except four are at or near The Nature Conservancy's (TNC) Vina Plains Preserve. Known occurrences are on properties owned or managed by DFG, USFWS, TNC, and private and unknown parties. Known populations occur within seven miles of the Primary Study Area in the Sacramento NWR. Potential habitat may exist in parts of the Primary Study Area wherever vernal pools occur. Existing threats to this species include agriculture, altered hydrology, erosion or runoff, trampling, grazing, and competition from non-native plants. Populations are protected, in part, at the DFG Stone Corral Ecological Reserve in Tulare County, USFWS Sacramento NWR, and TNC Vina Plains Preserve, but most occurrences of Hoover's spurge are on privately owned land (USFWS, 2002).

Palmate-bracted bird's-beak *(Cordylanthus palmatus)*

Palmate-bracted bird's-beak, a State and federal Endangered species, is an annual herb in the Snapdragon family (Scrophulariaceae) that flowers from May through October. Its habitat is vernally (springtime) wet open flats with chenopod (Goosefoot family) scrub on saline/alkaline soil in valley and foothill grassland at elevations ranging from 16 to 510 feet (5 to 155 meters). Twenty-six occurrences of Palmate-bracted bird's-beak are known from Alameda, Colusa, Fresno, Glenn, Madera, San Joaquin and Yolo counties (DFG, 2010a). However, the five occurrences of this species in Madera County are thought to be extirpated, and the two occurrences listed for Glenn County and one for Fresno County are recent re-introductions. The 18 remaining natural populations occur on land owned and managed by the City of Woodland, DFG, City of Livermore, USFWS, and private parties. It is known to occur within two miles of the Primary Study Area; these occurrences in Colusa County (Delevan NWR) represent the northernmost occurrences in the existing natural range of this species. Potential habitat exists in the proposed Delevan Pipeline construction disturbance area, and in the proposed Holthouse Reservoir footprint. Existing threats include agriculture, urbanization, altered hydrology, competition from exotic plants, biocides, grazing, ORV use, vandalism/dumping, and road and trail construction. Populations are protected at the DFG Alkali Sink Ecological Reserve and Mendota Wildlife Area, and at the Colusa, Delevan and Sacramento NWRs.

Milo Baker's lupine (*Lupinus milo-bakeri*)

Milo Baker's lupine, a State Threatened species, is not recognized as a distinct species in the current Jepson Manual (Hickman, 1993), but instead is considered part of Pale yellow lupine (*Lupinus luteolus).* This lupine is, however, recognized as a distinct species by the CNDDB and the CNPS Inventory (CNPS, 2009). Compared to the yellow-flowered assumed parent, Pale yellow lupine, Milo Baker's lupine plants are apparently taller and flowers have a bluish-purplish tinge. This annual herb in the pea family (Fabaceae) flowers from June through September. Its habitat is vernally wet gravelly depressions such as drainage channels, ditches, and often roadsides in cismontane woodland and foothill and valley grasslands at elevations ranging from 1,300 to 1,410 feet (395 to 430 meters). *L. milo-bakeri* has been reported from 13 occurrences in Colusa and Mendocino counties (DFG, 2010a). At least four of the Mendocino County sites may have been extirpated, and three are recent re-introductions. The remaining six sites are not located near the Primary Study Area. Known occurrences are on land owned and managed by Bureau of Indian Affairs (BIA), California Department of Transportation (CALTRANS), and private parties. Potential habitat exists in the vicinity of the Project; the closest occurrence is in Bear Valley, approximately seven miles southwest of the Primary Study Area and 13 miles from the town of Sites. This species is currently threatened by biocides, grazing, and road and trail construction.

Colusa grass (*Neostapfia colusana*)

Colusa grass, a State Endangered and federal Threatened species, is an annual grass that flowers from May to August. Its habitat is large and/or deep vernal pools and alkali playas, on uncultivated adobe and saline/alkaline clay soils, at elevations ranging from 16 to 660 feet (5 to 200 meters). Colusa grass is reported from 59 occurrences in Colusa, Merced, Solano, Stanislaus, and Yolo counties (DFG, 2010a). However, this species is thought to be extirpated from Colusa County, and from some sites in Stanislaus, Merced, and Glenn counties. Colusa grass occurs on land owned by TNC, Solano County Farmlands and Open Space Foundation, Stanislaus County, the U.S. Department of Defense, private parties, and unknown entities. Potential habitat occurs in the vicinity of the Project; the one reported occurrence in Colusa County was in alkali pools beside what is now County Road 68 between Princeton and Norman, three to nine miles east of I-5, approximately four miles to the north of the proposed Delevan Pipeline route and 10 miles east of the proposed Sites Reservoir footprint. Potential habitat for Colusa grass also exists in the proposed Holthouse Reservoir footprint. The nearest occurrence that still exists is over 60 miles to the southeast in Yolo County. Existing threats to these populations include agricultural practices and grazing, altered flood regime and surface water diversion, biocides, competition from exotics, inundation, foot traffic, off-road vehicle activity, and road construction. Some populations are protected by TNC and Solano County Farmlands and Open Space Foundation.

Hairy Orcutt grass *(Orcuttia pilosa)*

Hairy Orcutt grass, a State and federal Endangered species, is an annual grass that flowers from May to September. Its preferred habitat is drying edges and beds of vernal pools in heavy clays, ranging in elevation from 180 to 660 feet (55 to 200 meters) (CNPS, 2010). Thirty-four occurrences of Hairy Orcutt grass have been reported in Butte, Glenn, Madera, Merced, Stanislaus, and Tehama counties (DFG, 2009b). However, several of these occurrences have been extirpated, many in Merced County. Existing populations occur on land owned by Reclamation, CALTRANS, TNC, USFWS, and private parties. Potential habitat exists within the vicinity of the Project, and known populations occur within six miles of the Primary Study Area in the Sacramento NWR. Nine known occurrences, in and near Vina Plains, are several miles east of the Sacramento River in southern Tehama County. Existing threats include agriculture, competition from exotic plants, development, grazing, off road vehicle use, and road and trail construction. Some populations are protected at the TNC Vina Plains Preserve and at the Sacramento NWR.

Keck's checkerbloom *(Sidalcea keckii)*

Keck's checkerbloom, a federal Endangered species, is an annual herb that flowers from April to May. This plant was presumed extinct in the 1993 Jepson Manual (Hickman, 1993), was rediscovered in 1992, listed at the federal level in February 2000 (CNPS, 2010), and added back into the CNPS online inventory in 2004 as a List 1B species (U.C., 2004). Many specimens of *S. keckii*, including those nearest the Primary Study Area, were originally thought to be the common fringed checkerbloom *(Sidalcea diploscypha)*; these specimens were annotated to Keck's checkerbloom by Steven Hill in 2008 (U.C. Consortium, 2011). Its habitat consists of clay soils often of serpentine origin, in valley and foothill grassland and open woodland, at elevations from 394 feet (120 meters), to over 1,394 feet (425 meters). Sixteen occurrences of Keck's checkerbloom are reported in Colusa, Fresno, Merced, Napa, Solano, Tulare, and Yolo counties (DFG, 2010a). One occurrence is considered to be extirpated from Tulare County. Existing populations occur on land owned and managed by TNC, DFG, BLM, Reclamation, private parties, and unknown entities. Potential habitat occurs along the western edge of the Primary Study Area. One occurrence is immediately northwest of the Primary Study Area, and three occurrences are in Colusa County in the vicinity of the existing East Park Reservoir. The remaining 11occurrences are not located near the Primary Study Area. Existing threats include grazing, utility maintenance, and competition from exotic plants. The identity of the plants assigned to Keck's checkerbloom from the northern end of the species' distribution, in Colusa, Napa, Solano and Yolo counties, has not yet been confirmed by ongoing scientific investigations. The necessary molecular work needed to resolve the question of whether these plants are truly Keck's checkerbloom is still in progress as of mid-2010 (Baldwin, 2010). This includes the specimens collected during Project field surveys from the hills along Grapevine Creek, at the western edge of the Primary Study Area.

Red Mountain catchfly (*Silene campanulata* ssp. *campanulata*)

Red Mountain catchfly, a State Endangered species, was listed on CNPS List 1B during field surveys conducted in 1998 to 2003; it is on List 4 as of 2010. This species is a perennial herb in the carnation family (Caryophyllaceae) that flowers from May to June. Its habitat includes chaparral and lower montane coniferous forest with serpentinite or rocky soils at elevations ranging from 1,390 to 6,840 feet (425 to 2,085 meters). CNDDB information dating back to this species' List 1B status (Skinner & Pavlik, 1994) indicates that seven occurrences of this California endemic plant have been found in Colusa and Mendocino counties. These populations occur on land owned and managed by BLM and private parties. This species also occurs in Glenn, Tehama, Del Norte, Humboldt, Trinity and Shasta counties. The current CalFlora Occurrence Database lists 24 records, some of which may be duplicate entries, so the species does not have a large number of known occurrences. A known population of Red Mountain catchfly grows within five miles of the Primary Study Area. The proposed Project facilities are located well below the observed elevation range of the species. Existing threats include erosion or runoff, mining, and possibly logging activities.

Greene's tuctoria *(Tuctoria greenei)*

Greene's tuctoria, a federal Endangered species, is an annual grass that flowers from May to July. Its habitat consists of drying small or shallow vernal pools, or the early-drying portions of large deeper vernal pools, mostly at elevations less than 660 feet (200 meters), but can occur over 3,000 feet (1,065 meters). These sites occur mostly in open grassland, on Anita clay or reddish clays of Tuscan or other volcanic origin, but can be found on alkaline adobe clay substrate. Forty-five occurrences of Greene's tuctoria are known (DFG, 2010a). Twenty-one of those populations occur in Merced, Butte, Shasta, and Tehama counties. Nineteen other occurrences are thought to be extirpated from Fresno, Stanislaus, Tulare, and San Joaquin counties, as well as others extirpated from Madera County. One additional occurrence, known from a herbarium specimen, exists in Glenn County on the Sacramento NWR (Oswald, 2002; U.C. Consortium, 2011). The remaining four occurrences are not located near the Primary Study Area. Existing populations occur on land owned and managed by TNC, USFWS, private parties, and unknown entities. Potential habitat occurs within the vicinity of the Project. The Sacramento NWR occurrence is within 10 miles of the Primary Study Area and within seven miles of the proposed Delevan Pipeline route. Existing threats include agriculture, altered hydrology and surface water diversions, competition from exotic plants, and grazing. Populations are protected, in part, at TNC Vina Plains Preserve, and the Sacramento NWR.

13.2.3.3 Plant Species Biology and Life History of *Species of Concern*

Bent-flowered fiddleneck *(Amsinckia lunaris)*

Bent-flowered fiddleneck is a CNPS List 1B species, considered to be "fairly endangered in California." This upright annual forb in the borage family (Boraginaceae) grows one to three feet tall. It flowers from March to June, and flowers must be present to distinguish it from co-occurring common look-alike species. It is found in grassy openings on slopes in oak woodlands with chaparral understories and coastal scrub. It exists at elevations of 10 to 1,500 feet (3 to 500 meters) on crumbly shale, mudstone, clay, and serpentine substrates (CNPS, 2010; Kelley and Patterson, 2011). There are currently 50 occurrences recorded for Bent-flowered fiddleneck, scattered in the central Coast Ranges from Lake County through most counties south to San Benito County (DFG, 2010a). Many recorded occurrences are old and may no longer exist. Prior to Project surveys in 2001 to 2004, the occurrences nearest to the Primary Study Area were approximately seven miles to the west, near the Colusa/Lake County line. Three new occurrences of Bent-flowered fiddleneck were found during Project surveys in the hills to the west and east of the proposed Sites Reservoir footprint. Additional occurrences of this species may occur in suitable habitat that exists in the hills surrounding the reservoir footprint, especially the canyons along the western side. Because it is very similar in appearance to common species, this species may have been overlooked in early Project surveys in those areas. Primary Study Area occurrences represent the northeasternmost extent of the range for this species.

Jepson's milkvetch (*Astragalus rattanii* var. *jepsonianus*)

Jepson's milkvetch is a CNPS List 1B species, considered to be "fairly endangered in California." This annual herb in the pea family (Fabaceae) grows from 1.5 to 12 inches tall, lying partly on the ground but with erect stem tips, and flowers from April through June. It is found in shaley mudstone or serpentinite soils in woodland, chaparral, or grassland at elevations from 1,000 to 2,000 feet (300 to 600 meters). There are 29 occurrences recorded for Jepson's milkvetch (DFG, 2009b), narrowly distributed over in the Inner Coast Ranges from western Tehama County to Napa County, in a band approximately 110 miles long by five to 20 miles wide. Most occurrences are thought to still exist, but many have not been recently confirmed. Three occurrences are known from hills approximately seven miles west of the Primary Study Area. Existing threats to this species include road maintenance and off-road vehicle use (CNPS, 2010). Potential habitat is present in the Primary Study Area in the hills to the west of the proposed Sites Reservoir footprint, but Jepson's milkvetch was not found during Project surveys in that area.

Ferris' milk-vetch (*Astragalus tener* var. *ferrisiae*)

Ferris' milk-vetch is a CNPS List 1B species, considered to be "fairly endangered in California." This delicate annual herb in the legume family (Fabaceae) grows from 2.5 to 11 inches tall, flowers from mid-March to May, and is endemic to California. Its habitat consists of vernally moist meadows and weakly alkaline flats on valley grasslands at elevations below 246 feet (75 meters) (CNPS, 2010). It has been found in adobe clay soils of rice fields, fallow pastures, and other low valley sites (Oswald, 2002). Most historically occupied habitat has been destroyed by agriculture. Fifteen occurrences of Ferris' milk-vetch have been reported in Solano, Yolo, Colusa, Glenn, and Butte counties in a narrow band 100 miles long (DFG, 2009b). Of these, six are probably extirpated, and others have not been observed recently. One 1884 occurrence is presumed extant (still in existence) in Colusa County. Most of the nine occurrences known to exist are on lands under public ownership in USFWS refuges, or state Wildlife Areas (e.g., Gray Lodge, Butte Sink). Known populations occur within eight miles of the proposed Project features at the Sacramento NWR. The main existing threat to this species has been habitat destruction due to intensive agriculture and overgrazing. Potential habitat for Ferris' milk-vetch exists in the Primary Study Area around Salt Lake (located within the proposed Sites Reservoir footprint), along the route for the proposed Delevan Pipeline, in the proposed Holthouse Reservoir footprint, and possibly adjacent to portions of the GCID Canal. No occurrences of this species were found during Project surveys.

Heartscale (*Atriplex cordulata*)

Heartscale is a CNPS List 1B species, considered to be "fairly endangered in California." This coarse erect annual herb in the goosefoot family (Chenopodiaceae) grows from four to 20 inches tall, flowers from April to October, and is endemic to California. Its habitat includes saline or alkaline soils in alkali meadow, saltbush scrub, and alkali sink communities at elevations below 1,225 feet (375 meters) (CNPS, 2010). It has been found in dry alkaline soils of grassy fields, levees, margins of seasonally flooded marshes, and other low valley sites. Sixty-three occurrences of heartscale have been reported in Central Valley counties from Kern north to Solano, with isolated occurrences in Glenn and Butte counties (DFG, 2009b). Most are presumed extant. These sites are on lands under federal ownership in USFWS refuges, in state Wildlife Areas, other agency preserves, and private and unknown ownership. Known populations occur within six miles of the Primary Study Area at the Sacramento NWR (Oswald, 2002). The main existing threats to this species have been levee, road, or aqueduct right-of-way maintenance, grazing, development, and invasive weeds. Potential habitat for Heartscale exists in parts of the Primary Study Area around Salt Lake, along the route for the proposed Delevan Pipeline, in the proposed Holthouse Reservoir footprint, and possibly along portions of the GCID Canal. No occurrences of this species were found during Project surveys.

Brittlescale (*Atriplex depressa*)

Brittlescale is a CNPS List 1B species, considered to be "fairly endangered in California." This low-growing annual herb in the goosefoot family (Chenopodiaceae) grows from two to eight inches tall, has sprawling partially prostrate stems, flowers from May to October, and is endemic to California. Its habitat consists of saline or alkaline soils in alkali meadow, saltbush scrub, and alkali sink communities at elevations below 1,050 feet (320 meters) (CNPS, 2010). It has been found in dry alkaline clay soils of grassy fields, levees, margins of seasonally flooded marshes, and other low valley sites. Fifty-six occurrences of brittlescale have been reported in the Central Valley from Glenn County south to Kern County in a narrow band approximately 300 miles long by 20 miles wide (DFG, 2009b). Most known occurrences are presumed to still exist, but at least 15 have not been confirmed recently. Known sites are on lands under federal ownership in USFWS refuges, in state Wildlife Areas, other agency preserves, and private and unknown ownership. The main existing threats to this species have been levee, road, or aqueduct right-of-way maintenance, grazing, agriculture, development, and invasive weeds. Known populations occur within one to three miles of project features, on the Delevan NWR (Oswald, 2002), and other sites now under intensive agriculture. Potential habitat exists in parts of the Primary Study Area around Salt Lake, along the route for the proposed Delevan Pipeline, in the proposed Holthouse Reservoir footprint, and possibly along portions of the GCID Canal. Three occurrences of brittlescale were found during Project surveys: two in the vicinity of (but not within) the proposed Delevan Pipeline construction disturbance area, and one to the east of the proposed Holthouse Reservoir Complex.

San Joaquin spearscale *(Atriplex joaquiniana)*

San Joaquin spearscale is a CNPS List 1B species, considered to be "fairly endangered in California." This stiffly erect annual herb in the goosefoot family (Chenopodiaceae) grows from four to 40 inches tall, flowers from April to October, and is endemic to California. Its habitat consists of strongly saline or alkaline soils in alkali meadow, saltbush scrub, and alkali sink communities at elevations below 1,050 feet (320 meters) (CNPS, 2010). It has been found in dried vernally wet alkaline clay soils of grassy fields, levees, margins of seasonally flooded marshes, and other low valley sites. Ninety-one occurrences of San Joaquin spearscale have been reported along the west edge of the Central Valley and the inner Coast Range margin, from Glenn County south to Kern County in a loose band approximately 300 miles long by five to 25 miles wide (DFG, 2009b). Most known occurrences are presumed to still exist, but at least 12 have not been confirmed since the late 1800s or early 1900s. Known sites are on lands under federal ownership in USFWS refuges, in State Wildlife Areas, other agency preserves, and private and unknown ownership. The main existing threats to this species have been grazing, agriculture, development, and road maintenance. Known populations occur within one to three miles of Project features, on the Sacramento NWR (Oswald, 2002), and other sites now under intensive agriculture. Potential habitat exists in parts of the Primary Study Area around Salt Lake, along the route for the proposed Delevan Pipeline, in the proposed Holthouse Reservoir footprint, and possibly along portions of the GCID Canal. One occurrence of San Joaquin spearscale was found during Project surveys in the vicinity of (but not within) the proposed Delevan Pipeline construction disturbance area; inspection of 2009 aerial photos indicates that this occurrence may have been extirpated due to recent conversion to intensive agriculture.

Vernal pool smallscale *(Atriplex persistens)*

Vernal pool smallscale is a CNPS List 1B species, considered to be “fairly endangered in California.” This coarse erect annual herb in the goosefoot family (Chenopodiaceae) flowers from June to October. It is found only in large alkaline vernal pools at elevations from 30 to 375 feet (10 to 115 meters) (CNPS, 2010). There are 33 occurrences recorded for vernal pool smallscale, scattered in the Central Valley from Glenn County to Tulare County (DFG, 2009b). Most occurrences are thought to still exist. Existing threats to this species include agriculture and flood control activities. The largest concentration, 11 occurrences, is on the Sacramento NWR in Glenn County, approximately three miles north of the proposed Delevan Pipeline. Potential habitat exists in parts of the Primary Study Area around Salt Lake, in the proposed Holthouse Reservoir footprint, along the route for the proposed Delevan Pipeline, and possibly along portions of the GCID Canal. No occurrences of vernal pool smallscale were found during Project surveys.

Big-scale balsamroot (*Balsamorhiza macrolepis* var. *macrolepis*)

Big-scale balsamroot is a CNPS List 1B species, considered to be “fairly endangered in California.” This herbaceous perennial in the sunflower family (Asteraceae) grows from a coarse woody rootstock, with basal leaves and several flowering stems four to 16 inches tall. It flowers from March to June, and is found on rocky slopes with chaparral and in foothill woodland and grasslands, often on serpentine substrates from 300 to 4,600 feet (90 to 1,400 meters) elevation (CNPS, 2010). There are 25 occurrences recorded for Big-scale balsamroot, scattered in the Coast Ranges from Tehama County in the North Coast Ranges south to Santa Clara County in the South Coast Ranges, and in the Sierra Nevada foothills from Butte County to Mariposa County (DFG, 2009b). Most occurrences are thought to still exist. The populations nearest to the Primary Study Area are 7.5 miles to the southwest of the proposed Sites Reservoir footprint on serpentine substrate along Walker Ridge. Potential habitat exists in the canyons along the western edges of the Primary Study Area, but no occurrences of this species were found during Project surveys.

Round-leaved filaree (*California macrophylla*)

Round-leaved filaree, a recent addition to CNPS List 1B, is considered to be “seriously endangered in California”. At the time of Project surveys, this species was on List 2 and considered to be “rare or endangered in California but more common elsewhere.” This species is identified as *Erodium macrophyllum* in The Jepson Manual (Hickman, 1993). This low-growing annual to biennial forb in the geranium family (Geraniaceae) grows up to six inches tall, and blooms from March through May. Flowers and fruits are needed for identification to distinguish Round-leaved filaree from look-alike relatives. It is found in heavy clay soils in open foothill savannas and grasslands from 50 to 3,900 feet

(15 to 1,200 meters) elevation (CNPS, 2010). Prior to the start of Project field surveys, Round-leaved filaree was known from 74 occurrences in an extensive California range throughout most Coast Range counties, from southern Tehama County to the Mexican border. As of 2009, it is known from 115 occurrences statewide (DFG, 2009b). However, many occurrences are historic, on private lands, and have not been confirmed for decades. Grazing, urbanization, habitat alteration, vehicles, pipeline construction, feral pigs, and invasive weeds are the main existing threats to this species (CNPS, 2010). Prior to Project surveys, the nearest confirmed occurrence was 30 miles south of the Primary Study Area; three others to the north and east date to the early 1900s. One new occurrence of Round-leaved filaree was found during Project surveys in the hills immediately west of the proposed Sites Reservoir. Potential habitat for this species is common in that area.

Pink creamsacs (*Castilleja rubicundula* ssp. *rubicundula*)

Pink creamsacs is a CNPS List 1B species, considered to be "fairly endangered in California." This small, but showy, annual herb in the figwort family (Scrophulariaceae) flowers from April to June. It is found in annual grassland, sometimes associated with seeps and ponds, and with chaparral in foothill woodlands from 65 to 3,000 feet (20 to 900 meters) elevation (CNPS, 2010). There are 18 occurrences recorded for Pink creamsacs, scattered around the grasslands and foothills in and around the Sacramento Valley in Butte, Shasta, Glenn, Colusa, Lake, and Napa counties, with an outlier population 175 miles south of the Primary Study Area in southern Santa Clara County (DFG, 2009b). Most occurrences are thought to still exist. Existing threats to this species include grazing, mining, vehicles, and road construction. The populations nearest to the Primary Study Area are four to eight miles west of the proposed Sites Reservoir. Potential habitat for Pink creamsacs exists in many locations of the Primary Study Area, but no occurrences of this species were found during Project surveys.

Pappose tarplant (*Centromadia parryi* ssp. *parryi*)

Pappose tarplant, a recent addition to CNPS List 1B, is considered to be "fairly endangered in California." This species is identified as *Hemizonia parryi* ssp. *parryi* in The Jepson Manual (Hickman, 1993). This coarse annual herb in the sunflower family (Asteraceae) flowers from May to November. It is found in seeps, springs, and other vernally wet places, often alkaline, in valley and foothill grasslands, coastal prairie, and chaparral from 6 to 1,400 feet (2 to 420 meters) elevation (CNPS, 2010). Pappose tarplant is known from 23 occurrences scattered through the southern Sacramento Valley, southern North Coast Ranges, and in the San Francisco Bay region (DFG, 2009b). Approximately half of the occurrences are in Solano County. There is one occurrence each in Butte, Glenn, and Lake counties. All of the occurrences are thought to still exist. Threats to pappose tarplant include agriculture, competition, development, grazing, habitat disturbance, and road maintenance. Prior to surveys conducted for this Project, the populations nearest to the Primary Study Area were 7.5 miles west and 17.5 miles southwest of the proposed Sites Reservoir footprint, and 12 miles east of the proposed Delevan Pipeline Intake Facilities on the Sacramento River. One new occurrence was discovered during Project surveys, the first for Colusa County, in the vicinity of (but not within) the proposed Delevan Pipeline route, between the GCID and T-C canals. Potential habitat for pappose tarplant exists around Salt Lake, along the route for the proposed Delevan Pipeline, in the proposed Holthouse Reservoir footprint, and possibly adjacent to some of the GCID Canal, but no other occurrences of this species were found during Project surveys.

Stony Creek spurge (*Chamaesyce ocellata* ssp. *rattanii*)

Stony Creek spurge is a CNPS List 1B species, considered to be "fairly endangered in California." This flat mat-forming annual forb in the spurge family (Euphorbiaceae) grows one to three inches tall, flowers from May to October, and is endemic to California. It is found in openings in grassland and chaparral from 280 to 2,600 feet (85 to 800 meters) elevation (CNPS, 2010), mostly on Lodo shale substrates, but also on creek gravels. Twenty-five occurrences have been recorded for Stony Creek spurge, tightly clustered only in Tehama and Glenn counties (DFG, 2009b). Most occurrences are presumed to still exist. Occurrences nearest the Primary Study Area are more than 10 miles to the northwest, near Stony Gorge Reservoir. Twelve new occurrences of Stony Creek spurge were found during Project surveys in the Newville vicinity, approximately 35 miles north of the Primary Study Area. No potential habitat for Stony Creek spurge exists in the Primary Study Area.

Dwarf soaproot (*Chlorogalum pomeridianum* var. *minus*)

Dwarf soaproot is a CNPS List 1B species, considered to be "fairly endangered in California." This herbaceous perennial member of the lily family (Liliaceae) sends up new leaves and a flowering stem each year from an underground bulb. It flowers from May to August. Dwarf soaproot is found with chaparral on serpentine substrates within oak woodlands and foothill grasslands from 1,000 to 3,300 feet (305 to 1,000 meters) elevation (CNPS, 2010). There are 18 occurrences, 14 of them in the North Coast Ranges and the other four occurrences 250 miles to the south in the South Coast Ranges of San Luis Obispo County (DFG, 2009b). All occurrences are thought to still exist. The populations nearest to the Primary Study Area are seven miles to the west on serpentine substrate southeast of East Park Reservoir. There is no serpentine substrate within the Primary Study Area. Although the plant communities supporting dwarf soaproot exist in many parts of the Primary Study Area, no occurrences of this species were found during Project surveys.

Deepscarred cryptantha *(Cryptantha excavata)*

Deepscarred cryptantha is a CNPS List 1B species. It is considered to be "not very endangered in California" despite being known from five or fewer occurrences, four of which date back to the early 1900s. This annual member of the borage family (Boraginaceae) grows to three to 12 inches tall, with few to several branches. It flowers in April and May. Deepscarred cryptantha is found in sandy crumbly shale or gravelly non-serpentine soil, within foothill oak woodlands, sometimes on dry streambanks, from 300 to 1,500 feet (100 to 500 meters) elevation (CNPS, 2010). This species occurs in the inner North Coast Ranges in Colusa, Lake, Mendocino, and Yolo counties (CNPS, 2010). There are three occurrences in Colusa and Mendocino counties (DFG, 2010a). All occurrences are thought to still exist; however, they were last seen in the late 1800s, or 1968 (most recent). There are five specimens that are known to exist: one specimen from 1903 in Yolo County, two from the late 1800s from Lake County, and two from Colusa County (U.C. Consortium, 2011). Of the two specimens from Colusa County, one 1968 collection is from near Wilbur Springs; the other is a late 1800s Katherine Brandegee collection from "Stites, Colusa Co.". This location may be at Stites Spring, southeast of East Park Reservoir (DFG, 2010a). If so, it is the population nearest to the Primary Study Area (approximately five miles to the west). Although the plant communities and soils supporting deepscarred cryptantha may exist in many parts of the Primary Study Area, no occurrences of this species were found during Project surveys.

Recurved larkspur (*Delphinium recurvatum*)

Recurved larkspur is a CNPS List 1B species, considered to be "fairly endangered in California." This herbaceous perennial member of the buttercup family (Ranunculaceae) sends up new leaves and a flowering stem each year from a shallow rootstock (although not during some drought years). It flowers from March to June. Recurved larkspur is found in somewhat alkaline areas in grasslands, foothill woodlands, and saltbush scrub at elevations from 10 to 2,460 feet (3 to 750 meters) (CNPS, 2010). There are 79 reported occurrences, the vast majority of which are from the San Joaquin Valley and the adjacent South Coast Ranges (DFG, 2010a). In the Sacramento Valley, there is one occurrence each reported from Butte, Glenn, and Colusa counties. Most occurrences are thought to still exist, although many of them have not been re-visited for many years. In the Sacramento Valley, the Butte County site is considered to be extirpated. The other locations were last seen in the 1930s to 1940s. Existing threats to the species include agricultural conversion and grazing. The populations of recurved larkspur nearest to the Primary Study Area are 13 miles south of the Primary Study Area near the southernmost end of Antelope Valley. Potential habitat may be found in the Primary Study Area in low-lying alkaline areas, especially along the route for the proposed Delevan Pipeline, and possibly in the proposed Holthouse Reservoir footprint. No occurrences of this species were found during Project surveys.

Norris' beard-moss (*Didymodon norrissii*)

Norris' beard-moss is a CNPS List 2 species, considered to be "fairly endangered in California" although more widely distributed outside California. This moss is a member of the family Pottiaceae, and grows on rocks, outcrops, fields and cliffs. Norris' beard-moss has been found on serpentine substrates and basalt rock surfaces in intermittently moist open grassland, in grassy openings in oak woodland, conifer forest, and chaparral, at elevations from 600 to 4,500 feet (200 to 1,500 meters) (USDA, 2008). There are 40 occurrences of this taxon, known from several counties throughout California, including Colusa and Lake counties (DFG, 2010a). The nearest known occurrence is from serpentine rock at the head of Doyle Canyon, approximately 12 miles southwest of the Primary Study Area. Suitable non-serpentine habitat probably occurs in scattered woodland sites in the west edge of the Primary Study Area. However, this taxon had not yet been reported from within the Project vicinity, so was not included in 1998 to 2002 Project surveys.

Brandegee's eriastrum *(Eriastrum brandegeeae)*

Brandegee's eriastrum is a CNPS List 1B species, considered to be "fairly endangered in California." This small upright annual forb in the phlox family (Polemoniaceae) grows from two to 12 inches tall, blooms from April through August, and is endemic to California. It is found mainly in dry Lodo shale/decomposing mudstone transition soils, but also in gravelly greenstone, volcanic, and serpentine-derived soils from 1,000 to 3,300 feet (305 to 1,030 meters) elevation (CNPS, 2010). Habitat consists of very sparse dry open foothill pine/chaparral vegetation. Its appearance is very similar to other uncommon and co-occurring members of its genus. Prior to Project field studies, Brandegee's eriastrum was known to occur in a restricted range at the eastern edge of the inner Coast Range, consisting of 47 occurrences in a band approximately 120 miles long and 10 to 15 miles wide, from the junction of Shasta, Trinity and Tehama counties to Lake County, with one disjunct (distantly separated) occurrence in Santa Clara County (DFG, 2009b). Abundance within occurrences varies widely from a few individuals to several hundred or 1,000 individuals. Approximately half of known occurrences are on federal (BLM or Mendocino National Forest) land and half are on private lands. Grazing, road work, and development are the main existing threats to this species. Prior to Project surveys, the nearest known occurrences were five to six miles west of the proposed Sites Reservoir. Three new occurrences of Brandegee's eriastrum were found during 2001 to 2002 surveys in the Newville area, approximately 35 miles north of the Primary Study Area. No occurrences or potential habitat for Brandegee's eriastrum exist in the Primary Study Area.

Tracy's eriastrum *(Eriastrum tracyi)*

During Project surveys, Tracy's eriastrum was considered to be the same species as Brandegee's eriastrum, and has only very recently been classified as a separate species (U.C., 2001). The discussion of Brandegee's eriastrum also applies to Tracy's eriastrum.

Snow Mountain buckwheat *(Eriogonum nervulosum)*

Snow Mountain buckwheat is a CNPS List 1B species, considered to be "fairly endangered in California." This annual herb in the buckwheat family (Polygonaceae) flowers from June to September. It is found on dry serpentine outcrops and other barren stony sites in chaparral, from 980 to 7,000 feet (300 to 2,105 meters) elevation (CNPS, 2010). There are 12 known occurrences of Snow Mountain buckwheat scattered through Colusa, Lake, Sonoma, and Yolo counties (DFG, 2009b). Eleven of these occurrences are thought to still exist. Existing threats to this species include energy development, mining, and vehicles. The occurrences nearest to the Primary Study Area are seven miles to the west. There is no serpentine substrate within the Primary Study Area, although the plant communities supporting Snow Mountain buckwheat exist in many parts of the Primary Study Area. No occurrences of this species were found during Project surveys.

Diamond-petaled California poppy *(Eschscholzia rhombipetala)*

Diamond-petaled California poppy is a CNPS List 1B species, considered to be "seriously endangered in California." This annual herb in the poppy family (Papaveraceae) flowers from March to April. It is found on clay slopes and flats of valley and foothill grasslands, often somewhat alkaline, from zero to 3,200 feet (zero to 975 meters) elevation (CNPS, 2010). Diamond-petaled California poppy has a scattered distribution, with occurrences in Colusa County in the north, Contra Costa, Alameda, San Joaquin, and Stanislaus counties in the central part of its range, and in San Luis Obispo County to the south. There are 10 occurrences, all of which are considered to still exist (DFG, 2010a). Diamond-petaled California poppy is listed as extirpated in Colusa County, as well as in Contra Costa and Stanislaus counties (CNPS, 2010). Existing threats to Diamond-petaled California poppy include agriculture and grazing. Potential habitat exists in many parts of the Primary Study Area, but no occurrences of this species were found during Project surveys.

Adobe lily (*Fritillaria pluriflora*)

Adobe Lily is a CNPS List 1B species, considered to be "fairly endangered in California." This perennial bulb-forming herb in the lily family (Liliaceae) grows from five to 16 inches tall, blooms from February through April, and is endemic to California. It is found in heavy clay soils, in open grassland, and at semi-shaded blue oak/foothill pine/chaparral woodland edges, at elevations from 200 to 2,300 feet (60 to 705 meters) (CNPS, 2010). Prior to Project surveys, Adobe Lily was known to occur in a restricted range of 97 occurrences in narrow bands along the west and east sides of the Sacramento Valley, from Tehama County to Solano County on the west side, and from Tehama County to Butte County on the east side (DFG, 2010a). Abundance within occurrences varies widely from a few individuals to several hundred or 1,000 individuals. Several known occurrences are on federal (BLM or USFS) land or preserves (TNC Vina Plains), but most are on private lands. Grazing, road work, and off-road recreation are the main threats to this species. Prior to Project surveys, the nearest known occurrences of Adobe Lily were four miles west of the Primary Study Area. Eighteen new occurrences of adobe lily were found during Project surveys, with five occurring at the west edge of the Primary Study Area, and the remaining 13 occurrences located farther north in the Newville area (northern Glenn County and southern Tehama County). Potential habitat for adobe lily exists in the hills to the west of the proposed Sites Reservoir footprint.

Hall's harmonia (*Harmonia hallii*)

Hall's harmonia is a CNPS List 1B species, considered to be "seriously endangered in California." This annual herb in the sunflower family (Asteraceae) flowers from April to June. This species is identified as *Madia hallii* in The Jepson Manual (Hickman, 1993). It is found on serpentine soils, in openings in chaparral, from 1,600 to 3,000 feet (500 to 900 meters) elevation (CNPS, 2010). Hall's harmonia is known from 16 occurrences, from within a 250-square-mile area of the North Coast Ranges in Colusa, Lake, Napa, and Yolo counties (DFG, 2010a). All occurrences are thought to still exist. Existing threats to the species include mining activities. The occurrences of Hall's harmonia nearest to the Primary Study Area are 6.5 miles to the southwest on Walker Ridge. There is no serpentine substrate within the Primary Study Area, although the plant communities supporting Hall's harmonia exist along the western parts of the Primary Study Area. No occurrences of this species were found during Project surveys.

Drymaria-like western flax *(Hesperolinon drymarioides)*

Drymaria-like western flax is a CNPS List 1B species, considered to be "fairly endangered in California." This delicate annual herb in the flax family (Linaceae) flowers from May to August. It is found on serpentine soils, mostly within chaparral, and within foothill woodlands and grasslands from 320 to 3,700 feet (100 to 1,130 meters) elevation (CNPS, 2010). Drymaria-like western flax is known from 20 occurrences in the inner North Coast Ranges of Colusa, Glenn, Lake, Napa, and Yolo counties (DFG, 2010a). All occurrences are thought to still exist. Existing threats to the species include mining and vehicles. The occurrences of drymaria-like western flax nearest to the Primary Study Area are seven miles to the west along Walker Ridge. There is no serpentine substrate within the Primary Study Area, although the plant communities supporting drymaria-like western flax exist along the western parts of the Primary Study Area. No occurrences of this species were found during Project surveys.

Woolly rose-mallow or California hibiscus *(Hibiscus lasiocarpos* ssp. *occidentalis)*

Woolly rose-mallow or California hibiscus, a recent addition to CNPS List 1B (Hill, 2011), is considered to be "fairly endangered in California." This herbaceous perennial member of the mallow family (Malvaceae) sends up clusters of new stems three to six feet tall each year from underground rhizomes. It flowers from June to September, but plants can generally be recognized much of the year. It is found on wet banks of streams and freshwater marshes from zero to 400 feet (zero to 120 meters) elevation (CNPS, 2010). Woolly rose-mallow or California hibiscus is known from 134 occurrences in California, in low-lying areas of the Central Valley from Butte County to San Joaquin County (DFG, 2010a). Most of the occurrences are concentrated in the northern and southern ends of the range. All California occurrences are thought to still exist. Existing threats to this sub-species include development, agriculture, recreation, and channelization of the Sacramento River and its tributaries. Occurrences of woolly rose-mallow or California hibiscus nearest to the Primary Study Area are along the Sacramento River and along Butte Creek five miles east of the proposed Delevan Pipeline Intake Facilities. One occurrence has also been found in the Sacramento NWR, five miles north of the proposed Delevan Pipeline route (Oswald, 2002). Potential habitat exists in the Primary Study Area in wet low-lying areas, but no occurrences of this species were found during Project surveys.

Coulter's goldfields (*Lasthenia glabrata* ssp. *coulteri*)

Coulter's goldfields is a CNPS List 1B species, considered to be "seriously endangered in California." This short annual herb in the sunflower family (Asteraceae) flowers from February to June. It is found in vernal pools and other vernally wet places, including coastal salt marshes in southern California from 3 to 4,000 feet (1 to 1,220 meters) elevation (CNPS, 2010). Coulter's goldfields is known from 66 occurrences; 65 are located in the southern third of California (DFG, 2010a). The one northern California occurrence, in Colusa County, is represented by two collections from 1917 and 1926 from alkali plains west of Colusa (DFG, 2011); the species has not been seen in Colusa County since, though it is thought to still exist. One occurrence is reported (for 1987) from The Nature Conservancy's Vina Plains Preserve in Tehama County (CalFlora, 2011). Approximately half of the occurrences in southern California have been extirpated by the growth of the metropolitan areas in the Los Angeles basin and in Bakersfield. Threats to the species include urbanization and agricultural development. The species is known to have declined significantly by 1966 (CNPS, 2010). The Colusa County location of Coulter's goldfields is 10 miles south of the proposed Delevan Pipeline route; therefore, potential habitat may exist in parts of the Primary Study Area along the route for Delevan Pipeline, and possibly in the proposed Holthouse Reservoir footprint; however, no occurrences were found during Project surveys in these areas.

Colusa layia (*Layia septentrionalis*)

Colusa layia is a CNPS List 1B species, considered to be "fairly endangered in California." This short annual herb in the sunflower family (Asteraceae) flowers in April and May. It is found in chaparral, oak woodlands, and valley and foothill grasslands, often on serpentine substrates, from 325 to 3,600 feet (100 to 1,095 meters) elevation (CNPS, 2010). Colusa layia is known from 44 occurrences, most of which are scattered in the inner North Coast Ranges from Tehama County to Napa County, with a couple of isolated Sacramento Valley sites in Colusa and Sutter counties (DFG, 2010a). Almost all occurrences are thought to still exist, although one-third of them have not been re-visited in over 50 years, including the two sites in the Sacramento Valley. The main existing threat to the species is development. The two occurrences of Colusa layia nearest to the Primary Study Area are four to six miles to the west, around East Park Reservoir and by the Sites Lodoga Road west of Grapevine Pass. Potential habitat exists in many parts of the Primary Study Area, but no occurrences of this species were found during Project surveys.

Heckard's pepper-grass (*Lepidium latipes* var. *heckardii*)

Heckard's pepper-grass is a CNPS List 1B species, considered to be "fairly endangered in California." This short annual herb in the mustard family (Brassicaceae) flowers from March through May. It is found in alkaline flats in valley and foothill grasslands from 30 to 650 feet (10 to 200 meters) elevation (CNPS, 2010). Heckard's pepper-grass is known from 11 Sacramento Valley occurrences, in Glenn, Solano, and Yolo counties (DFG, 2010a). All occurrences are thought to still exist. All of the Glenn County occurrences are on the Sacramento NWR, four miles north of the proposed Delevan Pipeline route. Potential habitat exists in the Primary Study Area in low-lying areas, especially along the route for the Delevan Pipeline, and possibly in the proposed Holthouse Reservoir footprint; however, no occurrences of this species were found during Project surveys.

Red-flowered lotus *(Lotus rubriflorus)*

Red-flowered lotus is a federal Species of Special Concern and a CNPS List 1B species, considered to be "seriously endangered in California." This low-growing small annual herb in the legume family (Fabaceae) grows up to four inches tall, blooms from April through June, and is endemic to California. It is found mostly in vernally moist heavy clay soils, at blue oak/foothill pine/chaparral-grassland edges at elevations from 650 to 1,400 feet (200 to 425 meters) (CNPS, 2010). Red-flowered lotus is known from only four widely-separated occurrences in the low foothills off the west edge and northeast edge of the Sacramento Valley in Tehama, Colusa, and Stanislaus counties (DFG, 2010a). Abundance within these occurrences varies from a few to thousands of individuals. All known occurrences are on private lands or utility corridors. Development, grazing, and invasive weeds are the main existing threats to this species.

Prior to Project surveys, the nearest known occurrences of red-flowered lotus were approximately seven miles west of the Primary Study Area. Eight new occurrences of red-flowered lotus were found during 2001 to 2002 surveys, with six occurrences near the west edge of the Primary Study Area and two occurrences in the Newville area, approximately 35 miles north of the Primary Study Area (southwest Tehama County). These sites fill a major distribution gap for this species and triple the number of known occurrences. Potential habitat for red-flowered lotus is common in the hills to the west of the proposed Sites Reservoir footprint.

13.2.3.4 Vegetation Communities

The Primary Study Area falls within the Jepson Manual's "Inner North Coast Range" geographic subdivision of the California Floristic Province (Hickman, 1993), as well as the western edge of the "Sacramento Valley" subdivision of the Manual's Great Valley floristic region.

Vegetation communities are described as they typically occur over much of the northern half of California, where vegetation is strongly influenced by precipitation, temperature, soils, aspect, slope, disturbance history, and elevational changes. This area is characterized by a Mediterranean climate of hot dry summers and moderately cold wet winters. Approximately 95 percent of the annual precipitation occurs during the winter months and is influenced by the "rain shadow" of the North Coast Ranges along the west edge of the Primary Study Area. Soils of mainly marine-sedimentary origin also influence vegetation patterns within the Primary Study Area.

Localized sites in the foothills support fire-dependent stands of chamise chaparral, as well as more diverse mixed chaparrals. Unique habitats that support specialized plant associations include the vernal pools and swales found on valley floors or clay terraces, and low-elevation saline/alkaline flats. Unique plant associations adapted to certain soil types include the endemic serpentine floras (sets of plants restricted to serpentine substrates) found mostly in lower Coast Range slopes immediately west of the Primary Study Area, but also occasionally found on Lodo shale and other crumbly shale in the lower foothills within the Primary Study Area. Bear Valley, which is situated between the foothills in western Colusa County just south of the Primary Study Area, supports spring wildflower displays on its partly serpentinite-derived alluvium.

Vegetation communities in the vicinity of the Primary Study Area vary from riparian forest/scrub along the Sacramento River and its tributaries to mainly agricultural lands and occasional annual grass/forbland in the Sacramento Valley. Further west are blue oak savanna or woodland on the low foothills and mixed oak/gray pine/ chaparral shrub communities in the lower slopes of the Coast Range, and finally transitioning into mixed conifer forest in the upper Coast Range elevations.

Vegetation communities mapped on land surrounding proposed Project features include five natural vegetative community types and one non-native community Natural communities include grassland, chaparral/shrubland, blue oak woodland, valley oak woodland, and riparian forest/woodland; agriculture comprises the non-native community. These broad communities contain 12 more specific plant associations, or vegetation types (Figure 13-2); also mapped were other land cover types, such as canals, ponds, and urbanized areas. Unique habitats supporting specialized plant associations include the vernal pools and swales found on valley floors or clay terraces, and low- elevation saline/alkaline flats. These are mapped as part of the grassland community (also refer to Chapter 15 Wetlands and Other Waters of the U.S. addressing wetlands, such as vernal pools or alkaline wetlands). Unique plant associations adapted to certain soil types include the endemic serpentine floras (sets of plants restricted to serpentine substrates) found mostly in lower Coast Range slopes, but these species also occasionally occur on the Lodo shale and other crumbly shales in the lower foothills, especially as part of the chaparral/shrubland community. No serpentine soils or flora are located within the Primary Study Area; soils derived from shale are found on some of the hillslopes in the Primary Study Area.

Grassland

The mapping unit termed "Annual grassland" corresponds roughly to the "California Annual Herbland" alliance in Sawyer et al. (2009), with some elements of Associations dominated by brome *(Bromus)* and wild oats *(Avena)*. Annual grassland best fits the description for the Annual Grassland (AGS) WHR habitat type. It is typically dominated by introduced (non-native) annual grass species, such as wild oats (*Avena* spp.), barleys (*Hordeum* spp.), and ryegrass (*Lolium* spp.), with a small minority (less than 15 percent relative cover) of native perennial species. This vegetation community also supports areas of native herbaceous spring annuals, sometimes called "wildflower fields," and native perennial bunchgrasses, such as hook three-awn (*Aristida ternipes* ssp. *hamulosa*) or needlegrass (*Nassella* spp.). Trees comprise less than 10 percent total cover, with occasional small groupings or individuals of valley or blue oaks. Areas dominated by noxious weeds, such as yellow star-thistle (*Centaurea solstitialis*), are common. The annual grassland vegetation community dominates valley bottomlands and rolling hills immediately adjacent to the valleys. It can make a slow transition into adjacent wooded areas by forming a mosaic, occurring as understory in open oak savanna, or can transition abruptly to woodland. Within the grassland vegetation type, vernal pools and swales occurring over clay hardpans, or vernally moist saline or alkaline soils on the valley floor, may support unique native floras that sometimes include several distinctive special-status plant species. Annual grassland comprises 45 percent of the mapped vegetation in the Primary Study Area (Figure 13-2), and approximately 75 percent of the Project's construction disturbance area (Table 13-6). Annual grassland is common throughout California; this community in the Primary Study Area represents less than 1 percent of the state's annual grasslands.

Area vegetated by annual grassland can vary over the years as more or less acreage is converted to agriculture within the Primary Study Area. For example, in the 12 years between the 1997 aerial imagery used for Project vicinity mapping and the 2009 National Agricultural Imagery Program (NAIP) imagery, over 200 acres of grassland were converted to agriculture (all dryland grain) inside the proposed Sites Reservoir footprint area, and approximately 1,000 acres outside of the proposed Sites Reservoir (northeast of Funks Reservoir) were converted, mostly to dryland grain, and also to rice, orchards, and irrigated fields (DWR, 2004).

Table 13-6
Vegetation Types within the Primary Study Area

Vegetation Type	Acreage	
	Primary Study Area[a]	Percent of Primary Study Area Total
Annual grassland	14,765.0	75.4
Alkaline wetland	14.0	0.1
Blue oak woodland	831.5	4.2
Blue oak savanna	645.9	3.3
Blue oak/Mixed chaparral	54.5	0.3
Canal	22.4	0.1
Chamise	2.5	0[b]
Crops/agriculture	2,964.8	15.1

Table 13-6
Vegetation Types within the Primary Study Area

Vegetation Type	Acreage	
	Primary Study Area[a]	Percent of Primary Study Area Total
Fremont Cottonwood riparian	1.1	0.0[b]
Freshwater marsh	4.5	0.0[b]
Open water	1.6	0.0[b]
Mixed Chaparral	2.6	0.0[b]
Ponds	28.8	0.2
Urban/Disturbed	136.8	0.7
Valley-foothill riparian	86.0	0.5
Valley oak riparian	26.5	0.1
Valley Oak Woodland	3.5	0.0[b]
TOTAL	**19,592.0**	**100**

[a]The Primary Study Area includes the proposed Alternative C facility footprints, and the construction disturbance area for the Road Relocations, Delevan Transmission Line, Delevan and TRR pipelines, TRR to Funks Creek Pipeline, Holthouse to T-C Canal Pipeline, and GCID Canal Facilities Modifications. This total does not include acreage occupied by existing facilities, namely Funks Reservoir and the GCID Canal, or other proposed facilities that include no affected natural vegetation communities.

[b]Represents less than 0.1 percent of total.

Chaparral/Shrubland

Shrub-dominated vegetation communities consist mainly of chaparral types that are either dominated by chamise (*Adenostoma fasciculatum*) or that are a mixed chaparral composed of a diverse assemblage of species such as manzanita (*Arctostaphylos* spp.), buckbrush (*Ceanothus cuneatus*), scrub oak (*Quercus berberidifolia*), and poison oak (*Toxicodendron diversilobum*). Both vegetation types are sometimes found with an overstory of sparsely scattered blue oaks and/or gray pines. The chamise type usually occurs as nearly pure stands or with a minor component of buckbrush, and is found in small and large patches in the Coast Range foothills at the west edge of the Primary Study Area. Mixed chaparral is also sporadically distributed in the low foothills at the western edge, but is more common among the higher wooded hills farther to the west. Both types are often interspersed within a mosaic of blue oak woodlands and grassland openings. On substrates of decomposing shale, the mixed chaparral community occasionally includes some California juniper (*Juniperus californicus*) and may contain several special-status plant species. The chamise vegetation type comprises four percent of the vegetation mapped around the Primary Study Area (Figure 13-2), and less than one percent of the state's patchy, but extensive, chamise shrubland. Mixed chaparral accounts for approximately one percent of vegetation mapped around the Primary Study Area. Both types of chaparral/shrublands occupy less than one percent of the Project's construction disturbance area. Such non-chamise-dominated chaparral shrublands are not rare in the state, but are distributed in bands and discontinuous patches that vary in species composition geographically. This vegetation within the Primary Study Area represents less than one percent of the state's mixed chaparral shrublands.

Blue Oak Woodland

The blue oak woodland vegetation community, dominated by blue oak (*Quercus douglasii*), is the most common vegetation in the low foothills in the western portion of the Primary Study Area. These woodlands vary from open grassy stands of blue oaks on south facing slopes and ridge tops to moderately to very dense stands of small blue oak trees mixed with interior live oak (*Quercus wislizenii*) on north facing slopes. In the low foothills, the woodlands can also include some chaparral species and/or an open overstory of sparsely scattered Gray pines (*Pinus sabiniana*). Special-status plant species are sometimes found in clay or crumbly shale soils where grasslands transition into woodlands, or where chaparral shrubs are present as a woodland understory. Weedy areas often contain localized infestations of Italian thistle (*Carduus pycnocephalus*). Approximately 20 percent of the vegetation mapped around the Primary Study Area is blue oak woodland of varying density; more than half of this woodland includes an extensive mixed chaparral understory (Figure 13-2). Blue oak woodland, with and without a chaparral understory, accounts for approximately seven percent of the Project's construction disturbance area (Table 13-6). Blue oak woodland in the Primary Study Area represents one percent of the state's existing blue oak woodlands. Blue oak woodland with gray pine represents less than one percent of the vegetation in the Primary Study Area, and much less than one percent of this vegetation type in the state. The character of blue oak woodland in the Primary Study Area has changed during the 12 years from 1997 to 2009. A comparison of the hillslopes in the 1997 aerial imagery used for mapping the vegetation for this analysis to the same slopes in the 2009 NAIP imagery shows that many acres of moderately dense blue oak woodland have been converted to open grassland or extremely sparse oak savanna, due to cutting for firewood. At least 2,000 acres of mapped vegetation in the Primary Study Area have been affected, located mostly on the hillslopes around the northwest corner of the proposed Sites Reservoir footprint.

Valley Oak Woodland

Valley oak woodland and savanna (dominated by Valley oak (*Quercus lobata*) are occasionally found on stream terraces where the larger creeks emerge from the foothills onto the valley floors. These areas, with scattered large individual trees or with denser stands closer to creeks, are not common or very large in the Primary Study Area. Weedy areas within valley oak woodlands include localized patches of Milk thistle (*Silybum marianum*), Bull thistle (*Cirsium vulgare*), Italian thistle *(Carduus* spp.*)*, or star thistle (*Centaurea* spp.). Some of the valley oak woodlands can be very disturbed by livestock and ranching activities because these operations tend to concentrate in the larger valley bottoms where most of these woodlands are found. No special-status plant species are known from this vegetation community within the region. Valley oak woodlands account for a fraction of one percent of the vegetation mapped around the Primary Study Area and Project construction disturbance area vegetation, and also account for less than one percent of the Valley Oak woodland in the state.

Riparian

Riparian forest or woodland is found intermittently in the Primary Study Area, usually as very narrow strips, with the exception of larger areas along the edges of the Sacramento River. These narrow strips are most frequently found along creeks and near springs higher than the coast range foothills up and away from the valley floors. Riparian vegetation can be dominated by Fremont cottonwood (*Populus fremontii*), occasionally by Valley oak (*Quercus lobata*), by tree willows (*Salix gooddingii*, *S. laevigata*) or shrubby willows (*S. exigua* and others), often with a varied shrub, vine, and herbaceous understory. Most of the patches of riparian habitat within the Primary Study Area (including springs) are small, sparse, and degraded by intensive cattle use. This disturbed riparian habitat does not support special-status plant species. Intermittent creeks across interior valley floors tend to be almost barren or lined by narrow interrupted strips of sparse riparian vegetation. Many of the larger trees along these disturbed creeks are not native, such as walnut (*Juglans* spp.), fig (*Ficus carica*), and tree-of-heaven (*Ailanthus altissima*).

Well-developed multiple-storied native riparian vegetation occurs in small remnant patches along foothill portions of a few of the Primary Study Area's larger creeks, and in a few large patches along the Sacramento River.

The riparian woodland vegetation community comprises less than one percent of the vegetation mapped around the Primary Study Area, and less than one percent of the Project's construction disturbance area. Riparian vegetation communities are not common in the rest of the state relative to other vegetation communities; riparian vegetation within the Primary Study Area represents approximately 0.4 percent of the state's riparian woodlands.

Freshwater Marsh

Marsh (freshwater), or emergent wetland, occurs in two places in the Primary Study Area: in a strip along the northern edge of the Delevan National Wildlife Refuge (NWR), and very infrequently at edges of riparian areas, ponds, or irrigation ditches. Other than the Delevan NWR strip, this community was rarely mapped in the Primary Study Area, due to the extremely small size of marshy sites. Freshwater marsh/emergent wetland is typically dominated by cattails (*Typha* spp.), rushes (*Scirpus* spp.) and sometimes sedges (*Carex* spp.) and spikerush (*Eleocharis* spp.), and often has patchy willow shrubs (*Salix* spp.). The strip of managed wetland along the Delevan NWR boundary consists of both wet and temporarily dry areas, depending on where water is directed. Freshwater marsh accounts for less than one percent of the vegetation mapped around the Primary Study Area and also within the Project's construction disturbance area.

Alkaline Wetland

Alkaline (and probably weakly saline) marsh and wetlands are present at two locations within the Primary Study Area: one parcel north of the Delevan NWR within the Delevan Pipeline construction disturbance area, and a second site located southeast of Funks Reservoir. Alkaline marshes support many of the same species as in freshwater marsh (such as spikerush, rush), but also support a unique flora (such as saltgrass [*Distichlis spicata*]) tolerant of saline and alkaline conditions. These wetlands are a remnant of a much more extensive patchwork of saline/alkaline wetlands that once existed on the Central Valley floor and western edges, and can support several sensitive plant species. Alkaline wetland accounts for less than one percent of the vegetation mapped around the Primary Study Area and also within the Project's construction disturbance area. Wetlands are considered in more detail in Chapter 15 Wetlands and Other Waters of the U.S.

Agriculture

Agriculture accounts for much of the land cover in the Sacramento Valley between the Sacramento River and the Coast Range foothills. In addition, the smaller interior valleys have scattered hayfields, pastures, and small orchards. Crops on larger farms include rice, irrigated grains and row crops, pastures, hayfields, and deciduous orchards. Agricultural lands account for 27 percent of the vegetation around the Primary Study Area, as originally mapped for this Project in 2002. Because this land cover type is so extensive in California, the agricultural lands within the Primary Study Area represent only a fraction of one percent of the state's total agricultural land. Agricultural fields account for approximately 16 percent of the Project's construction disturbance area.

Agricultural land uses contract and expand over time, and the type of crop under cultivation can change in any given year. GIS analysis of the Primary Study Area over 2009 NAIP imagery shows that in the years since vegetation was first mapped for this Project (2002), approximately 200 acres of annual grasslands within the proposed Sites Reservoir footprint have been converted to dryland grain fields. Outside of the proposed Sites Reservoir footprint, more than 1,000 additional acres northeast of Funks Reservoir have been converted from annual grasslands to mostly dryland grain, with smaller acreages of orchard, rice, and irrigated crops.

Vegetation mapped around the Primary Study Area (shown in Figure 13-2) was also analyzed according to distribution within the confines of proposed Project facilities, i.e., “footprints” of land within which all Project-related ground disturbance would occur. The total acreage affected by Project facilities, and the percent that each vegetation type represents of the total Project acreage, are presented in Table 13-6. Acreage totals are based on the largest Project alternative (Alternative C) and reflect baseline conditions. Acreage totals represent a combination of the facility footprints and the defined construction disturbance area for Delevan Pipeline.

Table 13-7 shows the presence of the above vegetation types within the anticipated disturbance areas for proposed Project features.

[a]Alkaline wetland in Delevan Pipeline construction disturbance area is now managed as freshwater wetland.
[b]Alkaline wetland in the Holthouse Reservoir footprint is a small part of a continuous 13-acre alkaline wetland extending to the southeast.
[c]These Project facilities disturb only areas within existing structures, so have no 'footprint' on surrounding lands.
[d]Alkaline wetland in the Delevan Pipeline construction disturbance area is managed as freshwater wetland.

13.2.3.5 Invasive Plant Species

Table 13-8 shows that 49 species of noxious weeds either are known to occur in the Primary Study Area because they were found during Project surveys, or are likely to occur there because they have been documented from Glenn or Colusa counties and occur in similar habitats. Twenty-eight of those 49 species have been identified in the Primary Study Area during botanical resource surveys for the Project. Among the species in Table 13-8 are two CDFA "A" species and eight "B" species (the State's weed categories of greatest concern for invading natural areas). Also represented are 12 species of "High" concern and 25 species of "Medium" concern for Cal-IPC in terms of invasiveness. Also included on Table 13-8 are most of the weed species of concern on the lists of the Mendocino National Forest and the local Weed Management Area.

[a]Likelihood of occurring in the Primary Study Area vicinity west of the Sacramento River
H = High; on species checklist from 1998 to 2003 plant surveys
M = Medium; not on Project survey checklist but documented from Colusa and/or Glenn County in CalFlora, CalIPC, CDFA or Oswald
[b]California Department of Food & Agriculture List of Noxious Weeds (List from Important Notice update of January, 2010):
List A - Most invasive wildland pest plants - eradication, containment, or other holding action at the State-county level
List B - Includes species less widespread and more difficult to contain - eradication, containment, control, or other holding action at the discretion of the Commissioner
List C - Weeds that are so widespread that the agency does not endorse State- or county-funded eradication except in nurseries
[c]California Invasive Plant Council (Cal-IPC, 2010) California Invasive Plant Inventory:
H = High: invasive species with most severe wildland ecological impacts, widespread
M = Moderate: invasive species with substantial wildland impacts; local to widespread
L = Low: invasive species with minor wildland ecological impacts; limited distribution, although may be locally problematic
D = Evaluated, but not listed, due to low ecological impacts
[d]On "Dirty Dozen" Noxious Weeds List for Colusa, Glenn, and Tehama County Weed Management Area (CGTWMA, 2002).
[e]On list of weed species of greatest concern and target weed species for Mendocino National Forest (Ruhl, 2006).

Nearly all plant communities within the Primary Study Area have invasive and/or noxious weeds as a component. Some habitats have more serious invasive weed infestations than others. For example, valley annual grassland has 25 to 30 percent exotic species (DWR, 2005), which may include multiple invasive species, such as ripgut (*Bromus diandrus*) or other bromes (*Bromus* spp), hedgehog dogtail (*Cynosurus echinatus*), or medusahead (*Taeniatherum caput-medusae*), resulting in adverse ecological impacts to the native grassland. Certain weed species of greatest concern tend to invade riparian habitats almost exclusively; examples are salt-cedar (or tamarisk - *Tamarix* spp.), giant reed grass (*Arundo donax*) and scarlet wisteria (*Sesbania punicea*). Others invade sensitive wetlands, marsh edges, or vernally wet areas; for example, purple loosestrife (*Lythrum salicaria*), Himalayan blackberry (*Rubus discolor*), pennyroyal (*Mentha pulegium*), tree of heaven (*Ailanthus altissima)*, or edible fig (*Ficus carica*).

Invasive plants potentially occurring in the Primary Study Area that tend to infest still waters (at riparian edges or ponds) include water hyacinth (*Eichhornia crassipes*) (a Cal-IPC "Alert" species[2]), water iris (*Iris pseudacorus*), water primrose (*Ludwigia peploides*), and hydrilla (*Hydrilla verticillata*) (a Cal-IPC "Alert" species and the only species potentially found in the Primary Study Area that is on the federal weed list). Although water primrose is the only one of these aquatic species known to occur in the Primary Study Area, the others are in the Sacramento River watershed and could infest the area at any time. Upland habitats, such as disturbed areas by roads in grassy foothill blue oak woodlands, can become infested with milk thistle (*Silybum marianum*), European olive (*Olea europaea*), California bur-clover

[2] A Cal-IPC Alert species is a species that has an urgent need for eradication.

(*Medicago polymorpha*), Klamathweed (*Hypericum perforatum*), cutleaf geranium (*Geranium dissectum*), or some of the thistles (*Cirsium* and *Centaurea* spp.), or mustards (*Brassica* spp.). Edges of agricultural fields, ranches or homesteads, and roadsides through agricultural areas are also vulnerable to infestations of many invasive weed species.

Banks and terraces along the Sacramento River near the Primary Study Area have infestations of varying sizes of giant reed grass (*Arundo donax*). Other invasive weed species found within the riparian corridor along the river include edible fig (*Ficus carica*), Himalayan blackberry (*Rubus discolor*), and occasional tree tobacco (*Nicotiana glauca*). Scarlet wisteria (*Sesbania punicea*) (a Cal-IPC "Alert" species), has been spotted along the Sacramento River and Feather River and could be spreading downstream in these watersheds into the Primary Study Area. Adjacent sloughs and backwaters along the Sacramento River often are infested by the non-native subspecies of water primrose (*Ludwigia peploides*) and other weedy species. Areas of human habitation along the river often are infested by tree of heaven (*Ailanthus altissima*).

Yellow star-thistle (*Centaurea solstitialis*) is widespread in the proposed Sites Reservoir footprint, as well as in other locations of the Primary Study Area. Many other exotic species of varying degrees of invasiveness (many rated "Moderate" on the current Cal-ICP list) occur in the extensive annual grasslands of the proposed Sites Reservoir footprint and recreation areas. Most of the grassland contains brome (*Bromus*) species and medusahead (*Taeniatherum caput-medusae*) (rated "High" in ecological impacts by Cal-IPC). Italian thistle (*Carduus pycnocephalus*) infestations appear to be spreading rapidly in the foothill canyons at the proposed Sites Reservoir's western edges. Bull thistle (*Cirsium vulgare*) and minor amounts of other thistles occur in scattered small infestations throughout the grassland-oak woodland edges of the proposed Sites Reservoir.

13.2.3.6 Special-Status Plant Species

Federal- or State-Listed Species

During field surveys, no known federal- or State-listed species were found within the Primary Study Area. However, plants observed in the western edges of the Primary Study Area in oak savanna/mixed chaparral have the potential to be identified as Keck's checkerbloom *(Sidalcea keckii)*, a federally endangered species. During field surveys, voucher collections were made for plants thought at the time to be the common northern California species fringed checkerbloom *(Sidalcea diploscypha)*. The two species are similar in appearance and habitat; until 2009, Keck's checkerbloom was understood to occur only in southern California. However, at least one of the Project survey voucher specimens has been annotated to "*cf S. keckii*" (U.C., 2004). This means that plants from this part of western Colusa County could be the federally endangered member of this look-alike pair. When ongoing molecular studies are completed, the potential for occurrence of Keck's checkerbloom in the Primary Study Area will be better understood. As of March 2011, there is some potential that Keck's checkerbloom does occur in the western edges of the Primary Study Area.

Species of Concern

Tables 13-9 and 13-10 provide lists of federal- and State-listed plant species and Species of Concern potentially present in the Primary Study Area. The former federal category "Species of Concern" has been dropped to be consistent with current practices of the CNDDB (DFG, 2010a). In this chapter, "Species of Concern" refers to plant species on CNPS lists 1, 2, and 3; List 4 species are not mapped or tracked by quadrangle map in the CNDDB, so are not included in Table 13-11. As shown in Table 13-9, nine federal- and/or State-listed species potentially occur in the Primary Study Area. For all species listed in Table 13-9, habitat, range, threats, and likelihood of occurrence in the Primary Study Area are discussed in more detailed Life History accounts. For the 30 Species of Concern with potential to occur in the Primary Study Area, habitat information is summarized in Table 13-10.

Table 13-9
Federal- and State-Listed Plant Species with Potential to Occur in the Primary Study Area

Species	Federal Status[a]	State Status[b]
Federal- and State-Listed Plant Species		
Indian Valley Brodiaea (*Brodiaea coronaria* ssp. *rosea)*	None	SE

Table 13-10
CNPS List 1, 2, and 3 Plant Species with Potential to Occur in the Primary Study Area

Common name Species[a]	New as of Fall 2009[b]	CNPS status[c]	Habitat Type and Typical Elevation Range
Bent-Flowered Fiddleneck *Amsinckia lunaris*[d]		1B.2	Sunny steeply-sloping openings in woodland, grassland/clay-loam with some weathered mudstone; three to 500 meter elevation
Jepson's Milk-Vetch *Astragalus rattanii* var. *jepsonianus*		1B.2	Woodland, grassland/often serpentinite or shaley mudstone dry creek banks; 320 to 600 meter elevation
Ferris' Milk-Vetch *Astragalus tener* var. *ferrisiae*[d]		1B.1	Meadows, grassland, sub-alkaline flats; five to 75 meter elevation
Heartscale *Atriplex cordulata*[d]		1B.2	Chenopod scrub, meadows, grassland, saline/alkaline; one to 375 meter elevation
Brittlescale *Atriplex depressa*[d]		1B.2	Chenopod scrub, meadows, playas, grassland, vernal pools/alkaline, clay; one to 320 meter elevation
San Joaquin Spearscale *Atriplex joaquiniana*[d]		1B.2	Chenopod scrub, meadows, playas, grassland, vernal pools/alkaline; one to 320 meter elevation
Vernal Pool Smallscale *Atriplex persistens*[d]		1B.2	Vernal pools/alkaline; 10 to 115 meter elevation
Big-Scale Balsamroot *Balsamorhiza macrolepis* var. *macrolepis*		1B.2	Chaparral, woodland, grassland/sometimes serpentinite; 90 to 1,400 meter elevation
Round-Leaved Filaree *California macrophylla*[d] [=*Erodium macrophyllum* in Jepson Manual]		1B.1	Woodland, grassland/ clay; 15 to 1,200 meter elevation

Table 13-10
CNPS List 1, 2, and 3 Plant Species with Potential to Occur in the Primary Study Area

Common name Species[a]	New as of Fall 2009[b]	CNPS status[c]	Habitat Type and Typical Elevation Range
Coast Range Bindweed *Calystegia collina* ssp. *tridactylosa*	X	1B.2	Chaparral/woodland/serpentinite, gravelly or rocky openings; zero to 600 meter elevation
Pink Creamsacs *Castilleja rubicundula* ssp. *rubicundula*		1B.2	Grassy openings in chaparral, woodland, meadows, grassland/serpentinite; 20 to 900 meter elevation
Pappose Tarplant *Centromadia parryi* ssp. *parryi*[d] [=*Hemizonia parryi* ssp. parryi in Jepson Manual]		1B.2	Vernally moist alkaline areas in valley and foothill grassland, chaparral, meadows, seeps; two to 420 meter elevation
Stony Creek Spurge *Chamaesyce ocellata* ssp. *rattanii*		1B.2	Chaparral, grassland/sandy, rocky or steep shale slopes, gravelly creek edges; 85 to 800 meter elevation
Dwarf Soaproot *Chlorogalum pomeridianum* var. *minus*		1B.2	Chaparral/serpentinite; 305 to 1,000 meter elevation
Deep-Scarred Cryptantha *Cryptantha excavata*[b]	X	1B.3	Cismontane woodland, sandy or gravelly soil; 100 to 500 meter elevation
Recurved Larkspur *Delphinium recurvatum*		1B.2	Chenopod scrub, woodland, grassland/alkaline; three to 750 meter elevation
Norris' Beard-Moss *Didymodon norrissii*[b]	X	2.2	Cismontane woodland; 600 to 1,973 meter elevation
Brandegee's Eriastrum *Eriastrum brandegeeae*		1B.2	Chaparral, woodland/volcanic or clay-shale soil transition zone; 305 to 1,030 meter elevation
Tracy's Eriastrum *Eriastrum tracyi*		1B.2	Chaparral, woodland; 315 to 975 meter elevation
Snow Mtn. Buckwheat *Eriogonum nervulosum*		1B.2	Chaparral/ serpentinite; 300 to 2,105 meter elevation
Diamond-Petaled California Poppy *Eschscholzia rhombipetala*		1B.1	Grassland/alkaline, clay; zero to 975 meter elevation
Adobe Lily *Fritillaria pluriflora*[d]		1B.2	Chaparral, woodland, grassland/adobe clay, often cool exposures; 60 to 705 meter elevation
Hall's Harmonia *Harmonia hallii*		1B.2	Chaparral/serpentinite; 500 to 900 meter elevation
Drymaria-Like Western Flax *Hesperolinon drymarioides*		1B.2	Chaparral, woodland, grassland/serpentinite; 100 to 1,130 meter elevation
Woolly Rose-Mallow *Hibiscus lasiocarpos* ssp. *occidentalis*		1B.2	Freshwater marsh, slough edges; zero to 120 meter elevation
Bolander's Horkelia *Horkelia bolanderi*	X	1B.2	Chaparral, valley and foothill grassland, meadows and seeps; 450 to 1,100 meter elevation
Coulter's Goldfields *Lasthenia glabrata* ssp. *coulteri*[d]		1B.1	Coastal salt marsh, saline vernal pools, playas, alkali flats; one to 1,220 meter elevation
Colusa Layia *Layia septentrionalis*		1B.2	Chaparral, woodland, grassland/sandy, serpentinite; 100 to 1,095 meter elevation

Table 13-10
CNPS List 1, 2, and 3 Plant Species with Potential to Occur in the Primary Study Area

Common name Species[a]	New as of Fall 2009[b]	CNPS status[c]	Habitat Type and Typical Elevation Range
Heckard's Pepper-Grass *Lepidium latipes* var. *heckardii*[d]		1B.2	Grassland/alkaline flats; 10 to 200 meter elevation
Red-Flowered Lotus *Lotus rubriflorus*[d]		1B.1	Openings in woodland, grassland/heavy clay; 200 to 425 meter elevation

[a]Nomenclature corresponds to CNPS, 2010.

[b]New as of Fall 2009: these species were not included on previous lists of special-status species potentially present in the Primary Study Area, including lists used for conducting rare plant surveys due to new occurrences being recently added to the CNDDB spatial layer or appearing in updated (November 2009) Rarefind queries of Primary Study Area quadrangle maps. Exception: *Cryptantha excavata* was on CNPS List 4 during Project surveys.

[c]California Native Plant Society (CNPS, 2009): List 1A= plants presumed extinct in California; List 1B = plants rare, threatened, or endangered in California and elsewhere; List 2 = plants rare, threatened, or endangered in California but common elsewhere; List 3 = plants about which more information is needed to determine current status. CNPS threat codes: 0.1: Seriously endangered in California. 0.2: Fairly endangered in California; 0.3: Not very endangered in California.

[d]Species reported to occur (DFG, 2009b) near the Primary Study Area, or found during Project surveys.

CNPS List 4 species from Colusa and Glenn counties that occur in elevations and habitats of the Primary Study Area are listed in Table 13-11; species added to List 4 since fall 2009 are noted.

Seven CNPS List 1B species were found during field surveys that were conducted within the Primary Study Area (Table 13-12). New occurrences of Adobe lily (*Fritillaria pluriflora*), Bent-flowered fiddleneck (*Amsinckia lunaris*), Round-leaved filaree (*California macrophylla)*, and Red-flowered lotus (*Lotus rubriflorus)* were found in the western edges of the Primary Study Area in blue oak savanna. The Red-flowered lotus was not known from the area prior to Project surveys; the nearest known occurrences was seven miles west of the proposed Sites Reservoir footprint. Brittlescale (*Atriplex depressa)*, San Joaquin spearscale (*A. joaquiniana*), and *Centromadia parryi* (both subspecies) were found at the eastern edge of the Primary Study Area in weakly saline/alkaline flats. Table 13-12 lists the special-status species found during field surveys, with number of occurrences per species.

Table 13-11
Special-Status/CNPS List 4 Limited Distribution Plant Species known from Colusa or Glenn Counties, with Potential to Occur in the Vicinity of the Primary Study Area

Common Name	Scientific Name
Purdy's Onion	*Allium fimbriatum* var. *purdyi*
Fairy Candelabra	*Androsace elongata* ssp. *acuta*
Dimorphic Snapdragon	*Antirrhinum subcordatum*
Serpentine Milkweed	*Asclepias solanoana*
Brewer's Milk-Vetch	*Astragalus breweri*
Cleveland's Milk-Vetch	*Astragalus clevelandii*
Depauperate Milk-Vetch	*Astragalus pauperculus*
Rattan's Milk-Vetch	*Astragalus rattanii* var. *rattanii*
Crownscale	*Atriplex coronata* var. *coronata*[a]
Parry's Red Tarplant	*Centromadia [=Hemizonia] parry* ssp. *rudis*[a]
Tracy's Clarkia	*Clarkia gracilis* ssp. *tracyi*[a]
Serpentine Collomia	*Collomia diversifolia*
Small Spikerush	*Eleocharis parvula*[a]

Table 13-11

[a]Not on the search list during 1998 to 2003 Project surveys, but included on search lists used in 2010 and 2011.
[b]One or more occurrences found during 2010 and 2011 surveys.
Notes:
All occurrences found in 1998 to 2003 surveys unless otherwise noted with "b".
CNPS, 2009: CNPS 1B (Plants rare, threatened, or endangered in California and elsewhere); CNPS List 4 (Plants of limited distribution).

None of the other special-status species listed in Tables 13-9, 13-10, and 13-11 as having potential to occur in the Primary Study Area were found during Project field surveys. Six CNPS List 1B species known from saline/alkaline vernal wetlands or flats in the Sacramento Valley, mostly in and around the Sacramento, Colusa, and Delevan NWRs near the Primary Study Area (DFG, 2010a), were not found during Project field surveys.

Eight CNPS List 4 species were found during Project surveys while searching for the state- and federally listed and List 1B species (Table 13-12). Prior to Project surveys, Fairy candelabra (*Androsace elongata* ssp. *acuta)* had not been reported in Glenn or Colusa County. As a result of Project survey findings, distributions were similarly updated or expanded for other species such as Heller's bush mallow (*Malacothamnus helleri)*, Sylvan scorzonella (*Microseris sylvatica)*, Tehama navarretia (*Navarretia heterandra)*, and Adobe navarretia (*Navarretia nigelliformis)*.

Project field surveys were all floristic (all plants observed were identified to species and recorded). A complete list of plant species found by Project feature location is included in the Botanical Progress Reports prepared during the course of these studies (DWR, 2005).

13.3 Environmental Impacts/Environmental Consequences

13.3.1 Regulatory Setting

Botanical resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

13.3.1.1 Federal Plans, Policies, and Regulations

- National Environmental Policy Act
- Federal Endangered Species Act
- Executive Order 11312: Invasive Species

13.3.1.2 State Plans, Policies, and Regulations

- California Environmental Quality Act
- California Endangered Species Act
- California Native Plant Society List
- Natural Communities Conservation Planning Act
- California Fish and Game Code Section 1900-1013: Native Plant Protection Act
- Sections of the California Fish and Game Code Pertaining to Invasive and Noxious Plant Species

13.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan
- Colusa County Voluntary Oak Woodlands Management Plan

13.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for botanical resources:

Would the Project:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game (DFG) or U.S. Fish and Wildlife Service (USFWS)?

- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by DFG or USFWS?

- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?

- Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- A substantial adverse effect, including conversion to non-native vegetation, on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by DFG or USFWS, or any native plant community known to be rare, unusual, or becoming uncommon in the biogeographic region of the Project (for the Primary Study Area, the Inner North Coast Range/Sacramento Valley edge).
- A substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by DFG or USFWS.
- An increase in potential for the invasion or spread of noxious weed species.
- Indirect impacts to native plants from human disturbance.
- Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local or regional habitat conservation plan, or conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

13.3.3 Impact Assessment Assumptions and Methodology

13.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to botanical resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect

effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge facilities would be required.
- Borrow areas for dam construction materials would be located within the proposed Sites Reservoir footprint, or materials would be obtained from commercial sources outside of the Primary Study Area.
- Frequent Sites Reservoir water level fluctuations would create a barren drawdown zone.
- For all Project facilities that do not have a defined construction disturbance area, an additional 10 percent of the facility footprint acreage is assumed to be the size of the associated disturbance area.
- Periodic maintenance of the proposed pipelines and transmission lines would be conducted on foot and/or by using established roads for vehicle access, and would not require vehicle access over established or restored vegetation.

13.3.3.2 Methodology

Impacts to native vegetation communities were assessed in relation to lost[3], altered[4], or disturbed[5] vegetation. Impacts to special-status plant species were evaluated relative to both habitat loss and loss or disturbance to known occurrences. Impacts relative to noxious weeds were also addressed in terms of potential for increase and spread. Analysis of the impacts of human disturbance to native plants included consideration of the impacts of human disturbance to special-status plant species. Direct impacts to vegetation communities include permanent loss, disruption of hydrological regime, and mechanical disturbance. Indirect impacts include ground-disturbing activities that result indirectly from the Project (i.e., erosion, dust, or trampling from increased foot traffic or human pet use), as well as changes to habitat suitability due to accidental introduction of invasive weeds. Impacts can be positive or negative, and can be short-term (temporary) or long-term (permanent). In some cases, apparently short-term/temporary impacts can be equivalent to long-term impacts, where a disturbed area does not return to its original state after construction activities cease.

Approximately 15 percent of the total footprint of each Recreation Area would be subject to permanent disturbance. Because the exact location and area affected by the construction of the recreation areas is not known, the extent of permanent vegetation loss was estimated by applying a 15 percent multiplier to each vegetation type present.

Of the 200-foot-wide total construction disturbance area associated with road construction, an approximate average of 60 feet (30 percent) would result in the permanent loss of native vegetation. A 30 percent multiplier was, therefore, applied to each vegetation type present.

---

[3] Lost vegetation communities cannot be restored.

[4] Altered vegetation communities are communities that have been manipulated.

[5] Disturbed vegetation communities are communities that have been damaged or compromised (such as by trampling or driving through) but are still the same vegetation type.

For the Delevan Transmission Line, a worst-case scenario of 70 transmission line towers with a concrete pad for a base along the entire length of the transmission line was used to calculate the area of permanent disturbance for Alternatives A and C. A worst-case scenario of 15 transmission towers with a concrete pad for a base for the length of the transmission line was used to calculate the area of permanent disturbance for Alternative B.

Calculated acres of natural habitats and agricultural lands represent the 2009 baseline conditions (i.e., Existing Conditions).

The botanical resources impact assessment relied on hydrologic and operational modeling performed using CALSIM II to provide a quantitative basis from which to assess the potential impacts of the alternatives on vegetation communities in portions of the Extended and Secondary study areas. Monthly river flows, and water surface elevations derived based on monthly river flows and end-of-month reservoir storages from CALSIM II, provided a quantitative basis to assess the potential impacts of operations on vegetation communities, relative to the CEQA and NEPA bases of comparison, for the period of simulation extending from water year 1922 through 2003 (82-year simulation period). Detailed discussion of the CALSIM II model is provided in Appendix 6B.

Further, in assessing the impacts to the valley foothill riparian vegetation along the Sacramento River in the Secondary Study Area, modeling specific to riparian vegetation, including results from the SRH-1DV and SacEFT models, was used.

The SRH-1DV model simulates the establishment, growth, and mortality of vegetation, in addition to computing hydraulics and groundwater surface in the riparian zone near the river. The simulation tracks daily vegetation changes through 82 years of simulated flow within the 107 river miles of Sacramento River from upstream of Red Bluff to Colusa. The SRH-1DV analysis focuses on four key valley foothill riparian vegetation types: cottonwood, mixed forest, Gooding's black willow, and narrow leaf willow. The detailed description of the SRH-1DV model and the associated alternatives evaluation is provided in Appendix 8A.

The SacEFT is a decision support tool that links flow management actions on the Sacramento River to changes in the physical habitats for several focal species of concern. It specifically includes performance measures for evaluating the effects of various flow scenarios on the initiation success and post-initiation scour risk of the Fremont Cottonwood seedlings. These performance measures are used as a general indicator for assessing the impacts on riparian vegetation along the Sacramento River in the Secondary Study Area. The detailed description of the SacEFT model and the associated alternatives evaluation is provided in Appendix 8B.

13.3.4 Topics Eliminated from Further Analytical Consideration

Because no Project facilities would be constructed or maintained within the Extended Study Area, only operational impacts associated with Alternatives A, B, and C are discussed in the impacts analysis for the Extended Study Area for the three alternatives.

As indicated in the Environmental Setting/Affected Environment discussion, no native vegetation types are described for the urban or agricultural lands included in the water delivery service areas of the Extended Study Area. They are, therefore, not evaluated.

Project-related activities that would occur within the Secondary Study Area at the Red Bluff Pumping Plant on the Sacramento River were not evaluated because those activities would occur within the footprint of the existing pumping plant facility, and therefore, are not anticipated to affect botanical resources. Because no construction or maintenance activities would occur within the remainder of the Secondary Study Area, only operational impacts associated with Alternatives A, B, and C are discussed in the impacts analysis for the reservoirs and waterways included in the Secondary Study Area for the three alternatives.

The Tunnel from Sites Pumping/Generating Plant to Sites Reservoir and Existing Funks Reservoir Dredging (both facilities would be located within the Primary Study Area) were not evaluated because construction, operation, and maintenance of these facilities would occur within the footprint of the existing facility, or would have no associated above-ground disturbance, and therefore, are not anticipated to affect botanical resources.

Because the Primary Study Area Project facilities with an above-ground footprint would result in permanent vegetation loss during their construction, the impact of the operation and maintenance of those facilities on vegetation communities (**Impact Bot-1**) is not discussed. Similarly, when the permanent loss of a vegetation community resulting from Project facility construction would make that location unsuitable for, or unable to support, specific special-status plant species, the impact of the operation and maintenance of that facility on the species (**Impact Bot-2**) is not discussed.

13.3.5 Impacts Associated with the No Project/No Action Alternative

13.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to native plant communities has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on native plant communities, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. Urbanization that is planned according to General Plans could be expected to cause the conversion of native vegetation, riparian habitat, and sensitive natural communities to urban uses. However, General Plans and any related construction activities would be subject to their own environmental reviews. Therefore, population growth associated with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on native vegetation, riparian habitat, and sensitive natural communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Bot-1** discussion. That discussion is also applicable to special-status plant species.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Refer to the **Impact Bot-1** discussion. That discussion is also applicable to noxious weed species.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-1** discussion. That discussion is also applicable to potential effects to native plants from human disturbance.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-1** discussion. That discussion is also applicable to conflicts with conservation plans.

San Luis Reservoir

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in the same or slightly decreased water level elevations during most water years, and the same or slightly increased water level elevations during Dry and Critical years at San Luis Reservoir. These negligible fluctuations in surface water elevations would not be expected to affect the small pockets of native riparian vegetation that exist around the reservoir, nor would it be expected to have substantial adverse effects on riparian-associated native plant species. Due to already large water level fluctuations, the drawdown zone of San Luis Reservoir supports virtually no native vegetation communities (only scattered vegetation composed of mostly non-native species). The slight changes in surface water elevations at San Luis Reservoir that would result from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on native plants and native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No native vegetation communities or associated special-status plant species are supported in the drawdown zone of San Luis Reservoir, and no special-status plant species are recorded for this location (DFG, 2010a). Therefore, the slight changes in surface water elevations at San Luis Reservoir resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status plant species, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Existing large water level fluctuations in the drawdown zone of San Luis Reservoir already spread non-native vegetation around in its available exposed substrate. The slight changes in surface water elevations at San Luis Reservoir resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on the invasion or spread of noxious weed species, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

None of the projects included in the No Project/No Action Alternative are located at San Luis Reservoir. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated water level fluctuations at San Luis Reservoir would be within the historical range of operation, and consequently, would not conflict with any HCPs, NCCPs, or local plans. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

13.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in no change to surface water elevations at Trinity or Shasta lakes, and therefore, **would not result in a substantial adverse effect** to native plant communities. Modeling shows expected slight decreases in surface water elevations at Lake Oroville and Folsom Lake, but the amounts are minor and would not be expected to affect native plant communities. Therefore, surface water elevation fluctuations at these two reservoirs associated with implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** to native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No change in surface water elevations are expected at Trinity or Shasta lakes; therefore, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on special-status plant species, when compared to Existing Conditions. At Lake Oroville and Folsom Lake, the expected slight decreases in water levels resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status plant species, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Existing water level fluctuations in the drawdown zone of all the listed lakes already spread non-native vegetation around in the available exposed substrate. No changes in surface water elevations are expected at Trinity or Shasta lakes; therefore, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on invasion or spread of noxious weed species at these reservoirs, when compared to Existing Conditions. At Lake Oroville and Folsom Lake, the slight decreases in surface water elevations expected from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on the invasion or spread of noxious weed species, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

The No Project/No Action Alternative assumes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to native plant species and communities has been addressed in those environmental documents. Therefore, implementation of these projects **would not have a substantial adverse effect** on native plant species and communities in the Secondary Study Area, when compared to Existing Conditions.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion. That discussion is also applicable to conflicts with conservation plans.

Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, and the Thermalito Complex

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling was not conducted for Lewiston Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex. However, modeling conducted on the reservoirs upstream of these reservoirs indicates that the No Project/No Action Alternative, when compared to Existing Conditions, would result in either no change or slight changes to surface water level elevations. Because these reservoirs would continue to operate as regulating reservoirs, it is assumed that there would be little or no change in surface water level elevations, and they, therefore, **would not have a substantial adverse effect** on bordering native plant communities, when compared to Existing Conditions. Modeling was conducted for Whiskeytown Lake for flows downstream of the lake, and flows would experience slight but insignificant changes. Because the reservoir upstream of Whiskeytown would not experience substantial changes, and the flows released from Whiskeytown would experience only slight changes, surface water elevations would not be expected to fluctuate, and therefore, **would not have a substantial adverse effect** on bordering native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because little or no change is expected in surface water elevations at Lewiston Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex, the No Project/No Action Alternative **would not result in a substantial adverse effect** on special-status plant species, when compared to Existing Conditions. At Whiskeytown Lake, the expected slight changes in water levels resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status plant species, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because little or no change is expected in surface water elevations at Lewiston Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on invasion or spread of noxious weed species, when compared to Existing Conditions. At Whiskeytown Lake, the expected slight changes in water levels resulting from implementation of the No Project/No Action Alternative would not have a **substantial adverse effect** on the invasion or spread of noxious weed species, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Trinity River

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results for Trinity River flows downstream of Lewiston Lake for the No Project/No Action Alternative, when compared to Existing Conditions, indicate slight changes in flows during Below Normal, Dry, or Critical water years. However, large decreases in flow are indicated during March and April of Wet water years, and large increases in February flows in Above Normal water years. These changes in the flow regime have the potential to adversely affect riparian plant communities bordering the river. However, native riparian vegetation is adapted to flow variations, and the expected timing of flow changes would result in the least effect on streamside vegetation. Decreases in spring flows during Wet water years, when flows are high, and increases in flow during late winter in Above Normal water years, would not be expected to substantially adversely affect riparian vegetation. These modifications of the flow regime of the Trinity River from implementation of the No Project/No Action Alternative, therefore,

would not have a substantial adverse effect on native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Little change in stream-edge native plant communities would occur due to expected flow modifications. Implementation of the No Project/No Action Alternative, therefore, **would not result in a substantial adverse effect** on special-status plant species on the Trinity River downstream of Lewiston Lake, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Little change in stream-edge native plant communities would occur due to expected flow modifications. Implementation of the No Project/No Action Alternative, therefore, **would not result in a substantial adverse effect** on the invasion or spread of noxious weed species on the Trinity River downstream of Lewiston Lake, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Klamath River downstream of the Trinity River

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results for the Klamath River downstream of the Trinity River for the No Project/No Action Alternative, when compared to Existing Conditions, indicate negligible changes in flows. These negligible changes in the flow regime would not be expected to adversely affect riparian plant communities. Implementation of the No Project/No Action Alternative, therefore, **would not result in a substantial adverse effect** on native plant communities on the Klamath River downstream of the Trinity River, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Klamath River flow regime downstream of the Trinity River would be negligible and would not adversely affect riparian plant communities, they would also not be expected to have an adverse effect on riparian-associated special-status plant species. Implementation of the No Project/No

Action Alternative, therefore, **would not result in a substantial adverse effect** on special-status plant species on the Klamath River downstream of the Trinity River, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Negligible flow regime changes would not be expected to result in changes in stream-edge native plant communities. Therefore, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on the invasion or spread of noxious weed species on the Klamath River downstream of the Trinity River, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Spring Creek

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Operational modeling was not performed for Spring Creek. However, if the No Project/No Action Alternative is implemented, operations of Whiskeytown Lake and Keswick Reservoir are expected to result in slight changes, and therefore, would not be expected to alter the released flows that dilute Spring Creek runoff. Because no change in the dilution of Spring Creek runoff is expected, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on any existing native streamside plant communities at Spring Creek, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because no change in stream-edge native plant communities due to flow modifications is expected, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on special-status plant species on Spring Creek, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because no change in stream-edge native plant communities due to flow modifications is expected, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on the invasion or spread of noxious weed species on Spring Creek, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Sacramento River

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall negligible change to the flow regime of the Sacramento River, with the exception of decreased flows downstream of Keswick Reservoir in November during Dry years. Large changes in the flow regime have the potential to adversely affect riparian plant communities. However, existing riparian vegetation is adapted to flow variations, and changes in flow during one month in Dry years would not be expected to substantially adversely affect riparian vegetation. Therefore, the modifications to the flow regime of the Sacramento River **would not have a substantial adverse effect** on bordering native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because little change in stream-edge native plant communities due to flow modifications is expected, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on special-status plant species on the Sacramento River downstream of Keswick Reservoir, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because little change in stream-edge native plant communities due to flow modifications is expected, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on the invasion or spread of noxious weed species on the Sacramento River downstream of Keswick Reservoir, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Clear Creek

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall small change to the flow regime of Clear Creek, with the exception of large increases in flows during Critical years. These changes in the flow regime have the potential to adversely affect riparian plant communities. However, an increase in flow during Critically Dry years could reduce or prevent the desiccation of riparian vegetation; therefore, implementation of the No Project/No Action Alternative **would have a potentially beneficial effect** on native plant communities bordering Clear Creek, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Clear Creek flow regime during Critical years would have a potentially beneficial impact on native riparian vegetation, the flow regime changes would not be expected to have an adverse effect on riparian-associated native plant species. Changes in the Clear Creek flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status native plant species, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because little change in stream-edge native plant communities due to flow modifications is expected, except for potential benefits from large flow increases during Critically Dry years, implementation of the No Project/No Action Alternative **would result in a potentially beneficial effect** on the invasion or spread of noxious weed species on Clear Creek (i.e., a reduction in the invasion or spread of the noxious weeds), when compared to Existing Conditions. The spread of invasive weed species can occur after mortality or disturbance to native vegetation, so preventing desiccation of native riparian vegetation would keep the native streamside plant communities more resistant to weed infestation.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Feather River

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in numerous large changes to the flow regime of the Feather River. These changes in the flow regime have the potential to adversely affect riparian native plant communities. The changes to the flow regime that are most likely to affect riparian vegetation include greatly increased flows ranging from June through September during certain water year types, which have the potential to inundate riparian vegetation. Adverse effects could also result from expected large decreases in flows during late August in Dry years, which could desiccate riparian vegetation. For the Feather River, this would be particularly adverse to native riparian vegetation because the controlled flow regime from Oroville Dam already subjects the river's low-flow channel edges to scouring flows, which keep streamside vegetation in an early successional stage, favoring invasion of noxious weed species; controlled conditions downstream of the Thermalito Afterbay Outlet are also not favorable to riparian forest recruitment or species diversity (DWR, 2007). The modifications of the Feather River's existing flow regime resulting from implementation of the No Project/No Action Alternative could further adversely affect riparian vegetation, and therefore, **would have a potentially substantial adverse effect** on bordering native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because potentially adverse changes in stream-edge native plant communities are expected due to expected flow modifications, the No Project/No Action Alternative has the potential to result in adverse impacts to any special-status plant species associated with streamside plant communities. However, no special-status plant species are currently known to exist at or adjacent to the stream edges of the Feather River downstream of the Lake Oroville facilities (DFG, 2010a; DWR, 2007). Therefore, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on special-status plant species on the Feather River downstream of Lake Oroville, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because potentially adverse changes in stream-edge native plant communities are expected due to expected flow modifications, implementation of the No Project/No Action Alternative has the potential to result in adverse impacts associated with the invasion or spread of noxious weed species on the Feather River downstream of Lake Oroville. Because the spread of invasive weed species can occur after mortality or disturbance to native vegetation, scouring or desiccation of riparian vegetation due to the further exaggerated seasonal flow regime alterations on the Feather River would make the already struggling native streamside plant communities less resistant to weed infestation. Modifications of the existing flow regime resulting from implementation of the No Project/No Action Alternative **would, therefore, have a potentially substantial adverse effect o**n the invasion or spread of noxious weed species on the Feather River, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Sutter Bypass

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in a small change in spills into Moulton, Tisdale, and Ord Ferry weirs. Colusa Weir would experience a decrease in spills during November, especially in Dry years. Changes to the flow regime of the Sutter Bypass have the potential to adversely affect riparian native plant communities that have accumulated along some of the edges of the Bypass. However, three of the four weirs that spill into the Bypass are not expected to experience large changes in flows, and Colusa Weir would only experience large decreases in flood flows during November. The riparian vegetation within the Sutter Bypass has adapted to flow variations, and changes in flow from one weir during one month would not be expected to substantially adversely affect the riparian vegetation. Therefore, the No Project/No Action Alternative's modifications of the existing flow regime **would not have a substantial adverse effect** on riparian native plant communities in the Sutter Bypass, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Becausee only minor potential changes are expected in the Sutter Bypass stream-edge native plant communities due to expected flow modifications, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status plant species associated with streamside plant communities along Bypass edges. One special-status plant species, the woolly rose-mallow or California hibiscus (*Hibiscus lasiocarpos* var. *occidentalis*) is currently known to exist at or adjacent to the edges of the Sutter Bypass (DFG, 2010a). Therefore, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on this special-status species, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because only minor potential changes are expected in the Sutter Bypass stream-edge native plant communities due to expected flow modifications, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on the invasion or spread of noxious weed species along Bypass edges, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative. That discussion is also applicable to conflicts with conservation plans.

Yolo Bypass

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in a small change in monthly flows into the Yolo Bypass, with the exception of large decreases in flow during late fall in Below Normal and Dry years. Changes to the flow regime of the Yolo Bypass have the potential to adversely affect riparian native plant communities that have accumulated along some of the edges of the Bypass. However, riparian vegetation is adapted to flow variations, and decreases in flood flows during late fall in Below Normal and Dry years would not be expected to substantially adversely affect riparian vegetation. Therefore, modifications to the flow regime of the Yolo Bypass resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on native plant communities, when compared to Existing Conditions. This would include riparian edges as well as communities established in the interior of the Bypass, such as grasslands and seasonal wetlands.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because only minor potential changes are expected in the Yolo Bypass stream-edge or interior native plant communities due to expected flow modifications, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status plant species associated with streamside plant communities along Bypass edges, when compared to Existing Conditions. Minor effects are expected to occur in interior Bypass herbaceous communities from the expected decreases in late fall flows in Dry years. Four special-status plant species (*Astragalus tener* var. *ferrisiae* [Ferris' milkvetch], *Astragalus tener* var. *tener* [alkali milkvetch], *Lepidium latipes* var. *heckardii* [Heckard's peppergrass], and *Navarretia leucocephala* ssp. *bakeri* [Baker's navarretia]) are currently known to exist in the interior of the Yolo Bypass (DWR, 2010a) in DFG Wildlife Area units. The Dry year late fall flow decreases resulting from implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on these special-status species (all are on CNPS List 1B), when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because only minor potential changes are expected in the Yolo Bypass stream-edge or interior native plant communities due to expected Dry year late fall flow decreases, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on the invasion or spread of noxious weed species, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative. That discussion is also applicable to conflicts with conservation plans.

American River

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in a decrease in flows in the American River in all months except for December. Large decreases in flows are also indicated in September of Above Normal years, September and October of Below Normal years, and in August and September in Critically Dry years. This reduction in flows, coupled with the substantial reductions in flows during early fall in some water year types, has the potential to affect riparian native plant communities adversely by desiccating established vegetation and reducing recruitment. Modifications to the existing flow regime of the American River resulting from implementation of the No Project/No Action Alternative **would, therefore, have a potentially substantial adverse effect** on bordering native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because substantial potential changes are expected in the native plant communities along the American River due to expected flow decreases, implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on special-status plant species associated with streamside plant communities along the river edges, when compared to Existing Conditions. One special-status plant species, *Sagittaria sanfordii* (Sanford's arrowhead), is currently known to exist near the edges of the American River (DFG, 2010a); the overall flow decrease and large decreases in late-summer/early fall resulting from implementation of the No Project/No Action Alternative **would result in a potentially significant impact** on this special-status species (a CNPS List 1B species), when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because potential adverse changes are expected in the native plant communities along the American River due to expected flow decreases, implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on the invasion or spread of noxious weed species along the river edges, when compared to Existing Conditions. The flow decrease and large decreases in late summer/early fall could reduce the extent and health of existing native riparian vegetation, making the native plant communities less resistant to the invasion and spread of noxious weeds if the No Project/No Action Alternative is implemented.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Sacramento-San Joaquin Delta

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in a negligible change in Delta monthly outflow. This lack of change to Delta outflow **would not have a substantial adverse effect** on native plant communities of the Delta, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because only minor potential changes are expected in the Delta waters-edge native plant communities due to expected flow modifications, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status plant species associated with native plant communities bordering Delta sloughs and channels, when compared to Existing Conditions. At least 69 special-status plant species are currently known to exist in the Delta (DFG, 2010a; refer to Table 13-5 and Appendix 13B). Implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on these special-status species, when compared with Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because only minor potential changes are expected in the Delta waters-edge native plant communities due to expected flow modifications, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on the invasion or spread of noxious weed species along edges of Delta sloughs and channels, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in a negligible change in the position of X2, as well as a negligible change in Delta monthly outflow. Because Suisun, San Pablo, and San Francisco bays would not be expected to experience any large salinity or flow changes, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on bordering native riparian or wetland plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Bot-1** discussion. Because Suisun, San Pablo, and San Francisco bays would not be expected to experience any large salinity or flow changes, implementation of the No Project/No Action

Alternative **would not have a substantial adverse effect** on special-status plant species occurring along Bay edges, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Refer to the **Impact Bot-1** discussion. Because Suisun, San Pablo, and San Francisco bays are not expected to experience any large salinity or flow changes, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on the invasion or spread of noxious weed species along edges of the bays, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with conservation plans.

13.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

If the No Project/No Action Alternative is implemented, the Project would not be built and there would, therefore, be no construction, operation, or maintenance impacts within the Primary Study Area. In addition, none of the projects included in the No Project/No Action Alternative are located within the Primary Study Area.

It is expected that current patterns of land use would continue in the area, and despite expected growth within Glenn and Colusa counties throughout the period of Project analysis (i.e., 100 years), no large-scale development or other substantial changes in land use would occur. Cattle grazing, fuelwood harvest, and agricultural cultivation would most likely continue at or near current levels. In addition, the slow compaction, erosional, and seedling removal effects of grazing would continue in all grassland and most blue oak woodland areas.

Continued fuelwood harvest in blue oak woodlands at the valley's edges would eventually convert whole hillsides from wooded to open grassland, and agricultural lands would continue to occupy the same or slightly increased areas of formerly native vegetation, Therefore, activities within the Primary Study Area that would occur as a result of implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on native plant communities, when compared to Existing Conditions.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Bot-1** discussion. In addition, habitat deterioration at the blue oak-grassland interface would reduce the suitable area available to *Amsinckia lunaris* (bent-flowered fiddleneck), *Lotus rubriflorus*, (red-flowered lotus), *Sidalcea keckii* (Keck's checkerbloom), *California macrophylla* (round-leaved filaree), and other special-status species that depend on this native plant community ecotone. Therefore, activities within the Primary Study Area with implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on special-status plant species, when compared to Existing Conditions.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Refer to the **Impact Bot-1** discussion. In addition, the spread of non-native species, such as Italian plumeless thistle (*Carduus pycnocephalus*), yellow star-thistle (*Centaurea solstitialis*), and others would continue in all disturbed grassland and blue oak woodland areas with grassy understories at edges of disturbance. Similar impacts would continue in and along stream channels in grazed areas, producing a slow deterioration of their riparian character. The feral pig population would most likely continue to increase and contribute to increased invasion of non-native plant species in their areas of ground disturbance (mostly at the blue oak woodland/grassland interface). Continued fuelwood harvest in blue oak woodlands at the valley's edges would eventually convert whole hillsides from wooded to open grassland, further contributing to the increase in non-native species that is typical of the annual grasslands of the Primary Study Area. Agricultural lands would continue to occupy the same or slightly increased areas of formerly native vegetation, and continue to provide seed sources for non-native plant species.

Therefore, activities within the Primary Study Area with implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on the spread of noxious weed species, when compared to Existing Conditions.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

None of the projects included in the No Project/No Action Alternative would occur within the Primary Study Area. Therefore, **there would not be a substantial adverse effect** to native plant species or communities from construction, operation, or maintenance-related activities, when compared to Existing Conditions.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

There are no HCPs or NCCPs located within the Primary Study Area. Additionally, none of the projects included in the No Project/No Action Alternative would occur within the Primary Study Area. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

13.3.6 Impacts Associated with Alternative A

13.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Level 4 water supply benefits numerous native plant species and plant associations that use fresh emergent wetland habitat. Implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would provide an alternate source of Level 4 water in some years, but would not increase its reliability. Therefore, the provision of an alternate source of Level 4 water supply would have **no impact** on native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

An alternate source of Level 4 water would not change the reliability of Level 4 water supply, and therefore, would not affect native plant communities in the wildlife refuges. There would, therefore, be **no impact** on special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because an alternate source of Level 4 water supply with Alternative A would not affect plant communities in the refuges, there would be **no impact** on the spread of noxious weed species in the wildlife refuges from water level changes, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with the provision of an alternate source of Level 4 water supply. Therefore, there would be **no impact** to native plants, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because the provision of an alternate source of Level 4 refuge water use would not affect areas of native vegetation, it would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

San Luis Reservoir

San Luis Reservoir currently experiences severe water level fluctuations. Operational modeling for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates that operation of the Project would cause San Luis Reservoir water levels to continue to fluctuate, but the fluctuations would occur more often and could be more severe than what currently happens.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Severe water level fluctuations could adversely affect the wetland and riparian scrub vegetation that exists within the tributary drainages in the drawdown zone. However, these patches of vegetation are located in areas that have their own hydrology. The existing vegetation in tributary drainage bottoms within the drawdown zone is already adapted to fluctuating water levels. Increases in such fluctuations could cause some of the small amounts of existing native woody vegetation to die off and be replaced by herbaceous non-native vegetation that can tolerate higher levels of disturbance. Changes or reductions in this vegetation resulting from the more frequent or larger fluctuations associated with implementation of Alternative A would represent a **less-than-significant impact** to existing riparian or wetland vegetation within the San Luis Reservoir drawdown zone, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No native vegetation communities or associated special-status plant species are supported in the drawdown zone of San Luis Reservoir, and no special-status plant species are recorded for this location (DFG, 2010a). Therefore, the changes in surface water elevations at San Luis Reservoir resulting from implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **no impact** on special-status plant species.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Existing large water level fluctuations in the drawdown zone of San Luis Reservoir already spread non-native vegetation around in its available exposed substrate. The more severe changes in surface water elevations at San Luis Reservoir would only reinforce the current disturbance, resulting in a **less-than-significant impact** on invasion or spread of noxious weed species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with fluctuating surface water levels (associated with Project operation) in the Extended Study area at San Luis Reservoir. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or

Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated water level fluctuations at San Luis Reservoir would be within its historical range of operation; therefore, the fluctuations would not conflict with any HCPs, NCCPs, or local plans. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

13.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake

Operational modeling for Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates that operation of the Project would provide operational flexibility to Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. Storage at these reservoirs would be improved in all months of all years, including during May through October in Dry and Critical year conditions. In other years, larger releases would be made to stabilize fall flow conditions. Seasonal and monthly improvements in storage would occur in comparison to Existing Conditions and the No Project/No Action Alternative. In addition to improved storage conditions, operational modeling indicates that these reservoirs would experience a reduced range of change in fluctuations, resulting in less severe drawdowns.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The shorelines of these reservoirs have the potential to support native wetland and lake-edge riparian vegetation. However, the availability of water in the shoreline root-zone decreases as water surface elevation decreases, so changes in reservoir surface water elevation fluctuations have the potential to adversely affect the colonization of native plants. Frequent and severe drawdowns tend to favor the establishment of upland plant communities and disturbance-tolerant non-native plants along the shoreline, rather than native riparian vegetation. The reduction in the reservoir level fluctuations resulting from the implementation of Alternative A has the potential to allow the establishment of native riparian plant communities in these shoreline areas. Therefore, changes in operations at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake that would result in improved storage and reduced water level fluctuations would have a **beneficial effect** to native riparian (lake-edge) plant communities and associated native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-status plant species associated with shoreline plant communities or found in upland plant communities close to the water's edge at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake would be expected to be affected by changes in reservoir water levels. Examples could be *Neviusia cliftonii* (Shasta snow-wreath) at Shasta Lake, *Gratiola heterosepala* (Boggs-Lake hedge-hyssop) at Folsom Lake, and *Clarkia* species at Oroville (DFG, 2010a). The native plant communities that these special-status species depend on are most likely to persist intact where water levels do not fluctuate and consequently expose plants to inundation or desiccation. Water level changes also tend to favor the establishment of disturbance-tolerant non-native plants along the shoreline, rather than native vegetation. Therefore, changes in operations resulting from implementation of Alternative A at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake would result in reduced water level fluctuations. These fluctuations are expected to have a **beneficial effect** to special-status species associated with lake-edge native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative, whether those plant communities are riparian/littoral (water dependent) or are in the forest or other upland communities existing in that area prior to construction of the reservoirs.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Existing water level fluctuations in the drawdown zones of Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake spread non-native vegetation around in the available exposed substrate. The less severe changes in surface water elevations at these lakes resulting from implementation of Alternative A would reduce the current disturbance levels, resulting in a **beneficial effect** on the invasion or spread of noxious weed species, when compared to Existing Conditions and the No Project/No Action Alternative. This would mean a reduced likelihood for new arrivals to the area to invade the lake edges, and for existing infestations to spread into the lake arms and other adjacent lands.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with improved storage conditions at these reservoirs. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime or storage conditions of Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake from Project operation would be within the historical range of operations. Therefore, their operations would not conflict with HCPs, NCCPs, or local plans, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, and the Thermalito Complex

Operational modeling was performed for Whiskeytown Lake; however, it is expected to operate as it has historically as a regulating reservoir for flow coming through the Clear Creek Tunnel. Operational modeling was not performed for Lewiston Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex (which includes the Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay). They are also expected to continue to operate as they have historically, as regulating reservoirs for upstream reservoirs. No change in operation is expected at any of these reservoirs as a result of Project operation.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Because no change in surface water elevations at Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex is expected, Project operations associated with Alternative A would result in **no impact** on bordering native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because no change in surface water elevations at Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex is expected, when compared to Existing Conditions and the No Project/No Action Alternative, Project operations associated with Alternative A would result in **no impact** on special-status plant species.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because no change in surface water elevations at Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex is expected, when compared to Existing Conditions and the No Project/No Action Alternative, Project operations associated with Alternative A would result in **no impact** on the invasion or spread of noxious weed species.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with operations in the Secondary Study Area at Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, there would be **no impact**.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because no change in operation is expected at any of these reservoirs as a result of Project operations, when compared to Existing Conditions and the No Project/No Action Alternative, there would be no conflict with any HCPs, NCCPs, or local plans and would, therefore, be **no impact**.

Trinity River, Klamath River downstream of the Trinity River, Spring Creek, and Clear Creek

Operational modeling indicates that operations associated with Alternative A would result in little or no change in existing flow regime for the Trinity River, Klamath River downstream of the Trinity River, Spring Creek, and Clear Creek. For the Trinity River, operational modeling indicates that flows would meet or exceed the Trinity River Record of Decision (ROD) requirements in all scenarios, with or without the Project. Project operations could change the timing of flows through the Clear Creek Tunnel, but not the amount supplied. Modeling results show little change from the existing flow schedule, and the small amount of change would rarely occur. For the Klamath River, no flow regime changes are indicated.

Operational modeling was not performed for Spring Creek; Spring Creek runoff is diluted by flows from Whiskeytown Lake through the Spring Creek Tunnel before it enters the Sacramento River. Those flows are diluted again by releases from Keswick Reservoir once they enter the Sacramento River. Operation of the Project would not change operation of Whiskeytown Lake or Keswick Reservoir, and therefore, is not expected to affect the released flows that dilute Spring Creek runoff. For Clear Creek, modeling indicates that flow requirements would be met or exceeded in all scenarios.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Because no change in flow regimes is expected from implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, its operation would result in **no impact** on native stream-edge native plant communities on the Trinity River downstream of Lewiston Lake, on the Klamath River downstream of the Trinity River, on Spring Creek, and on Clear Creek.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to **Impact Bot-1** discussion. That discussion would also be applicable to special-status plant species.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Refer to **Impact Bot-1** discussion. That discussion would also be applicable to noxious weed species.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with flow regime changes in the Secondary Study Area along the Trinity River downstream of Lewiston Lake, on the Klamath River downstream of the Trinity River, on Spring Creek, and on Clear Creek, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, there would be **no impact**.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Trinity River downstream of Lewiston Lake, the Klamath River downstream of the Trinity River, Spring Creek, and Clear Creek, would be within the historical range of their operations, and would, therefore, not adversely affect native plant species and communities, when compared to Existing Conditions and the No Project/No Action Alternative. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**.

Sacramento River

Operational modeling indicates that Sacramento River flows would meet or exceed the OCAP Biological Opinion requirements with or without the Project. When compared to Existing Conditions and the No Project/No Action Alternative, Alternative A operations would result in changes to the flow regime upstream of the Project diversions as a result of changes in operations at Shasta Lake that result from integration with Project operations. Systematic changes in flows downstream of each of the Project diversions would occur as a result of the combination of the changes in operation of Shasta Lake, as well as the diversion of up to 5,900 cfs at the Project intakes when diversions would occur.

Modeling results indicate that there would be no change in the frequency or severity of flood events, and consequently no large change in the movement of sediment or timing of scour events, as the modeling inputs purposely avoided effects to the river from regulation and diversion when the flow is between 15,000 and 25,000 cfs. For Sacramento River upstream of the Project diversions, Project operations would result in stage fluctuations of approximately -0.6 to 0.5 feet using the Bend Bridge location as the indicator, when compared to Existing Conditions and the No Project/No Action Alternative. September flows would be variable in the amount of increases. Downstream of Project diversions, July and August flow changes would be negligible. Using Wilkins Slough stage as an indicator for this reach, there would be changes in the stage of approximately -2.3 to 2.8 feet if Alternative A is implemented, when compared to Existing Conditions and No Project/No Action Alternative. The reduction in stage would mainly occur in the winter and spring months, when the water is diverted from the Sacramento River to Sites Reservoir; higher stage values occur in the summer and fall months because of the releases from the Sites Reservoir to the river. Fall flows from Shasta Lake to the Project intakes would decrease, but Project releases would stabilize fall flows downstream of the intakes, especially in Dry years.

Modeling performed using SRH-1DV and SacEFT indicates that the coverage of the valley foothill riparian vegetation alliance along the Sacramento River would increase or remain similar if Alternative A is implemented relative to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modifications to the existing flow regime could affect the establishment of new riparian vegetation or reduce the survival rate of early successional stages of existing riparian vegetation. An increase in river stage has the potential to cause partial inundation of some shrubs. However, the shrubs likely to be affected are already subjected to seasonal inundation, and the increase in river stage during the winter months would fall within the historical range of conditions. Project operational modeling, including modeling that is specific to riparian vegetation, indicates a minimal effect to early or mid-seral stage riparian plant communities (cottonwood forest) resulting from the described changes in the flow regime. Riparian vegetation would not be expected to be adversely affected, when compared to Existing Conditions or the No Project/No Action Alternative.

Modeling results indicate that that there would be no change in the frequency or severity of flood events, and up to a two to four inch increase in winter season river stage. Because the higher winter stage is within the historical range of river stage experienced by existing riparian vegetation, this slight increase is not expected to cause changes in riparian plant communities. River stage in June would be increased four to six inches, which has the potential to prolong wetting of cottonwood seedlings that survive May inundation and scouring. However, this brief increase in root-zone water is unlikely to affect cottonwood establishment rates, considering the much greater effects of earlier scouring and later dessication due to sudden summer dropoff in river stage (Mahoney & Rood, 1998).

It should be noted that, although modeling results indicate that there would be minimal change to riparian vegetation when compared to Existing Conditions or the No Project/No Action Alternative, Existing Conditions are not necessarily favorable for riparian forest, other riparian plant communities, and associated native plant species. Project operations are not expected to aggravate these conditions, but also are not expected to improve them. Therefore, the impact of modifications of the existing flow regime of the Sacramento River resulting from operation of Alternative A would have a **less-than-significant impact** on riparian plant communities along the Sacramento River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Analysis of recorded special-status plant species from within 100 feet of the Sacramento River downstream of Shasta Lake (DFG, 2010a) indicates that there are three special-status plant species that could be affected by changes in flow regime on the Sacramento River between Keswick Dam and the Delta: *Cryptantha crinita* (silky cryptantha), *Hisbiscus lasiocarpos* var. occidentalis (California hibiscus), and *Woffia brasiliensis* (Brazilian watermeal). All other potentially affected species are extirpated (e.g., *Juglans hindsii*, *Trichocoronis wrightii*), or occur only in adjacent upland habitats such as upper-terrace vernal pool landscapes that would not be subjected to river stage changes. The first species, silky cryptantha, is known only from gravel bars on tributaries of the Sacramento River, well away from the mouth, and would not be affected by the seasonal stage changes expected from operation of Alternative A.

The California hibiscus has been reported along the river edge only from the southern end of the valley in Sutter and Sacramento counties, and is not likely to experience any effects of the June four- to six-inch stage increase from Project operations. The Brazilian watermeal is known from one river site near Chico in an off-channel slough; it has been observed there through November, so a slight temporary increase in river stage in June is unlikely to affect this species of calm backwaters. One other species, *Carex comosa* (bristly sedge) is known from marshy areas in the Delta and Shasta County but not along the Sacramento River edge. Therefore, the impact of modifications of the existing flow regime of the Sacramento River resulting from operation of Alternative A would have a **less-than-significant impact** on special-status plant species along the Sacramento River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Existing water level fluctuations along the banks of the Sacramento River already spread non-native vegetation downstream along exposed banks, especially after high flow events when fresh silt and seed are deposited on banks. The expected slight seasonal changes in surface water elevations resulting from implementation of Alternative A would only reinforce the current disturbance and continue the existing spread of bordering non-native vegetation, and therefore, would have a **less-than-significant impact** on the invasion or spread of noxious weed species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with flow regime changes in the Secondary Study Area along the Sacramento River. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Sacramento River would be within the historical range of operation and would not adversely affect native plant species and communities. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Feather River

Operational modeling indicates that Feather River flows would meet or exceed the FERC Settlement Agreement's minimum flow requirements in all scenarios, with or without operation of the Project. The operational flexibility provided by the Project would result in a Feather River flow regime that would be less reactive to Delta conditions during summer and fall months. Consequently, when compared with Existing Conditions and the No Project/Action Alternative, flows in June through September in drier years would be improved. However, flows would generally be decreased during October, November, and December.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The higher Feather River flows that are currently released during summer months to improve Delta conditions (i.e., Existing Conditions) have the tendency to scour or inundate riparian vegetation, preventing growth of mature woody riparian vegetation (DWR, 2007). Implementation of Alternative A would return the river to a flow regime that is more stable during summer and fall months. Lower and more stabilized flows would reduce the risks of these adverse effects on riparian vegetation growth. The lower summer flows resulting from implementation of Alternative A would not likely have a substantial adverse effect on established riparian vegetation, and could be beneficial in drier years when flows would be higher than Existing Conditions and the No Project/No Action Alternative. The reduced summer flows would also not be likely to adversely affect the hydrology of backwater habitats, and the resulting reduction in the velocity and temperature of the river flows could be beneficial to some native vegetation. Because the modification of the existing flow regime in the Feather River from implementation of Alternative A is not expected to adversely affect riparian vegetation, the expected changes would have a **less-than-significant impact** on native vegetation on the Feather River downstream of Lake Oroville, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because modification of the existing flow regime in the Feather River resulting from implementation of Alternative A is not expected to adversely affect riparian vegetation, and may benefit native plant communities along the water's edge, riparian-associated plant species are not expected to be adversely affected. Therefore, the expected changes to the flow regime would have a **less-than-significant impact** on riparian-associated special-status plant species on the Feather River downstream of Lake Oroville, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

The higher Feather River flows that are currently released during summer months to improve Delta conditions (i.e., Existing Conditions) have the tendency to scour or inundate riparian vegetation, tending to result in colonization of non-native species that are tolerant of repeated disturbance (DWR, 2007). Lower and more stabilized flows associated with implementation of Alternative A would reduce the risks of this adverse effect. Therefore, the expected changes to the flow regime would have a **less-than-significant impact** on the spread of noxious weed species on the Feather River downstream of Lake Oroville, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime in the Secondary Study Area along the Feather River. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Feather River would be within the historical range of operation and would not adversely affect native plant species and communities. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sutter Bypass and Yolo Bypass

Operation of Alternative A would result in the diversion of up to 5,900 cfs from the Sacramento River during winter flows. These diversions would occur at the T-C, GCID, and Delevan Pipeline intakes, all of which are (or would be) located upstream of, and therefore, would affect the hydrology of, both the Sutter and Yolo bypasses. The spills into the Sutter Bypass would consequently be reduced by up to 5,900 cfs, which would reduce the velocity and volume of incoming water, and could delay the point at which the weirs begin to spill. Likewise, operational modeling indicates that that there would be a reduction in the duration and magnitude of flows entering into the Yolo Bypass if Alternative A is implemented.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Approximately 80 percent of the Sutter NWR is located in the Sutter Bypass, and the Yolo Bypass includes the Yolo WA. The riparian and floodplain wetland habitats within both the Sutter and Yolo bypasses support numerous species of native (and non-native) plants that are adapted to various degrees of inundation, and occur in various patterns relative to receding floodwaters. A reduction of the velocity and volume of floodwaters entering the bypasses from the Sacramento River would reduce the amount of flooding that the NWR and WA experience; the Sutter NWR can at times be covered with up to12 feet of water. If Alternative A is implemented, reduction in the velocity and volume of water could benefit riparian and wetland vegetation by reducing the duration of inundation and the amount of seedling scour that occurs during high flows. Therefore, the modification of the existing flow regime of the Sutter and Yolo bypasses that would result in reduced velocity and volume of incoming floodwaters would be a **potentially beneficial effect** to native plant communities and native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

One special-status plant species, currently known to exist at or adjacent to the edges of the Sutter Bypass, and four special-status species known to occur in the interior of the Yolo Bypass, are described in the Bypass impact analyses for the No Project/No Action Alternative. Assuming possible increased longevity in the Sutter and Yolo bypass water-related native plant communities due to expected flow modifications, operation of Alternative A would have a **potentially beneficial effect** on special-status plant species associated with Sutter and Yolo bypass riparian or wetland plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Assuming possible decreased scouring and increased longevity in the Sutter and Yolo bypass' stream-edge and interior wetland native plant communities, due to expected reduced flow levels and velocities, operation of Alternative A would reduce the invasion or spread of noxious weed species in the two bypasses, resulting in a **potentially beneficial effect**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime in the Secondary Study Area in the Sutter and Yolo bypasses. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Sutter and Yolo bypasses would be within the historical range of operation and would not adversely affect native plant species and communities. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

American River

Operational modeling indicates that operation of Alternative A would have effects on the American River that are similar to those described for the Feather River. The operational flexibility provided by implementation of Alternative A would result in an American River flow regime that would be more consistent with hydrologic conditions, rather than reactive to Delta conditions. Consequently, when compared to Existing Conditions and the No Project/No Action Alternative, flows would generally be decreased during June through September with the largest reductions in July. However, in drier years, flows would be improved from June through September when compared to the No Project/No Action Alternative.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The channel edges and backwater sloughs of the American River support mature riparian forests, as well as early to middle seral-stage riparian vegetation. Modifications to the existing flow regime of the American River have the potential to adversely affect these native plant communities. However, operation of Alternative A would return the river to a flow regime that is more stable during summer months. Under Existing Conditions, the higher flows that are released during summer months to improve Delta conditions have the potential to scour or inundate riparian vegetation. Lower and more stabilized flows would reduce risks of scouring. The lower summer flows associated with implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian vegetation, and could be beneficial in drier years when flows in June through September would be higher than for the No Project/No Action Alternative. Consequently, flow regime modifications resulting from implementation of Alternative A would have a **less-than-significant impact** on riparian native plant communities along the American River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

As indicated in **Impact Bot-1**, the lower summer flows associated with implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian vegetation, and could be beneficial in drier years when June through September flows would be higher than for the No Project/No Action Alternative. Consequently, flow regime modifications would not be likely to have a substantial adverse effect on special-status plant species associated with riparian vegetation. Therefore, flow regime modifications resulting from implementation of Alternative A would have a **less-than-significant impact** on riparian-associated special-status plant species along the American River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

As indicated in the **Impact Bot-1** discussion, operation of Alternative A would return the river to a flow regime that is more stable during summer months, reducing the area of exposed banks that are vulnerable to weed invasions. Flow regime modifications resulting from implementation of Alternative A would, therefore, have a **less-than-significant impact** on the invasion or spread of noxious weed species along the American River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with flow regime changes in the Secondary Study Area along the American River. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the American River would be within the historical range of operation and would not adversely affect native plant species and communities. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento-San Joaquin Delta

Operational modeling indicates that operation of Alternative A would result in a flow reduction in the Delta in December and January, resulting in a one to two kilometer shift in the position of X2. However, this shift would occur during wet months when X2 position is well within compliance of salinity standards for the Delta, and would, therefore, fall within the historical range of species tolerance for plant and animal life. Project operational modeling also indicates an improvement in salinity conditions in August through October, and increased inflows into the Delta during Critically Dry years.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modification of the flow regime associated with implementation of Alternative A would result in a shift in the X2 position that would still be within the historical range of tolerance of existing native plant communities. In addition, Delta salinity would be reduced in August through October, as well as in Critically Dry years. These conditions would result in a **less-than-significant impact** on native plant communities in the Delta, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The conditions described in the **Impact Bot-1** discussion that would occur from implementing Alternative A would result in a **less-than-significant impact** on special-status plant species in the Delta, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

The conditions described in the **Impact Bot-1** discussion that would occur from implementing Alternative A would result in a **less-than-significant impact** on the invasion or spread of noxious weed species in the Delta, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime in the Secondary Study Area within the Delta, so there would be no human disturbance associated with these activities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Delta would be within the historical range of operation and would not adversely affect native plant species and communities. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative

Suisun Bay

Operational modeling indicates that the diversions associated with Alternative A would substantially increase electrical conductivity (EC) (a measure of salinity levels) in the Suisun Marsh in December. However, for Existing Conditions and the No Project/No Action Alternative, EC would be very low in December, so the substantial increase in EC associated with implementation of Alternative A would result in overall EC levels that would be within the historic range of species tolerance.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Modifications to the existing flow regime of the bay and marsh could potentially result in adverse effects to Suisun Bay's and Marsh's extensive native wetland plant communities. However, because the modification of the flow regime associated with operation of Alternative A would result in an increase in Suisun Bay EC that would be within the historic range of tolerance of the plant communities, there would be a **less-than-significant impact** on native plant communities in Suisun Bay and Marsh, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The extensive native wetland plant communities of Suisun Bay and Marsh support many endemic and special-status plant species. Modifications to the existing flow regime of the bay and marsh could adversely affect these special-status species. However, because the modification of the flow regime associated with operation of Alternative A would result in an increase in Suisun Bay EC that would be within the historic range of tolerance of species, there would be a **less-than-significant impact** on special-status species in Suisun Bay and Marsh, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Modifications to the existing flow regime of the bay and marsh could potentially create conditions more favorable to non-native or invasive plant species. However, because the modification of the flow regime associated with operation of Alternative A would result in an increase in Suisun Bay EC that would be within the historic range of tolerance of species in existing plant communities, there would be a **less-than-significant impact** on the invasion or spread of noxious weed species in Suisun Bay and Marsh, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime in the Secondary Study Area within the Suisun Bay and Marsh, so there would be no human disturbance associated with these activities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Suisun Bay and Marsh would fall within the historical range of operation and would not adversely affect native plant species and communities. Consequently, these changes would not conflict with any HCPs, NCCPs, or local plans and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

San Pablo Bay and San Francisco Bay

Operation of Alternative A is not expected to affect the hydrology of San Pablo and San Francisco bays.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Because there would be no effect on hydrology within San Pablo or San Francisco bays from operation of Alternative A, there would be **no impact** to bordering native plant communities along edges of the bays, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because no effect on hydrology from operation of Alternative A is expected within San Pablo or San Francisco bays, there would be **no impact** to special-status plant species along edges of the bays, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because there would be no effect on hydrology within San Pablo or San Francisco bays from operation of Alternative A, there would be **no impact** on the invasion or spread of noxious weed species along edges of the bays, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

No Project-related human disturbance would be associated with flow regime changes in the Secondary Study Area within San Pablo and San Francisco bays, so there would be no human disturbance associated with these activities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because Project operation is not expected to affect the flow regime of San Pablo and San Francisco bays, there would be no conflict with any HCPs, NCCPs, or local plans and would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

13.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area and Sites Reservoir Dams

The construction of a 1.27-MAF Sites Reservoir would also require the construction of Sites Dam, Golden Gate Dam, and seven saddle dams. Construction-related ground-disturbing activities, vegetation removal, and the subsequent filling of the reservoir, would result in the direct and permanent loss of native plant communities and special-status plants within the inundation area, i.e., facility footprint (Table 13-13). Varying extents of several vegetation communities would be replaced by either standing water or sterile subsoil.

Table 13-13
Permanent Vegetation Loss Due to the Construction of the 1.27-MAF Sites Reservoir and Associated Dams: Alternative A

Vegetation Type	Permanent Loss (Acres)
Annual grassland	11,654.6
Blue oak woodland	182.3
Blue oak savanna	163.1
Blue oak/mixed chaparral	8.1
Cropland	267.9
Ponds	20.2
Urban/disturbed	76.1
Valley foothill riparian	64.0
Valley oak riparian	17.5
Valley oak woodland	3.4
TOTAL	**12,457.2**

Vegetation located outside of the facility footprint would also be temporarily disturbed during Project construction. This construction disturbance area would be located on the north and east sides of the reservoir in the vicinity of Sites and Golden Gate dams, and could consist of as much as 1,000 additional acres of land. The majority of vegetation that would be disturbed in those areas is annual grassland, but valley foothill riparian, and possibly wetland vegetation within the grasslands, could also be disturbed. Disturbed areas would be restored to their original habitat type following completion of construction.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland

The grassland landscape in and around the Sites Reservoir footprint supports some vernal pools and other vernally wet areas; for impacts to these and other wetland features, refer to Chapter15 Wetlands and Other Waters of the U.S. Construction of Sites Reservoir would result in the permanent loss of annual grassland, as described below.

Valley Edges

Although the grassland in the Sites Reservoir footprint area is mostly highly disturbed, the hillslopes around the footprint edges support a more diverse flora. The hillslopes around the Sites Reservoir footprint fall within the grassland-blue oak woodland edge. Because the floor and the edges of the reservoir footprint are comprised of grasslands of such different ecological and botanical value, it is useful to distinguish them in terms of degree of impact from the Project. The loss of approximately 2,500 acres of footprint-edge (moderately high quality) annual grassland would be a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Floor

In contrast to the reservoir edges, the reservoir footprint floor has been subject to such intensive human use that it is unlikely to have the capacity to support botanically rich or diverse native grassland in the foreseeable future. A substantial acreage of this valley floor is also often converted to hayfields, pasture and other agricultural uses from time to time, and other parts have been heavily grazed for many decades. Loss of over 9,000 acres of highly disturbed (very low quality) annual grassland in the footprint floor would be a **less-than-significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Salt Lake Wetlands

An exception to the botanically degraded Sites Reservoir footprint is the Salt Lake saline/alkaline wetland area, including additional seasonal vernally wet flats both upstream and downstream of the existing Salt Lake impoundment. Along with other wetland features, this area was mapped as part of the Annual Grassland community which surrounds it, and its acreage (approximately 20 acres) is included within the “annual grassland” type. Salt Lake and the adjacent flats are fed by warm saline springs that are also within the 520 foot expected water surface elevation of the Sites Reservoir. Inundation of the Salt Lake area would represent permanent loss of a rare habitat supporting unique saline-substrate flora. The related “Alkaline Meadow” vegetation association has a State Rank of 2.1 - “Imperiled by rarity due to very restricted range, steep declines, and other factors” (CNPS, 2011). Although the Salt Lake area is currently heavily compacted and disturbed by cattle, occasional representatives of the saline flora were found during Project surveys, indicating that the saline/alkaline habitat can support this suite of species. The loss of this saline/alkaline wetland vegetation would be a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative. For more detail on this long-term direct loss, refer to Chapter 15 Wetlands and Other Waters of the U.S.

Construction Staging Area

Disturbance to, and partial loss of, up to 1,000 acres of grassland outside of the Sites Reservoir footprint to the east and northeast due to reservoir and dam construction activities would occur in an area (in the northeast) containing seasonal wetlands. Some of this grassland, although also disturbed, is less disturbed than the interior of the reservoir footprint, and part of a vernal pool-seasonal wetland landscape. Therefore, losses of grassland in the reservoir's construction disturbance area could have a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Blue Oak Woodland

Blue oak woodland, blue oak savanna, and blue oak/mixed chaparral would be permanently lost from filling the Sites Reservoir. These wooded vegetation communities, mostly concentrated around the western and some southeastern edges of the reservoir footprint, support some of the most diverse native flora in the vicinity. They also represent a dwindling vegetation type in California, as more acres of blue oak woodlands are urbanized, converted to wine-grape vineyards, or cut for firewood, with slow to no regeneration in many grazed areas (U. C., 2007; U.C., 2008; U.C., 2011). The loss of more than 180 acres of blue oak woodland would be a **significant impact** to this inner coast-range foothills plant community, when compared to Existing Conditions and the No Project/No Action Alternative. Likewise, the loss of more than 160 acres of blue oak savanna and approximately eight acres of blue oak woodland supporting a substantial mixed-chaparral understory would each be a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Riparian Vegetation

Construction of Sites Reservoir would result in the permanent removal of riparian vegetation. Approximately 64 acres of valley-foothill and 17 acres of valley-oak riparian vegetation would be removed by clearing and filling of the 1.27-MAF Sites Reservoir. The riparian vegetation would be lost from mostly small (0.1- to 1-acre) fragments of woody streamside vegetation in highly disturbed and interrupted narrow ribbons along the edges and banks of Funks, Grapevine, and Antelope creeks. The largest areas (all under 3 acres in size) of well-developed riparian vegetation that would be lost are in the northwest part of the reservoir footprint along Grapevine Creek. The 81-acre total of riparian vegetation represents a remnant of these communities along watercourses in the Antelope Valley. Loss of any one of these small areas of riparian woodland and associated mixed native and non-native shrub and herbaceous flora would be a **less-than-significant impact** to native plant communities in this part of the state, when compared to Existing Conditions and the No Project/No Action Alternative. However, the loss of the 81 acres, combined with the additional acres subject to disturbance in the construction staging area, would be a **potentially significant impact** to this vegetation community that is already greatly diminished in the state (SRCAF, 2003) and recognized as a sensitive habitat (DFG, 2010a), when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Oak Woodland

Construction of Sites Reservoir would result in the permanent removal of valley oak woodland. Approximately 3.4 acres of valley oak woodland would be removed by construction and filling of the 1.27-MAF reservoir. The valley oak woodland occurs in small sites each smaller than 1.5 acres, and is in some cases a mixture of valley oak and other (possibly non-native) tree species such as walnut. The 3.4 acres of valley oak woodland lost to the reservoir footprint represent 100 percent of this vegetation type in the vicinity of the reservoir. Because this vegetation type is considered "Imperiled by rarity due to very restricted range, steep declines and other factors" (State Rank 2.1) (CNPS, 2011), its loss would be a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Land Cover Types

Agricultural fields, ponds, and urban/disturbed land support almost no native flora. The exceptions are a few of the stock ponds, which are mostly unvegetated, but in some seasons support small amounts of water-dependent vegetation. However, field observations indicate that most of this vegetation is also non-native (e.g., dock, cocklebur, and similar species). Construction impacts to these vegetation types would represent a **less-than-significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

CNPS List 1B and State- or Federally Listed Species

Construction and filling of the 1.27-MAF Sites Reservoir would result in no loss of known occurrences of any CNPS List 1B species or State- or federally listed species. However, two species with suitable habitat around the reservoir footprint edges were likely not adequately included in the reservoir footprint surveys of 1998-99, and therefore, may occur within the footprint: *Amsinckia lunaris* (AMLU - CNPS List 1B) and *Sidalcea keckii* (SIKE - CNPS List 1B and federally endangered). The possibility of these species occurring in the Project vicinity was reported after surveys were completed (2000 for AMLU when it was discovered adjacent to Project feature footprints, and 2008 for SIKE when specimens from an adjacent site were annotated to this taxon). It is possible that one or both occur in the similar habitat of grassland slopes within blue oak savanna or just downslope from blue oak woodland, located around the western and southeastern edges of the Sites Reservoir footprint. It is possible that these rare species were observed during the 1998-99 Project surveys, but entered to the species inventory list under the name for the common look-alikes (i.e., *Amsinkia intermedia* for AMLU, *Sidalcea diploscypha* for SIKE), for which occurrence locations are not documented. Because surveys targeting these species have not been completed, their presence must be assumed. Loss of occurrences of one or both of these rare species would be a **significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

One occurrence of an additional CNPS List 1B species, *Lotus rubriflorus* (LORU), is located approximately 150 feet uphill from the maximum expected water surface elevation for the 1.27-MAF reservoir footprint. Although outside of the reservoir's inundation area, this rare occurrence could easily be disturbed or destroyed by Project construction or recreation activities. The disturbance or loss of this species would be a **significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

CNPS List 4 Species

Construction and filling of the 1.27-MAF Sites Reservoir would result in the loss of 13 occurrences of four CNPS List 4 species: two occurrences of *Androsace elongata* ssp. *acuta* (fairy candelabra); five of *Hesperevax caulescens* (hogwallow starfish), one of *Navarretia eriocephala* (hoary navarretia), and five of *Navarretia heterandra* (Tehama navarretia). The latter three species are fairly common in vernally moist clay-soil grasslands in the Inner Coast Range foothills. Fairy candelabra is less common, and in fact, is not known from Glenn or Colusa counties prior to Project surveys. Although CNPS List 4 plants are not the rarest of California's special-status plants, they are considered uncommon (have a limited distribution) in California. For example, the fairy candelabra is considered vulnerable and possibly threatened in California (State Rank S3.2); in the Inner Coast Range foothills, it is found in a very restricted habitat of north-facing crumbly shale slopes. The *Hesperevax* and the two *Navarretias* both require heavy adobe clay soil and flat to gently sloping grasslands with very little thatch buildup. The hoary navarretia occurrences found during Project surveys are the northernmost recorded for the species. The 13 occurrences of all four species are located around the western and southeastern edges of the proposed Sites Reservoir footprint, at or near the grassland-blue oak woodland edge, often on or at the base of gentle hillslopes. The permanent loss of these CNPS List 4 occurrences would be a **potentially significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

During filling of Sites Reservoir and after it reaches full pool, it is possible that on some of the more gently sloping hillsides, especially within concave drainage areas, water-related vegetation that does not now occur in the Antelope Valley could grow. Most of this vegetation would be ephemeral, due to fluctuations in water levels. The added groundwater pressure of the reservoir could induce not only this type of annual riparian or wetland vegetation, but also some scattered annual herbaceous growth in fill-line-related bands around the barren draw-down zone, or "bath-tub ring". Much of this volunteer growth would be non-native species that responds to infertile, continually disturbed soil conditions. The reservoir footprint would thus become a productive substrate for many invasive species already occurring in the area, as well as others that have not yet invaded (e.g., thistles, bindweed, cocklebur, amaranth, and other species typical of reservoir edges). These populations would become a potential seed source for further invasion of surrounding grasslands and foothill environments, which would have a **potentially significant impact** on the invasion or spread of noxious weed species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Native plants may be directly or indirectly affected by dust generated from Project-related construction, operation, and maintenance, and recreation activities associated with the proposed Sites Reservoir and Dam. Construction activities would include the use of large equipment, and would result in temporarily increased dust, which could coat plants and lead to short-term decreased vigor in occurrences of native plants, including special-status plants potentially growing within 100 feet of the reservoir maximum expected water surface elevation. However, due to its temporary nature the human disturbance associated with construction, operation, and maintenance of these facilities would have a **less-than-significant impact** on native plants adjacent to the reservoir and dams, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

The Primary Study Area is not included in any HCPs or NCCPs. The Colusa County Voluntary Oak Woodlands Management Plan provides guidelines for voluntary participation, and Project mitigation for oak woodlands would exceed those guidelines. Therefore, there is no conflict with this plan and consequently **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas and Associated Electrical Distribution Lines

The Antelope Island, Lurline Headwaters, Stone Corral, Peninsula Hills, and Saddle Dam recreation areas all have footprints that represent the total area within which land-based recreation could occur. However, only approximately 15 percent of each footprint (approximately 175 acres total) would experience a permanent loss of vegetation cover as a result of the construction of facilities, such as boat ramps, picnic areas, roads, fire rings, restroom facilities, and campgrounds. The remainder of the acreage within each recreation area footprint could experience indirect impacts from ongoing recreational activities.

Three of the recreation areas also have associated electrical distribution lines. The total acreage of plant communities affected by each recreation area and its associated electrical distribution line is presented in Table 13-14.

Table 13-14
Permanent Vegetation Loss and Temporary Disturbance Due to the Construction of Recreation Areas and Associated Electrical Distribution Lines: Alternative A

Vegetation Type	Total Number of Acres Affected						
	Saddle Dam[a]	Peninsula Hills[a]	Stone Corral	Antelope Island	Lurline Headwaters[a]	TOTAL Disturbance	Permanent Loss[b]
Annual grassland	271.6	78.2	132.8	12.3	79.2	**574.1**	86.1
Blue oak woodland	0.0	115.3	102.3	20.3	96.4	**334.3**	50.0
Blue oak savanna	0.0	185.9	0.0	13.5	48.2	**247.6**	37.0
Blue oak/mixed chaparral	0.0	0.0	0.0	3.1	11.6	**14.7**	2.2
Chamise	0.0	0.0	0.0	0.0	1.0	**1.0**	0.2
Ponds	1.2	0.0	0.0	0.0	0.0[c]	**1.2**	0.2
TOTAL	**272.8**	**379.4**	**235.1**	**49.2**	**236.4**	**1,172.9**	**175.7**

[a]Acreage includes construction disturbance area for associated electrical distribution line.
[b]Permanent loss is calculated as 15 percent of the total construction disturbance area.
[c]This recreation area footprint has a pond with a total area of less than 0.1 acre

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland

Annual grasslands within the footprints of the proposed Antelope Island, Lurline Headwaters, Stone Corral, and Peninsula Hills recreation areas have similar value to native plant communities as the “edge” grasslands described in the impact assessment for Sites Reservoir and Dams. This grassland is relatively high quality because it is much less disturbed than grassland located within the reservoir footprint, has remnant native bunchgrass components, and is at or within the grassland-blue oak woodland edge. Annual grassland in the Saddle Dam Recreation Area footprint is also high quality, despite its grazing history and lack of blue oak woodland, because it is part of a surrounding landscape with abundant seasonal wetlands, vernal pools and saline/alkaline wetlands. The potential disturbance of up to 574 acres and permanent loss of approximately 86 acres of annual grasslands in these recreation area footprints during construction of the recreation areas would represent a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Blue Oak Woodland

Blue oak woodlands within the footprints of the proposed Antelope Island, Lurline Headwaters, Stone Corral, and Peninsula Hills recreation areas and their associated transmission lines vary from savanna to woodland, with and without a substantial mixed chaparral understory. These woodlands are of the same value to native plant communities as those described in the impact assessment for Sites Reservoir and Dams. All types of blue oak woodland in these recreation area footprints are high quality because they have not been heavily grazed. The potential disturbance of up to almost 600 acres and the permanent loss of 89 acres of blue oak woodlands around the slopes above Antelope Valley during construction of the recreation areas would represent a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Chamise

Chamise shrubland occurs within the transmission line route for the Lurline Headwaters Recreation Area. This densely vegetated plant community is very common in the Coast Range and has a low diversity of native plant species. Potential disturbance of one acre and virtually no permanent loss of chamise on these slopes above Antelope Valley during construction of the recreation areas would represent a **less-than-significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Land Cover Types

Ponds support almost no native flora. The ponds are stock ponds, which are mostly unvegetated, but may in some seasons support small amounts of water-dependent vegetation. However, field observations indicate that most of this vegetation is also non-native (e.g., dock, cocklebur, and similar species). Construction impacts to this vegetation type would represent a **less-than-significant impact** to native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

CNPS List 1B and State- or Federally Listed Species

No habitats for, or occurrences of, any of the vernal pool-related special-status plant species occur in the five recreation area footprints, so there would be **no impact** on these species, when compared to Existing Conditions and the No Project/No Action Alternative. Suitable habitat for the special-status plant species associated with heavy clay or crumbly clay-loam hillside oak woodland/grassland edges (*Fritillaria pluriflora, Amsinckia lunaris, California macrophylla*, or *Lotus rubriflorus*) occurs in most or all of the recreation areas and associated distribution line footprints. The federally endangered *Sidalcea keckii* is also potentially present. No occurrences of the first four species were found during Project surveys.

One small occurrence of *Lotus rubriflorus* was found in the footprint of the Peninsula Hills Recreation Area during Project surveys. All or part of this small occurrence, found just above the western 520-foot contour above Antelope Valley, would likely be lost, either from direct destruction during construction of Sites Reservoir, or construction of recreation areas within the reservoir footprint, because the occurrence is located where the two footprints meet. *Lotus rubriflorus* was not known from the Sites Reservoir area prior to Project surveys. The two nearest known occurrences were seven miles west of the reservoir footprint, and more than 40 miles to the northeast. However, during Project surveys, an abundant occurrence of *L. rubriflorus w*as discovered approximately four miles southwest of the Peninsula Hills Recreation Area footprint along Grapevine Creek. Loss of the one small occurrence at the Peninsula Hills Recreation Area edge would diminish the numbers of *L. rubriflorus* in this part of its range to a minor degree, which would have a **potentially significant impact** on this special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Sidalcea keckii, Amsinckia lunaris or *California macrophylla* can be easily overlooked or misidentified. The *Amsinckia* was not included on the 1998 to 2000 survey search lists, and some parts of some of the recreation area footprints were not surveyed. The *Sidalcea* was not included on any of the survey search lists because it was thought to be either extinct or to occur only in southeastern California. Therefore, it is possible that occurrences of one or all three species exist in the Antelope Island, Stone Corral, Peninsula Hills, or western portion of Lurline Headwaters recreation areas, and could be affected by construction of the recreation areas. Loss or disturbance to any of these three species would be a **potentially significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative, because very few occurrences of these species are known from the portion of their ranges near proposed Project features.

It should be noted that some adverse effects to occurrences of special-status plant species in adjacent lands could occur due to competition and habitat alteration resulting from invasion of noxious weed species (refer to the **Impact Bot-3** discussion). The known occurrences that could be affected are those of *Amsinckia lunaris* and *California macrophylla* in the hills 0.2 to 0.3 mile west of the Peninsula Hills Recreation Area. Other as yet undiscovered occurrences of these species, and possibly *Lotus rubriflorus* or *Sidalcea keckii*, could also be affected if they exist in lands surrounding the recreation areas.

CNPS List 4 Species

Although habitats for some of the CNPS List 4 species exist in the recreation area footprints, no occurrences of these species were found during Project surveys, so **no impact** is expected to these special-status plant species from construction of recreation areas or recreational use of the areas, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance in the grasslands and open blue-oak woodland slopes of the recreation area footprints would result in many small edges and areas of bare soil. On their own, these disturbed areas would revegetate with mostly non-native annual plant species, with high potential for spread or new colonization by common noxious weeds in the surrounding foothills and valley, such as yellow star-thistle, Italian plume-thistle, barbed goat-grass, mustards and milk thistle. Revegetation by native species in disturbed ground is very unlikely, due to the rapid growth rates and other superior competitive abilities of most invasive weedy species. Therefore, even temporary disturbance of up to 1,000 acres of land while constructing the five recreation areas, as well as potential ground-disturbance associated with recreational activities during operation, and maintenance activities such as road grading, would increase the probability of the spread of noxious weeds. These weed populations would not only displace native vegetation, but would then become a potential seed source for further invasion of surrounding grasslands and foothill environments, which would have a **potentially significant impact** on the remaining native vegetation, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Native plants may be directly or indirectly affected by Project-related construction, operation, and maintenance, and recreation activities associated with the five proposed recreation areas. Indirect impacts from increased human use and vehicle traffic would affect some portion of the grasslands and woodlands. Construction activities would include the use of large equipment, and would result in temporarily increased dust, which could coat plants and lead to short-term decreased vigor in occurrences of native plants. Potential indirect impacts also include introduction of noxious weeds, death of shrubs or trees from disruption of water sources or drainage patterns, disturbance or destruction of bulbs and roots by digging pets, disturbance of plants, and degradation of soil by off-road vehicle compaction. Indirect impacts from human recreational activities, such as hiking, camping in undesignated areas, and off-road vehicle or mountain bike use, and from human trampling could erode and introduce weeds into much of the area surrounding the facilities. Because special-status plant species not included in Project surveys may occur in at least four of the five recreation area footprints, human disturbance could have a **potentially significant impact** on native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Road Relocations and South Bridge

The road relocations and South Bridge include portions of the existing Huffmaster, Peterson, Maxwell Sites, Sites Lodoga, and private property roads; new access roads to facilities, such as recreation areas and dams; connections between existing and new roads; and an approach to a new bridge.

The 200-foot-wide construction disturbance area includes the surface areas of more than 35 miles of roads, the associated shoulders and cut and fill slopes, plus additional area for equipment staging and other construction activities. Both sides of the roads are proposed to be fenced. Construction of the road relocations and South Bridge would result in direct and permanent loss of existing vegetation within the entire construction disturbance area, as well as some temporary loss. Areas disturbed only during Project construction would be allowed to return to their original vegetation cover following completion of construction. Acreage for the South Bridge is not included in this analysis because the bridge would not have an on-the-ground footprint. The construction disturbance area for the bridge would fall within the footprint of Sites Reservoir, and is, therefore, already accounted for in the permanent loss of habitat associated with the reservoir.

Of the 200-foot total construction disturbance area width, an approximate average of 60 feet (30 percent) would result in the direct and permanent loss of native plant communities and other land cover resulting from the footprint of the roads and the required cut and fill. The permanent loss of habitat would, therefore, be approximately 285 acres. The majority of the acreage affected by construction of the roads would be annual grassland and blue oak woodlands.

The acres of each vegetation type that would be affected by the road relocations and South Bridge are listed in Table 13-15.

Table 13-15
Permanent Vegetation Loss and Temporary Disturbance Due to the Construction of the Road Relocations and South Bridge: Alternative A

Vegetation Type	Total Number of Acres Affected	Permanent Loss* (Acres)
Annual grassland	719.9	216.0
Blue oak woodland	98.9	29.7
Blue oak savanna	84.6	25.3
Blue oak/mixed chaparral	12.3	3.7
Canal	0.6	0.2
Chamise	1.5	0.4
Cropland	15.9	4.8
Mixed chaparral	2.6	0.8
Pond	0.5	0.2
Urban/disturbed	9.7	2.9
Valley foothill riparian	4.0	1.2
Valley oak riparian	0.2	0.1
TOTAL	**950.7**	**285.3**

*Permanent loss is calculated as 30 percent of the total construction disturbance area.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland

Annual grasslands within the footprint and construction disturbance area of the proposed road relocations have similar value to native plant communities as the “edge” grasslands as described in the impact assessment for Sites Reservoir and Dams. This grassland is relatively high quality because it is much less disturbed than the grassland in the reservoir footprint, has remnant native bunchgrass components, and is at or within the grassland-blue oak woodland edge. Annual grassland in the road relocation footprint of the North Road to Saddle Dam Road is also high quality, despite its grazing history and lack of blue oak woodland, because it is part of a surrounding landscape with abundant seasonal wetlands, vernal pools and saline/alkaline wetlands. The road relocation route in this area would be immediately adjacent to several wetland features within surrounding grasslands. Disturbance of up to 719 acres of moderately high quality annual grasslands, of which approximately 285 acres would be a permanent loss, due to construction of the proposed road relocations would represent a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Blue Oak Woodland

Blue oak woodlands within the footprint and construction disturbance area of the road relocations vary from savanna to woodland both with and without a substantial mixed chaparral understory. These woodlands are of the same value to native plant communities as those described in the impact assessment for Sites Reservoir and Dams and for four of the five Recreation Areas. All types of blue oak woodland in the road route disturbance area are high quality because they have not been heavily grazed, and their grassland edges are potential habitat for special-status plant species. The road disturbance area contains almost 100 acres of blue oak woodland (very little shrub understory), approximately 85 acres of more open blue oak savanna, and approximately 12 acres of blue oak woodland with a substantial mixed chaparral understory. Temporary disturbance of blue oak woodlands of any type can result in long-term or permanent conversion to another type of vegetation cover (usually of weedy grassland or shrubland), due to the slow and problematic regeneration of blue oak as a species. The disturbance and potentially permanent loss of up to almost 200 acres of blue oak woodlands from road relocation construction would represent a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Chamise

Chamise shrubland within the footprint and construction disturbance area of the road relocations occurs only within the route serving the Communication towers north of the Lurline Headwaters Recreation Area (Com Road). The densely vegetated chamise shrubland plant community is very common in the Coast Range and has low diversity of native plant species. Areas temporarily disturbed during Project construction activities in the disturbance area would be likely to revegetate readily with chamise. The permanent loss of approximately 0.4 acre of chamise on these slopes above Antelope Valley during road construction would be less than one percent of the 114 acres of this plant community mapped east of Logan Ridge in the Project vicinity. The chamise community is very common in the main ridges of the Coast Range. Therefore, this loss would represent a **less-than-significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Mixed Chaparral

Mixed chaparral shrubland within the footprint and construction easement of the road relocations occurs only within the route serving the south end of the reservoir (Sulfur Gap Road to Lurline Road to Huffmaster Road segment). The densely vegetated chaparral plant community is not potential habitat for any special-status species. Mixed chaparral is very common in the Coast Range, although not common on the east side of Antelope Valley. Its edges can support a high diversity of native plant species, some unique to chaparral. The 2.6 acres that would be temporarily disturbed during construction activities in the corridor would likely revegetate readily with chaparral species. The permanent loss of 0.8 acre of mixed chaparral represents approximately seven percent of the 11.8 acres of this plant community mapped on these slopes above the east edge of Antelope Valley. Construction activities in the road relocation corridor would result in a **less-than-significant impact** to native plant communities and associated native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Riparian Vegetation

Riparian woodland, either mixed species or dominated by valley oak, within the footprint and construction disturbance area of the road relocations occurs in various locations around the Primary Study Area where the road route crosses Funks, Lurline, Antelope, and unnamed creeks. Although this plant community is not potential habitat for any special-status species, it is an ecologically important and sensitive plant community and potentially supports a unique set of native plant species. Disturbance to the seven stream crossings with mixed riparian growth, and one crossing of the south end of Antelope Creek with valley-oak-dominated riparian forest, would most likely be permanent, rather than temporary; mature woody riparian vegetation would likely return as weedy herbaceous growth after completion of construction. The loss of 4.2 acres of riparian vegetation during road construction would represent a **significant impact** to native plant communities and associated native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Land Cover Types

Canal, crops/agriculture, ponds, and urban/disturbed land support almost no native flora; the ponds are stock ponds, which are mostly unvegetated, but may in some seasons support small amounts of water-dependent vegetation. However, field observations indicate that most of this is also non-native (e.g., dock, cocklebur, and similar species). Construction impacts to these vegetation types would represent a **less-than-significant impact** to native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

CNPS List 1B and State- or Federally Listed Species

Ground disturbance along the road relocation disturbance area during Project construction would result in no direct impact to any known occurrences of special-status species that are State or federally listed or on CNPS List 1B. However, the road relocation disturbance area traverses through potential habitat for the federally endangered *Sidalcea keckii* (SIKE), which was added to survey search lists after Project surveys were conducted, and may, therefore, be present in areas surveyed before 2010. Potential habitat is associated with all road segments except for the Eastside Road (property north of Golden Gate Dam to North Road segment).The road segments with the highest probability of impacting SIKE would be those on the west side of the reservoir footprint in the Peninsula Hills Recreation Area vicinity; SIKE could also be present in other segments of the road construction disturbance area. If occurrences of this rare species are found within the road relocation disturbance area, any direct loss resulting from Project construction would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Known occurrences of CNPS List 1B special-status species were avoided when designing the location of the road relocation route based upon estimates of land required for cut-and-fill and the road surface. However, when the route was expanded to a 200-foot-wide construction disturbance area, parts of two occurrences of *Amsinckia lunaris* (AMLU), a CNPS List 1B species, were included within the road relocation segments to the west and south of the Peninsula Hills Recreation Area. In addition, one occurrence of *California macrophylla* (CAMA), also a CNPS List 1B species, is located immediately adjacent to the expanded construction disturbance area of the road relocation west of the Peninsula Hills Recreation Area. Any loss in either AMLU occurrence or the CAMA occurrence during road construction would represent a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Other than the overlap with AMLU, as long as all construction-related ground disturbance occurs within the 200-foot construction disturbance area, there should be **no impact** of construction-related direct loss or direct disturbance to known occurrences of CNPS List 1B species, when compared to Existing Conditions and the No Project/No Action Alternative.

CNPS List 4 Species

Known occurrences of CNPS List 4 special-status species were avoided when designing the location of the road relocation route except for the Eastside Road/Road 69 connector, which was added after initial (1998 to 2001) Project surveys were completed. Also, when the road construction disturbance area was expanded to include a 200-foot buffer, portions of several occurrences of CNPS List 4 species were included in the construction disturbance area to the west of the Peninsula Hills Recreation Area. Potentially affected are 1 site of *Androsace elongata* ssp. *acuta* (ANELA) and two sites of *Heseperevax caulescens* (HECA). Their direct loss during road construction would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

For all segments of the road relocation construction disturbance area except within the Eastside Road corridor and the Peninsula Hills roads, habitats for some of the CNPS List 4 species exist, but no occurrences of these species were found within the construction disturbance area during Project surveys. Therefore, **no impact** of direct loss is expected to these species from road construction activities, when compared to Existing Conditions and the No Project/No Action Alternative, with the exception of the two segments named.

For the Eastside Road (property north of Golden Gate Dam to North Road segment), abundant occurrences of CNPS List 4 species were found within the construction disturbance area during 2010 surveys. This corridor lies within grassy hills of mostly clay soils, which retain moisture in the spring. These vernally moist grasslands are the preferred habitat for the three species found in abundance within this corridor: 48 sites of *Hesperevax caulescens* (HECA), totaling 13 acres; 43 sites of *Navarretia nigelliformis* (NANI), totaling 13.8 acres; and two sites of *Navarretia heterandra*, totaling 0.14 acre. The occurrences of HECA and NANI are mostly intermingled, so total acreage of special-status plants within this corridor would be closer to 15 acres rather than the sum of all their acreages. At least two patches of native bunch-grasses, *Stipa pulchra*, also occur within this corridor. Although permanent losses would occur within 30 percent of the Project construction disturbance area, even temporary ground disturbance during the construction period would likely result in long-term to permanent losses to these plants. Although some of the HECA and NANI may return, the land is most likely to revegetate with non-native weedy species common in the surrounding grasslands. Therefore, total loss during road construction would be expected; this magnitude of loss would represent a **potentially significant impact** to these three CNPS List 4 species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance along the road relocation corridor during Project construction would result in many small edges and areas of bare soil. These disturbed areas would likely revegetate with mostly non-native annual plant species, with high potential for spread or new colonization in the surrounding foothills and valley by common noxious weeds, such as yellow star-thistle, Italian plume-thistle, barbed goat-grass, mustards and milk thistle. Spontaneous revegetation by native species in disturbed ground is very unlikely, due to the rapid growth rates and other superior competitive abilities of many invasive weedy species. Therefore, even temporary disturbance of up to 950 acres of land while constructing the road relocations, as well as the potential ground disturbance associated with vehicles driving on the shoulder during operation and road maintenance, would increase the probability of spread of noxious weeds. These weed populations would not only displace native vegetation, but would then become a potential seed source for further invasion of surrounding grasslands and foothill environments, affecting the remaining native vegetation, including potentially present special-status plant species. Some adverse effects to occurrences of special-status plant species in adjacent lands could occur due to competition and habitat alteration. The known occurrences which could be affected include those of *Amsinckia lunaris*, *California macrophylla*, and *Hesperevax caulescens* (HECA) in the hills within one mile of the Peninsula Hills Recreation Area. Other as yet undiscovered occurrences of these species, and possibly *Lotus rubriflorus* or *Sidalcea keckii*, could also be affected if they exist in lands surrounding Antelope Valley. Other special-status species potentially affected by weed infestations from road construction include *Navarretia heterandra* (NAHE) in the area southeast of the Lurline Headwaters Recreation Area, and *Navarretia nigelliformis*, NAHE and HECA along the Eastside Road connecting Road 69 with the dam facilities road system near Funks Reservoir. The high potential for new weed infestation and spread from the road relocation construction to these special-status occurrences and their remaining habitats would be a **significant impact** to native vegetation and plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

As a result of Project-related construction, operation, and maintenance activities, or potential lack of fence maintenance, indirect impacts from increased human use and vehicle traffic would also affect some portion of these grasslands, woodlands, shrublands, and riparian creek crossings, including habitat areas for adjacent or nearby special-status plant species. Potential indirect impacts include introduction of noxious weeds, death of shrubs or trees or the decline of native species from disruption of water sources or drainage patterns, disturbance or destruction of bulbs and roots, disturbance of plants, and degradation of soil by off-road vehicle compaction. These indirect impacts would be minimized where the road is fenced on both sides; however, the indirect effects along any portions of the route where fencing is not maintained would represent a **potentially significant impact** on native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

The construction of the Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard would require ground-disturbing activities that would result in the direct and permanent loss of grassland and riparian plant communities. The acreage of land cover lost to Project construction of these facilities represents the actual footprint of the facilities, and would result in complete loss of existing ground cover (Table 13-16).

Table 13-16
Permanent Vegetation Loss Due to Construction of the Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard: Alternative A

Habitat	Permanent Loss (Acres)
Annual grassland	81.6
Pond	0.2
Urban/disturbed	4.3
Valley foothill riparian	3.1
TOTAL	**89.2**

Additional acreage of temporary disturbance (to occur only during the construction period) would be required; assuming an additional requirement of 10 percent of footprint acreage, the construction disturbance area would be approximately nine acres. The majority of land occupied by the construction disturbance area would be adjacent grassland.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland

Annual grassland within the footprint of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard has the same value to native plant communities and native plants as described in the impact assessment for Sites Reservoir and Dams; this grassland area has a very low botanical value because it is very disturbed and consists almost totally of non-native weedy grasses and invasive species. This grassland is not a wetland or vernal pool landscape, and supports no special-status plant species. The permanent loss of 81.6 acres and the potential temporary disturbance of an additional nine acres of annual grassland resulting from the construction of these facilities would be a **less-than-significant impact** to native plants communities in the Project vicinity, when compared to Existing Conditions and the No Project/No Action Alternative.

Riparian Vegetation

Riparian vegetation within the footprint of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard has the same value to native plant communities and native plants as described in the impact assessment for Sites Reservoir and Dams. Construction of these facilities would permanently displace riparian vegetation within approximately 0.2 mile of Funks Creek's natural channel upstream of Funks Dam, in two sites (Figure 13-3), when compared to Existing Conditions and the No Project/No Action Alternative.

One of the two sites consists of the flooded area of the creek channel upstream of Funks Reservoir, and supports almost no riparian vegetation. The second site of spotty interrupted riparian vegetation consists of a thin ribbon of very few riparian trees (cottonwood, willow) and small patches of introduced trees such as walnut, fig, or tree-of-heaven, separated by stretches having little or no vegetation. Weedy non-native herbaceous vegetation is also common along this stretch of Funks Creek, parts of which are very disturbed by cattle crossings. This site supports no special-status plant species. Disturbance of these 3 acres of riparian land (most of which is open water) during construction of these facilities would represent a **less-than-significant impact** to native plant communities due to the degraded nature of the existing riparian community at this site, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Land Cover Types

Ponds and urban/disturbed land support almost no native flora; the ponds are stock ponds, which are mostly unvegetated, but may in some seasons support small amounts of water-dependent vegetation. However, field observations indicate that most of this is also non-native (e.g., dock, cocklebur, and similar species). Permanent loss of these ponds and urbanized areas during construction of these facilities would represent a **less-than-significant impact** to native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-Status Plant Species

Construction of the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard would result in **no impact**, direct or indirect, to any known occurrences of special-status species that are State or federally listed or on any CNPS lists, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, no special-status plant species were found during Project surveys of the footprint areas for these facilities.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance due to construction activities within the footprints for the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard and construction disturbance area would result in many areas of bare soil. These disturbed areas would likely revegetate with mostly non-native annual plant species, with high potential for spread or new colonization in the surrounding foothills and valley by common noxious weeds, such as yellow star-thistle, Italian plume-thistle, barbed goat-grass, mustards and milk thistle. Spontaneous revegetation by native species in disturbed ground is highly unlikely due to the abundance of non-native species in surrounding land. Therefore, even temporary disturbance of up to 90 acres of land while constructing the facilities would increase the probability of spread of noxious weeds. These weed populations would not only displace the little remaining native vegetation in the area, but would then become a potential seed source for further invasion of surrounding grasslands and foothill environments and affect the remaining native vegetation, which would represent a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance of these facilities would not be expected to result in additional ground disturbance, and would, therefore, have a **less-than-significant impact** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Grasslands adjacent to the footprints for the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard may be directly or indirectly affected by Project-related human activities, such as increased road traffic, dust, possible introduction of non-native plant species, or other disturbance during construction, operation, and maintenance. However, due to the already highly disturbed nature of these footprint areas and the absence of any special-status plant species, increased human activity around these facilities would have a **less-than-significant impact** on native plants, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Construction of Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would result in the direct and permanent loss of native and non-native plant communities (Table 13-17). This group of facilities within the Complex includes the Holthouse Reservoir and Dam, the breached Funks Dam, as well as the associated Holthouse Spillway and Stilling Basin, Holthouse Pumping Plant, T-C Canal Discharge Dissipater, and the Funks Bypass Pipeline, and the Holthouse to T-C Canal Pipeline. Except for the 24-acre T-C Canal discharge pipeline construction disturbance area, the acreage lost represents the direct impact area; i.e., only the footprint of the facilities. Construction of the Holthouse to T-C Canal Pipeline would result in the temporary disturbance of non-native vegetation (Table 13-17). Areas disturbed only during Project construction would be allowed to return to their original vegetation cover following completion of construction.

Table 13-17
Permanent Vegetation Loss and Temporary Disturbance Due to the Construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard: Alternative A

Habitat	Temporary Disturbance* (Acres)	Permanent Loss (Acres)
Annual grassland	9.7	112.7
Alkaline wetland	0	0.5
Canal [existing T-C Canal]	0.4	7.3
Crops/agriculture	14.2	212.3
Urban/disturbed [existing Funks Dam]	0	0.6
Valley foothill riparian	0	7.0
TOTAL	**24.3**	**340.4**

*Acreage represents temporary disturbance associated with the defined construction disturbance area of the Holthouse to T-C Canal Pipeline.

Additional acreage of temporary disturbance would occur as a result of a construction disturbance area for these facilities. The construction disturbance areas for the Delevan Transmission Line and the Delevan and TRR pipelines would be located immediately adjacent to the footprint of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard facilities. The construction disturbance area for these facilities would be approximately 36 acres in size, but could overlap with the pipeline construction disturbance area. Areas of temporary disturbance would be restored to their original land cover type following completion of Project construction. The majority of vegetation affected by these facilities would be agricultural fields, with some annual grassland.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland

Annual grassland within the footprint of each of the Holthouse Reservoir facilities has similar value to native plant communities and native plants as described in the impact assessment for Sites Dam and Reservoir facilities; most of this grassland area has a very low botanical value because it is very disturbed and consists almost totally of non-native weedy grasses and forbs, and is not a wetland or vernal pool landscape. However, there is an area of unknown acreage of grassland within the T-C Canal discharge pipeline construction disturbance area, and possibly extending into parts of the Holthouse Dam footprint, that supports the headwaters of an alkaline wetland swale that extends to the southeast (Figure 13-4). Permanent loss or disturbance of this acreage could disrupt the water supply to the swale. Therefore, direct loss of this portion of the Holthouse Reservoir Complex grassland during construction would be a **potentially significant impact** to native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Riparian Vegetation

Riparian vegetation within the footprint of the Holthouse Reservoir facilities consists of approximately seven acres along Funks Creek downstream of Funks Dam. Much of this strip is narrow, but at least two acres immediately downstream of the dam outlet supports a patch of mature and diverse multi-storied riparian vegetation. The remainder is also dotted with mature woody growth, mostly of fairly tall trees and some shrubs and minor amounts of herbaceous understory. Permanent loss of these seven acres of riparian vegetation during construction would be a **significant impact** to native plant communities and native plant species in the area, when compared to Existing Conditions and the No Project/No Action Alternative.

Alkaline Wetland

Direct and permanent loss of up to 0.5 acre of saline/alkaline wetland swale within the grasslands affected by construction of the Holthouse Reservoir facilities would be a loss of a sensitive plant community. The Holthouse Reservoir Complex could block or otherwise disrupt the water supply (whether overland or underground or both) to this alkaline wetland swale. It is also a sensitive and rare native vegetation community (CNPS, 2011) and feeds into a larger saline/alkaline marsh to the southeast. The direct and permanent loss of up to 0.5 acre of saline/alkaline wetland swale within the grasslands affected by construction of Holthouse Reservoir Complex would be a **significant impact** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Once Holthouse Reservoir is filled, the weight of the water behind the dam would likely change the level and probably the chemistry of the groundwater in the adjacent lands to the south and east (refer to Chapter 10 Groundwater Resources). Because the water in Holthouse Reservoir would be fresh water originating from the Sacramento River, leakage of this water into the groundwater to the east would likely raise the water table with much less saline water than has existed in the past. This change would be likely, over time, to convert the alkaline wetland, vernal pools, flats and swales into a freshwater marsh plant community. Such conversion from rare alkaline meadow/wetland to freshwater seasonal wetland would most likely cause disappearance of most of the saltgrass and other plant species of the current plant community; moisture-loving non-native species already occurring in adjacent weedy fields and ditches would likely invade the area. This probable conversion away from alkaline wetland due to groundwater pressure from Holthouse reservoir would be a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Land Cover Types

Canal, crops/agriculture, and urban/disturbed land support almost no native flora. Construction impacts to these vegetation types would represent a **less-than-significant impact** to native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-Status Plant Species

Construction of the Holthouse Reservoir facilities would result in **no impact** (no direct loss) to any known occurrences of special-status species that are State or federally listed or on any CNPS lists, when compared to Existing Conditions and the No Project/No Action Alternative. No special-status plant species were found during field surveys in the Holthouse Reservoir Complex footprint area.

However, after inundation the weight of the water behind Holthouse Dam would have a high potential to leak fresh water into adjacent groundwater tables to the east, converting the existing alkaline wetlands, flats, swales, and vernal pools to a freshwater marsh plant community, with moisture-loving weed infestations also likely. Such conversion from rare alkaline meadow/wetland to freshwater seasonal wetland would most likely cause disappearance of all of the special-status plant species that now occur around the saltgrass-dominated plant community and alkaline wetland swales. These species include *Atriplex depressa* (brittlescale – CNPS List 1B) and *Centromadia parryi* ssp. *rudis* (Parry's rough tarplant – CNPS List 4). Other special-status species known from nearby and likely to occur in this area, but suppressed by non-native vegetation growth, include *Atriplex joaquiniana* (San Joaquin spearscale – CNPS List 1B) and *Centromadia parryi* ssp. *parryi* (pappose tarplant – CNPS List 1B). This eventual conversion from alkaline wetland and loss of special-status plant species due to groundwater pressure from Holthouse Reservoir would be a **potentially significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance due to construction activities within the Holthouse Reservoir facilities footprints and T-C Canal pipeline construction disturbance area would result in many areas of bare soil. The Holthouse Dam and Reservoir would have the potential to contribute to weedy growth because the dam would be an earthen structure. In addition, the 24-acre pipeline construction disturbance area would remain with an exposed disturbed surface. This strip would typically revegetate with mostly non-native annual plant species, with high potential for spread or new colonization in the surrounding foothills and valley by common noxious weeds, such as yellow star-thistle, Italian plume-thistle, barbed goat-grass, mustards, and milk thistle. Spontaneous revegetation by native species in disturbed ground is highly unlikely due to the abundance of non-native species in surrounding land. Therefore, even temporary disturbance of up to 24 acres of land while constructing the pipeline would increase the probability of spread of noxious weeds. Operation of these facilities would not be expected to result in additional ground disturbance, but maintenance of the earthen dam and associated roads could result in ground disturbance and therefore also increase the probability of spread of noxious weeds. These weed populations would not only displace the little remaining native vegetation in the area, but would then become a potential seed source for further invasion of surrounding grasslands and adjacent sensitive wetland swales and affect the remaining native vegetation, which would represent a **potentially significant impact** to native plant communities and species, including special-status species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Grasslands adjacent to the Holthouse Reservoir facilities may be directly or indirectly affected by Project-related human activities such as increased road traffic, dust, possible introduction of non-native plant species, or other disturbance such as foot traffic during construction, operation, and maintenance. Due to the already highly disturbed nature of most of the footprint area, this activity would not have much impact. However, due to the proximity of sensitive wetland swales and the presence within them of special-status plant species, increased human activity around these facilities would have a **potentially significant impact** on native plants, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Modifications to the GCID Canal would result in the temporary disturbance of the existing facilities and existing water surface, and could affect adjacent urban/disturbed areas (Table 13-18).

Table 13-18
Temporary Disturbance of Vegetation Communities Due to Modifications of the Glenn-Colusa Irrigation District Canal Facilities: Alternative A

Vegetation Type	Temporary Disturbance (Acres)
Canal (existing GCID Canal)	3.1
Urban/disturbed	1.6
TOTAL	**4.7**

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Other Land Cover Types

Canals and urban/disturbed land support almost no native flora. Construction impacts to these vegetation types would represent a **less-than-significant impact** to native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative. However, if any material is sidecast onto toe drain areas, some vernally wet areas could be adversely affected and wetland-related or vernal pool-related vegetation could be affected. For more detail on these and other wetland-related vegetation impacts, refer to Chapter 15 Wetlands and Other Waters of the U.S.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

If any material is sidecast onto toe drain areas, some vernally wet areas could be adversely affected and special-status plant species which potentially occur in those habitats (e.g., *Atriplex joaquiniana* or *A. depressa*, CNPS List 1B species) could be affected.

However, because ground disturbance is expected to occur within the footprint of the existing canal at this Project facility location, it is expected that there would be **no impact** on special-status plant species during construction, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because ground disturbance is expected to occur within the footprint of the existing canal, there would be no expected increase in invasion or spread of noxious weed species during construction, resulting in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Because the GCID facilities are existing facilities and operation and maintenance of the facilities with the Project are expected to be similar to what currently occurs, **no impact** on native plant communities or species from human disturbance would occur, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Construction of the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and GCID Canal Connection to the TRR facilities would require ground-disturbing activities that would result in the direct and permanent loss of ground cover (Table 13-19). Construction of the TRR to Funks Creek Pipeline would result in temporary disturbance to ground cover (Table 13-19). However, none of the Project construction activities would disturb areas of native vegetation.

Table 13-19
Permanent Vegetation Loss and Temporary Disturbance Due to the Construction of the Terminal Regulating Reservoir Facilities: Alternative A

Vegetation Type	Temporary Disturbance* (Acres)	Permanent Loss (Acres)
Canal (existing GCID Canal)	0.0	0.9
Crops/agric.	13.6	194.0
Urban/disturbed	0.8	0.0
TOTAL	**14.4**	**194.9**

*Acreage represents temporary disturbance associated with the defined construction disturbance area of the TRR to Funks Creek Pipeline.

Additional temporary ground disturbance would occur as a result of a construction disturbance area for these facilities. Two sides of the reservoir are surrounded by the construction disturbance area for the Delevan and TRR pipelines, which overlap with the footprint of the reservoir. The construction disturbance area acreage would be approximately 19 acres in size, but could overlap with the adjacent pipeline construction disturbance area. Disturbed areas would be restored to their original habitat type following completion of construction.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans,

Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Other Land Cover Types

Because the ground that would be disturbed for the TRR-related facilities is in urban, canal, or agricultural land uses that do not support native plant communities or species, construction of the TRR facilities would have **no impact** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-Status Plant Species

Because the ground that would be disturbed for the TRR-related facilities is in urban, canal or agricultural land uses, construction of the TRR facilities would have **no impact** on special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Because the TRR facilities would be surrounded on all sides by developed land, their construction, operation, and maintenance would have **no impact** on spread of noxious weeds, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Because the TRR facilities would be surrounded on all sides by developed land, their construction, operation, and maintenance would have **no impact** of the disturbance of native plants or their habitats by an increase in human activities at this location, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-**5 discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

The Delevan Pipeline would connect the proposed Delevan Pipeline Intake Facilities to the Holthouse Reservoir Complex. The TRR Pipeline would be aligned parallel to the Delevan Pipeline, and would be completely within the construction disturbance area of the Delevan Pipeline. The TRR Pipeline Road would be located atop the length of the TRR Pipeline, and the Delevan Pipeline Electrical Switchyard would be located where the Delevan Pipeline would cross the existing PG&E transmission line. The construction of the pipelines would require ground-disturbing activities that would result in temporary disturbance; the construction of the TRR Pipeline Road and Delevan Pipeline Electrical Switchyard would require ground-disturbing activities that would result in permanent loss, of mostly agricultural lands (Table 13-20). Areas of temporary disturbance would be restored to their original cover after construction is completed. Temporary disturbance of the alkaline wetland vegetation type would result in long-term conversion to other plant communities or permanent loss because wetland vegetation is unlikely to return to its original state after major mechanical disturbance and disruption of its water regime.

Table 13-20
Permanent Vegetation Loss and Temporary Disturbance Due to the Construction of the Delevan and Terminal Regulating Reservoir Pipelines, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard: Alternative A

Vegetation Type	Temporary Disturbance (Acres)	Permanent Loss (Acres)
Alkaline wetland	14.0	0.0
Canal	8.2	0.1
Crops/agriculture	2,225.6	8.2
Ponds	5.1	0.0
Urban/disturbed	36.8	0.0
Freshwater emergent marsh	4.5	0.0
TOTAL	**2,294.2**	**8.3**

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Alkaline Wetland

Temporary disturbance from constructing the Delevan Pipeline to the 14-acre parcel of disturbed alkaline wetland located approximately three miles west of the Sacramento River and adjacent to the Delevan NWR could affect native plant communities and native plant species. Saline or alkaline wetland meadows represent a disappearing sensitive native plant community. However, a 2011 field survey indicated that this parcel has been altered, and the water regime and vegetation have been managed as an artificial freshwater seasonal wetland. Disturbance of this parcel during Delevan Pipeline construction would be a **less-than-significant impact** to native plant communities and native plant species if the parcel is still highly manipulated at the time of Project construction, when compared to Existing Conditions and the No Project/No Action Alternative.

Freshwater Emergent Marsh

A narrow strip of moisture-dependent vegetation, with some woody species, has colonized the roadside depression and irrigation ditch adjacent to the Delevan NWR on the southern edge of the Delevan Pipeline construction disturbance area (Figure 13-5). Although this strip is located outside of the NWR, this emergent vegetation likely consists of many of the wetland species present in the NWR (tules, cattails, rushes, sedges, small willows). Temporary disturbance of these 4.5 acres of freshwater emergent marsh during Delevan Pipeline construction would likely result in the long-term absence or permanent loss of this vegetation and would represent a **potentially significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Other Land Cover Types

Other vegetation or land types that would be temporarily displaced from construction of the Delevan and TRR pipelines, and permanently disturbed by construction of the TRR Pipeline Road and Delevan Pipeline Electrical Switchyard, would include agricultural fields, urban/disturbed land, and stock ponds or irrigation ditches (refer to Figure 13-5 for the location of the five-acre agricultural pond). All of these vegetation or land cover categories support almost no native flora. The exception may be the edges of some of the canals that may support native wetland-type vegetation. Almost all of the canal loss would be temporary because the agricultural land uses could be reestablished after construction is complete, resulting in a **less-than-significant impact** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-Status Plant Species

No special-status plant species are known or expected to occur within the entirely agricultural areas within the footprint or construction disturbance area of these facilities, with the exception of the vicinity of the 14-acre alkaline wetland parcel mentioned previously along the Delevan Pipeline route. Construction of these facilities and most of the Delevan Pipeline would result in **no impact** to known occurrences of special-status species that are State or federally listed or on any CNPS lists, when compared to Existing Conditions and the No Project/No Action Alternative.

Around the vicinity of the 14-acre alkaline wetland parcel, some possibility exists for presence of special-status plant species associated with a saline/alkaline wetland or meadow habitat, which are currently known to occur less than two miles to the south in the Delevan NWR. These species include *Cordylanthus palmatus* and *Atriplex depressa*. Other special-status plant species known from the Sacramento NWR approximately six miles to the northwest include *Astragalus tener* var. *ferrisiae*, *Atriplex cordulata*, *A. joaquiniana, A. persistens, Chamaesyce hooveri, Hibiscus lasiocarpos* var. *occidentalis, Lepidium latipes* var. *heckardii, Neostapfia colusana, Orcuttia pilosa*, and *Tuctoria greenei* (DFG, 2010a). Also known from this vicinity are both subspecies of *Centromadia parryi*. Potential disturbance or loss of any of these species due to construction within the Delevan Pipeline construction disturbance area would be a **potentially significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative. Field surveys conducted in late summer 2011 indicate no presence of any of the above species or their suitable habitat within the highly manipulated wetland in this parcel, which is being managed as a duck hunting club. However, the presence of *Centromadia parryi* ssp. *rudis* around berms, road edges, and other disturbed sites indicates that a degree of vestigial saline wetland habitat remains, at least for species adapted to disturbance. Therefore, construction of the Delevan Pipeline through the area around this parcel would have a **potentially significant impact** on special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance due to construction activities within the construction disturbance area of these facilities would result in many areas of newly exposed bare soil. This strip would typically revegetate with mostly non-native annual plant species, with high potential for spread or new colonization in the surrounding valley by common noxious weeds, such as yellow star-thistle, Italian plume-thistle, mustards, milk thistle, sow-thistle, and many other invasive species. Spontaneous revegetation by native species in the disturbed ground is highly unlikely due to abundance of non-native species in surrounding land. Therefore, even temporary disturbance of more than 2,000 acres of land while constructing these facilities would increase the probability of spread of noxious weeds. Operation of these facilities would not be expected to result in additional ground disturbance, but ground disturbance would occur during maintenance of the gravel road and could increase the probability of spread of noxious weeds. Spread of these weed populations would introduce more weeds into surrounding agricultural areas, and would also become a potential seed source for further invasion of adjacent sensitive wetlands of the Delevan NWR, a **potentially significant impact** to native plant communities and species, including special-status species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Throughout most of its length, the Delevan and TRR pipeline construction disturbance area is surrounded on all sides by agricultural and other developed land. The TRR Pipeline Road and Delevan Pipeline Electrical Switchyard are also surrounded by agricultural land. Because no native vegetation communities occur adjacent to the construction disturbance area, an increase in human activity associated with construction, operation, and maintenance would be expected to have **no impact** on native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

The exception to this is in the vicinity of the Delevan NWR, where an increase in vehicle use, foot traffic, possible siltation from erosional damage, litter, dust, and other disturbances associated with Delevan Pipeline construction could temporarily disturb native plant communities and special-status plant species in the NWR. Although restricted to the Project construction period, these indirect effects could degrade the NWR habitat, and represent a **potentially significant impact** to the NWR's native plant communities and species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Delevan Transmission Line

The Delevan Transmission Line would parallel, and be located completely within, the construction disturbance area of the Delevan Pipeline, with the exception of the westernmost approximately four miles. Because the impacts of the eastern approximately nine miles of the transmission line construction disturbance area are already accounted for in the impact assessment for the Delevan Pipeline, only the temporary ground disturbance of the remaining four miles of the transmission line are discussed in this section. Disturbed habitats would be restored to their original habitat type following the completion of construction. The construction disturbance area of the Delevan Transmission Line would result in the temporary disturbance of several vegetation communities (Table 13-21).

Table 13-21
Temporary Disturbance of Vegetation Due to the Construction of the Delevan Transmission Line: Alternative A

Vegetation Type	Number of Acres Affected for the Entire Length of the Transmission Line	Number of Acres Affected for the Section of the Transmission Line outside of the Delevan Pipeline Construction Disturbance Area
Annual grassland	69.5	69.5
Alkaline wetland	2.1	0.0
Canal	1.5	1.2
Crops/agriculture	203.7	2.0
Pond	1.04	0.0
Urban/disturbed	1.1	0.0
Valley foothill riparian	1.1	1.1
TOTAL	**280.0**	**73.8**

Although the transmission line would be an above-ground feature and have no associated permanent ground-disturbance, the footings of the transmission towers would result in the permanent loss of vegetation or ground cover. Based on a worst-case scenario, the total permanent vegetation loss associated with the footings would be approximately 2.5 acres of a combination of rice and annual grassland vegetation.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland

Annual grassland within the footprint of the Delevan Transmission Line has the same value to special-status plant species habitat as was described in the impact assessment for the proposed Road Relocations. This grassland is almost completely composed of non-native species and supports no wetland vegetation communities. This portion of the transmission line route would traverse some lands that were not included in original Project surveys; the probability of special-status species occurring in these grasslands is low. The temporary disturbance of 69.5 acres and the potential permanent loss of up to 2.5 acres of annual grassland resulting from the construction of the transmission line would represent a **less-than-significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Riparian Vegetation

Valley foothill riparian vegetation within the construction disturbance area of the Delevan Transmission Line has the same value to native plant communities as described in the impact assessment for the Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard. The small segments of riparian vegetation are located at two crossings of Funks Creek, both of which support moderate to large individual trees. These trees could be relatively easily avoided during construction of the transmission line. However, even temporary disturbance of

1.1 acres of valley foothill riparian vegetation resulting from the construction of the Delevan Transmission Line would be a **significant impact** to the remnant riparian plant community in this area, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Other Land Cover Types

Concrete-lined canal and agricultural land support virtually no native flora. Temporary disturbance or small amounts of permanent loss of canal or agricultural areas during transmission line construction would have **no impact** to native plants or native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-Status Plant Species

Construction within the Delevan Transmission Line construction disturbance area would result in **no impact** of direct loss to any known occurrences of special-status species that are State or federally listed or on any CNPS lists. No special-status plant species were found during field surveys conducted in most of the areas traversed by the transmission line route.

Because 1.25 miles of the proposed route would be outside of original survey areas, there is a possibility that one or more special-status plant species could be found in the transmission line construction disturbance area. The species most likely occurring in this area is *Hesperevax caulescens* (HECA*)*, a locally common CNPS List 4 species. One occurrence of HECA found during Project surveys is located immediately adjacent to the transmission line construction disturbance area. Temporary disturbance during construction to a possible occurrence of this species would be a **less-than-significant impact**, as would permanent loss of a small portion due to placement of a tower, when compared to Existing Conditions and the No Project/No Action Alternative. Because such localized sites would be easy to avoid, the overall impact to this species would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

However, small seasonal wetlands, depressions, or swales, including some with slightly alkaline soils, are scattered in the annual grasslands in the vicinity of the unsurveyed portion of the proposed Delevan Transmission Line route. Other CNPS List 4 or List 1B plant species may occur in seasonal wetland habitats potentially present in the unsurveyed area. CNPS-listed species potentially present include *Astragalus*, *Navarretia* or *Hemizonia (=Centromadia)* spp. Even temporary disturbance of small patches of seasonal wetland habitat for some CNPS List 1B or 4 species resulting from the construction of the Delevan Transmission Line would be a **potentially significant impact** to special-status plant species in this area, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance due to construction activities within the Delevan Transmission Line construction disturbance area would result in areas of bare soil. However, parts of the 74-acre transmission line construction disturbance area (the portion outside of Delevan Pipeline construction disturbance area) would remain with an exposed disturbed surface. This strip would typically revegetate with mostly non-native annual plant species, with high potential for spread or new colonization in the surrounding foothills and valley by common noxious weeds, such as yellow star-thistle, Italian plume-thistle, barbed goat-grass, mustards and medusahead. Spontaneous revegetation by native species in disturbed ground in this area is highly unlikely due to abundance of non-native species in surrounding land. Therefore, even the temporary disturbance of up to 74 acres of land while constructing the transmission line would increase the probability of spread of noxious weeds. These weed populations could not only displace the little remaining native vegetation in the area, but would then become a potential seed source for further invasion of surrounding grasslands. East of the T-C Canal, the weed infestations could also affect sensitive alkaline wetland swales and known special-status plant occurrences approximately 0.25 mile to the north of the transmission line construction disturbance area, resulting in a **potentially significant impact** to native plant communities and species, including special-status species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Grasslands adjacent to the Delevan Transmission Line construction disturbance area may be directly or indirectly affected by Project-related human activities, such as increased dust, possible introduction of non-native plant species, or other disturbance, such as foot traffic. Due to the already highly disturbed nature of the grassland area, this activity would not have much impact, and the activity would be limited to the construction period. Human activity associated with construction and maintenance is unlikely to extend north by 0.25 mile to the sensitive alkaline swales. The transmission line would be operated remotely, and therefore, would not have human disturbance associated with its operation. Increased human activity during Project construction and maintenance could temporarily disturb the Funks Creek riparian crossings; however, because they are already highly disturbed, this would be a **less-than-significant impact** on native plants and native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Delevan Pipeline Intake Facilities

Alternative A includes a fish screen and pumping/generating facility that has a 2,000 cfs diversion capacity and 1,500 cfs release capacity, to be located on the Sacramento River. The construction of the Delevan Pipeline Intake Facilities would require ground-disturbing activities that would result in the direct and permanent loss of native vegetation communities (Table 13-22).

Additional acreage of temporary disturbance would occur as a result of a construction disturbance area for these facilities. The construction disturbance area for the Delevan Pipeline Intake Facilities would be approximately 1.9 acres in size.The construction disturbance area of the Delevan Pipeline is located immediately adjacent to these facilities and could be used as a staging area. Disturbed areas would be restored to their original habitat type following completion of construction. The vegetation affected by the construction disturbance area proposed for the Intake Facilities would be agricultural (orchards).

Table 13-22
Permanent Vegetation Loss Due to the Construction of the Delevan Pipeline Intake Facilities: Alternative A

Vegetation Type	Permanent Loss (Acres)
Canal	0.6
Crops/agriculture	11.1
Fremont cottonwood riparian	1.1
Open water (Sacramento River)	1.6
Urban/disturbed	4.2
Valley foothill riparian	0.5
TOTAL	**19.1**

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Riparian Scrub

The riparian vegetation that would be permanently lost due to construction of the Delevan Pipeline Intake Facilities includes a 0.5-acre strip of mostly herbaceous growth on the existing levee bank. The herbaceous growth is a dense mixture of native and non-native plant species, mainly Johnson-grass (*Sorghum halepense*), mustards, horseweed (*Conyza* sp), cocklebur (*Xanthium* sp.), *Verbena* species, mugwort (*Artemisia douglasiana*) and occasional willow shrubs. Because this vegetation has colonized the levee slope over the years, it is a product of disturbance, and its loss during construction would be a **less than-significant-impact** to native plant communities and species, when compared to Existing Conditions and the No Project/No Action Alternative.

Fremont Cottonwood Forest

The Fremont cottonwood-dominated riparian forest area that would be permanently lost due to construction of the Delevan Pipeline Intake Facilities is a small remnant of previously more extensive forests along this part of the Sacramento River. It consists of Fremont cottonwoods (*Populus fremontii*) that are more than 60 feet tall and wild grape (*Vitis californica*), with a mid-story of box elder (*Acer negundo*) and tree willows (Red willow, *Salix laevigata*). Occasional large valley oaks grow at the outer edges of this area. The permanent loss of 1.1 acres of this remnant mature and multi-layered riparian forest during construction of the intake facilities would be a **significant impact** to the continuity of the remaining riparian forest along the Sacramento River and to native plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Special-Status Plant Species

No special-status plant species were found during field surveys conducted in the footprint area of these facilities. Construction within the Delevan Pipeline Intake Facilities footprint would result in **no impact** of direct loss to any known occurrences of special-status plant species that are State or federally listed or on any CNPS lists, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Ground disturbance due to construction activities within the Delevan Pipeline Intake Facilities construction disturbance area would result temporarily in areas of bare soil. Most of the exposed area would be quickly covered with facility structures. However, edges would remain as recently disturbed soil. Spontaneous revegetation by a few native species in disturbed ground in this area is possible, due to abundance of both native and non-native species in adjacent riparian vegetation and upstream seed sources via river flows. However, these disturbed edges would tend to revegetate with mostly non-native plant species, with high potential for spread or new colonization along the river and in the edges of adjacent riparian forests by common noxious weeds, such as Johnson-grass, cocklebur, horseweed, telegraph weed, verbenas, and even giant reed (*Arundo donax*). Therefore, even temporary disturbance of up to 19 acres of land while constructing the intake facilities would increase the probability of spread of noxious weeds. These weed populations could not only displace the remaining native vegetation in the area, but would then become a potential seed source for further invasion, especially downstream, and would be a **potentially significant impact** to native plant communities and species, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance activities would not be expected to result in additional ground disturbance, and therefore, would have a **less-than-significant impact** on the spread of noxious weed species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Riparian forests adjacent to the Delevan Pipeline Intake Facilities construction area may be directly or indirectly affected by Project-related human activities such as increased dust, refuse, fire, pollutants, possible introduction of non-native plant species, or other disturbance such as foot traffic. The increased activity would be limited to the construction period because operation and maintenance would take place entirely within the facility perimeters. Increased human activity during construction would be a **less-than-significant impact** on native plants and native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Project Buffer

Exception for fence construction, demolition of existing structures, and the creation of a fuelbreak, the native plant species and vegetation communities within the Project Buffer would not be subject to construction activities. The acreage of vegetation types included within the Project Buffer, but outside of facility footprints, is presented in Table 13-23.

Table 13-23
Acres of Vegetation Types Within the Project Buffer*: Alternative A

Vegetation Type	Acres within Project Buffer
Annual grassland	8,083.1
Agriculture	403.0
Blue oak woodland	4,180.1
Canal	15.8
Chamise	1.9
Open water	0.1
Ponds	17.2
Urban/disturbed	35.4
Valley foothill riparian	63.4
TOTAL	**12,800.0**

*Calculated by subtracting the acreage of permanent disturbance associated with each proposed Project facility that is surrounded by the Project Buffer, the acreage of existing Funks Reservoir, and the acreage of the portion of the existing GCID Canal that is surrounded by the Project Buffer, from the total acreage of land that would be acquired for the Project.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Annual Grassland, Blue Oak Woodland, Canal, Chamise, Ponds and Valley-Foothill Riparian

The above-listed vegetation or land cover types within the Project Buffer have the same value to native plant communities and species as described for other Project features, and would not be altered or converted to other vegetation or land cover types. Construction activities associated with fence building would have a negligible impact on these vegetation types because the footprint of the fence posts would be small, and a large portion of the Project Buffer is already fenced. However, the potential creation and maintenance of a fuelbreak would require vegetation clearing that, if maintained around the entire perimeter of the buffer, could result in a substantial adverse effect due to the loss of native plant communities and portions of native plant species populations. Therefore, the potential loss of native vegetation associated with construction of the Project Buffer fuelbreak resulting from implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

<u>Agriculture</u>

The agricultural land cover within the Project Buffer has the same value to native plant communities and species as described for other Project features, but would not be maintained as agricultural lands following Project implementation. These agricultural lands would be converted to natural vegetation, most likely to annual grassland. Native plant species would benefit from this conversion, and no native plant species would be adversely affected (because they do not occur in agricultural lands). Therefore, the loss of 211.4 acres of agricultural land cover that would be converted to natural vegetation within the Project Buffer as a result of implementation of Alternative A would be a **beneficial effect** to native plant communities and species, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the Project Buffer consists of roads and structures. Construction activities within the Project Buffer would include the demolition of existing structures; following demolition, the urban/disturbed areas would be converted to natural vegetation, most likely to annual grassland. This habitat conversion would benefit native species, and no native plant species would be adversely affected (because they do not occur in urban or disturbed lands). Demolition of structures within the Project Buffer resulting from implementation of Alternative A would be a **beneficial effect** to native plant communities and species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The only Project-related activities within the Project Buffer that could result in the potential loss of special-status plant species would be the creation and maintenance of a perimeter fuelbreak. Loss of both individuals and habitat of some special-status plant species, in particular *Sidalcea keckii*, *Lotus rubriflorus* or *Amsinckia lunaris*, could occur in these fuelbreak impact areas. The extent of this potential disturbance or loss is unknown because much of the land within the Project Buffer has not been surveyed. However, the grasslands within the buffer provide suitable habitat for these species. Therefore, construction and maintenance of a perimeter fuelbreak within the Project Buffer resulting from implementation of Alternative A would be a **potentially significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

Construction activities associated with fence building would result in areas of ground disturbance around the footprint of the fence posts. The potential creation and maintenance of a fuelbreak would require vegetation clearing that, if maintained around the entire perimeter of the buffer, could result in a substantial amount of ground disturbance. This disturbed ground, if not actively restored to its original condition, could result in the spread of weed species. The demolition of existing structures and their foundations could result in areas of bare ground that, if not actively restored to a pre-determined vegetation community, would have the potential for invasion by weed species. Therefore, the potential invasion or spread of noxious weed species within the Project Buffer resulting from implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance

Although signs would be posted to prevent recreationists from using the Project Buffer lands, it is possible that unauthorized hiking, biking, or other recreational activity would occur within the buffer during Project operation. In addition, the construction crews required to demolish existing structures or build fences would cause a temporary disturbance to vegetation within that area. Therefore, human disturbance associated with Project Buffer activities would have a **potentially significant impact** on native plant species and vegetation communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-5: Conflict with the Provisions of an Adopted Habitat Conservation Plan, Natural Community Conservation Plan, or Other Approved Local or Regional Habitat Conservation Plan, or

Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Bot-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Summary of Alternative A Impacts to Vegetation Types

Construction, operation, and maintenance of Alternative A would result in the permanent loss of 13,572.6 acres, and the temporary disturbance of an additional 5,357.9 acres, of vegetation (Table 13-24).

Table 13-24
Acres of Vegetation Types Subject to Alternative A Construction Impacts[a]

Vegetation Type	Acreage	
	Permanent Loss[b]	**Temporary Disturbance[c]**
Annual grassland	12,151.8	2,091.4
Alkaline wetland	0.5	14.0
Blue oak woodland	262.0	353.5
Blue oak savanna	225.4	269.8
Blue oak /mixed chaparral	14.0	21.2
Canal	9.1	14.1
Chamise	0.6	1.9
Crops/agriculture	700.0	2,307.7
Fremont cottonwood riparian	1.1	0.0
Fresh emergent wetland	0.0	4.5
Mixed chaparral	0.8	1.8
Pond	20.8	226.4
Open water	1.6	0.0
Urban/disturbed	88.1	46.9
Valley foothill riparian	75.9	4.6
Valley oak riparian	17.5	0.1
Valley oak woodland	3.4	0.0
TOTAL	**13,572.6**	**5,357.9**

[a]Calculated acreage does not include acres associated with the Project Buffer because the location and extent of disturbance is not yet specified.

[b]Total permanent vegetation loss acreage includes the footprint of Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and the Delevan Pipeline Intake Facilities. Total permanent loss acreage also includes the estimated permanent loss from construction of facilities within the footprint of the Recreation Areas, within the construction disturbance area for the Road Relocations, and from construction of the transmission tower footings associated with the Delevan Transmission Line.

[c]Total temporary disturbance acreage includes the footprint of the Recreation Areas (minus the acreage of estimated permanent loss) and the footprint of the existing Funks Reservoir, as well as the defined construction disturbance areas for the Road Relocations (minus the acreage of estimated permanent loss), Delevan and TRR pipelines, Holthouse to T-C Canal Pipeline, TRR to Funks Creek Pipeline, Delevan Transmission Line, and GCID Canal Facilities Modificaitons. Total temporary disturbance acreage also includes the estimated construction disturbance areas (outside of the facility footprints) for Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Intake Facilities.

13.3.7 Impacts Associated with Alternative B

13.3.7.1 Extended Study Area – Alternative B

<u>Construction, Operation, and Maintenance Impacts</u>

The impacts associated with Alternative B, as they relate to native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**), would be the same as described for Alternative A for the Extended Study Area.

13.3.7.2 Secondary Study Area – Alternative B

<u>Construction, Operation, and Maintenance Impacts</u>

The impacts associated with Alternative B operations on native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**) would be the same as described for Alternative A for Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, Thermalito Complex, Trinity River, Klamath River, Spring Creek, Clear Creek, Feather River, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

For the remaining facilities, the potential effects to native plants from human disturbance (**Impact Bot-4**) and conflicts with conservation plans (**Impact Bot-5**) would also be the same as described for Alternative A.

Operational differences for Alternative B, when compared to Alternative A for Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, the Sacramento River, Sutter Bypass, and Yolo Bypass, are discussed below.

Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake

Operational modeling results for Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, are similar to those described for Alternative A because Alternative B would also result in improved storage conditions. However, Alternative B operations would result in more variable reservoir surface water elevation fluctuations than Alternative A.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Surface water elevation fluctuations associated with implementation of Alternative B would be less severe than those associated with Existing Conditions or the No Project/No Action Alternative. Therefore, changes in operations at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake that would result in improved storage and reduced water level fluctuations would have a **beneficial effect** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Bot-1** discussion. Changes in operations at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake that would result in improved storage and reduced water level fluctuations would have a **beneficial effect** on special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

The reduced fluctuations associated with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would also include a **beneficial effect** of reduced potential for spread of noxious weeds, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento River

Operational modeling indicates that Alternative B Sacramento River flows would experience changes similar to those described for Alternative A. However, operation of Alternative B would result in the diversion of up to 3,900 cfs during winter flows, whereas Alternative A would divert up to 5,900 cfs during winter flows. The reduced rate of diversion associated with Alternative B would require a longer duration of diversion, lasting from February through May.

Modeling performed using SRH-1DV and SacEFT indicates that the coverage of the valley foothill riparian vegetation alliance along the Sacramento River would increase or remain similar if Alternative B is implemented, relative to the Existing Conditions and the No Project/No Action Alternative. The only exception is that the SacEFT indicates a slight increase in the number of years with post-initiation scour risk for Fremont cottonwood seedlings if Alternative B is implemented, relative to the No Project/No Action Alternative.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Despite the change in the rate and duration of diversion, operational modeling for Alternative B, including modeling that is specific to riparian vegetation, indicates only minimal effects to riparian vegetation resulting from the described changes in the flow regime. Riparian vegetation downstream of the intakes would not be expected to be adversely affected. Therefore, the modifications of the Sacramento River's existing flow regime resulting from operation of Alternative B would have a **less-than-significant impact** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes in the Sacramento River flow regime would not be expected to adversely affect riparian vegetation, they would also not be expected to affect riparian-associated special-status plant species.

Therefore, the modifications of the Sacramento River's existing flow regime resulting from operation of Alternative B would have a **less-than-significant impact** on special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

The minimal effects of operation of Alternative B on vegetation, when compared to Existing Conditions and the No Project/No Action Alternative, would result in a **less-than-significant impact** on the spread of noxious weeds.

Sutter Bypass and Yolo Bypass

Alternative B's reduced rate of diversion (3,900 cfs) of flow from the Sacramento River, when compared to Alternative A (5,900 cfs), would require a longer duration of diversion. Alternative B would reduce the velocity and volume of floodwaters entering the Sutter and Yolo bypasses from the Sacramento River by 2,000 cfs, when compared to Alternative A.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The reduction in the velocity and volume of water entering the bypasses could provide the same benefits of reduced scouring to native plant communities as was described for Alternative A. Therefore, the modification of the existing flow regime in both the Sutter and Yolo bypasses that would result in reduced magnitude and velocity of incoming floodwaters would have a **potentially beneficial effect** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because modification of the existing flow regime in the Sutter and Yolo bypasses would potentially benefit native plant communities, they would also be expected to benefit associated special-status plant species that may occur in the bypasses. Therefore, the modification of the existing flow regime in both the Sutter and Yolo bypasses that would result in reduced magnitude and velocity of incoming floodwaters would have a **potentially beneficial effect** on special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-3: An Increase in Potential for the Invasion or Spread of Noxious Weed Species

The reduced flow rates and water volume compared to Existing Conditions and the No Project/No Action Alternative would also include a **potentially beneficial effect** of reduced potential for spread of noxious weeds.

13.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to botanical resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

Although the footprint of the Recreation Areas would be the same for Alternatives A and B, the associated electrical distribution line alignment would differ as a result of the change in location of Golden Gate Dam. With implementation of Alternative B, 2.9 fewer acres of annual grassland would be affected by the Recreation Area Electrical Distribution Line construction disturbance area. However, this difference in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**) as described for Alternative A.

In addition, the road relocations associated with Alternative B differ from those for Alternative A, mostly due to changes to the saddle dam access roads. An additional 2.5 acres of vegetation would be affected by Alternative B roads. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**) as described for Alternative A.

For the remaining facilities, the impact of noxious weed species (**Impact Bot-3**), potential effects to native plants from human disturbance (**Impact Bot-4**), and conflicts with conservation plans (**Impact Bot-5**) would also be the same as described for Alternative A. However, for Alternative B, the footprint and/or construction disturbance area of Sites Reservoir and Dams, the Delevan Transmission Line, and the Delevan Pipeline Discharge Facilities differ from Alternative A. These changes would affect different acreages of vegetation. The differences between these facilities and their impacts on botanical resources are described below.

Sites Reservoir Inundation Area and Sites Reservoir Dams

Alternative B includes the construction of a 1.81-MAF Sites Reservoir, which would require the construction of Sites Dam, Golden Gate Dam, and nine saddle dams. Sites and Golden Gate dams would have a larger footprint, and the Golden Gate Dam location would be shifted for Alternative B, when compared to Alternative A. Construction-related ground-disturbing activities and vegetation removal, and the consequent filling of the reservoir, would result in the direct and permanent loss of the same vegetation communities as described in Alternative A, but more acreage of some communities would be lost with the construction and filling of the larger reservoir (Table 13-25).

Table 13-25
Permanent Vegetation Loss Due to the Construction and Filling of the 1.81-MAF Sites Reservoir and Associated Dams: Alternative B Compared to Alternative A

Vegetation Type	Permanent Loss (Acres) Alternative A	Permanent Loss (Acres) Alternative B	Additional Loss Associated with Alternative B when Compared to Alternative A
Annual grassland	11,654.6	13,196.9	1542.3
Blue oak woodland	182.3	399.0	216.7
Blue oak savanna	163.1	313.2	150.1
Blue oak/mixed chaparral	8.1	27.5	19.4
Cropland	267.9	267.9	0.0
Ponds	20.2	21.8	1.6
Urban/disturbed	76.1	78.8	2.7
Valley foothill riparian	64.1	71.1	7.1
Valley oak riparian	17.4	26.4	9.0
Valley oak woodland	3.4	3.5	0.1
TOTAL	**12,457.2**	**14,406.1**	**1,948.9**

The construction disturbance area for the 1.81-MAF Sites Reservoir would be the same as described for the 1.27-MAF reservoir. The construction disturbance area could disturb as much as 1,000 acres of land, with the majority of disturbed habitat consisting of annual grassland vegetation.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

Substantially larger areas of the most botanically diverse vegetation communities would be lost with implementation of Alternative B, when compared to Alternative A, because the additional acreage lost would be within the blue oak associations and at the blue oak woodland-annual grassland edges around the perimeter of Antelope Valley. This permanent vegetation loss, as well as the temporary disturbance of the construction disturbance area, resulting from the construction and filling of Sites Reservoir and Dams would be a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The additional acreage lost with implementation of Alternative B, when compared to Alternative A, is likely to support several different special-status plant species, including the federally endangered *Sidalcea keckii*. Construction of the larger reservoir with implementation of Alternative B would also result in the loss of one known occurrence of the rare *Lotus rubriflorus*, which lies outside of the inundation area for the 1.27-MAF reservoir footprint of Alternative A. In addition to this CNPS List 1B species, five occurrences of three CNPS List 4 species would be lost to construction of the larger Alternative B reservoir, in addition to those lost with implementation of Alternative A: two occurrences of *Androsace elongata* var. *acuta*, two of *Hesperevax caulescens*, and two of *Navarretia heterandra*. The direct impacts to special-status plant species, as well as the temporary impacts within the construction disturbance area, resulting from the construction and filling of Sites Reservoir and Dams would be a **significant impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

The Alternative B design of the Delevan Transmission Line differs from that of Alternative A. Because there would be no pumping/generating plant associated with Delevan Pipeline Discharge Facility, there would be no transmission line alignment from the Sacramento River westward to the existing WAPA or PG&E transmission line. There would, however, still be a transmission line alignment from approximately three miles east of the Sites Electrical Switchyard to the existing WAPA or PG&E transmission line. The construction disturbance area of the Alternative B Delevan Transmission Line would result in the temporary disturbance and small amounts of permanent loss of vegetation, but at a much smaller scale than with Alternative A (Table 13-26).

Table 13-26
Temporary Disturbance of Vegetation Due to the Construction of the Delevan Transmission Line: Alternative B Compared to Alternative A

Vegetation Type	Temporary Disturbance (acres) for the Entire Length of the Delevan Transmission Line: Alternative A	Temporary Disturbance (acres) for the 4-mile Section of the Delevan Transmission Line outside of the Construction Disturbance Area of the Delevan Pipeline: Alternative A	Temporary Disturbance (acres) for the Entire Length of the Delevan Transmission Line*: Alternative B
Annual grassland	69.5	69.5	54.6
Alkaline wetland	2.1	0.0	0.0
Canal	1.5	1.2	0.6
Cropland	203.7	2.0	0.0
Pond	1.04	0.0	0.0
Urban/disturbed	1.1	0.0	0.0
Valley foothill riparian	1.1	1.1	1.1
TOTAL	**280.0**	**73.8**	**56.3**

*Length of the Alternative B Delevan Transmission Line calculated from the start of the line (approximately three miles east of the Sites Electrical Switchyard) to the existing PG&E transmission line. Number of affected acres would be slightly reduced if the Project connects to the existing WAPA transmission line.

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The footings of the transmission towers would result in the permanent loss of vegetation. Based on a worst-case scenario, the total permanent vegetation loss associated with the transmission line tower footings would be approximately 0.5 acre of annual grassland vegetation, which is less than the 2.5-acre loss associated with the implementation of Alternative A. Despite the reduced amount of permanent vegetation loss associated with implementation of Alternative B, the permanent loss and temporary disturbance of vegetation communities resulting from construction of the transmission line would be a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The temporary construction disturbance to as-yet unsurveyed occurrences of *Hesperevax caulescens* (HECA) is possible along the central 1.25 miles of this route; this disturbance would represent a **less-than-significant impact** to special-status plant species due to HECA's widespread distribution and tolerance for disturbance, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Discharge Facility

If Alternative B is implemented, the Delevan Pipeline would be operated as a release-only pipeline. The associated Delevan Pipeline Discharge Facility would, therefore, not include a fish screen or any of the facilities needed for pumping and generating operations that are associated with Alternative A. The construction of the Delevan Pipeline Discharge Facility would require ground-disturbing activities that would result in the direct and permanent loss of native vegetation communities (Table 13-27), but at a smaller scale than described for the Intake Facilities associated with Alternative Aover the entire length of the transmission lineacrestservoir 19 acresasement for the Delevan and TRR pipelines. size. Them ma.

Table 13-27
Permanent Vegetation Loss Due to the Construction of the Delevan Pipeline Discharge Facility: Alternative B Compared to the Alternative A Delevan Pipeline Intake Facilities

Vegetation Type	Permanent Loss (Acres) by Alternative A	Permanent Loss (Acres) by Alternative B
Canal	0.6	0.1
Crops/agriculture	11.1	3.9
Fremont cottonwood riparian	1.1	1.5
Open water (Sacramento River)	1.6	0.1
Urban/disturbed	4.2	2.0
Valley foothill riparian	0.5	0.1
TOTAL	**19.1**	**7.7**

Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project

The main native plant community lost to construction of the Delevan Pipeline Discharge Facility would be mature Fremont cottonwood riparian forest. Although the affected length of this plant community bordering the Sacramento River edge would be somewhat less with Alternative B than for the Alternative A Intake Facilities, the total acreage removed would be greater by more than 36 percent, or 0.4 acre. This permanent loss of vegetation communities resulting from construction of the discharge facility would be a **significant impact** to native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Additional acreage of temporary disturbance would occur as a result of a construction disturbance area for these facilities. The construction disturbance area for the Delevan Pipeline is located immediately adjacent to these facilities and could potentially be used as a staging area. The construction disturbance area acreage for the Delevan Pipeline Discharge Facility would be approximately 0.8 acre in size. Disturbed areas would be restored to their original land cover following completion of construction. The land cover that would be affected by this construction disturbance area would be agricultural (orchards). Orchards support almost no native flora, and areas of disturbance would be reestablished after construction is complete, resulting in a **less-than-significant impact** on native plant communities, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No special-status plant species were found during field surveys conducted in the footprint of these facilities. Therefore, construction within the Delevan Pipeline Discharge Facility footprint would result in **no impact** to special-status plant species, when compared to Existing Conditions and the No Project/No Action Alternative.

Summary of Alternative B Impacts to Vegetation Types

Construction, operation, and maintenance of Alternative B would result in the permanent loss of 15,508.3 acres, and the temporary disturbance of an additional 5,341.4 acres, of vegetation (Table 13-28).

Table 13-28
Acres of Vegetation Subject to Alternative B Construction Impacts

Vegetation Types	Acreage	
	Permanent Loss[a]	Temporary Disturbance[b]
Annual grassland	13,694.4	2079.4
Alkaline wetland	0.5	14.0
Blue oak woodland	478.6	353.5
Blue oak savanna	375.5	269.7
Blue oak /mixed chaparral	33.4	21.1
Canal	8.6	13.5
Chamise	0.6	1.9
Crops/agriculture	691.1	2,304.6
Fremont cottonwood riparian	1.4	0.0

Table 13-28
Acres of Vegetation Subject to Alternative B Construction Impacts

Vegetation Types	Acreage	
	Permanent Loss[a]	Temporary Disturbance[b]
Fresh emergent wetland	0.0	4.5
Mixed chaparral	0.8	1.8
Pond	22.4	226.4
Open water	0.1	0.0
Urban/disturbed	88.6	46.9
Valley foothill riparian	82.4	4.0
Valley oak riparian	26.4	0.1
Valley oak woodland	3.5	0.0
TOTAL[c]	**15,508.3**	**5,341.4**

[a]Total permanent vegetation loss acreage includes the footprint of Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and the Delevan Pipeline Discharge Facilities. Total permanent loss acreage also includes the estimated permanent loss from construction within the footprint of the Recreation Areas, within the construction disturbance area for the Road Relocations, and from construction of the transmission tower footings associated with the Delevan Transmission Line.

[b]Total temporary disturbance acreage includes the footprint of the Recreation Areas (minus the acreage of estimated permanent loss) and the footprint of the existing Funks Reservoir, as well as the defined construction disturbance areas for the Road Relocations (minus the acreage of estimated permanent loss), Delevan and TRR pipelines, Holthouse to T-C Canal Pipeline, TRR to Funks Creek Pipeline, Delevan Transmission Line, and GCID Canal Facilities Modifications. Total temporary disturbance acreage also includes the estimated construction disturbance areas (outside of the footprints) for Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Modifications, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Discharge Facilities.

[c]Total acreage does not include acreage associated with the Project Buffer.

13.3.8 Impacts Associated with Alternative C

13.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**), would be the same as described for Alternative A for the Extended Study Area.

13.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C operations on native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**) would be the same as described for Alternative A for Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, Thermalito Complex, Trinity River, Klamath River, Spring Creek, Clear Creek, Feather River, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

Because Alternative C includes the three Project intake locations that were described for Alternative A, the operational impacts associated with Alternative C, as they relate to native plant communities (**Impact Bot-1**), special-status plant species (**Impact Bot-2**), and noxious weed species (**Impact Bot-3**), as well as the potential effects from human disturbance (**Impact Bot-4**) or conflicts with conservation plans (**Impact Bot-5**), would be the same as described for Alternative A for Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, Sacramento River, Sutter Bypass, and Yolo Bypass.

13.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to botanical resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating PlantTRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Delevan Transmission Line and Delevan Pipeline Intake Facilities included in Alternative C are the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to botanical resources as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Electrical Distribution Lines associated with the Recreation Areas, and Road Relocations and South Bridge are the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to botanical resources as described for Alternative B.

The boundary of the Project Buffer is the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

Summary of Alternative C Impacts to Vegetation Types

Construction, operation, and maintenance of Alternative C would result in the permanent loss of 15,521.7 acres, and the temporary disturbance of an additional 5,257.6 acres, of vegetation (Table 13-29).

Table 13-29
Acres of Vegetation Types Subject to Alternative C Construction Impacts

Vegetation Type	Acreage	
	Permanent Loss[a]	Temporary Disturbance[b]
Annual grassland	13,694.7	2091.5
Alkaline wetland	0.5	14.0
Blue oak woodland	478.6	353.5
Blue oak savanna	375.5	269.7
Blue oak /mixed chaparral	33.4	21.1
Canal	9.1	14.1
Chamise	0.6	2.1
Crops/agriculture	700.0	2,307.7
Fremont cottonwood riparian	1.1	0.0
Fresh emergent wetland	0.0	4.5
Mixed chaparral	0.8	1.8
Pond	22.4	226.6
Open water	1.6	0.0
Urban/disturbed	90.8	46.9
Valley foothill riparian	82.6	4.0
Valley oak riparian	26.5	0.1
Valley oak woodland	3.5	0.0
TOTAL[c]	**15,521.7**	**5,357.6**

[a]Total permanent vegetation loss acreage includes the footprint of Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and the Delevan Pipeline Intake Facilities. Total permanent loss acreage also includes the estimated permanent loss from construction within the footprint of the Recreation Areas, within the construction disturbance area for the Road Relocations, and from construction of the transmission tower footings associated with the Delevan Transmission Line.

[b]Total temporary disturbance acreage includes the footprint of the Recreation Areas (minus the acreage of estimated permanent loss) and footprint of the existing Funks Reservoir, as well as the defined construction disturbance areas for the Road Relocations (minus the acreage of estimated permanent loss), Delevan and TRR pipelines, Holthouse to T-C Canal Pipeline, TRR to Funks Creek Pipeline, Delevan Transmission Line, and GCID Canal Facilities Modifications. Total temporary disturbance acreage also includes the estimated construction disturbance areas (outside of the footprints) for Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Intake Facilities.

[c]Total acreage does not include acreage associated with the Project Buffer.

13.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 13-30 for the impacts that have been identified as significant or potentially significant.

Table 13-30
Summary of Mitigation Measures for NODOS Project Impacts to Botanical Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Bot-1: A Substantial Adverse Effect, Including Conversion to Non-Native Vegetation, on any Riparian Habitat or Other Sensitive Natural Community Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS, or any Native Plant Community Known to be Rare, Unusual, or Becoming Uncommon in the Biogeographic Region of the Project				
Impact Bot-1a: Loss of Vegetation Community	Sites Reservoir and Dams, Salt Lake wetlands, construction disturbance area outside of the Sites Reservoir footprint; Recreation Areas; Road Relocations; Delevan Transmission Line; Delevan Pipeline; Delevan Pipeline Intake/Discharge Facilities; Project Buffer	Potentially Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant
	Holthouse Reservoir Complex	Potentially Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant or Potentially Significant and Unavoidable
Impact Bot-1b: Annual Grassland (of higher botanical value)	Valley edges of Sites Reservoir and Dams, Salt Lake wetlands, staging area outside of Sites Reservoir footprint; Recreation Areas; Road Relocations; Holthouse Reservoir Complex swale area; Project Buffer	Potentially Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant
	Holthouse Reservoir Complex	Potentially Significant	Mitigation Measure Bot-1b: Conduct Watershed Hydrological Studies	Less than Significant
Impact Bot-1c: Blue Oak Woodland (includes savanna and woodland with chaparral understory)	Valley edges of Sites Reservoir and Dams, Recreation Areas, Road Relocations; Project Buffer	Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant
	Recreation Areas, Road Relocations, Project Buffer	Significant	Mitigation Measure Bot-1c: Avoid/Minimize Loss or Disturbance of Vegetation by Refining the Siting of Facilities and Implementing BMPs	Less than Significant

Table 13-30
Summary of Mitigation Measures for NODOS Project Impacts to Botanical Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Bot-1d: Riparian Vegetation	Sites Reservoir and Dams, Road Relocations, Holthouse Reservoir Complex, Delevan Transmission Line, Delevan Pipeline Intake/Discharge Facilities; Project Buffer	Potentially Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant
	Road Relocations, Delevan Transmission Line, Project Buffer	Potentially Significant	Mitigation Measure Bot-1c: Avoid/Minimize Loss or Disturbance of Vegetation by Refining the Siting of Facilities and Implementing BMPs	Less than Significant
Impact Bot-1e: Valley Oak Woodland	Sites Reservoir and Dams	Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant
Impact Bot-1f: Alkaline Wetland	Holthouse Reservoir Complex	Potentially Significant	Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS	Less than Significant or Potentially Significant and Unavoidable
			Mitigation Measure Bot-1d: Conduct Groundwater Hydrological Studies	Less than Significant or Potentially Significant and Unavoidable
			Mitigation Measure Bot-1e: Minimize Impacts by Siting Facilities Away from Drainage Swales and Implementing BMPs	Less than Significant or Potentially Significant and Unavoidable
Impact Bot-1g: Freshwater Emergent Marsh	Delevan Pipeline	Potentially Significant	Mitigation Measure Bot-1f: Implement BMPs to Avoid Disturbance of Marsh Vegetation in Adjacent Delevan National Wildlife Refuge	Less than Significant
Impact Bot-2: A Substantial Adverse Effect, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS				
Impact Bot -2a Fed/1B-A: Special-Status Plant Species: CNPS List 1B and State- or Federally Listed Species	Sites Reservoir and Dams	Significant or Potentially Significant	Mitigation Measure Bot-2a: Conduct Pre-Construction Surveys for Sidalcea keckii and Amsinckia lunaris; if Found, Compensate According to USFWS Guidelines	Significant and Unavoidable

			Mitigation Measure Bot-1c: Avoid/Minimize Loss or Disturbance of Vegetation by Refining the Siting of Facilities and Implementing BMPs	Less than Significant when combined with Mitigation Measures Bot-2d and Bot-2e
Impact Bot-2c: Special-Status Plant Species	Holthouse Reservoir Complex	Potentially Significant	Mitigation Measure Bot-1d: Conduct Groundwater Hydrological Studies	Potentially Significant and Unavoidable
Impact Bot-3: An Increase in the Potential for Invasion and Spread of Noxious Weeds	Sites Reservoir and Dams, Recreation Areas, Road Relocations, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard, Holthouse Reservoir Complex, Delevan Pipeline, TRR Pipeline, Delevan Transmission Line, Delevan Pipeline Intake/Discharge Facilities; Project Buffer	Potentially Significant or Significant	Mitigation Measure Bot-3a: Implement Preventive Actions by Following Weed Control BMPs; Minimize Exposed Ground; Reduce Weed Seed by Removal of On-Site and Off-Site Weeds ;	Less than Significant

Table 13-30
Summary of Mitigation Measures for NODOS Project Impacts to Botanical Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
	Delevan Pipeline, Delevan Transmission Line	Potentially Significant or Significant	Mitigation Measure Bot-3b:Implement Avoidance Measures in Areas Adjacent to the Delevan National Wildlife Refuge	Less than Significant
Impact Bot-4: Indirect Impacts to Native Plants from Human Disturbance	Recreation Areas, Road Relocations, Holthouse Reservoir Complex, Delevan Pipeline (near Delevan NWR), Project Buffer	Potentially Significant	Mitigation Measure Bot-1c: Avoid/Minimize Loss or Disturbance of Vegetation by Refining the Siting of Facilities and Implementing BMPs	Less than Significant
			Mitigation Measure Bot-4: Implement Vegetation Monitoring in Coordination with USFWS	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure Bot-1a: Implement Vegetation Community Mitigation Measures Recommended by USFWS

For the three alternatives (Alternatives A, B, and C), the acreage of permanent vegetation loss within the Recreation Areas and the Road Relocations, as well as the temporary vegetation disturbance within the construction disturbance areas for most facilities, has been estimated. Because these acres were estimated, it may be possible to avoid impacts to certain areas or vegetation communities.

A Habitat Evaluation Procedures assessment of the Primary Study Area was conducted under USFWS' leadership. The results of that assessment, as well as consultation with USFWS pursuant to the Fish and Wildlife Coordination Act, shall aid in the determination of appropriate mitigation measures for the habitat types, and by extension, the corresponding vegetation types, that would be adversely affected within the Primary Study Area. Measures shall include mitigation for impacts to grassland that contains wetlands, is suitable habitat for special-status plant species, and/or contains native grass stands; impacts to blue oak woodlands, including savanna and woodlands with chaparral understory; impacts to riparian vegetation, including distinction between degraded/disturbed areas (e.g., Sites Reservoir) versus mature forest (e.g., Funks Creek at Holthouse Reservoir Complex and Delevan Pipeline Intake/Discharge Facilities); impacts to valley oak woodlands, taking into consideration the small and fragmented sites; and impacts to alkaline wetlands. Mitigation measures could include, but not be limited to, protection, enhancement, restoration, or conservation easement.

Mitigation Measure Bot-1b: Conduct Watershed Hydrological Studies

DWR and Reclamation shall conduct hydrological studies to determine how much of the grassy upland acts as a watershed for the alkaline wetland swale that feeds the downstream alkaline marsh. The studies shall provide guidance regarding how to avoid impacts to the grasslands that direct water to the marsh.

Mitigation Measure Bot-1c: Avoid/Minimize Loss of Vegetation by Refining the Siting of Facilities and Implementing BMPs

DWR and Reclamation shall implement BMPs, protective measures such as fencing and erosion, sedimentation, and dust control, and where possible refine the siting of facilities to minimize construction disturbance to sensitive vegetation communities.

Mitigation Measure Bot-1d: Conduct Groundwater Hydrological Studies

DWR and Reclamation shall conduct hydrological studies to determine the effects of groundwater pressure on the alkaline habitat quality of the swale and the marsh. Measures may include protection of nearby similar vegetation communities, or USFWS may determine the effects are unavoidable and there may be no means of mitigation if there are no equivalent nearby vegetation communities that are feasible to protect or enhance.

Mitigation Measure Bot-1e: Minimize Impacts by Siting Facilities Away from Drainage Swales and using BMPs

DWR and Reclamation shall implement measures that mitigate impacts within the Holthouse Reservoir Complex to alkaline wetland vegetation in the on-site swale to avoid sedimentation of the swale during Project construction, according to recommendations received during consultation with USFWS.

Mitigation Measure Bot-1f: Implement BMPs to Avoid* D*isturbance of Marsh Vegetation in Adjacent Delevan National Wildlife Refuge

DWR and Reclamation shall set back all construction activities and equipment at least 20 feet away from the strip of marshy vegetation along the south end of the Delevan Pipeline construction disturbance area bordering the north edge of Delevan NWR. In addition, construction workers shall be prohibited from entering the NWR. BMPs, including signage on existing fencing, shall also be used to minimize erosion, sedimentation, and dust.

Mitigation Measure Bot-2a: Conduct Pre-Construction Surveys for* Sidalcea keckii *and* Amsinckia lunaris*; if Found, Compensate According to USFWS Guidelines

If either plant species is found during the Project pre-construction surveys, DWR and Reclamation shall immediately report the location and size of occurrences to CDFG and USFWS. If found, DWR and Reclamation shall compensate for the loss or temporary disturbance of either species according to USFWS guidelines and DFG recommendations, which could include protection of known occurrences in nearby habitat. Mitigation measures will be as consistent as possible with the provisions of the CNPS policy guidelines on mitigation of impacts of rare, threatened and endangered plants (CNPS, 1998).

Mitigation Measure Bot-2b: Avoid Occurrences of CNPS List 1B and State- or Federally-Listed Plant Species

DWR and Reclamation shall avoid occurrences of Sidalcea keckii, Amsinckia lunaris, and Lotus rubriflorus by refining the siting of facilities where feasible, and minimizing construction impacts with protection measures and BMPs, such as fencing and erosion, dust, and sedimentation control. Mitigation Measure Bot-2c: Conduct Pre-Construction Surveys for Rare Alkaline Wetland Species in the Managed Alkaline Wetland Parcel of the Delevan Pipeline

DWR and Reclamation shall conduct pre-construction surveys to determine if rare alkaline wetland species are present. If determined to be present during the pre-construction survey, DWR and Reclamation shall compensate for the loss and temporary disturbance of alkaline wetland species according to USFWS guidelines and DFG recommendations, which could include protection of known occurrences in nearby habitat. Mitigation measures will be as consistent as possible with the provisions of the CNPS policy guidelines on mitigation of impacts of rare, threatened and endangered plants (CNPS, 1998).

Mitigation Measure Bot-2c: Conduct Pre-Construction Surveys for Rare Alkaline Wetland Species in the Managed Alkaline Wetland Parcel of the Delevan Pipeline

DWR and Reclamation shall conduct pre-construction surveys to determine if rare alkaline wetland species are present. If determined to be present during the pre-construction surveys, DWR and Reclamation shall compensate for the loss and temporary disturbance of alkaline wetland species according to USFWS guidelines and DFG recommendations, which could include protection of known occurrences in nearby habitat. Mitigation measures will be as consistent as possible with the provisions of the CNPS policy guidelines on mitigation of impacts of rare, threatened and endangered plants (CNPS, 1998).

Mitigation Measure Bot-2d: Conduct Pre-Construction Surveys for Special-Status Plant Species:

DWR and Reclamation shall conduct pre-construction surveys to determine if habitats that support special-status species are present.

Mitigation Measure Bot-2e: Compensate for Loss or Disturbance of CNPS List 4 Species According to CDFG Guidelines

DWR and Reclamation shall compensate for the loss of 13 occurrences CNPS List 4 species pursuant to consultation with DFG, which could include protection of known occurrences in nearby habitat. DWR and Reclamation shall also compensate for the temporary disturbance of four CNPS List 4 species pursuant to consultation with DFG, which could include preserving habitat available for recolonization by three of the four species by revegetating with local natives and using weed-free mulch to prevent post-construction takeover by weeds. Mitigation measures will be as consistent as possible with the provisions of the CNPS policy guidelines on mitigation of impacts of rare, threatened and endangered plants (CNPS, 1998).

Mitigation Measure Bot-3a: Implement Preventive Actions by Following Weed Control BMPs; Minimize Exposed Ground; Reduce Weed Seed by Removal of On-Site and Off-Site Weeds

DWR and Reclamation shall minimize the introduction of new weed seeds into the construction disturbance area or transport weed seeds between construction disturbance areas by following weed control BMPs (e.g., equipment washing). DWR and Reclamation shall minimize the exposed ground within the construction disturbance area that is available for weed colonization or spread by mulching with weed-free materials or planting the exposed ground with native cover crops local to the Project area. In addition, DWR and Reclamation shall reduce the weed seed that is available for invasion into the Project construction disturbance area by appropriate removal of on-site weeds and by implementing selective adjacent off-site weed removal.

Mitigation Measure Bot-3b: Implement Avoidance Measures in Areas Adjacent to the Delevan National Wildlife Refuge

During construction of the Delevan Pipeline and Transmission Line, DWR and Reclamation shall avoid the placement of large staging areas within the portion of the construction disturbance area that borders the Delevan NWR.

Mitigation Measure Bot-4: Implement Vegetation Monitoring in Coordination with USFWS

DWR and Reclamation, in coordination with USFWS, shall monitor the effects of human activities on the health of sensitive areas adjacent to Project facilities.

Implementation of **Mitigation Measures Bot-1b**, **Bot-1c**, **Bot-1f**, **Bot-2b**, **Bot-2c**, **Bot-2d**, **Bot-3a**, **Bot-3b**, and **Bot-4** would reduce the level of significance of Project impacts to botanical resources to **less than significant.**

Implementation of **Mitigation Measures Bot-1a**, **Bot-1d**, **Bot-1e**, **Bot-2a**, and **Bot-2e** would reduce the level of significance of Project impacts to botanical resources to **less than significant,** or they would remain **potentially significant and unavoidable.**

14. Terrestrial Biological Resources

14.1 Introduction

This chapter describes the terrestrial biological resources setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Terrestrial biological resources include wildlife habitats and their associated invertebrates, reptiles, amphibians, birds, and mammals. Wildlife habitat descriptions focus on the value of the vegetation community to wildlife, rather than on the plant species that comprise the habitat type. For more detailed descriptions of vegetation communities, refer to Chapter 13 Botanical Resources.

The regulatory setting for terrestrial biological resources is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

14.2 Environmental Setting/Affected Environment

14.2.1 Extended Study Area

14.2.1.1 Methodology

Wildlife Habitats and Associated Wildlife

California Department of Fish and Game's (DFG's) California Wildlife Habitat Relationships (WHR) System (DFG, 2008a) was used to identify the potential number of species that could exist within the Extended Study Area. WHR is a predictive model that relates the suitability of each of California's habitat types to individual wildlife species based on their reproductive, cover, and feeding requirements. For the WHR analysis of the contracted municipal, industrial, and agricultural water deliveries within the Extended Study Area, only the urban and agricultural habitat types were considered. WHR separates agriculture into crop types. The crops that could be affected by a more reliable water source are rice, irrigated grain crops, irrigated row and field crops, irrigated hayfields, evergreen orchard, deciduous orchard, pasture, and vineyard.

A WHR species list was generated for each habitat type listed above based on their occurrence within the 39 counties of the CVP and SWP service areas. Because only ten counties can be entered into the WHR System at one time, 4 species lists were generated and then merged for each habitat type. The habitat types listed above may not occur in every county within the Extended Study Area.

For the analysis of wildlife refuges and wildlife areas (WAs) that receive Level 4 water deliveries within the Extended Study Area[1], a WHR species list was generated for fresh emergent wetland habitat based on its occurrence within 7 counties (Colusa, Fresno, Glenn, Kern, Kings, Merced, and Tulare).

[1]The Level 4 water deliveries that could be affected by Project operation are contracted to the Sacramento and Colusa NWRs within the Sacramento River Basin; to the West Bear Creek unit of the San Luis NWR Complex and the Merced unit of the Merced NWR, as well as the Los Banos, Volta, and Mendota WAs, the China Island and Salt Slough units of the North Grasslands WA, and private wetlands of the Grassland Resource Conservation District within the San Joaquin River Basin; and to the Kern and Pixley NWRs within the Tulare Lake Basin.

For the analysis of wildlife that occur within San Luis Reservoir, a WHR species list was generated for lacustrine habitat based on its occurrence in Merced County.

Special-Status Wildlife Species

A list of special-status wildlife species that may occur within the service areas of the Extended Study Area was generated using the Sacramento U.S. Fish and Wildlife Service (USFWS) Office's Endangered Species Program website (USFWS, 2009a). The list includes federal endangered, threatened, and candidate species that may be affected within 28 of the 39 counties of the Extended Study Area that are within its jurisdiction, as well as areas of designated critical habitat. Critical habitat is habitat that is essential to the conservation of the species and is protected pursuant to the federal Endangered Species Act (FESA). The USFWS' Endangered Species Database (TESS) was used to generate species lists for Monterey, San Benito, Santa Barbara, Santa Cruz, and Ventura counties (USFWS, 2009b). The Carlsbad Fish and Wildlife Office's website was used to access a list of species by county within its jurisdiction, which includes Imperial, Los Angeles, Orange, Riverside, San Bernardino, and San Diego counties (USFWS, 2009c).

A list of special-status wildlife species was also generated using the Sacramento Fish and Wildlife Office's Endangered Species Program website (USFWS, 2009a) for the four USGS 7.5 minute quadrangles within which San Luis Reservoir is located (map numbers are provided in parentheses): Los Banos Valley (384A), Mariposa Peak (384B), Pacheco Pass (404C), and San Luis Dam (404D).

The California Natural Diversity Database (CNDDB) *State and Federally Listed Endangered and Threatened Animals of California* (October, 2009) and *Special Animals* (July, 2009) lists were also consulted for State-listed species and species of special concern (DFG, 2009a).

Commercially or Recreationally Important Wildlife Species

The agricultural lands and wildlife refuges within the Extended Study Area provide seasonal and year-round habitat for a variety of commercially or recreationally important wildlife species. The WHR System (DFG, 2008a) was used to generate a list of all harvest (hunted or trapped) species that could occur within the rice, irrigated grain crops, irrigated row and field crops, irrigated hayfields, evergreen orchard, deciduous orchard, pasture, and vineyard habitats within the 39 counties that comprise the Extended Study Area. Because only ten counties can be entered into the WHR System at one time, four species lists were generated and then merged for each habitat type. A separate list was generated for all harvest species that could occur within fresh emergent wetland habitat within the counties that are in the Extended Study Area wildlife refuges and areas (Colusa, Fresno, Glenn, Kern, Kings, Merced, and Tulare). Finally, a list of harvest species that could occur within the lacustrine habitat of San Luis Reservoir was generated for Merced County.

14.2.1.2 Wildlife Habitats and Associated Wildlife

Urban

Urban habitat includes vegetation in city parks, tree strips along city streets, residential gardens, and landscaping, such as shrubs, shade trees, and lawns. Vegetation in urban habitat is comprised of native and non-native species that usually receive some level of maintenance. The species found in urban habitat are greatly influenced by the type of habitat that is adjacent to the urban area; most large cities are surrounded by agricultural and grazing lands. Many non-native wildlife species thrive in urban areas (Mayer and Laudenslayer, 1988a).

Up to 225 species (170 birds, 43 mammals, 8 reptiles, and 4 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with urban habitat include the Virginia opossum (*Didelphis virginiana*), Brazilian free-tailed bat (*Tadarida brasiliensis*), California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), house mouse (*Mus musculus*), striped skunk (*Mephitis mephitis*), western fence lizard (*Sceloporus occidentalis*), pacific chorus frog (*Pseudacris egilla*), rock pigeon (*Columba livia*), numerous hummingbird species, western scrub jay (*Aphelocoma californica*), yellow-billed magpie (*Pica nuttalli*), northern mockingbird (*Mimus polyglottos*), European starling (*Sturnus vulgaris*), house finch (*Carpodacus mexicanus*), house sparrow (*Passer domesticus*), and American robin (*Turdus migratorius*).

Rice

Rice is a flood-irrigated annual crop that is usually planted in the spring and harvested in the fall. Rice is typically grown in leveed fields that have heavier clay soils that hold water well – many rice field locations historically supported seasonal wetlands. Flooded rice fields support many species that were once supported by wetlands, and some waterfowl species depend on waste rice (Mayer and Laudenslayer, 1988a).

Up to 196 species (137 birds, 33 mammals, 20 reptiles, and 6 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with rice habitat include the ring-necked pheasant (*Phasianus colchicus*), sandhill crane (*Grus canadensis*), greater white-fronted goose (Anser *albitrons*), common muskrat (*Ondatra zibethicus*), numerous waterfowl species, herons, egrets, and the giant garter snake (*Thamnophis gigas*).

Irrigated Grain Crops

Irrigated grain and seed crops include corn, safflower, dry beans, milo, grain sorghum, and sunflowers. These crops are annuals that are typically planted in the spring and harvested in the summer or fall. Wheat and barley are also irrigated grain crops, but are typically planted in the fall and harvested in the spring. Approximately 50 percent of all barley crops and 75 percent of wheat crops are irrigated. Irrigated grain and seed crops are established on very fertile soils, which historically supported native vegetation that provided high habitat suitability and an associated abundance of wildlife. Irrigated grain and seed crops do not support that same abundance of wildlife, but several species have adapted to this habitat type, and some species depend on the waste grain that remains in the field after harvesting (Mayer and Laudenslayer, 1988a).

Up to 173 species (108 birds, 53 mammals, 5 reptiles, and 7 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with irrigated grain and seed crops include the black rat (*Rattus rattus*), Botta's pocket gopher, wild pig (*Sus scrofa*), mule deer (*Odocoileus hemionus*), gopher snake (*Pituophis catenifer*), greater white-fronted goose, Canada goose (*Branta canadensis*), mallard (*Anas platyrhynchos*), northern harrier (*Circus cyaneus*), ring-necked pheasant, killdeer (*Charadrius vociferus*), barn owl (*Tyto alba*), tri-colored blackbird (*Agelaius tricolor*), herons, egrets, and numerous bat species.

Irrigated Row and Field Crops

Irrigated row and field crops include cotton, asparagus, strawberries, tomatoes, lettuce, melons, broccoli, cauliflower, carrots, celery, cucumber, potatoes, and onions. Most of these crops are annual, but some, such as asparagus and strawberries, are perennial. Similar to irrigated grain and seed crops, most row and field crops are planted on very fertile soils and do not support the abundance of wildlife that the historical native vegetation once supported (Mayer and Laudenslayer, 1988a).

Up to 116 species (46 birds, 51 mammals, 10 reptiles, and 9 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with irrigated row and field crops include the black-tailed jackrabbit (*Lepus californicus*), California ground squirrel, Botta's pocket gopher, western harvest mouse (*Reithrodontomys megalotis*), great blue heron (*Ardea herodias*), great egret (*Ardea alba*), snow goose (*Chen caerulescens*), ring-necked pheasant, killdeer, barn owl, red-winged blackbird (*Agelaius phoeniceus*), and numerous bat species.

Irrigated Hayfield

Irrigated hayfields include alfalfa fields and grass hayfields. Alfalfa fields are plowed every three to six years, with some fields plowed every year. Within the Central Valley, alfalfa fields can be harvested as many as 6 times per year. Alfalfa fields are an important part of a crop rotation, because alfalfa renews soil nitrogen. Grass hayfields are intensively mowed and managed fields of annually-planted introduced grasses, or can also be naturally-occurring perennial grasses and sedges. A mixture of these grass types is common. This habitat provides a high quality seasonal resource for many wildlife species, but frequent harvesting makes this habitat type unsuitable for ground nesting species (Mayer and Laudenslayer, 1988a).

Up to 223 species (158 birds, 58 mammals, 6 reptiles, and 1 amphibian) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with irrigated hayfields include the great blue heron, great egret, cattle egret (*Bubulcus ibis*), tundra swan (*Cygnus columbianus*), several goose species, mallard, northern pintail (*Anas acuta*), northern harrier, ring-necked pheasant, sandhill crane, long-billed curlew (*Numenius americanus*), burrowing owl (*Athene cunicularia*), red-winged blackbird, Botta's pocket gopher, and gopher snake.

Evergreen Orchard

Evergreen orchards are single species tree-dominated habitats in which the trees are arranged in a linear pattern and are spaced evenly. Understory species may include low-growing grasses or other herbaceous plants, but evergreen orchards are typically managed to prevent any understory growth. Evergreen orchards include avocados, dates, grapefruit, lemons, limes, olives, oranges, tangerines, and tangelos. Evergreen orchards are planted on fertile soil that once supported diverse habitats and numerous wildlife species. This heavily managed monoculture does not support the abundance of wildlife once associated with the native vegetation, but some species have adapted and have become pests by feeding on the leaves and fruit of the trees. Other wildlife species use evergreen orchards for cover and nesting sites, with the year-round tree canopy providing shelter from hot or cold temperatures (Mayer and Laudenslayer, 1988a).

Up to 90 species (30 birds, 45 mammals, 9 reptiles, and 6 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with evergreen orchards include the mourning dove (*Zenaida macroura*), California quail (*Callipepla californica*), barn owl, European starling, western gray squirrel (*Sciurus griseus*), Botta's pocket gopher, black-tailed jackrabbit, and mule deer.

Deciduous Orchard

Similar to evergreen orchards, deciduous orchards are single species tree-dominated habitats in which the trees are arranged in a linear pattern and are spaced evenly. Understory species may include low-growing grasses or other herbaceous plants, but some deciduous orchards are managed to prevent any understory growth. Deciduous orchards include almonds, apples, apricots, cherries, figs, nectarines, peaches, pears, pecans, pistachios, plums, prunes, and walnuts. The tree canopy can provide shelter from heat, but does not provide much cover from rain and cold during the winter after the leaves have dropped (Mayer and Laudenslayer, 1988a).

Up to 167 species (107 birds, 48 mammals, 9 reptiles, and 3 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with deciduous orchards include the northern flicker (*Colaptes auratus*), western scrub jay, American crow (*Corvus brachyrhynchos*), oak titmouse (*Baeolophus inornatus*)), Brewer's blackbird (*Euphagus cyanocephalus*), American robin, western gray squirrel, California ground squirrel, raccoon (*Procyon lotor*), and black bear (*Ursus americanus*).

Pasture

Pasture habitat is a mix of perennial grasses and legumes that is irrigated and used for grazing livestock. The height of the vegetation depends on management practices, the type of livestock, stocking rates, and grazing duration. Pasture is typically planted on soils that are not suitable for other crops. Ground-nesting birds will nest in pasture habitat when adequate vegetation is present at the start of the nesting season, and flood-irrigated pasture provides feeding and roosting sites for shorebirds, wading birds, and waterfowl. Large mammals, such as deer, antelope, and elk will graze pastures if adjacent escape cover exists (Mayer and Laudenslayer, 1988a).

Up to 108 species (9 birds, 69 mammals, 13 reptiles, and 17 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with pasture include the bullfrog (*Rana catasbeiana*), burrowing owl, broad-footed mole (*Scapanus latimanus*), black-tailed jackrabbit, California ground squirrel, Botta's pocket gopher, San Joaquin pocket mouse (*Perognathus inornatus*), pronghorn (*Antilocapra americana*), and gopher snake.

Vineyard

Vineyards are composed of a single species planted in rows, with the vines supported by a trellis. The area beneath the vines is usually managed to prevent plant growth, but the area between rows is typically planted with grasses or other herbaceous plants. Vineyards include boysenberries, raspberries, kiwifruit, and grapes. Vineyards are planted on highly fertile soils that once supported diverse native habitats which, in turn, supported an abundance and diversity of wildlife. Some wildlife have adapted to vineyards by browsing on the vines, eating the fruit, or using the habitat for nesting and cover. Raptors use vineyards to feed on rodents and other crop pests (Mayer and Laudenslayer, 1988a).

Up to 105 species (43 birds, 46 mammals, 10 reptiles, and 6 amphibians) may be found within this habitat type within the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with vineyards include the mule deer, black-tailed jackrabbit, California ground squirrel, mourning dove, barn owl, northern mockingbird, Brewer's blackbird, house finch, Botta's pocket gopher, and American kestrel (*Falco sparverius*).

Fresh Emergent Wetland

Fresh emergent wetlands are one of the most productive wildlife habitats in California. Located in land depressions, these wetlands are flooded frequently and are dominated by rooted perennial vegetation, such as cattail (*Typha* sp.), bulrush (*Scirpus* sp.), and arrowhead (*Sagittaria* sp.). The wetlands of the wildlife refuges and WAs are primarily managed to provide wintering habitat for waterfowl, but many other species benefit from their management practices, including special-status species that depend on ponded water for all or part of their life cycles (Mayer and Laudenslayer, 1988a).

Up to 180 species (119 birds, 32 mammals, 12 reptiles, and 17 amphibians) may be found within this habitat type within the wildlife refuges and WAs in the Extended Study Area (DFG, 2008a). Wildlife species commonly associated with fresh emergent wetland include the California newt (*Taricha torosa*), western spadefoot (*Spea hammondii*), Pacific chorus frog, California red-legged frog (*Rana draytonii*), eared grebe (*Podiceps nigricollis*), black-crowned night heron (*Nycticorax nycticorax*), Canada goose, mallard, northern shoveler (*Anas clypeata*), sandhill crane, white-faced ibis (*Plegadis chihi*), short-eared owl (*Asio flammeus*), red-winged blackbird, American beaver (*Castor canadensis*), common muskrat, American mink (*Mustela vison*), raccoon, western pond turtle (*Actinemys marmorata*), and giant garter snake.

Lacustrine

Lacustrine habitat includes permanently flooded lakes and reservoirs, intermittent lakes, and ponds – some of which may be shallow enough to support rooted plants (Mayer and Laudenslayer, 1988a). Operations at San Luis Reservoir cause severe reservoir level fluctuations, but the fluctuations are gradual enough to support some wetland and riparian scrub vegetation species in seeps within the drawdown zone.

Up to 130 species (103 birds, 14 mammals, 5 reptiles, and 8 amphibians) may be found within this habitat type within Merced County at San Luis Reservoir (DFG, 2008a). Wildlife species commonly associated with lacustrine open-water habitat include the bald eagle (*Haliaeetus leucocephalus*), western grebe (*Aechmophorus occidentalis*), double-crested cormorant (*Phalacrocorax auritus*), common loon (*Gavia immer*), and osprey (*Pandion haliaetus*). Bats and some insectivorous bird species can be found foraging over open water.

Wildlife species commonly associated with the nearshore portion of lacustrine habitat include the great blue heron, snowy egret (*Egretta thula*), killdeer, and long-billed curlew. Shallow areas also provide habitat for amphibians and reptiles. Lacustrine habitat also serves as a source of drinking water for wildlife that uses adjacent habitat types.

14.2.1.3 Special-Status Wildlife Species

More than 175 State- or federally-listed threatened or endangered species, candidate species, and State species of special concern may occur within the 39 counties that are included in the Extended Study Area (USFWS, 2009a; USFWS, 2009b; USFWS, 2009c; DFG, 2009a). The counties of the Extended Study Area also include numerous areas of designated critical habitat. However, most of these special-status species would be unlikely to occur in, or depend upon, the urban habitat type.

Although agricultural habitat types tend to be of less value to wildlife than native habitats, some special-status species have adapted to agricultural lands. Species, such as the Swainson's hawk (*Buteo swansoni*), greater sandhill crane (*Grus canadensis tabida*), and bank swallow (*Riparia riparia*) use agricultural fields as foraging areas. Flooded fields and deciduous orchards have the potential to meet the cover, feeding, and reproduction needs of the giant garter snake and the western yellow-billed cuckoo (*Coccyzus americanus occidentalis*), respectively (DFG, 2008a).

The fresh emergent wetlands of the wildlife refuges and WAs within the Extended Study Area have the potential to meet the cover, feeding, and reproduction needs of special-status species such as the

California tiger salamander (*Ambystoma californiense*), California red-legged frog, greater sandhill crane, and giant garter snake (DFG, 2008a).

The lacustrine habitat of San Luis Reservoir has the potential to support several special-status wildlife species, including the bald eagle and osprey. However, there are no known occurrences of bald eagles or osprey within the four USGS 7.5 minute quadrangles within which San Luis Reservoir is located. The nearest known locations are in eastern Merced County for both species (DFG, 2009a). No bald eagle perch sites have been documented around the reservoir, which is surrounded by annual grassland and blue oak woodland habitats, but occasionally winter use by bald eagles may occur (Reclamation, 2007). The open water habitat of the reservoir has the potential to support special-status species, such as the common loon, redhead (*Aythya americana)*, Barrow's goldeneye (*Bucephala islandica)*, black tern (*Chlidonias niger)*, western snowy plover (*Charadrius alexandrinus nivosus)*, and American white pelican (*Pelecanus erythrorhyncos)*.

14.2.1.4 Commercially or Recreationally Important Wildlife Species

Many of the harvest species found on agricultural lands are considered to be crop pests, and landowners consequently provide hunting opportunities to control these species. Up to 67 harvest species (39 birds, 27 mammals, and 1 amphibian) may occur within the urban and agricultural habitat types within the Extended Study Area, and up to 38 harvest species (26 birds, 11 mammals, and 1 amphibian) may occur within the fresh emergent wetland habitat on the WAs and refuges within the Extended Study Area (DFG, 2008a). Seasonal waterfowl hunting occurs at San Luis Reservoir. Up to 27 waterfowl harvest species may occur within the lacustrine habitat of this reservoir.

Harvest birds include waterfowl, such as the mallard and greater white-fronted goose, and upland game birds, such as the ring-necked pheasant and wild turkey (*Meleagris gallopavo*). The WAs and refuges within the Extended Study Area have wetlands that are managed for waterfowl and provide waterfowl hunting opportunities to the public in designated areas. Private hunting opportunities exist on the flooded rice fields that are also managed for waterfowl.

Harvest mammals include furbearers, such as the American beaver and American mink; small game, such as the black-tailed jackrabbit and western gray squirrel; and big game, such as the black bear, wild pig, and mule deer.

14.2.2 Secondary Study Area

14.2.2.1 Methodology

<u>Wildlife Habitats and Associated Wildlife</u>

The WHR System (DFG, 2008a) was used to identify the potential number of species that could occur within the 22 counties included in the Secondary Study Area. A WHR species list was generated for the lacustrine, riverine, estuarine, montane riparian, valley foothill riparian, fresh emergent wetland, saline emergent wetland, barren, rice, irrigated grain crops, and irrigated row and field crops habitat types.

Because only 10 counties can be entered into the WHR System at one time, three species lists were generated and then merged for each habitat type.

<u>Special-Status Wildlife Species</u>

A list of special-status wildlife species that may occur within the Secondary Study Area was generated using the Sacramento Fish and Wildlife Office's Endangered Species Program website (USFWS, 2009a).

The list includes federal endangered, threatened, and candidate species that may be affected within the 19 of the 22 counties within the Secondary Study Area that are within their jurisdiction, as well as areas of designated critical habitat. The Arcata Fish and Wildlife Office's Species List Search page was used to generate species lists for Del Norte, Humboldt, and Trinity counties (USFWS, 2009d). The CNDDB *State and Federally Listed Endangered and Threatened Animals of California* (October 2009) and *Special Animals* (July 2009) lists were also consulted for State-listed species and species of special concern (DFG, 2009a). The generated lists include the entire county, and therefore, may contain species that would be found within the county, but not within the specific habitat types listed above. In addition, CNDDB's Rarefind 4 was queried for known occurrences within the 22 counties in the specified habitat types.

Commercially or Recreationally Important Wildlife Species

The Secondary Study Area provides seasonal and year-round habitat for a variety of commercially or recreationally important wildlife species. The WHR System (DFG, 2008a) was used to generate a list of all harvest (hunted or trapped) species that could occur within the lacustrine, riverine, estuarine, valley foothill riparian, fresh emergent wetland, saline emergent wetland, and barren habitat types within the 22 counties listed above. Because only ten counties can be entered into the WHR System at one time, three species lists were generated and then merged. A separate list was generated of all harvest species that could exist within the rice, irrigated grain crops, and irrigated row and field crops habitat types within the bypasses of Yolo and Sutter counties.

14.2.2.2 Wildlife Habitats and Associated Wildlife

Lacustrine

Lacustrine habitat is described in the Extended Study Area discussion. Lacustrine habitat within the Secondary Study Area primarily exists at the reservoirs, as well as at the Thermalito Forebay and Afterbay. The Forebay does not experience large water level fluctuations and, is therefore, able to support emergent aquatic vegetation (DWR, 2007a). Portions of the drawdown zone at Shasta Lake are also able to support limited amounts of early successional vegetation, such as willow, cottonwood, and various grasses and forbs (Reclamation, 2004).

Up to 166 species (120 birds, 18 mammals, 9 reptiles, and 19 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with lacustrine habitat are listed in the Extended Study Area discussion (Section 14.2.1.2).

Riverine

Riverine habitat includes free-flowing streams and rivers (Mayer and Laudenslayer, 1988a). Riverine habitat within the Secondary Study Area includes the Feather, Sacramento, Trinity, Lower Klamath, and American rivers, as well as Clear and Spring creeks.

Up to 159 species (101 birds, 26 mammals, 8 reptiles, and 24 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with the open-water zones of large rivers include the osprey, bald eagle, gulls, terns, and waterfowl. Insectivorous species, such as the Yuma myotis (*Myotis yumanensis*), bank swallow, black swift (*Cypseloides niger*), and black phoebe forage over open water.

Wildlife species commonly associated with the near-shore portions of rivers and streams include the belted kingfisher (*Megaceryle alcyon*), mallard, great egret, killdeer, American dipper (*Cinclus* *mexicanus*), foothill yellow-legged frog (*Rana boylii*), western pond turtle, northern river otter, American mink, and common muskrat. Riverine habitat also serves as a source of drinking water for wildlife.

Estuarine

Estuarine habitat occurs on periodically or permanently flooded substrates where tidal seawater mixes with, and is diluted by, flowing fresh water (Mayer and Laudenslayer, 1988a). Estuaries within the Secondary Study Area include the San Francisco, San Pablo, and Suisun bays, the mouth of the Klamath River, and the Sacramento-San Joaquin Delta.

The salinity of estuarine habitats varies seasonally depending on freshwater inflow and tidal action. Estuarine habitat has a low number of species, but a high density of those species that can tolerate the fluctuating salinity levels, such as benthic (bottom dwelling) invertebrates and plankton. Many bird and mammal species use estuarine habitat for feeding, resting, reproduction, and cover. Estuarine sub-tidal habitat supports eel grass (*Zostera* sp.), which the brant (*Branta bernicla*) depends on (Mayer and Laudenslayer, 1988a).

Up to 127 species (120 birds and 7 mammals) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with estuaries include the common loon, western grebe, double-crested cormorant, red-breasted merganser (*Mergus serrator*), lesser scaup (*Aythya affinis*), black-necked stilt (*Himantopus mexicanus*), Caspian tern (*Hydroprogne caspia*), and harbor seal (*Phoca vitulina*).

Montane Riparian

Montane riparian habitat usually occurs as a narrow, often dense, grove of broad-leaved winter deciduous trees, such as maple (*Acer* sp.), cottonwood (*Populus* sp.), and alder (*Alnus* sp.), with a sparse understory. This habitat type is found associated with montane lake, ponds, seeps, bogs, and meadows, as well as rivers, streams and springs, typically below 2,440 meters (m) (8,000 feet) in elevation (Mayer and Laudenslayer, 1988a).

Within the Secondary Study Area, montane riparian habitat that could be affected by Project operation exists along the Trinity and Klamath rivers. In Trinity County, dominant tree species include bigleaf maple (*Acer macrophyllum*), white alder (*Alnus rhombifolia*), Oregon ash (*Fraxinus latifolia*), black cottonwood (*Populus balsamifera)*, and black willow (*Salix gooddingii*). Typical understory species include mugwort (*Artemisia douglasiana*), virgin's bower (*Clematis ligusticifolia*), American dogwood (*Cornus sericea*), Oregon golden-aster (*Heterotheca oregona*), straggly gooseberry (*Ribes divaricatum*), Himalayan blackberry (*Rubus discolor*), California blackberry (*Rubus ursinus*), narrow-leaved willow, arroyo willow (*Salix lasiolepis*), and California wild grape (*Vitis californica*) (Reclamation, 2009).

Up to 300 species (159 birds, 91 mammals, 22 reptiles, and 28 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with montane riparian habitat include the roughskin newt (*Taricha granulosa*), Pacific chorus frog, Pacific giant salamander (*Dicamptodon tenebrosus*), osprey, peregrine falcon, great horned owl, belted kingfisher, vagrant shrew, long-eared myotis (*Myotis evotis*), western harvest mouse, common muskrat, American mink, California mountain kingsnake (*Lampropeltis zonata*), and western terrestrial garter snake (*Thamnophis elegans*).

Valley Foothill Riparian

Valley foothill riparian habitat occurs in valleys and foothills and is usually associated with low-velocity flows or floodplains. The canopy is dominated by cottonwood, California sycamore (*Platanus racemosa*), and valley oak (*Quercus lobata*). The sub-canopy is dominated by white alder, box elder (*Acer negundo*), and Oregon ash (*Fraxinus latifolia*). The typically impenetrable understory shrub layer includes wild grape, California blackberry, poison oak (*Toxicodendron diversilobum*), and willows. Elderberry shrubs (*Sambucus* sp.) are often associated with this habitat type (Mayer and Laudenslayer, 1988a).

DFG has designated riparian habitat as a sensitive habitat because of its limited abundance and high value to wildlife. Numerous wildlife species use this habitat type for food, water, migration corridors, escape habitat, nesting habitat, and thermal cover. Valley foothill riparian habitat exists within the Secondary Study Area along the rivers and creeks, as well as within the Yolo and Sutter bypasses. Most remaining stretches of riparian habitat are narrow and fragmented. However, the Oroville WA contains over 3,000 acres of valley foothill riparian habitat, representing the largest remaining block of riparian habitat along the Feather River (DWR, 2007b).

Up to 312 species (188 birds, 73 mammals, 27 reptiles, and 24 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with valley foothill riparian habitat include the California slender salamander (*Batrachoseps attenuatus*), foothill yellow-legged frog, green heron (*Butorides virescens*), osprey, California quail, great horned owl (*Bubo virginianus*), belted kingfisher, downy woodpecker (*Picoides pubescens*), black phoebe, bank swallow, canyon wren (*Catherpes mexicanus*), vagrant shrew (*Sorex vagrans*), several bat species, western gray squirrel, ringtail (*Bassariscus astutus*), American mink, western pond turtle, western skink (*Eumeces skiltonianus*), common kingsnake (*Lampropeltis getula*), and western aquatic garter snake (*Thamnophis couchii*). The WHR System does not include invertebrates, but the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) is also associated with this habitat type when elderberry shrubs are present.

Fresh Emergent Wetland

Fresh emergent wetland is described in the Extended Study Area discussion (Section 14.2.1.2). Fresh emergent wetland occurs throughout the secondary study area at the confluence of streams and reservoirs, in landscape depressions along the creeks and rivers, in backwater areas of the rivers, in dredger ponds, around Thermalito Forebay and Afterbay, and in the Yolo and Sutter bypasses. Wetlands also occur in seeps and springs above the high water lines of the reservoirs, but typically are absent within the drawdown zone of the reservoirs. More than 850 acres of wetlands are present within the Thermalito Complex (DWR, 2007b; Reclamation, 2009).

Up to 189 species (121 birds, 36 mammals, 12 reptiles, and 20 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with fresh emergent wetland are listed in the Extended Study Area discussion (Section 14.2.1.2).

Saline Emergent Wetland

Saline emergent wetland consists of salt or brackish marshes and contains vegetation, such as cordgrass (*Spartina* sp.), pickleweed (*Salicornia* sp), saltgrass (*Distichlis spicata*), and glasswort (*Salicornia* sp.). These wetlands occur above intertidal sand and mud flats and below upland communities not subject to tidal action, mainly along the margins of bays, lagoons, and estuaries. Within the Secondary Study Area, saline emergent wetland habitat occurs around San Pablo Bay, Suisun Bay, and portions of the Delta, with the largest stands of saline emergent wetland occurring in San Francisco Bay (Mayer and Laudenslayer, 1988a).

Up to 119 species (112 birds and 17 mammals) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with saline emergent wetland include the eared grebe, black-crowned night heron, peregrine falcon (*Falco peregrinus*), California black rail (*Laterallus jamaicensis coturniculus*), California clapper rail (*Rallus longirostris obsoletus*), short-eared owl, red-winged blackbird, salt marsh harvest mouse (*Reithrodontomys raviventris*), and American mink.

Barren

Barren habitat is defined by the absence of vegetation, although opportunistic grasses and forbs or weedy species may occur. Barren habitat exists in many forms throughout the Secondary Study Area. The mudflats surrounding estuarine, fresh emergent wetland, and saline emergent wetland habitats are considered to be barren habitat. Along rivers, barren habitat includes vertical river banks and canyon walls, sealed rip-rap features, dredger tailings, rock outcrops, and gravel bars adjacent to the rivers. Barren habitat also includes the drawdown zone of reservoirs (Mayer and Laudenslayer, 1988a; Reclamation, 2004; Reclamation, 2009).

Up to 124 species (86 birds, 35 mammals, 2 reptiles, and 1 amphibian) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with barren habitat include the killdeer, bank swallow, belted kingfisher, black swift and American avocet (*Recurvirostra americana*).

Rice

Rice habitat is described in the Extended Study Area discussion (Section 14.2.1.2). Rice is the predominant crop type within the Yolo and Sutter bypasses. Up to 194 species (136 birds, 33 mammals, 19 reptiles, and 6 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with rice are listed in the Extended Study Area discussion (Section 14.2.1.2).

Irrigated Grain Crops

Irrigated grain crops are described in the Extended Study Area discussion (Section 14.2.1.2). Crops, such as corn and safflower, are grown in the Secondary Study Area within the Yolo and Sutter bypasses. Up to 157 species (98 birds, 50 mammals, 5 reptiles, and 4 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with irrigated grain crops are listed in the Extended Study Area discussion (Section 14.2.1.2).

Irrigated Row and Field Crops

Irrigated row and field crops are described in the Extended Study Area discussion (Section 14.2.1.2). Crops, such as tomatoes and melons, are grown in the Secondary Study Area within the Yolo and Sutter bypasses. Up to 107 species (43 birds, 50 mammals, 9 reptiles, and 5 amphibians) may be found within this habitat type within the Secondary Study Area (DFG, 2008a). Wildlife species commonly associated with irrigated row and field crops are listed in the Extended Study Area discussion (Section 14.2.1.2).

14.2.2.3 Special-Status Wildlife Species

More than 60 State- and federally-listed species, candidate species, and species of special concern may occur within the counties of the Secondary Study Area (USFWS, 2009a; USFWS, 2009d; DFG, 2009a). These counties also include numerous areas of designated critical habitat. Many of these special-status species would not be affected by changes in stream flow patterns or fluctuating reservoir levels. Thirteen of these special-status species could be affected by changes to existing facility operations in the Secondary Study Area as a result of the Project. The 13 listed species that could be affected by these operational changes are discussed below.

Reptiles and Amphibians

California Red-Legged Frog

The California red-legged frog inhabits humid forests, woodlands, grasslands, and stream sides where dense shrubby or riparian vegetation provides good cover. This species can be found in streams, lakes, reservoirs, ponds, or other permanent sources of water, but is generally absent from water sources that are inhabited by the bullfrog (Stebbins, 1985, Stebbins and Cohen, 1995).

The California red-legged frog is known to occur in streams in 13 of the 22 counties within the Secondary Study Area. The locations of those occurrences include tributary creeks, coastal streams, and small ponds and lakes (DFG, 2010b). In 2002 the USFWS prepared the *Recovery Plan for the California Red-Legged Frog*. The objective of the plan is to reduce threats and improve the population status of the California red-legged frog sufficiently to warrant delisting. The plan contains maps of recovery units. Within the recovery units, there are several areas that have been identified as core areas where recovery actions will be focused. Two of those core areas are located within the Secondary Study Area. The Cottonwood Creek Core Area includes Lower Cottonwood Creek and its confluence with the Sacramento River in Shasta and Tehama counties. The South San Francisco Bay Core Area includes the edge of San Francisco Bay within Marin County (USFWS, 2002).

Foothill Yellow-Legged Frog

The foothill yellow-legged frog ranges from the Oregon border to Los Angeles County along the Coast Ranges, in northern California west of the Cascade Crest, and along the Sierras to Kern County at elevations ranging from near sea level to 1942 m (6,370 ft). This frog is found in a variety of habitats in or near rocky streams, including valley foothill riparian, mixed chaparral, mixed conifer, and wet meadow.

This species uses submerged rock or sediment as cover when disturbed, and seeks cover under rocks instream or near water during periods of inactivity. The foothill yellow-legged frog is rarely found away from a permanent water source, and tadpoles require a permanent water source for up to four months during development. Breeding and egg-laying occur from mid-March to May following spring flooding (Mayer and Laudenslayer, 1988b).

The foothill yellow-legged frog is known to occur in 20 of the 22 counties within the secondary study area, but is not found in the valley portions of many of those counties. Foothill yellow-legged frogs have been observed in the canyon reach of lower Clear Creek downstream of Whiskeytown Dam, and are known to occur in the Trinity River from Lewiston Dam to the North Fork Trinity River (Reclamation, 2009; BLM, 2008).

Giant Garter Snake

The giant garter snake inhabits agricultural wetlands and other waterways, such as irrigation and drainage canals, sloughs, ponds, small lakes, low gradient streams, and adjacent uplands in the Central Valley. Because of the direct loss of natural habitat from agricultural and urban development, the giant garter snake relies heavily on rice fields and their associated drains and canals in the Sacramento Valley. Giant garter snakes are typically absent from larger rivers because of lack of suitable habitat and emergent vegetative cover, and from wetlands with sand, gravel, or rock substrates. Riparian woodlands typically do not provide suitable habitat because of excessive shade, lack of basking (sunning) sites, and absence of prey populations (USFWS, 2009e).

Within the Secondary Study Area, the giant garter snake is presumed to occur in Butte, Colusa, Glenn, Sacramento, Solano, Sutter and Yolo counties. Suitable giant garter snake habitat exists within portions of the Thermalito Forebay and Afterbay, the Oroville WA, lands subject to rice agriculture adjacent to Thermalito Afterbay, and in isolated patches of backwater habitats along the Feather River (DWR, 2007a). This species is known to occur along the western border of the Yolo Bypass, and was documented in the western Delta in 1998 in the vicinity of Sherman Island. Although giant garter snakes have not been documented within the Sutter Bypass, they are known to occur on the lands immediately adjacent to the bypass and therefore may occur within suitable habitat in the bypass.

The USFWS has proposed recovery units where recovery actions are needed to benefit the giant garter snake. The Sacramento Valley and Mid Valley recovery units, which are located within the Secondary Study Area, include stretches of the Sacramento, Feather, and American rivers, the Yolo and Sutter bypasses, and portions of the Sacramento-San Joaquin Delta (USFWS, 1999a). Although the rivers are not expected to provide suitable habitat for the giant garter snake, some of the oxbows and backwater sloughs, as well as the lands immediately adjacent to the rivers, may provide suitable habitat.

San Francisco Garter Snake

The San Francisco garter snake's *(Thamnophis sirtalis tetrataenia*) preferred habitat is densely vegetated ponds that are located near open hillsides or levees. Hillsides and levees are also used by the snake for basking, feeding, and cover (e.g., rodent burrows) (USFWS, 2002).

Currently, this species is found in only a few localities in San Francisco and San Mateo counties. Within the Secondary Study Area, occurrences of the San Francisco garter snake are known in the vicinity of South San Francisco Bay.

Western Pond Turtle

The western pond turtle ranges throughout California west of the Sierra-Cascade crest, with the exception of the desert regions, at elevations ranging from near sea level to 1430 m (4,690 ft). This turtle is associated with water that is permanent or nearly permanent in a variety of habitats. The western pond turtle uses rocks, floating vegetation, or other partially submerged substrates as basking sites, and seeks cover underwater when disturbed. Females travel on land to seek out suitable nest sites in spring or early summer, laying eggs from March to August (Mayer and Laudenslayer, 1988b).

Western pond turtles can be found throughout the Secondary Study Area in lacustrine, riverine, fresh emergent wetland, montane riparian, and valley foothill riparian habitats.

Birds

Bald Eagle

Wintering bald eagles use a wide variety of habitats including lacustrine, riverine, riparian, emergent wetland, and agricultural croplands. Nesting bald eagles are restricted to habitats associated with large fish-bearing lakes, reservoirs, and rivers with suitable nest trees (Lehman, 1979; Mayer and Laudenslayer, 1988c). The breeding season ranges from February through July.

Bald eagles winter throughout most of the Secondary Study Area in suitable habitat, with extensive winter use occurring at Lake Oroville and Lake Shasta, and regular use occurring along the Feather and Sacramento rivers. A substantial number of bald eagle nests have been documented at Lake Shasta. Nesting bald eagles have also been documented on Lake Oroville and at the Diversion Pool; on the Feather, Klamath, Sacramento, and Trinity rivers; and at Folsom, Lewiston, Trinity, and Whiskeytown lakes (DFG, 2007b; BLM, 2008; DWR, 2007a; Reclamation, 2008; DFG, 2010a).

Bank Swallow

Bank swallows are migratory birds that live in colonies and nest in cavities. Bank swallows use a variety of habitats in and around the Sacramento Valley. Nesting is restricted to riparian, lacustrine, or riverine habitats with vertical cliffs or banks composed of sandy or loamy soils near water (Garrison et al., 1987, Mayer and Laudenslayer, 1988c). Nesting does not normally occur on ephemeral streams or on compacted clay or gravelly substrates. The breeding season ranges from mid-March through July. Foraging activities occur primarily over riparian habitat where insects are taken while flying.

Within the Secondary Study Area, bank swallows are known to occur in many areas, including along the Sacramento River in Shasta, Tehama, Butte, Glenn, Colusa, Sutter and Yolo counties, along the Feather River, in coastal areas of San Francisco County, along the American River in the San Juan Rapids area, and along Seven-Mile slough near Three-Mile Slough in the Sacramento-San Joaquin Delta. Nesting bank swallows have also been observed on lower Clear Creek.

Annual protocol-level bank swallow surveys are conducted on the Sacramento and Feather rivers by DFG, USFWS, and DWR. Surveys on the Sacramento River in 2008 and 2009 documented 65 and 64 active bank swallow colonies, respectively. The 2008 surveys were conducted from the Red Bluff Diversion Dam to Verona, and the 2009 surveys were conducted from Keswick Dam to Verona. Surveys on the Feather River in 2008 and 2009 documented 18 and 20 active bank swallow colonies, respectively, located from downstream of the Thermalito Afterbay outlet to the confluence with the Sacramento River (DFG, 2008b; DFG, 2009e).

California Black Rail

The California black rail is found in the high wetland zones of saline or brackish emergent wetlands associated with heavy growth of pickleweed or with bulrush in association with pickleweed. In freshwater emergent wetlands, it prefers bulrushes, cattails, and saltgrass. This species typically does not occur in low wetland areas with considerable fluctuations in water levels. This species is mostly resident, but may winter in areas where it does not breed (Mayer and Laudenslayer, 1988c).

Within the Secondary Study Area, California black rails occur in San Francisco, San Pablo, and Suisun bays, as well as in portions of the Delta. The majority of breeders occur at San Pablo Bay.

California Clapper Rail

The California clapper rail is a resident in saline, fresh, or brackish emergent wetlands in the vicinity of San Francisco Bay. This species is restricted to emergent wetlands and tidal sloughs with heavy growth of pickleweed and cordgrass, and in brackish wetlands with pickleweed, cordgrass, and bulrush. California clapper rails require shallow water and mudflats for foraging, as well as adjacent higher vegetation for cover during high water (Mayer and Laudenslayer, 1988c).

Within the Secondary Study Area, the California clapper rail is known to occur along San Francisco Bay, San Pablo Bay, and Suisun Bay and Marsh.

Greater Sandhill Crane

Greater sandhill cranes currently breed in Great Basin habitats in northern California where they select open, shallow lacustrine, irrigated pasture, or wetland habitats for nesting. Saline waters are avoided. Winter habitat consists of annual and perennial grasslands, moist croplands (corn, sorghum, barley, and rice), or emergent wetlands (Mayer and Laudenslayer, 1988c).

Within the Secondary Study Area, many greater and lesser sandhill cranes winter in the interior of the Sacramento Valley. The emergent wetlands of the Delta also provide suitable foraging habitat for these species.

Willow Flycatcher

The willow flycatcher prefers montane riparian areas and large wet meadows with abundant willows. They are most numerous where there are extensive thickets of low dense willows on the edge of wet meadows, ponds, or backwaters (Mayer and Laudenslayer, 1988c).

Within the Secondary Study Area, willow flycatchers have been regularly observed foraging along lower Clear Creek during spring and fall migration, but no nesting has been observed in the lower Clear Creek watershed (BLM, 2008). This species has also been observed along the Trinity River corridor (Reclamation, 2009), and may use riparian woodlands during migration along the Upper Sacramento River from the Red Bluff Diversion Dam to Shasta Dam (Reclamation, 2008).

Western Yellow-Billed Cuckoo

The western yellow-billed cuckoo is a migratory species that does not winter in California. Suitable nesting habitat, typically in dense mixed riparian forest habitat, consists of extensive (25 acres or larger) riparian forest with dense understory (willow) near slow moving waters (Mayer and Laudenslayer, 1988c). Walnut orchards adjacent to riparian areas have also been used successfully as nesting habitat (Laymon, 1980).

Within the Secondary Study Area, several small isolated breeding populations occur in suitable habitat along the upper Sacramento River, as well as along the lower Feather River. One individual western yellow-billed cuckoo was observed in lower Clear Creek in 2004, but this species is not believed to nest in that area (DFG, 2008a; Reclamation, 2008; DWR, 2007a; BLM, 2008).

Mammals

Salt-Marsh Harvest Mouse

The salt-marsh harvest mouse (*Reithrodontomys raviventris*) is found only in saline emergent wetland habitat, with a preference for areas of dense pickleweed. This species also requires nearby non-submerged, salt-tolerant vegetation for escape during highest tides (Mayer and Laudenslayer, 1988d).

The salt-marsh harvest mouse is found within the Secondary Study Area in the saline emergent wetlands around San Francisco, San Pablo, and Suisun bays, as well as portions of the Delta (DFG, 2008a; Reclamation, 2006).

14.2.2.4 Commercially or Recreationally Important Wildlife Species

Up to 67 harvest species (43 birds, 23 mammals, and 1 amphibian) may occur in the Secondary Study Area within the 7 natural habitat types, and up to 52 harvest species (31 birds, 20 mammals, and 1 amphibian) may occur in the Sutter and Yolo county portion of the Secondary Study Area within the 3 agricultural habitat types (DFG, 2008a). Examples of harvest bird and mammal species are listed in the Extended Study Area discussion (Section 14.2.1.4).

The Secondary Study Area includes portions of 11 of the State's deer hunting zones (DFG, 2009b). The Oroville WA, as well as the managed wetlands and flooded rice fields of private duck clubs within the Sutter and Yolo bypasses, provide waterfowl hunting opportunities (DWR, 2007a).

14.2.3 Primary Study Area

14.2.3.1 Methodology

Wildlife Habitats and Associated Wildlife

The vegetation types within the proposed Sites Reservoir footprint were delineated by hand on aerial photo overlays, field-verified, and digitized. Vegetation types in other Project facility locations were delineated using ArcView GIS software, aerial photo interpretation, and field verification. A detailed description of survey methods used to map vegetation is provided in Chapter 13 Botanical Resources. Mapped vegetation types were reclassified into WHR habitat types. The WHR System (DFG, 2008a) was then used to identify the potential number of wildlife species that could occur within the habitat types in the Primary Study Area.

A variety of research and field survey methods were used to sample wildlife. Preliminary research included general literature searches, consultation with agency and species experts, aerial photo habitat interpretations, and landowner interviews. In addition, reviews of the CNDDB, WHR System, and the Federal Register of Threatened, Endangered, and Special-Status Species were conducted.

Initial field surveys were conducted within the Primary Study Area from 1998 to 2004 at all Project facility locations, then again in 2010 to 2011 at newly proposed Project facility locations. Amphibian and reptile surveys included night driving, dip-netting, seining, ground searches, and habitat assessment. Avian surveys included line transects and bank swallow, cuckoo, and owl surveys. Mammal surveys included small mammal trapping, mist netting, acoustical surveys, roost searches, track plates, camera stations, spotlighting, general habitat measurements and assessment, and incidental observation. Detailed descriptions of these survey methods are listed in their associated survey progress reports (DFG, 2003a; DFG, 2003b; DWR, 2003).

Special-Status Wildlife Species

A current list of special-status wildlife was generated using the Sacramento USFWS Office's Endangered Species Program website (USFWS, 2009a). The list covered the following U.S. Geological Survey 7.5-minute quadrangle maps (map numbers are provided in parentheses): Leesville (547B), Manor Slough (547A), Lodoga (563C), Sites (563D), Maxwell (562C), Moulton Weir (562D), Rail Canyon (563B), and Logan Ridge (563A). The list includes federal endangered, threatened, and candidate species that may be affected within the Primary Study Area, as well as areas of designated critical habitat. The list was generated prior to initiation of field surveys (September 1997 and October 1998), updated during the development of the progress report (July 2002), and updated again during the preparation of this environmental document (October 2009).

The CNDDB *State and Federally Listed Endangered and Threatened Animals of California* (October 2009) and *Special Animals* (July 2009) lists were also consulted for State-listed wildlife species and species of special concern. Wildlife species listed as federal species of concern, State species of special concern, or State fully protected species were included. Species which were listed at the start of field surveys, but have since been delisted, were not included. Species designated as only BLM or USFS Sensitive Species were not included because the Project features are not proposed to be constructed on USFS or BLM land. In addition, bat species designated as High Priority by the Western Bat Working Group, but not with a State or federal status, were not included.

The CNDDB's Rarefind 3 and Rarefind 4 software were used to document the nearest known locations to the Primary Study Area of threatened or endangered species that were not observed during field surveys. Lack of documentation in the Rarefind database within a county does not imply absence of the species in that county.

During field surveys, the valley elderberry longhorn beetle (VELB) was surveyed according to procedures outlined in the USFWS 1996 report on mitigation guidelines. Subsequent surveys followed the 1999 guidelines. Vernal pool crustaceans were sampled in accordance with the USFWS protocols contained in "Interim Survey Guidelines to Permittees for Recovery Permits pursuant to Section 10(a)(1)(A) of the Endangered Species Act for the Listed Vernal Pool Branchiopods" (April 19, 1996).

Amphibian and reptile surveys included night driving, dip-netting, seining, ground searches, habitat assessment, consultation with USFWS, and the use of USFWS and DFG's protocol guidelines for red-legged frog and California tiger salamander. Avian surveys included line transects and bank swallow, owl, and yellow-billed cuckoo surveys. Mammal surveys included small mammal trapping, mist netting, acoustical surveys, roost searches, track plates, camera stations, spotlighting, general habitat measurements and assessment, and incidental observation. Detailed descriptions of these survey methods, as well as more detailed species life history accounts, are included in their associated survey progress reports (DFG, 2003a; DFG, 2003b; DWR, 2003).

Commercially or Recreationally Important Wildlife Species

The Primary Study Area provides seasonal and year-round habitat for a variety of commercially or recreationally important wildlife species. The WHR System (DFG, 2008a) was used to generate a list of all harvest (hunted or trapped) species that could occur in Colusa and Glenn counties within the habitat types present in the Primary Study Area.

14.2.3.2 Wildlife Habitats and Associated Wildlife

Eighteen wildlife habitat types were identified within the Primary Study Area. Of those 18 wildlife habitat types, the principal types, based on total acreage within the Primary Study Area, include annual grassland, blue oak woodland, rice, dryland grain and seed crops, irrigated row and field crops, pasture, lacustrine, urban/disturbed, and valley foothill riparian. The total acreage of each habitat type within the Primary Study Area, as well as the percent that each habitat type represents of the total Project acreage, is presented in Table 14-1. Acreage totals reflect baseline conditions[2] and represent the Project alternative that has the largest construction-related on-the-ground disturbance (Alternative C). Acreage totals include the footprint of each Project facility and the defined construction disturbance area for the Delevan Pipeline. The principal habitat types are described below.

Table 14-1
Wildlife Habitat Types within the Primary Study Area

Habitat Type	Acreage	
	Primary Study Area[a]	Percent of Primary Study Area Total
Annual grassland	14,765.5	75.4
Barren[b]	21.6	0.1
Blue oak woodland	1,531.9	7.8
Canal	22.4	0.1
Chamise-redshank chaparral	2.5	0[e]
Deciduous orchard	188.6	1.0
Dryland grain and seed crops	535.9	2.7
Eucalyptus	46.2	0.2
Fresh emergent wetland[c]	18.5	0.1
Irrigated row and field crops	366.1	1.9
Lacustrine[d]	28.8	0.2
Mixed chaparral	2.6	0[e]
Pasture	312.7	1.6
Rice	1,493.7	7.6
Riverine	1.6	0[e]
Urban/disturbed	136.8	0.7
Valley foothill riparian	113.6	0.6
Valley oak woodland	3.5	0[e]
TOTAL	**19,592.0**	**100**

[a]The Primary Study Area includes the proposed Alternative C facility footprints, and the construction disturbance area for the Road Relocations, Delevan Transmission Line, Delevan and TRR pipelines, TRR to Funks Creek Pipeline, Holthouse to T-C Canal Pipeline, and GCID Canal Facilities Modifications. This total does not include acreage occupied by existing facilities, namely Funks Reservoir and the GCID Canal.

[b]Barren habitat includes fallowed agricultural fields.

[c]Fresh Emergent Wetland includes alkaline wetlands.

[d]Lacustrine habitat includes ponds.

[e]Represents less than 0.1 percent of total.

Annual Grassland

Annual grassland habitat occurs mostly on flat plains to rolling foothills and is composed primarily of introduced annual plant species. Perennial species can occur in moist areas, and vernal pools can occur within annual grassland habitat where depressions are underlain by impervious clay or hardpan soils. Grassland composition and structure depends on precipitation and grazing practices (Mayer and Laudenslayer, 1988a).

[2] Agricultural habitat types change from year to year and vary between actively managed and fallowed fields. Additional acreage of natural habitat types have been converted to agricultural habitat types since the time of baseline.

Approximately 75 percent of the Primary Study Area is annual grassland habitat (representing less than one percent of the total acreage of this habitat type found throughout California). Extensive annual grassland habitat occurs at all Project facility locations, except for the Delevan Pipeline Intake/Discharge facilities. Within the grassland areas are livestock ponds, small rock outcrops, and vernal pools and swales. Yellow star thistle infestations are common.

Up to 196 species (116 birds, 51 mammals, 18 reptiles, and 11 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species frequently observed during field surveys in annual grassland habitat included the Pacific chorus frog, western fence lizard, western rattlesnake (*Crotalus viridis*), western meadowlark (*Sturnella neglecta*), horned lark (*Eremophila alpestris*), American kestrel, turkey vulture (*Cathartes aura*), deer mouse (*Peromyscus maniculatus*), San Joaquin pocket mouse, California ground squirrel, black-tailed jackrabbit, American badger (*Taxidea taxus*), mule deer, and coyote (*Canis latrans*).

Blue Oak Woodland

Blue oak woodland habitat generally has an overstory of scattered trees, with varying densities of blue oaks (*Quercus douglasii*) comprising 85 to 100 percent of the trees present. This habitat includes the interior live oak (*Q. wislizenii)* and the valley oak. Shrubs, such as chamise (*Adenostoma fasciculatum*), buckbrush (*Ceanothus cuneatus*), and whiteleaf manzanita (*Arctostaphylos viscida*), are often present, and the typical understory is composed of an extension of annual grassland vegetation. Blue oaks grow slowly and regeneration is rarely successful on grazed lands (Mayer and Laudenslayer, 1988a).

More than seven percent of the Primary Study Area is blue oak woodland habitat (representing less than one percent of the total acreage of this habitat type found throughout California). Blue oak woodland habitat occurs in varying forms within the Primary Study Area in smaller valleys, on slopes, on ridge tops, and in moderately rocky to well-drained areas. Project facility locations vary widely in the representation of blue oak-dominated woodlands. Woodlands range from sparse stands of large-diameter trees to dense stands of small-diameter trees. Stands include a few snags and logs, as well as brush piles and stumps that are the result of fuel wood harvest activities. Blue oak woodland exists within the proposed Sites Reservoir footprint, along portions of most of the road relocations (excluding the North Road and Eastside Road), and at all of the Recreation Areas, with the exception of Saddle Dam.

Up to 227 species (141 birds, 54 mammals, 19 reptiles, and 13 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species frequently observed during field surveys in blue oak woodland habitat included the California slender salamander, western fence lizard, southern alligator lizard (*Elgaria multicarinata*), acorn woodpecker (*Melanerpes formicivorus*)), northern flicker (*Colaptes auratus*), brush mouse, California ground squirrel, black-tailed jackrabbit, raccoon, and wild pig.

Dryland Grain and Seed Crops

Dryland grain and seed crops habitat includes non-irrigated barley, oats, and wheat. These grain and seed crops are typically planted in the fall and harvested in the spring, often in rotation with irrigated crops or fallowed for a few seasons. Dryland grain and seed crops are usually planted on fertile soils that once supported diverse native habitats, although barley can be grown on poor quality saline or alkaline soils. These monoculture, harvested, and chemically-controlled crops have limited value to most wildlife, but species, such as deer, elk, and pigs, have adapted and can be crop pests (Mayer and Laudenslayer, 1988a).

More than two percent of the Primary Study Area is dryland grain and seed crops (representing less than one percent of the total acreage of this habitat type found throughout California). Dryland grain and seed crops exist within the Primary Study Area mainly within the proposed Sites Reservoir footprint, and in smaller amounts along the Delevan Pipeline, within the footprints of the Terminal Regulating Reservoir (TRR) and Holthouse Reservoir, and along Sulphur Gap Road.

Up to 106 species (54 birds, 42 mammals, 6 reptiles, and 4 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species commonly associated with dryland grain and seed crops include the northern harrier, ring-necked pheasant, red-winged blackbird, and Botta’s pocket gopher.

Irrigated Row and Field Crops

Irrigated row and field crops are described in the Extended Study Area discussion (Section 14.2.1.2). Nearly two percent of the Primary Study Area is irrigated row and field crops (representing less than one percent of the total acreage of this habitat type found throughout California). This crop type is found within the footprint of Holthouse Reservoir, and within the construction disturbance areas of the Delevan Pipeline and Delevan Transmission Line.

Up to 94 species (41 birds, 43 mammals, 6 reptiles, and 4 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species commonly associated with irrigated row and field crops habitat are described in the Extended Study Area discussion (Section 14.2.1.2).

Lacustrine

Lacustrine habitat is described in the Secondary Study Area discussion (Section 14.2.2.2). Approximately one percent of the Primary Study Area is lacustrine habitat[3]. Lacustrine habitat, in the form of human-made ponds, is found in small amounts within the proposed Sites Reservoir footprint and Saddle Dam and Lurline Headwaters recreation areas, as well as along the portions of all road segments and the Delevan Pipeline. The majority of the acreage of lacustrine habitat occurs at the existing Funks Reservoir.

Up to 135 species (103 birds, 17 mammals, 5 reptiles, and 10 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species frequently observed during field surveys in lacustrine habitat included the mallard, western grebe, great blue heron, and American coot.

Pasture

Pasture habitat is described in the Extended Study Area discussion (Section 14.2.1.2). More than one percent of the Primary Study area is pasture habitat (representing less than one percent of the total acreage of this habitat type found throughout California). Within the Primary Study Area, pasture is found mainly within the proposed Sites Reservoir footprint. Pasture is also found to a lesser extent along the Delevan Pipeline and within the footprint of the TRR.

Up to 72 species (9 birds, 49 mammals, 10 reptiles, and 4 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species commonly associated with pasture habitat are described in the Extended Study Area discussion (Section 14.2.1.2).

---

[3] The total acreage of lacustrine habitat throughout California is not available. Therefore, the percentage of total lacustrine habitat that the lacustrine habitat in the Primary Study Area would encompass cannot be determined.

Rice

Rice habitat is described in the Extended Study Area discussion (Section 14.2.1.2). More than seven percent of the Primary Study Area is rice habitat (representing less than one percent of the total acreage of this habitat type found throughout California). Within the Primary Study Area, the Delevan Pipeline route and TRR have substantial rice coverage.

Up to 186 species (133 birds, 33 mammals, 15 reptiles, and 5 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species frequently observed during field surveys in rice habitat included the great blue heron, great egret, and raccoon.

Urban/Disturbed

Urban/disturbed habitat is described in the Extended Study Area discussion (Section 14.2.1.2). Less than one percent of the Primary Study Area is urban/disturbed habitat (representing less than one percent of the total acreage of this habitat type found throughout California). Urban/disturbed habitat exists within the Primary Study Area in the form of residences, outbuildings, and stockyards. These sites may include non-native ornamental varieties of plants, or may support very little or no vegetation. Urban areas are located within most of the proposed Project facility locations, with the exception of the Delevan Pipeline Intake/Discharge facilities, Holthouse Reservoir, Funks Reservoir, and the Recreation Areas. Up to 192 species (147 birds, 34 mammals, 7 reptiles, and 4 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species frequently observed during field surveys in this habitat type and associated with structures included the house sparrow, yellow-billed magpie, and pallid bat (*Antrozous pallidus*).

Valley Foothill Riparian

Valley foothill riparian habitat is described in the Secondary Study Area discussion (Section 14.2.2.2). Less than one percent of the Primary Study Area is valley foothill riparian habitat (representing less than one percent of the total acreage of this habitat type found throughout California).Valley foothill riparian habitat was mapped in areas where no single woody species dominated the riparian canopy, and where streamside vegetation was dominated by the valley oak. Mexican elderberry (*Sambucus mexicana*) occurs within or adjacent to riparian areas, as individuals or in small stands. Streams within this habitat type are intermittent, and streambeds are typically dry or contain only isolated pools of water during summer.

Disturbed valley foothill riparian is scattered in small patches throughout the proposed Sites Reservoir footprint, at Funks and Holthouse reservoirs, at the Delevan Pipeline Intake/Discharge facilities, and is found in very small amounts along portions of most roads (excluding the saddle dam and recreation area access roads) and the Delevan Pipeline route. Up to 267 species (176 birds, 58 mammals, 19 reptiles, and 14 amphibians) may be found within this habitat type within the Primary Study Area (DFG, 2008a). Wildlife species frequently observed during field surveys in this habitat type included the bullfrog, western toad, western fence lizard, common garter snake, killdeer, raccoon, gray fox (*Urocyon cinereoargenteus*), coyote, and mule deer.

14.2.3.3 Wildlife Habitats at the Proposed Project/Proposed Action Facility Locations

The wildlife habitat types at each Project facility location are presented in Table 14-2.

Table 14-2
Wildlife Habitat Types at each Project Facility Location

Project facility	Annual Grassland	Barren	Blue oak Woodland	Canal	Chamise-redshank Chaparral	Deciduous Orchard	Dryland grain and Seed Crops	Eucalyptus	Fresh Emergent Wetland	Irrigated row and Field Crops	Lacustrine	Mixed Chaparral	Pasture	Rice	Riverine	Urban/Disturbed	Valley Foothill Riparian	Valley Oak Woodland

14.2.3.4 Special-Status Wildlife Species – Threatened, Endangered, or Candidate Species

Fifteen threatened, endangered, or candidate wildlife species may occur within the Primary Study Area (Table 14-3) (USFWS, 2009a; DFG, 2009a). Of those 15 species, field surveys, consultations, and post-survey observations resulted in the documentation of five species. Species accounts for the

15 species are provided below. No critical habitat for any species has been designated within the Primary Study Area.

Table 14-3
State-and Federally-Listed Terrestrial Wildlife Species that may Occur in the Primary Study Area

Species	Scientific Name	Status[a]	Habitat Association[b]
Invertebrates			
Conservancy fairy shrimp	*Branchinecta conservatio*	FE	AGS
Vernal pool fairy shrimp	*Branchinecta lynchi*	FT	AGS
Vernal pool tadpole shrimp	*Lepidurus packardi*	FE	AGS
Valley elderberry longhorn beetle[c]	*Desmocerus californicus dimorphus*	FT	VRI
Reptiles and Amphibians

Swainson's hawk[c]	*Buteo swansoni*	ST	AGS, BOW, VRI, VOW
Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*	FC, SE	DOR, VRI
Willow flycatcher	*Empidonax traillii*	SE	VRI, MRI, WTM
Mammals			
Pacific fisher	*Martes pennanti pacifica*	CST or CSE	MHC, SMC

[a]Status Key

FE = Federal Endangered
FT = Federal Threatened
FC = Federal Candidate
D = Delisted
SE = State Endangered
ST = State Threatened
CSE = Candidate State Endangered
CST = Candidate State Threatened

[b]Habitat Key

AGS = Annual grassland
BAR = Barren
BOP = Blue oak-foothill pine
BOW = Blue oak woodland
DFR = Douglas Fir
FEW = Freshwater emergent wetland
LAC = Lacustrine
MHC = Mixed hardwood conifer
RDW = Redwood
RIC = Rice
RIV = Riverine
SMC = Sierran Mixed Conifer
VOW = Valley oak woodland
VRI = Valley/foothill riparian
WTM = Wet meadow

[c]Species documented during field surveys.
[d]Species confirmed as present within Primary Study Area by USFWS.
[e]Status changed from CSE to ST on 03-03-10.

Invertebrates

Conservancy Fairy Shrimp, Vernal Pool Tadpole Shrimp, and Vernal Pool Fairy Shrimp

Fairy and tadpole shrimps are restricted to temporary pools in California. Typical habitat includes vernal pools, ponded areas within vernal swales, rock outcrop ephemeral pools, playas, alkali flats, and salt lakes (Eng et al., 1990). Fairy shrimp are typically absent from permanent water bodies. These shrimp are not abundant in ponds that contain large invertebrate predators, and are rarely found in bodies of water that contain carnivorous fish (Smith, 2001).

The federally endangered Conservancy shrimp is known to exist in a pool located within ten miles of the Primary Study Area. The federally threatened vernal pool fairy shrimp and the federally endangered vernal pool tadpole shrimp are widespread throughout the Central Valley, and are reported to occur within Glenn and Colusa counties.

The quality of potential habitat found within the proposed reservoir footprint is marginal. Many of the pools do not remain ponded for entire seasons, and some potential habitats do not pond at all. The pools are dominated by non-native vegetative species and are heavily affected by cattle ranching. The soils are alkaline and are unsuitable for many species (Eng et al., 1990, Eriksen and Belk, 1999). Conservancy fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp were not identified within the Primary Study Area during protocol-level field surveys.

Valley Elderberry Longhorn Beetle

The federally threatened valley elderberry longhorn beetle (VELB) is endemic to riparian systems along the margins of rivers and streams, occasional seeps, and in adjacent grassy savannas in the Sacramento and San Joaquin valleys. VELB feeds on two species of elderberry shrubs, and the adult females deposit eggs in the crevices of the bark of these plants. Emergence holes are typically observed in shoots or branches of mature healthy plants (Barr, 1991).

The elderberry shrubs within the Primary Study Area are individuals with multiple trunks and range from unhealthy stressed plants to occasional large healthy plants. During protocol-level field surveys, VELB emergence holes were found on 18 (3 percent) of 672 elderberry stems surveyed within the proposed Sites Reservoir footprint, primarily along Grapevine and Antelope creeks. Elderberry shrubs were also surveyed east of the proposed reservoir along Funks Creek, along a previously proposed road route west of the reservoir footprint, and at the proposed Delevan Pipeline Intake/Discharge facilities, but no emergence holes were observed.

Amphibians

California Red-Legged Frog

The federally threatened California red-legged frog is described in the Secondary Study Area discussion (Section 14.3.2.3). The nearest known locations of red-legged frogs to the Primary Study Area are in Butte and Tehama counties, typically in meadow or grassland ponds that are surrounded by pine forest or blue-oak woodland. All water sources within the primary study area are considered suitable, although most ponds contain bullfrogs. The California red-legged frog was not observed within the Primary Study Area during protocol-level field surveys.

California Tiger Salamander

The federally- and State-threatened California tiger salamander is most commonly found in annual grassland habitat, but can also occur in the understory of hardwood habitats. The adults spend most of the year underground, inhabiting the burrows of ground squirrels, gophers, and badgers. This species lays eggs in vernal pools or other temporary ponds that contain submerged and/or emergent vegetation, and will use permanent human-made ponds if predatory fish are absent (Mayer and Laudenslayer, 1988b; Stebbins, 1985).

The nearest known locations of tiger salamanders to the Primary Study Area are in Sacramento and Yolo counties, typically in ponds, vernal pools, or slow-moving creeks surrounded by grassland or oak savanna. The USFWS list does not include this species as potentially occurring in the Primary Study

Area, and Colusa County appears to be outside of its current range. However, the WHR System lists this species as potentially occurring in Colusa County within the habitat types of the Primary Study Area. The California tiger salamander was not observed during protocol-level field surveys within the proposed Sites Reservoir Inundation Area, although potentially suitable habitat exists within the Primary Study Area.

Reptiles

Giant Garter Snake

The federally- and State-threatened giant garter snake is described in the Secondary Study Area discussion (Section 14.2.2.3). Consultation with the USFWS confirmed that giant garter snakes occur within the Primary Study Area, mainly within rice habitat found along portions of Delevan Pipeline.

Birds

Bald Eagle

The federally delisted and State-endangered bald eagle is described in the Secondary Study Area discussion (Section 14.2.2.3). Sporadic winter use by adult and immature bald eagles in the Primary Study Area has been documented. During initial field surveys, no nests, adult pairs, or nesting behavior were observed at any proposed Project facility location. However, during subsequent visits to the Primary Study Area a nesting pair of bald eagles was observed at the proposed Golden Gate Dam site. This pair successfully reproduced in 2008, 2009, 2010, 2011, and 2012.

Bank Swallow

The State-threatened bank swallow is described in the Secondary Study Area discussion (Section 14.2.2.3). The nearest known locations of nesting bank swallows to the Primary Study Area are in Glenn and Colusa counties along the Sacramento River.

The incised channels of virtually all of the streams within the Primary Study Area contain some unvegetated vertical banks, and all streams are ephemeral with only limited ponded water present by June 15 during most years. Sandy or loamy soils are generally absent. Bank swallow surveys along the streams within the Primary Study Area failed to detect any sign of nesting bank swallows.

The Delevan Pipeline Intake/Discharge facilities are proposed to be located on the Sacramento River at River Mile (RM) 158.5 on the right bank. The proposed facility location is geologically stable, with geologic control upstream and downstream along the levee (refer to Chapter 8 Fluvial Geomorphology and Riparian Habitat for a detailed description of this location). Annual bank swallow surveys are conducted along the Sacramento River in June by USFWS, DFG, and DWR personnel. Bank swallow survey data for most years between 2000 and 2009 showing the nearest colony locations to the proposed intake/discharge facility location, as well as the number of burrows in each colony, are presented in Table 14-4.

Table 14-4
Nearest Bank Swallow Colony Locations to the Delevan Pipeline Intake/Discharge Facilities

Bank Swallow Survey Year	Locations Upstream of Intake/Discharge Facilities		Locations Downstream of Intake/Discharge Facilities	
	Nearest River Mile (Side of Bank)	Estimated Number of Burrows in Colony	Nearest River Mile (Side of Bank)	Estimated Number of Burrows in Colony
2009	161.6 (L)	80	158.1 (L)	103
2008	161.4 (L)	32	157.0 (L)	160
2007	162.6 (L)	250	158.4 (R)	10
2006*				
2005	162.0 (R)	280	157.0 (L)	910
2004	159.0 (R)	100	156.8 (L)	370
2003	162.5 (R)	170	157.0 (L)	50
2002*				
2001	162.1 (R)	240	156.6 (L)	1270
2000	162.7 (L)	280	157.3 (L)	260

*Surveys were not conducted in 2002, and the stretch of the river near the proposed Delevan Pipeline Intake/Discharge facilities was not surveyed in 2006.

Northern Spotted Owl

The federally threatened northern spotted owl occurs throughout the mountainous portions of northwest California, including the extreme western portions of Glenn and Colusa counties. Suitable nesting habitat includes extensive stands (100 to 600 acres) of dense, multilayered, mature or old growth coniferous forest. Although some downslope movement during winter has been observed, little or no use of low-elevation grassland or open oak habitat has been observed in northern California (Mayer and Laudenslayer, 1988c). Suitable nesting and foraging habitat for the northern spotted owl is absent in the vicinity of the Primary Study Area.

Greater Sandhill Crane

The State-threatened greater sandhill crane is described in the Secondary Study Area discussion (Section 14.3.2.3). Within the Primary Study Area, wintering sandhill cranes (possibly greater sandhill cranes) were observed along Sacramento Valley floor habitats, including the Delevan Pipeline and the valley portion of Sulphur Gap Road.

Swainson's Hawk

The State-threatened Swainson's hawk is a migratory raptor present within the Sacramento Valley during the breeding season (March through September). Swainson's hawks use desert, grassland, and cropland where scattered large individual trees or small groves of large trees are present. This species forages primarily over irrigated pasture or croplands. Approximately 80 percent of the estimated statewide population occurs in the Central Valley (DFG, 1993).

Suitable nesting and foraging habitat is present within portions of the Primary Study Area. Foraging Swainson's hawks were observed on the Sacramento Valley floor adjacent to the Sites Reservoir footprint, as well as along the Delevan Pipeline and valley portion of Sulphur Gap Road.

Western Yellow-Billed Cuckoo

The federal candidate and State-endangered western yellow-billed cuckoo is described in the Secondary Study Area discussion (Section 14.2.2.3). Suitable nesting habitat within the Primary Study Area is associated with portions of the Delevan Pipeline and the Delevan Pipeline Intake/Discharge facilities. The mature riparian habitat and adjacent walnut orchards in this area were surveyed intensively for cuckoos during the breeding season, but none were detected during Project surveys.

In 2010, the Point Reyes Bird Observatory, in coordination with USFWS and DFG, conducted yellow-billed cuckoo surveys along the Sacramento River from Red Bluff to Colusa. A total of 18 individual cuckoos were detected ranging from RM 157 to RM 240. The detection locations nearest to the Primary Study Area included one detection at Princeton South (RM 163 - DFG land) and one detection at Moulton Island (RM 157 - private land). Both locations are within Colusa County (Dettling and Howell, 2011).

Willow Flycatcher

The State-endangered willow flycatcher is described in the Secondary Study Area discussion (Section 14.2.2.3). Migrating willow flycatchers are infrequently observed in Glenn or Colusa counties. Willow flycatchers are no longer present as a nesting species within the Central Valley (Remsen, 1978).

The nearest known locations to the Primary Study Area of the willow flycatcher are in Colusa (1973) and Tehama (2009) counties. No willow flycatchers were detected during field surveys within the Primary Study Area, and no suitable willow flycatcher habitat was observed.

Mammals

Pacific Fisher

The Pacific fisher is listed as a State Species of Special Concern and as of 2011 is a candidate for federal protection. This species is known to occur at high elevations in extreme western Glenn and Colusa counties. Fisher habitat includes large areas of mature dense coniferous forests and deciduous-riparian habitat with high percent canopy closures (Mayer and Laudenslayer, 1988d). Coniferous and hardwood forests usually provide these habitat requirements. The fisher also prefers forests with hollow trees, rock crevices, slash piles, and porcupine dens. These habitat features provide suitable denning sites.

Following USFS guidelines for fisher survey methods (Zielinski and Kucera, 1995), field crews determined that suitable fisher habitat is not present within the Primary Study Area. However, track plate and camera station sampling were conducted in areas of marginal habitat that occur only sporadically within the Primary Study Area. These efforts failed to detect fishers.

14.2.3.5 Species of Concern and Fully Protected Species

Forty-five federal and/or State terrestrial wildlife species of special concern may occur within the Primary Study Area. Field surveys resulted in the documentation of 28 of these species (Table 14-5). Life history accounts for these species are provided below.

Table 14-5
Terrestrial Wildlife Species of Special Concern that may Occur in the Primary Study Area

Common Name	Scientific Name	Status[a]	Habitat Association[b]
Amphibians			
Foothill yellow-legged frog[c]	*Rana boylii*	SC	VRI

[a]Status Key

FSC = Federal species of concern
SC = State species of special concern
SFP = State fully protected species

[b]Habitat Key

AGS = Annual grassland
BAR = Barren
BOP = Blue oak-foothill pine
BOW = Blue oak woodland
CRC = Chamise-redshank chaparral
FEW = Freshwater emergent wetland
GR = Irrigated grain and seed crops
IRH = Irrigated hayfield
JPN = Jeffrey pine
LAC = Lacustrine
MCH = Mixed chaparral
MHC = Mixed hardwood conifer
PAS = Pasture
PPN = Ponderosa pine
RIV = Riverine
VOW = Valley oak woodland
VRI = Valley/foothill riparian
WTM = Wet meadow

[c]Species documented during field surveys.

Amphibians

Foothill Yellow-Legged Frog

The foothill yellow-legged frog is described in the Secondary Study Area discussion (Section 14.2.2.3). This species is known to occur in southwest and western Colusa County. Although potentially suitable habitat exists, foothill yellow-legged frogs were not observed during extensive field surveys in the Primary Study Area.

Western Spadefoot

The western spadefoot is a toad that ranges throughout the Central Valley and foothills at elevations ranging from near sea level to 1359 m (4,460 ft). This toad is typically found in grasslands with shallow temporary pools, but some populations survive in orchards or vineyards. The western spadefoot spends most of the year in underground burrows. Breeding and egg-laying occurs during winter rains when temporary pools are formed. Eggs are attached to small submerged rocks or plants. Adults move above ground when the rains start, and normally end breeding activities by the end of March. Juveniles leave the breeding ponds in late spring. Adults tend to avoid predation in their underground burrows, but tadpoles are preyed upon by wading birds and some mammals, such as raccoons (Mayer and Laudenslayer, 1988b).

Within the Primary Study Area, one western spadefoot toad was observed during field surveys in grassland habitat along a formerly proposed road route. Although the location is no longer included in the Primary Study Area, it is adjacent to the southern portion of the proposed Sites Reservoir footprint, where similar suitable habitat exists.

Reptiles

Western Pond Turtle

The western pond turtle is described in the Secondary Study Area discussion (Section 14.2.2.3). Within the Primary Study Area, western pond turtles were observed during field surveys in riparian areas and at ponds along a canal within the Delevan Pipeline route, near Funks Reservoir, within the proposed Sites Reservoir footprint, and at the Sites Dam site.

Birds

American Peregrine Falcon

The peregrine falcon is a very uncommon nesting species within the northern Coast Range. This species generally selects high cliffs near lakes, rivers, or wetlands for nesting. Human-made structures, including tall buildings or bridges, have also been used in California for nesting (Jurek, 1989). During winter, peregrines use a wide variety of habitats including agricultural croplands and annual grasslands for foraging.

The nearest known nesting locations of peregrine falcons to the Primary Study Area are in Butte and Tehama counties, typically on volcanic rock or limestone cliffs surrounded by mixed hardwood conifer habitat. No peregrine falcons were observed within the Primary Study Area during field surveys, and no potentially suitable cliff nest sites exist at any proposed Project facility location.

American White Pelican

Habitat for the American white pelican includes rivers, natural lakes, reservoirs, and larger farm ponds containing fish. Historically, white pelicans nested on large lakes throughout California (Grinnell and Miller, 1944). This species may travel long distances between forage and resting areas. These pelicans are gregarious, and flocks can contain large numbers of individuals.

No pelicans were observed within the proposed Sites Reservoir footprint. Suitable habitat is generally lacking except on the larger farm ponds. Small groups of pelicans were observed on Funks Reservoir during winter and fall. Small numbers of pelicans were observed year round along the proposed Delevan Pipeline route. Most observations of habitat use along this route occurred at the Sacramento River or near the Delevan National Wildlife Refuge (NWR).

Barrow's Goldeneye

Barrow's goldeneye is an uncommon winter visitor to California. No breeding by this secondary cavity nester has been documented within California for many years. Nesting habitat is near alkaline lakes or slow moving rivers with abundant submerged aquatic vegetation and open water. Wintering habitats are riverine and lacustrine waters with rocky bottoms (Mayer and Laudenslayer, 1988c).

No Barrow's goldeneye has been observed within the Primary Study Area. However, a landowner within the proposed Sites Reservoir footprint reported the presence of a single Barrow's goldeneye within an ephemeral stock pond during winter 1998. This report was not confirmed. No suitable nesting habitat currently exists within the Primary Study Area. Potentially suitable wintering habitat is present at Funks Reservoir and along portions of the proposed Delevan Pipeline route.

Bell's Sage Sparrow

The Bell's sage sparrow is a subspecies of the common sage sparrow. This species occurs year round in western Glenn and Colusa counties where it frequents dense chaparral stands dominated by chamise

(Mayer and Laudenslayer, 1988c). Sage sparrows are absent from the proposed Sites Reservoir footprint. However, a sage sparrow was observed in suitable chaparral habitat along a formerly proposed road route, which is adjacent to the southern portion of the proposed Sites Reservoir footprint. Similar chaparral habitat occurs within or adjacent to several of the Recreation Areas.

Black Swift

The black swift is a migratory species that has very specific habitat requirements for nesting. This species nests on cliffs and frequently occurs in moist microhabitats including behind or adjacent to waterfalls (Mayer and Laudenslayer, 1988c).

The nearest occurrences of black swifts to the Primary Study Area are generally restricted to the eastern edge of Tehama County in the Sierra Nevada. No black swifts were detected during the field surveys, and potentially suitable nesting habitat is absent from the Primary Study Area.

Black Tern

The black tern is a migratory species that occurs in the Central Valley portion of Glenn and Colusa counties. Black terns use lakes, ponds, rivers, wetlands, moist grassland, and agricultural habitats. It is unknown if this species currently breeds within the Sacramento Valley (Mayer and Laudenslayer, 1988c).

No black tern habitat use was observed within the proposed Sites Reservoir footprint. The proposed Delevan Pipeline route was the only Project feature where black terns were observed, with most use associated with foraging birds over flooded rice fields. No black tern use was observed at Funks Reservoir, which provides potentially suitable foraging habitat.

Burrowing Owl

The western burrowing owl is a semi-colonial year-round resident that uses grassland habitats and a variety of early successional stages of open shrub and forest vegetative types where suitable burrows and perches are present. The burrowing owl uses old burrows of ground squirrels or other small mammals, or may dig its own burrow in soft soil, for roosting and nesting cover (Mayer and Laudenslayer, 1988c).

Small scattered groups of burrowing owls were detected within the proposed Sites Reservoir footprint during diurnal avian line transect sampling. Most of these observations were in upland settings near the grassland/blue oak habitat edge. However, a few individual sightings were made in open grassland habitat along stream channels. Sampling with pre-recorded calls was useful for determining the presence of burrowing owls. Responses were received at 42 percent of the call locations within the proposed Sites Reservoir footprint, indicating wide distribution at this location. Burrowing owls were also detected during winter and fall along a formerly proposed road route, which is adjacent to Road 69 and the North Road.

Caspian Tern

The Caspian tern is common to very common along the California coast and at scattered locations inland from April through early August. This species winters in Southern California, and nests in colonies in the San Francisco, San Pablo, Humboldt, and San Diego bays. The Caspian tern feeds primarily on small fish in freshwater lakes, estuaries, and salt ponds (Mayer and Laudenslayer, 1988c).

Within the primary study area, Caspian terns were observed along the Delevan Pipeline route. Potentially suitable foraging habitat exists at Funks Reservoir.

Common Loon

The common loon has an inland distribution that is extremely irregular and associated with large natural lakes and some reservoirs. This uncommon wintering species requires deep freshwater lakes with adequate small food fish (Mayer and Laudenslayer, 1988c).

Common loons were observed only at Funks Reservoir and only during spring and fall migration. Individual loons were observed on Funks Reservoir on two occasions. Funks Reservoir represents the only lacustrine habitat within the Primary Study Area, excluding some of the larger farm ponds.

Ferruginous Hawk

The ferruginous hawk is a relatively uncommon winter migrant. Ferruginous hawks are present in the Sacramento Valley from September through mid-April and use large tracts of open grasslands for winter foraging habitat (Mayer and Laudenslayer, 1988c).

Within the Primary Study Area, sporadic individual sightings of wintering ferruginous hawks were made within the proposed Sites Reservoir footprint.

Golden Eagle

The golden eagle nests throughout northern California, with the exception of the dense forests along the North Coast. Extensive wintering use of the Sacramento Valley can occur. This species forages in open habitats including grasslands, savannas, and early successional stages of open shrub and tree habitats (Mayer and Laudenslayer, 1988c).

The golden eagle is one of the most common large raptors year round within the Primary Study Area. Several active golden eagle nests were identified around the proposed Sites Reservoir rim areas, including nesting activity in, or near, three of the five proposed Recreation Areas. Golden eagle densities varied, with the highest density recorded during the winter. The highest densities associated with any proposed Project features were spring and fall densities on a formerly proposed road route, which is southeast of the proposed Sites Reservoir footprint. Along the proposed Delevan Pipeline route, golden eagles were recorded only during winter and only along the western end of the route where agricultural croplands meet the foothills.

Lawrence's Goldfinch

The Lawrence's goldfinch primarily occurs in Glenn and Colusa counties during the breeding season (March through September). Limited wintering use has been observed. This species breeds and forages in open oak or shrub habitats near water (Mayer and Laudenslayer, 1988c).

Lawrence's goldfinches were observed only sporadically within the Primary Study Area, although suitable nesting habitat exists. Observations were made in the reservoir footprint, at Funks Reservoir, and along a formerly proposed road route, which is southwest of the proposed Sites Reservoir footprint. Lawrence's goldfinches were frequently encountered in mixed flocks with other goldfinches. Only rarely were individuals of this species encountered, even during the breeding season.

Least Bittern

The least bittern occurs along the Sacramento River in eastern Glenn and Colusa counties from April through September. Least bitterns use dense emergent wetland vegetation for reproduction and foraging (Mayer and Laudenslayer, 1988c).

No least bitterns were detected within the Primary Study Area. Adequate amounts of suitable habitat for this reclusive species are present along portions of the proposed Delevan Pipeline route. Some of the farm ponds and roadside ditches within the proposed Sites Reservoir footprint have a limited amount of emergent vegetation present. However, adequate amounts of potentially suitable habitat for this species are absent from all proposed Project features.

Lesser Sandhill Crane

Lesser sandhill cranes do not breed in California, but winter mainly in the Central Valley, including areas of Glenn and Colusa counties west of the Sacramento River. Winter habitat consists of annual and perennial grasslands, moist croplands (corn, sorghum, barley, and rice), or emergent wetlands (Mayer and Laudenslayer, 1988c).

Within the Primary Study Area, wintering sandhill cranes (possibly lesser sandhill cranes) were observed along Sacramento Valley floor habitats, including the Delevan Pipeline route and the valley portion of Sulphur Gap Road.

Lewis' Woodpecker

The Lewis' woodpecker was not identified as a special- status species when field surveys began. Lewis's woodpecker occurs year round in western Glenn and Colusa counties. Preferred habitat includes open oak and conifer habitats that have snags with cavities (Mayer and Laudenslayer, 1988c).

This woodpecker occurred infrequently within the proposed Sites Reservoir footprint during spring and fall, as well as along the North and Sulphur Gap roads. Suitable habitat is generally lacking in the northern portion of the proposed reservoir area. No summer use was recorded.

Loggerhead Shrike

The loggerhead shrike occurs in open habitats with infrequent perch sites (trees, shrubs, fences, and power lines). Loggerhead shrikes forage over open sparse, low herbaceous cover. This territorial species occurs yearlong in Glenn and Colusa counties with resident and migrants present during the winter (Mayer and Laudenslayer, 1988c).

The loggerhead shrike is one of the more common and widespread avian species in grassland habitats within the Primary Study Area. This shrike's abundance appears to decrease rapidly with increasing tree density. Loggerhead shrike densities varied within the proposed Sites Reservoir footprint.

Long-Billed Curlew

The long-billed curlew winters in the Sacramento Valley. This large shorebird uses a variety of open habitats in the Sacramento Valley during the winter including croplands, mudflats, flooded areas, and open grasslands (Mayer and Laudenslayer, 1988c).

Long-billed curlews were present sporadically within the proposed Sites Reservoir footprint throughout the winter and spring. Large flocks were occasionally encountered foraging in the grassland habitats when the soils were at or near saturation. Extensive use of vernal pool areas was also observed. All curlew observations at Funks Reservoir were of birds foraging in exposed mudflats. The grasslands surrounding Funks Reservoir are ungrazed, relatively tall, dense, and apparently unsuitable for curlew foraging habitat. Curlew use along the proposed Delevan Pipeline route occurred in flooded rice fields and within annual grassland habitats along the westernmost end of the proposed route. The long-billed curlew was also observed along Sulphur Gap Road, as well as within the Saddle Dam Recreation Area.

Long-Eared Owl

The long-eared owl occurs year round in valley and foothill locations in Glenn and Colusa counties. Preferred nesting habitat is reported as dense riparian and live oak stands near open areas or forest/grassland edges (Mayer and Laudenslayer, 1988c).

Long-eared owls were observed regularly at a single location along the proposed Delevan Pipeline route during summer. Although no long-eared owls were detected along diurnal transect routes, nocturnal censusing with prerecorded taped calls indicate that long-eared owls are common along the blue oak/grassland edge habitats within the Primary Study Area. Long-eared owl responses were obtained at 54 percent of the half-mile segments sampled within the proposed Sites Reservoir footprint. This species appears to be less common in extensive open grassland habitats. However, an active nesting pair of long-eared owls was observed 0.5 mile northeast of the proposed Sites Reservoir footprint in an isolated cottonwood tree in grassland habitat.

Mountain Plover

The mountain plover is a winter resident in California, typically found on short open grasslands and plowed fields with little vegetation (Mayer and Laudenslayer, 1988c). This species is known to occur in southeast Colusa County.

No mountain plovers were observed within the Primary Study Area, but potentially suitable habitat exists at many of the proposed Project facility locations.

Northern Goshawk

The northern goshawk is an uncommon year-round resident that frequents mid- to high-elevation mature dense coniferous forests for reproduction. Some limited winter use of low-elevation foothill riparian habitat has been documented (Mayer and Laudenslayer, 1988c). This species is known from the higher elevations of Glenn and Butte counties.

No goshawks were encountered during avian transect sampling within the Primary Study Area. Further, potentially suitable nesting habitat is not present at this low elevation.

Northern Harrier

The northern harrier is a common year-round resident that uses a variety of open habitats including meadows, wetlands, and annual and perennial grasslands. This species seldom uses forest or woodland habitats, although some forest/grassland edge habitats are used. Agricultural habitats that mimic tall dense grasslands or freshwater emergent vegetation types are also used as foraging habitats (Mayer and Laudenslayer, 1988c).

Northern harriers were observed at all Project features. Northern harriers are a relatively common species in the proposed Sites Reservoir footprint during fall, spring, and winter. Relatively minor summer use has been documented within the proposed reservoir footprint. Relatively high densities have been documented at Funks Reservoir and along the proposed Delevan Pipeline route.

Olive-Sided Flycatcher

The olive-sided flycatcher occurs in western Glenn and Colusa counties. Preferred habitat includes mixed conifer, montane hardwood conifer, Douglas fir, redwood, red fir, and lodgepole pine. It is most common in forested habitats near open terrain (Mayer and Laudenslayer, 1988c).

Olive-sided flycatchers were not observed within the Primary Study Area, and potentially suitable habitat is generally absent at this low elevation.

Prairie Falcon

The prairie falcon nests in inland portions of the northern Coast Range, and winters in that area as well as within the Sacramento Valley. Preferred nesting habitat is a variety of open habitats (primarily perennial grasslands, savannas, rangeland, or open agricultural types) with a nearby sheltered cliff ledge. Winter migrants use a variety of open habitats (Mayer and Laudenslayer, 1988c).

Individual prairie falcons are occasionally present at the proposed Sites Reservoir footprint during winter and fall, but densities are generally low. The seasonal occurrence of this species suggests that breeding does not occur in the Primary Study Area. Prairie falcons were observed at Funks Reservoir and along the Delevan Pipeline and Sulphur Gap Road. A single prairie falcon was also sighted within the Antelope Island Recreation Area.

Purple Martin

The purple martin is a migratory species that returns to northern California during March and migrates south during September. A variety of habitat types are used for reproduction in the Coast Range including hardwood and coniferous habitats. Preferred breeding habitat includes open older forests and woodlands with suitable snags for nesting. This species forages for insects over a variety of habitats near the nest site including forest, woodland, chaparral, and riparian habitats (Mayer and Laudenslayer, 1988c). This species is known from Lake and Shasta counties.

Potential breeding habitat is generally absent from the Primary Study Area, and no purple martins were observed during field surveys.

Redhead

The redhead is found year round in the Central Valley. This species nests in fresh emergent wetlands where dense stands of cattails and tules border open water (Mayer and Laudenslayer, 1988c). Redheads are known to occur in eastern Glenn and Colusa counties.

Within the Primary Study Area, redheads were observed at Funks Reservoir, and suitable habitat exists at the duck clubs along the proposed Delevan Pipeline route.

Rufous Hummingbird

The rufous hummingbird is a common migrant and uncommon summer resident in California. This hummingbird is found in a variety of habitats that provide nectar-producing flowers, including riparian, open woodland, and chaparral habitats. Breeding occurs only in Trinity and Humboldt counties, but spring migration occurs mostly in the lowlands and foothills (Mayer and Laudenslayer, 1988c).

Rufous hummingbirds were not observed within the Primary Study Area, but could occur during migration.

Short-Eared Owl

The short-eared owl occurs in open habitats with dense vegetation, including annual and perennial grasslands, irrigated pasture, and fresh emergent wetlands. Forest and woodland areas are avoided (Mayer and Laudenslayer, 1988c).

Short-eared owls were observed during diurnal avian line transects at Funks Reservoir and along the proposed Delevan Pipeline route only. No summer use was recorded at any proposed Project facility location. Short-eared owls were regularly observed along the proposed Delevan Pipeline route in the vicinity of Delevan NWR in winter. Nocturnal owl calling identified the presence of a short-eared owl at two locations along the proposed Delevan Pipeline route.

Tricolored Blackbird

The tricolored blackbird is a colonial year-round resident of the Sacramento Valley that uses freshwater emergent wetland habitats (primarily cattail and tules) for nesting. This blackbird forages on the ground in a variety of habitats including grasslands, croplands, and seasonally flooded areas. Tricolored blackbirds may travel many miles between nesting and foraging areas (Mayer and Laudenslayer, 1988c).

Foraging tricolored blackbirds were commonly observed within open grassland habitats within the proposed Sites Reservoir footprint, as well as along the North and Sulphur Gap roads, at Funks Reservoir, and within the Saddle Dam Recreation Area. Although no nesting was observed within the Primary Study Area, suitable nesting habitat is present within the Delevan NWR near the proposed Delevan Pipeline route. Tricolored blackbirds frequently occurred in mixed flocks with Brewer’s blackbirds, red-winged blackbirds, and European starlings.

Tule Greater White-Fronted Goose

The tule greater white-fronted goose winters in California’s Central Valley, where it prefers wetlands dominated by tules, rushes, and cattails. This species also forages in agricultural fields, including rice fields (Shuford and Gardali, 2008). Tule greater white-fronted geese are known to occur in southeastern Glenn County and northeastern Colusa County, mainly on State and federal managed wetlands, but also on private wetlands managed for waterfowl hunting.

No tule greater-white fronted geese were observed within the Primary Study Area, but potentially suitable habitat exists along the proposed Delevan Pipeline route.

Vaux’s Swift

The Vaux’s swift is frequently observed in northern California during migration and less often during the breeding season. No winter use occurs. Preferred nesting habitat includes an appropriate nest site in a large hollow tree, primarily redwood or Douglas fir. This swift may also nest in chimneys or buildings. Vaux’s swifts forage in flight for insects over many habitat types near the nest tree, including riparian and lacustrine habitat (Mayer and Laudenslayer, 1988c).

No Vaux’s swifts were observed within the Primary Study Area.

Western Snowy Plover

The western snowy plover occurs year round along the California coast with a very limited summer distribution inland. Central Valley records are primarily from the San Joaquin Valley. This species frequents sandy or gravelly beaches of estuarine salt ponds or alkali lakes for foraging and nesting (Mayer and Laudenslayer, 1988c).

No western snowy plover were identified within the Primary Study Area. However, potentially suitable habitat is present along the proposed Delevan Pipeline route.

White-Tailed Kite

The white-tailed kite is found year round throughout the Sacramento Valley and adjacent foothill areas. Habitat preference includes open or herbaceous stages of most low-elevation vegetative types, primarily grasslands, meadows, farmland, and emergent wetlands. However, white-tailed kites are frequently associated with agricultural areas. Dense stands of trees are used as communal night roost sites (Mayer and Laudenslayer, 1988c).

White-tailed kites were an uncommon species within the proposed Sites Reservoir footprint. However, one pair of nesting kites was observed in open blue oak habitat near the southern end of the proposed Sites Reservoir in 1999. This species was commonly observed in cropland habitat downstream from Funks Reservoir and less frequently foraging the ungrazed grasslands around Funks Reservoir. Kites were observed along the length of the proposed Delevan Pipeline route, with the greatest habitat use associated with irrigated pasture or croplands as opposed to the more commonly occurring rice fields. Kites were also observed along Sulphur Gap Road. No communal roost trees were identified.

Yellow-Breasted Chat

The yellow-breasted chat, an uncommon warbler, is a migratory species that arrives in California during April and departs by October. Nesting habitats consist of dense riparian understory and other dense shrub habitats near water. Willow and blackberry patches are used extensively (Mayer and Laudenslayer, 1988c).

No yellow-breasted chats were observed within the Primary Study Area. Potentially suitable nesting habitat is generally absent except for a narrow strip of mature riparian habitat along the Sacramento River portion of the proposed Delevan Pipeline route.

Yellow-Headed Blackbird

The yellow-headed blackbird nests in fresh emergent wetland with dense vegetation and deep water, often along borders of lakes or ponds. This species forages in emergent wetland and moist open areas, especially in cropland and the muddy shores of lacustrine habitat (Mayer and Laudenslayer, 1988c). The yellow-headed blackbird is known to breed in Colusa County, including areas of the Delevan NWR.

This species was observed within the Primary Study Area at Funks Reservoir and along the proposed Delevan Pipeline route.

Yellow Warbler

The yellow warbler occurs in a variety of woodland and forest habitats in northern California during the breeding season (April through September). This species prefers open to moderate density forests or woodlands with a dense shrub understory. Yellow warblers are most common in open canopy riparian deciduous habitat (Mayer and Laudenslayer, 1988c).

Yellow warblers are a very uncommon species within the Primary Study Area. Sightings within the proposed Sites Reservoir footprint were restricted to spring in a short reach of riparian habitat between the community of Sites and the Sites Damsite. Habitat use along the proposed Delevan Pipeline route primarily occurred in the vicinity of the Colusa Basin Drain (CBD) and the Delevan NWR.

Mammals

American Badger

The American badger is an uncommon permanent resident found throughout most of California, except for the northern North Coast area. It is most abundant in the drier open stages of most shrub, forest, and herbaceous habitats with friable soils. Cultivated lands have been reported to provide little usable habitat for this species. The badger digs burrows in friable ("crumbly") soil types for cover and remains underground during the day. The badger frequently reuses old burrows, although it has been known to dig a new den each night, especially in summer (Messick and Hornocker, 1981; Mayer and Laudenslayer, 1988d).

Field surveys documented the American badger in grassland and oak woodland areas at Funks Reservoir, within the proposed Sites Reservoir footprint, at all proposed Recreation Areas, and along portions of all roads. Possible suitable habitat exists at all other proposed Project facility locations.

Pallid Bat

The pallid bat occurs throughout California, except in the high Sierra Nevada from Shasta to Kern counties, and the northwestern portion of California in Del Norte and western Siskiyou counties (Mayer and Laudenslayer, 1988d). This bat inhabits a variety of habitats, including grasslands, shrublands, woodlands, and forests, from sea level up through mixed coniferous forests below 2438 m (8,000 ft). In California, the pallid bat is associated with oak woodlands at lower elevations, and may roost in a variety of places including tree cavities, rock crevices, and human-made structures. The pallid bat prefers roosts where it can be out of sight and wedged into small tight crevices. Such sites include rock crevices, bridges, caves, mines, and hollow trees. The pallid bat uses these roosts in tight spaces to thermoregulate, especially during cooler weather. However, during warmer weather periods, it will roost in open areas, such as the sides of rafters and open barns. Barns seem to be a preferred roost. Breeding occurs from October to February, and young are born from May to June. The young are capable of flight at six weeks of age (Davis and Schmidly, 1947).

Field surveys documented the presence of the pallid bat in the grassland and oak woodland habitat within the proposed Sites Reservoir footprint and along the formerly proposed North and Sulphur Gap roads. A maternity roost was discovered in an abandoned ranch house near the North Road. Possible suitable habitat exists at all other proposed Project facility locations.

Spotted Bat

The spotted bat was thought to be found primarily in the southeastern Sierra foothills, mountains, and desert regions, but range expansions have been documented to include Ventura, Riverside, Mariposa, Kern, San Bernardino, San Diego, Fresno, Inyo, Shasta, Siskiyou, Tehama, Tuolumne, Mono, and Tulare counties (Pierson and Rainey, 1998a). Horizontal rock crevices provide optimal roost sites, although the spotted bat may occasionally also use caves and buildings. The spotted bat is apparently a solitary animal. It mates in the fall, with a single pup born before mid-June. Lactating females have been found from June to August (Mayer and Laudenslayer, 1988d).

Due to the rare nature of this animal and minimal information about its range, it has been included as a potentially occurring species. Field surveys failed to document the presence of the spotted bat within the Primary Study Area.

Townsend's Big-Eared Bat

The Townsend's big-eared bat is found throughout California, in all but subalpine and alpine habitats (Mayer and Laudenslayer, 1988d) Suitable roosting sites are restricted to caves and cave-like structures, such as tunnels, mines, and buildings, where this species roosts in the open, rather than in crevices (Pierson and Rainey, 1998b). Hibernation occurs from October to April. Females return to their natal group every spring, and young are born from May to June. One young is born per year and can fly by three weeks of age. Young are typically weaned at six weeks of age. This species is extremely sensitive to disturbance of roosting sites (Mayer and Laudenslayer, 1988d).

Field surveys failed to document the presence of Townsend's western big-eared bat within the Primary Study Area.

Western Mastiff Bat

The western mastiff bat is an uncommon resident ranging from Monterey County southward through southern California, and from the coast eastward to the Colorado Desert. This species occurs in semi-arid to arid habitats, including deciduous woodlands and annual and perennial grasslands (Mayer and Laudenslayer, 1988d). It primarily roosts in crevices in vertical cliffs of granite or consolidated sandstone, and in broken terrain with exposed rock faces (Dalquest, 1946). It is also occasionally found in high buildings (Howell and Little, 1920), trees, and tunnels. Roost sites may change from season to season. Due to its large size, this bat needs vertical faces to drop from to take flight. The western mastiff bat mates in the months surrounding the early spring, and one young is born between April and September (Mayer and Laudenslayer, 1988d).

No western mastiff bats were documented on Anabat recordings or during field surveys within the Primary Study Area.

Western Red Bat

The western red bat is locally common in some areas of California, occurring from Shasta County to the Mexican border, west of the Sierra Nevada/Cascade crest and deserts. The winter range includes western lowlands and coastal regions south of San Francisco Bay. This species is considered to be highly migratory, with migration occurring between summer and winter ranges. The western red bat roosts primarily in the foliage of trees or shrubs. Day roosts are commonly in edge habitats adjacent to streams or open fields, in orchards, and sometimes in urban areas. There may be an association with intact riparian habitat (particularly willows, cottonwoods, and sycamores). This species feeds on insects over a wide variety of habitats, including grasslands, shrublands, open woodlands, and forests. Red bats have been observed feeding around street lights and flood lights. Mating occurs in August and September, and young are born from late May through early June (Mayer and Laudenslayer, 1988d).

During surveys within the Primary Study Area, a juvenile male and juvenile female western red bat were captured along Sulphur Gap Road, immediately adjacent to the southern end of the proposed Sites Reservoir footprint. This species was captured in blue oak woodland habitat; similar suitable habitat exists in the proposed Sites Reservoir footprint, all Recreation Areas with the exception of Saddle Dam, and along portions of most of the roads.

14.2.3.6 Commercially or Recreationally Important Wildlife Species

Up to 58 harvest species (33 birds, 24 mammals, and 1 amphibian) may be found within the Primary Study Area (DFG, 2008a) (Table 14-6).

Wild pigs, and to a lesser extent black bear and mule deer, are important big game species within Colusa and Glenn counties. Field personnel often encountered hunters while conducting wildlife surveys. Detailed information is not available specifically for the Primary Study Area, but figures are available and presented at the county level. During the 2008 hunting season, 56 black bears were reported killed within Colusa and Glenn counties by licensed hunters, representing 2.8 percent of California's total bear harvest for the year (DFG, 2009c). A reported 307 mule deer were killed within Colusa and Glenn counties by licensed hunters, representing 1.9 percent of California's total deer harvest for the year (DFG, 2009d). During the 2006-2007 wild pig hunting season, a reported 374 wild pigs were killed within Colusa and Glenn counties by licensed hunters, representing 8.2 percent of California's total pig harvest for the year (DFG, 2007a).

Table 14-6
Commercially or Recreationally Important Wildlife Species that may Occur within the Primary Study Area

Common Name	Scientific Name
Harvested Amphibians	
Bullfrog*	*Rana catasbeiana*
Harvested Birds	
American coot*	*Fulica Americana*
American crow*	*Corvus brachyrhynchos*
American wigeon*	*Anas Americana*
Band-tailed pigeon	*Columba fasciata*
Blue-winged teal*	*Anas discors*
Bufflehead*	*Bucephala albeola*
California quail*	*Callipepla californica*
Canada goose*	*Branta Canadensis*
Canvasback*	*Aythya valisineria*
Cinnamon teal*	*Anas cyanoptera*
Common goldeneye*	*Bucephala clangula*
Common merganser*	*Mergus merganser*
Common moorhen*	*Gallinula chloropus*
Eurasian wigeon	*Anas Penelope*
Gadwall*	*Anas strepera*
Greater white-fronted goose*	*Anser albifrons*
Green-winged teal*	*Anas crecca*
Hooded merganser*	*Lophodytes cucullatus*
Lesser scaup*	*Aythya affinis*
Mallard*	*Anas platyrhynchos*
Mountain quail	*Oreortyx pictus*
Mourning dove*	*Zenaida macroura*
Northern pintail*	*Anas acuta*
Northern shoveler*	*Anas clypeata*
Redhead*	*Aythya Americana*
Ring-necked duck*	*Aythya collaris*

Table 14-6
Commercially or Recreationally Important Wildlife Species that may Occur within the Primary Study Area

Common Name	Scientific Name
Ring-necked pheasant*	*Phasianus colchicus*
Ross's goose	*Chen rossii*
Ruddy duck*	*Oxyura jamaicensis*
Sooty grouse	*Dendragapus fuliginosus*
Snow goose*	*Chen caerulescens*
Wild turkey*	*Meleagris gallopavo*
Wood duck*	*Aix sponsa*
Harvested Mammals	
American badger*	*Taxidea taxus*
American beaver*	*Castor Canadensis*
American mink	*Mustela vison*
Black bear*	*Ursus americanus*
Black-tailed jackrabbit*	*Lepus californicus*
Bobcat*	*Felis rufus*
Brush rabbit*	*Sylvilagus bachmani*
Common muskrat*	*Ondatra zibethicus*
Coyote*	*Canis latrans*
Desert cottontail	*Sylvilagus audubonii*
Eastern fox squirrel	*Sciurus niger*
Elk	*Cervus elaphus*
Ermine	*Mustela ermine*
Gray fox*	*Urocyon cinereoargenteus*
Long-tailed weasel	*Mustela frenata*
Mule deer*	*Odocoileus hemionus*
Pronghorn	*Antilocapra Americana*
Raccoon*	*Procyon lotor*
Red fox*	*Vulpes*
Striped skunk*	*Mephitis*
Virginia opossum*	*Didelphis virginiana*
Western gray squirre*	*Sciurus griseus*
Western spotted skunk	*Spilogale gracilis*
Wild pig*	*Sus scrofa*

*Species documented during field surveys.

The Delevan NWR and several private duck clubs along the eastern portion of the Delevan Pipeline route provide seasonal waterfowl and pheasant hunting opportunities.

Thirteen of the 58 harvest species that could occur within the Primary Study Area were not observed during field surveys: the Ross' goose, Eurasian wigeon, sooty grouse, mountain quail, band-tailed pigeon, desert cottontail, Eastern fox squirrel, long-tailed weasel, American mink, ermine, western spotted skunk, pronghorn, and elk.

Southwestern Colusa County includes a large portion of the management unit for the free-ranging Cache Creek Tule elk herd, which is estimated at a minimum of 187 animals. Two sub-herds frequent the Colusa County portion of the management area, which is southwest of the Primary Study Area. The range of these sub-herds has not been documented to include the Primary Study Area. The East Park Reservoir Tule elk herd, which is estimated at a minimum of 95 animals, is located west of the Primary Study Area. This herd tends to stay within 2 miles of East Park Reservoir and has not been documented within the Primary Study Area, but the hunt zone for this herd overlaps with the northern half of the footprint of the proposed Sites Reservoir, as well as with the Stone Corral, Peninsula Hills, and Saddle Dam recreation areas, Funks Reservoir, Holthouse Reservoir, most roads (excluding Sulphur Gap, Com, and Lurline roads), and portions of the Delevan Pipeline and T-C and GCID canals (Hobbs, pers. comm., 2010).

A small herd of pronghorn is present in Glenn County, north of the Primary Study Area. This herd was incidentally observed several times by field personnel, including along Maxwell Sites Road and Road 68, but their range has not been documented to include the footprint or construction disturbance area of facilities included in the Primary Study Area.

The remaining 11 unobserved wildlife species were not the focus of survey efforts. Suitable habitat exists for each, so it is, therefore, possible that they are present within the Primary Study Area.

14.3 Environmental Impacts/Environmental Consequences

14.3.1 Regulatory Setting

Terrestrial biological resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

14.3.1.1 Federal Plans, Policies, and Regulations

- National Environmental Policy Act
- Central Valley Project Improvement Act
- Federal Endangered Species Act
- Fish and Wildlife Coordination Act
- Executive Order 11312: Invasive Species
- Migratory Bird Treaty Act
- Bald and Golden Eagle Protection Act

14.3.1.2 State Plans, Policies, and Regulations

- California Environmental Quality Act
- California Endangered Species Act
- California Fish and Game Code Sections 3503, 3503.5, 3511, 4700, and 5050

14.3.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan
- Colusa County Voluntary Oak Woodlands Management Plan

14.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for biological resources:

Would the Project:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game (DFG) or U.S. Fish and Wildlife Service (USFWS)?
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by DFG or USFWS?
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?
- Conflict with the provisions of an adopted Habitat Conservation Plan (HCP), Natural Community Conservation Plan (NCCP), or other approved local, regional, or state HCP?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- A substantial adverse effect, including mortality, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by DFG or USFWS.
- A substantial adverse effect, including alteration of habitat suitability, on any wildlife habitat, especially riparian habitat or other sensitive natural communities identified in local or regional plans, policies, regulations, or by DFG or USFWS.
- Substantial interference with the movement of any native resident or migratory wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites.
- Indirect effects on common wildlife from human disturbance.
- Conflict with the provisions of an adopted HCP, NCCP, or other approved local or regional HCP, or conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance.

14.3.3 Impact Assessment Assumptions and Methodology

14.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to terrestrial biological resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge facilities would be required.
- Borrow areas for dam construction materials would be located within the proposed Sites Reservoir footprint, or materials would be obtained from commercial sources outside of the Primary Study Area.
- Frequent Sites Reservoir water level fluctuations would create a barren drawdown zone.
- For all Project facilities that do not have a defined construction disturbance area, an additional 10 percent of the facility footprint acreage is assumed to be the size of the associated disturbance area.
- Periodic maintenance of the proposed pipelines and transmission lines would be conducted on foot and/or by using established roads for vehicle access, and would not require vehicle access over established or restored vegetation.

14.3.3.2 Methodology

Impacts to common wildlife were assessed in relation to habitat alteration or destruction. Direct wildlife impacts include permanent loss of habitat, mortality, injury, displacement, disruption of travel corridors, and disturbance. Indirect wildlife impacts include disturbance activities that result indirectly from the Project (i.e., increased vehicle traffic, increased foot traffic, and noise), as well as changes to habitat suitability. Analysis of the impacts of human disturbance to common wildlife included consideration of the impacts of human disturbance to special-status wildlife species. Impacts can be positive or negative, and can be short-term (temporary) or long-term (permanent).

Approximately 15 percent of the total footprint of each Recreation Area would be subject to permanent construction disturbance. Because the exact location and area affected by the construction of the recreation facilities within the Recreation Areas is not known, the extent of permanent habitat loss was estimated by applying a 15 percent multiplier to each habitat type present.

Of the 200-foot-wide total construction disturbance area associated with road construction, an approximate average of 60 feet (30 percent) would result in the permanent loss of wildlife habitats. A 30 percent multiplier was, therefore, applied to each habitat type present.

For the Delevan Transmission Line, a worst-case scenario of 70 transmission towers with a concrete pad for a base along the entire length of the transmission line was used to calculate the area of permanent disturbance for Alternatives A and C. A worst-case scenario of 15 transmission towers with a concrete pad for a base for the length of the transmission line was used to calculate the area of permanent disturbance for Alternative B.

Calculated acres of natural habitats and agricultural lands represent the 2009 baseline conditions (i.e., Existing Conditions).

The terrestrial biological resources impact assessment relied on hydrologic and operational modeling performed using CALSIM II to provide a quantitative basis from which to assess the potential impacts of the alternatives on riparian and wetland habitat in portions of the Extended and Secondary study areas. Monthly river flows, and water surface elevations derived based on monthly river flows and end-of-month reservoir storages from CALSIM II, provided a quantitative basis to assess the potential impacts of operations on these habitat types, relative to the CEQA and NEPA bases of comparison, for the period of simulation extending from water year 1922 through 2003 (82-year simulation period). Detailed discussion of the CALSIM II model is provided in Appendix 6B.

Further, in assessing the impacts to the valley foothill riparian vegetation along the Sacramento River in the Secondary Study Area, modeling specific to riparian vegetation, including results from the SRH-1DV and SacEFT models, were used.

The SRH-1DV model simulated the establishment, growth, and mortality of vegetation, in addition to computing hydraulics and groundwater surface in the riparian zone near the river. The simulation tracked daily vegetation changes through 82 years of simulated flow, within the 107 river miles of Sacramento River from upstream of Red Bluff (RM 250) to upstream of Colusa (RM 143). SRH-1DV analysis focused on four key valley foothill riparian vegetation types: cottonwood, mixed forest, Gooding’s black willow, and narrow leaf willow. The detailed description of the SRH-1DV model and the associated alternatives evaluation is provided in Appendix 8A.

The SacEFT is a decision support tool that linked flow management actions on the Sacramento River to changes in the physical habitats for several focal species of concern. It specifically includes performance measures for evaluating the effects of various flow scenarios on the initiation success and post-initiation scour risk of the Fremont Cottonwood seedlings, as well as on habitat potential/suitability and peak flow during the nesting period for bank swallows. These performance measures were used as a general indicator for assessing the impacts on riparian vegetation and bank swallow colonies along the Sacramento River in the Secondary Study Area. The detailed description of the SacEFT model and the associated alternatives evaluation is provided in Appendix 8B.

14.3.4 Topics Eliminated from Further Analytical Consideration

Because no Project facilities would be constructed or maintained within the Extended Study Area, only operational impacts associated with Alternatives A, B, and C are discussed in the impacts analysis for the Extended Study Area for the three alternatives.

Because no construction or maintenance activities would occur within the Secondary Study (with the exception of the Red Bluff Pumping Plant), only operational impacts associated with Alternatives A, B, and C are discussed in the impacts analysis for the reservoirs and waterways included in the Secondary Study Area for the three alternatives.

Because the Primary Study Area Project facilities with an above-ground footprint would result in permanent wildlife habit loss during their construction, the impact of the operation and maintenance of those facilities on wildlife habitat (**Impact Wild-1**) is not discussed.

Similarly, when the permanent loss or conversion of a wildlife habitat type resulting from Project facility construction would make that location unsuitable for, or unable to support, specific special-status wildlife species, the impact of the operation and maintenance of that facility on the species (**Impact Wild-2**) is not discussed. Operation and maintenance impacts are discussed, however, for the bald eagle and golden eagle because those species would still be located in the Sites Reservoir and Dams area after Project construction is complete. Operation and maintenance impacts are not discussed for the remaining wildlife species because those species would lose their suitable habitat during Project construction, and would, therefore, no longer be present.

Operation and maintenance of the GCID Canal Facilities would resume following completion of the Project's construction activities associated with the proposed GCID Canal Facilities Modifications, and would have no Project-related impacts on wildlife or wildlife habitat. Therefore, operation and maintenance impacts associated with this facility are not discussed further.

For the proposed underground pipelines within the Primary Study Area, operations would occur underground and be coordinated remotely; therefore, the impacts of pipeline operation are not discussed.

Within the Project Buffer, no on-the-ground activities would occur during Project operation. Therefore, the impact of Project operation within the Project Bufferis not discussed.

14.3.5 Impacts Associated with the No Project/No Action Alternative

14.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to wildlife habitat has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. Urbanization that is planned according to General Plans could be expected to cause the conversion of natural wildlife habitats to urban uses. However, General Plans and any related construction activities would be subject to their own environmental reviews. Therefore, population growth associated with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to special-status wildlife species.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to the effects of human disturbance on common wildlife.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to conflicts with habitat plans.

San Luis Reservoir

Modeling results indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in the same or slightly decreased water level elevations during most water years, and the same or slightly increased water level elevations during Dry and Critical years at San Luis Reservoir.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Negligible fluctuations in San Luis Reservoir surface water elevations that are expected with implementation of the No Project/No Action Alternative would not be expected to adversely affect the small amount of riparian or wetland habitat that exists around the reservoir because the habitat is located in seeps and is already subject to large water level fluctuations. Because the reservoir already experiences large water level fluctuations, the relative availability of open water (lacustrine) habitat would not be expected to change. Slight changes in surface water elevations at San Luis Reservoir resulting from implementation of the No Project/No Action Alternative would, therefore, **not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because slight changes in surface water elevations at San Luis Reservoir would have a less-than-significant impact on lacustrine, riparian, and wetland habitat, the water level fluctuations would not be expected to have a substantial adverse effect on wildlife species associated with those habitat types. Therefore, slight changes in surface water elevations at San Luis Reservoir resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

None of the projects included in the No Project/No Action Alternative are located at San Luis Reservoir. Therefore, there **would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated water level fluctuations at San Luis Reservoir associated with implementation of the No Project/No Action Alternative would be within the historical range of operation, when compared to Existing Conditions, and consequently would not conflict with any HCPs, NCCPs, or local ordinances. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

14.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in no change to surface water elevations at Trinity or Shasta lakes, and therefore, **would not have a substantial adverse effect** on the surrounding wildlife habitat. Modeling results indicate slight decreases in surface water elevations at Lake Oroville and Folsom Lake, but the small decreases would not be expected to affect the lacustrine or surrounding riparian or wetland habitats. Therefore, the impacts of small surface water elevation fluctuations on wildlife habitat at these two reservoirs resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect,** when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in no change to surface water elevations at Trinity or Shasta lakes, and therefore, **would not have a substantial adverse effect** on special-status species. Because slight changes in surface water elevations at Lake Oroville and Folsom Lake would have a less-than-significant impact on lacustrine, riparian, or wetland habitats, the water level fluctuations would not be expected to have a substantial adverse effect on wildlife species associated with those habitat types. Slight changes in surface water elevations at these two reservoirs resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to wildlife habitat has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion. That discussion is also applicable to conflicts with habitat plans.

Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, and the Thermalito Complex

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling was not conducted for Lewiston Lake, Keswick Reservoir, Lake Natoma, or the Thermalito Complex. However, modeling conducted on the reservoirs upstream of these reservoirs indicates that the No Project/No Action Alternative, when compared to Existing Conditions, would result in either no change or slight changes to surface water level elevations. Because these reservoirs would continue to operate as regulating reservoirs, it is expected that there would be little or no change in surface water level elevations, and therefore, they **would not have a substantial adverse effect** on the lacustrine or surrounding riparian or wetland habitat. Modeling was conducted for Whiskeytown Lake for flows downstream of the lake, and flows would experience slight changes. Because the reservoir upstream of Whiskeytown would experience slight changes, and the flows released from Whiskeytown would experience slight changes, surface water elevations associated with implementation of the No Project/No Action Alternative would not be expected to fluctuate, and therefore, **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because slight changes in surface water elevations at these four reservoirs and the Thermalito Complex would have a less-than-significant impact on lacustrine and the surrounding riparian or wetland habitat, the water level fluctuations would not be expected to have a substantial adverse effect on wildlife species associated with those habitat types. Slight changes in surface water elevations at these facilities resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for the No Project/No Action Alternative. That discussion is also applicable to conflicts with habitat plans.

Trinity River

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results for Trinity River flows downstream of Lewiston Lake for the No Project/No Action Alternative, when compared to Existing Conditions, indicate slight changes in flows during Below Normal, Dry, or Critical water years. However, large decreases in flow are indicated during Wet water years during the months of March and April, and large increases in flows are indicated in Above Normal water years in the month of February. These changes in the flow regime have the potential to adversely affect riparian habitat. However, riparian habitat is adapted to flow variations. The expected decreases in spring flows during Wet water years and the expected increases in flow during late winter in Above Normal water years would, therefore, not be expected to substantially adversely affect riparian vegetation. These modifications of the flow regime of the Trinity River resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Trinity River flow regime in Wet and Above Normal water years would have a less-than-significant impact on riparian habitat, the water level fluctuations would not be expected to have a substantial adverse effect on riparian-associated wildlife species. Changes in the Trinity River flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status terrestrial wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Klamath River downstream of the Trinity River

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results for the Klamath River downstream of the Trinity River for the No Project/No Action Alternative, when compared to Existing Conditions, indicate negligible changes in flows. These negligible changes in the flow regime would not be expected to adversely affect riparian vegetation. Implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Klamath River downstream of the Trinity River would be negligible and would not adversely affect riparian vegetation, they would also not be expected to have an adverse effect on riparian-associated wildlife species. Implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Spring Creek

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Operational modeling was not performed for Spring Creek. However, with implementation of the No Project/No Action Alternative, operations of Whiskeytown Lake and Keswick Reservoir are expected to result in small changes, and therefore, would not be expected to affect the released flows that dilute Spring Creek runoff. Because no change in the dilution of Spring Creek runoff is expected with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to special-status wildlife species.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Sacramento River

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in negligible changes to the flow regime of the Sacramento River, with the exception of decreased flows downstream of Keswick in November during Dry years. Large changes in the flow regime have the potential to adversely affect riparian habitat. However, riparian habitat is adapted to flow variations, and changes in flow during one month in Dry years would not be expected to substantially adversely affect riparian vegetation. Therefore, the modifications to the flow regime of the Sacramento River resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Sacramento River flow regime in November during Dry years would have a less-than-significant impact on riparian habitat, the flow regime changes would not be expected to have a substantial adverse effect on riparian-associated wildlife species. Changes in the Sacramento River flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Clear Creek

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in small changes to the flow regime of Clear Creek, with the exception of large increases in flows during Critical years. These changes in the flow regime have the potential to adversely affect riparian habitat. However, an increase in flow during Critical years could reduce or prevent the desiccation of riparian vegetation. Therefore, changes to the flow regime of Clear Creek resulting from implementation of the No Project/No Action Alternative would have a **potentially beneficial effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Clear Creek flow regime during Critical years would have a potentially beneficial impact on riparian habitat, the flow regime changes would not be expected to have an adverse effect on riparian-associated wildlife species. Changes in the Clear Creek flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Feather River

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in numerous large changes to the flow regime of the Feather River. These changes in the flow regime have the potential to adversely affect riparian habitat. The changes to the flow regime that are most likely to affect riparian habitat include greatly increased flows ranging from June through September in all but Dry water year types, with the exception of decreases in July in Critical years. The increased flows have the potential to inundate riparian vegetation. Adverse effects could also result from large decreases in flows during late August in Dry years, which could desiccate riparian vegetation. The modifications of the existing flow regime of the Feather River resulting from implementation of the No Project/No Action Alternative could substantially adversely affect riparian vegetation, and therefore, **would have a potentially substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the Feather River flow regime would have a potentially significant impact on riparian habitat, the flow regime changes would also potentially have a substantial adverse effect on riparian-associated wildlife species. The increased June through September flows that could adversely affect riparian habitat could also inundate bank swallow burrows during the breeding season. Changes in the Feather River flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would have a potentially substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Sutter Bypass

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in small changes in spills into Moulton, Tisdale, and Ord Ferry weirs. Colusa Weir would experience a decrease in spills during November, especially in Dry years. Changes to the flow regime of the Sutter Bypass have the potential to adversely affect riparian habitat. However, three of the four weirs that spill into the Bypass are not expected to experience large changes in flows, and Colusa weir would only experience large decreases in flood flows during November. The riparian habitat within the Sutter Bypass has adapted to flow variations, and changes in flow from one weir during one month would not be expected to substantially adversely affect the riparian vegetation. Therefore, the modifications of the existing flow regime of the Sutter Bypass resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes in spills into the Sutter Bypass would have a less-than-significant impact on riparian habitat, the changes to the flow regime would not be expected to have a substantial adverse effect on riparian-associated wildlife species. Changes in the Sutter Bypass flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Yolo Bypass

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in small changes in monthly flows into the Yolo Bypass, with the exception of large decreases in flow during late fall in Below Normal and Dry years. Changes to the flow regime of the Yolo Bypass have the potential to adversely affect riparian habitat. However, riparian habitat is adapted to flow variations, and decreases in flood flows during late fall in Below Normal and Dry years would not be expected to substantially adversely affect riparian vegetation. Therefore, the modifications to the flow regime of the Yolo Bypass resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes in spills into the Yolo Bypass would have a less-than-significant impact on riparian habitat, the changes to the flow regime would not be expected to have a substantial adverse effect on riparian-associated wildlife species. Changes in the Yolo Bypass flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status terrestrial wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

American River

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in decreases in flows on the American River in all months. Large decreases in flow are also indicated in September of Above Normal years, September and October of Below Normal years, and in July and August in Critical years. This reduction in flows, coupled with the substantial reductions in flows during early fall in Below Normal and Dry water year types, has the potential to adversely affect riparian habitat by desiccating established vegetation and reducing recruitment. The modifications to the existing flow regime of the American River resulting from implementation of the No Project/No Action Alternative, therefore, **would have a potentially substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes to the American River flow regime would have a potentially significant impact on riparian habitat, the flow regime changes could also have a substantial adverse effect on riparian-associated wildlife species. Changes in the American River flow regime resulting from implementation of the No Project/No Action Alternative, therefore, **would have a potentially substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Sacramento-San Joaquin Delta

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in negligible changes in Sacramento-San Joaquin Delta monthly outflow. This lack of change to Sacramento-San Joaquin Delta outflow resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to special-status wildlife species.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modeling results indicate that the No Project/No Action Alternative, when compared to Existing Conditions, would result in an overall negligible change in the position of X2, as well as an overall negligible change in Delta monthly outflow. Therefore, Suisun, San Pablo, and San Francisco bays would also be expected to experience negligible changes. Negligible changes in the flow regime of these bays resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because changes in the flow regime of the bays would have a less-than-significant impact on riparian and wetland habitat types, the changes to the flow regime would not be expected to have a substantial adverse effect on riparian- or wetland-associated wildlife species. Changes in the flow regime of the three bays resulting from implementation of the No Project/No Action Alternative, therefore, **would not have a substantial adverse effect** on special-status terrestrial wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-4** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to conflicts with habitat plans.

14.3.5.3 Primary Study Area – No Project/No Action Alternative

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

With implementation of the No Project/No Action Alternative, the Project would not be built and there would, therefore, be no construction, operation, or maintenance impacts within the Primary Study Area. Additionally, none of the 14 projects included in the No Project/No Action Alternative are located within the Primary Study Area. Despite expected growth within Glenn and Colusa counties throughout the period of Project analysis (i.e., 100 years), no large-scale construction or growth is anticipated in the Primary Study Area. Funks Reservoir would be expected to continue to operate at current levels as a regulating reservoir. Landowners would continue to graze cattle, harvest crops, modify land uses based on the value of crops, and harvest fuel wood at levels similar to current practices. These continued activities would not be expected to decrease current habitat quantity, but could affect habitat quality.

Continued cattle grazing in areas that have unrestricted access to creeks would continue to degrade the quality of riparian habitat. The removal of blue oaks reduces habitat quality by reducing canopy cover and tree density. Continued fuel wood harvest, at the rate that has been observed since 2000, would eliminate large areas of blue oak woodland habitat because tree removal eventually converts the woodlands to annual grassland habitat. Therefore, the continued land use activities within the Primary Study Area that would continue to occur with implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on wildlife habitat, when compared to Existing Conditions.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because continued land use practices would have a potentially significant impact on riparian and blue oak woodland habitat, the habitat modifications could also have a substantial adverse effect on riparian- and blue oak woodland-associated wildlife species. However, no State- or federally-listed wildlife species were documented within the Primary Study Area that are associated with, or dependent upon, these wildlife habitats. Therefore, the continued land use activities within the Primary Study Area that would continue to occur with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on special-status wildlife species, when compared to Existing Conditions.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

None of the projects included in the No Project/No Action Alternative would occur within the Primary Study Area. Therefore, **there would not be a substantial adverse effect** on terrestrial wildlife from human disturbance associated with construction, operation, or maintenance-related activities, when compared to Existing Conditions.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

There are no HCPs or NCCPs that address the Primary Study Area. Additionally, none of the projects included in the No Project/No Action Alternative would occur within the Primary Study Area. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

14.3.6 Impacts Associated with Alternative A

14.3.6.1 Extended Study Area – Alternative A

<u>Construction, Operation, and Maintenance Impacts</u>

Agricultural Water Use

Operational modeling indicates that implementation of Alternative A would result in increased water supply reliability in all years for agricultural water users, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Increased agricultural water supply reliability has the potential to increase the amount of land in agricultural production, which could result in the conversion of natural wildlife habitats. The increased water supply reliability also has the potential to cause changes in cropping patterns, such as from annual crops to orchards. The surface water could also be used to replace existing groundwater use, which would have no effect on wildlife habitats. The actual effect would vary by region depending on water availability and associated costs. However, modeling results show that the potential effects of increased water supply reliability would be small, and would not occur on a large enough scale to have a substantial adverse effect on wildlife habitats. Therefore, the increase in water supply reliability to agricultural water users associated with implementation of Alternative A would have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because increased agricultural water supply reliability has the potential to result in the conversion of natural wildlife habitats and to change cropping patterns, the increased reliability could result in decreased habitat suitability for wildlife species. However, modeling results show that the potential effects of increased water supply reliability would be small, and they would, therefore, not be expected to have a substantial adverse effect on wildlife. Therefore, the increase in water supply reliability to agricultural water users associated with implementation of Alternative A would have a **less-than-significant** impact on special-status terrestrial wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with the increased water supply reliability resulting from implementation of Alternative A. Therefore, there would be **no impact** to wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Modeling results show that the potential effects of increased water supply reliability to agricultural water users would be small, and they would, therefore, not be expected to have a substantial adverse effect on wildlife or wildlife habitat. Therefore, increased water supply reliability associated with implementation of Alternative A would not conflict with any HCPs, NCCPs, or local ordinances, and would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Municipal and Industrial Water Use

Operational modeling indicates that implementation of Alternative A would result in increased water supply reliability to municipal and industrial water users in Dry years, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Increased water supply reliability has the potential to accommodate population growth, which could result in the conversion of natural wildlife habitats to urban/disturbed habitat. However, water supply reliability would not be increased in all water year types, and the increased reliability during Dry years would not be expected to accommodate population growth. Therefore, increased water supply reliability for municipal and industrial water users during Dry years resulting from implementation of Alternative A would result in a **less-than-significant** impact to wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because increased water supply reliability for municipal and industrial use would not be expected to adversely affect wildlife habitat, it would not be expected to affect wildlife species. Therefore, increased municipal and industrial water supply reliability resulting from implementation of Alternative A would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with the increased water supply reliability resulting from implementation of Alternative A. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because increased water supply reliability for municipal and industrial use would not be expected to adversely affect wildlife or wildlife habitat, it would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Wildlife Refuge Water Use

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Level 4 water supply would benefit numerous wildlife species that use fresh emergent wetland habitat. Implementation of Alternative A would provide an alternate source of wildlife refuge water in some years, but would not increase its reliability. Therefore, the provision of an alternate source of wildlife refuge water supply would have **no impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because the provision of an alternate source of wildlife refuge water supply would have no impact on wildlife habitat, it would also be expected to have **no impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with the provision of an alternate source of wildlife refuge water supply. Therefore, there would be **no impact** to wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because the provision of an alternate source of wildlife refuge water supply would not affect wildlife or wildlife habitat, it would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

San Luis Reservoir

San Luis Reservoir experiences severe water level fluctuations. Operational modeling indicates that implementation of Alternative A would result in continued water level fluctuations at San Luis Reservoir, but the fluctuations would occur more often and could be more severe, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Severe water level fluctuations could adversely affect the wetland and riparian scrub vegetation that exists within the tributary drainages in the San Luis Reservoir drawdown zone. However, these patches of wetland and riparian vegetation are located in areas that have their own hydrology, and have historically been subjected to severe drawdowns. These habitat types would not be expected to be substantially adversely affected by continued fluctuations at an increased rate. Therefore, the increased fluctuations in water levels at San Luis Reservoir resulting from implementation of Alternative A would have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Severe water level fluctuations could affect the quality of wetland and riparian scrub vegetation that exists within the tributary drainages in the San Luis Reservoir drawdown zone. Fluctuations could also reduce habitat suitability for wildlife that rely on the reservoir as a drinking water source because they could have a longer distance to travel from the cover of vegetation to the water’s edge. Small mammals, reptiles, and amphibians would have an increased risk of predation as the distance from the annual grassland or blue oak woodland habitat to the water’s edge increases. However, alternate water sources exist in the streams, creeks, springs, and seeps surrounding the reservoir.

Severe water level fluctuations could also result in a reduction of the open water portion of the lacustrine habitat that may be used by avian species of special concern. However, these avian species, as well as the riparian-associated small mammals, reptiles, and amphibians, have historically been subjected to severe drawdowns at the reservoir and have adapted to those conditions. These species would not be expected to be substantially adversely affected by continued fluctuations at an increased rate. Therefore, the increased fluctuations in water levels at San Luis Reservoir resulting from implementation of Alternative A would have a **less-than-significant impact** on special-status terrestrial wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with the operational changes at San Luis Reservoir resulting from implementation of Alternative A. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated water level fluctuations at San Luis Reservoir resulting from implementation of Alternative A would be within the historical range of operation, and consequently, would not conflict with any HCPs, NCCPs, or local ordinances. Therefore, there would be **no impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

14.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake

Operational modeling indicates that implementation of Alternative A would provide operational flexibility to Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake, when compared to Existing Conditions and the No Project/No Action Alternative. Storage at these reservoirs would be improved in all months of all years, including during May through October in Dry and Critical year conditions. In other years, larger releases would be made to stabilize fall flow conditions. Seasonal and monthly improvements in storage would occur, when compared to Existing Conditions and the No Project/No Action Alternative. In addition to improved storage conditions, operational modeling indicates that these reservoirs would experience a reduced range of change in fluctuations, resulting in less severe drawdowns.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Frequent and severe drawdowns tend to favor the establishment of upland plant communities along the shoreline, rather than riparian vegetation. A reduction in the reservoir level fluctuations has the potential to allow the establishment of riparian habitat in these shoreline areas. Therefore, changes in operations at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake associated with implementation of Alternative A that would result in improved storage conditions and reduced water level fluctuations would have a **beneficial effect** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The lacustrine habitat of these reservoirs supports numerous species of terrestrial wildlife, including the special-status bald eagle. Nesting bald eagles have been documented along the edge of each of these reservoirs. Bald eagle productivity would decrease as water surface elevation would decrease, so changes in reservoir surface water elevation fluctuations have the potential to adversely affect this species. However, the improved storage and reduced reservoir level fluctuations at these reservoirs would increase habitat suitability for bald eagles. These operational improvements would also be beneficial to the lacustrine wildlife species that use open water habitat, as well as wildlife that depend on the reservoirs as a source of drinking water. Therefore, changes in operations at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake associated with implementation of Alternative A that would result in improved storage conditions and reduced water level fluctuations would have a **beneficial effect** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with improved storage conditions at these reservoirs. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime or storage conditions of Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake resulting from implementation of Alternative A would be within the historical range of operation, and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, and the Thermalito Complex

Whiskeytown Lake is expected to operate as it has historically as a regulating reservoir for flow coming through the Clear Creek Tunnel. Lewiston Lake, Keswick Reservoir, Lake Natoma, and the Thermalito Complex (which includes the Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay) are also expected to continue to operate, as they have historically, as regulating reservoirs for upstream reservoirs.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Changes in reservoir surface water elevation fluctuations have the potential to adversely affect surrounding wildlife habitats. However, because no change in operation is expected at any of these reservoirs as a result of implementation of Alternative A, the lacustrine and surrounding habitat types would not be affected. Therefore, there would be **no impact** to wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The lacustrine habitat of these reservoirs supports numerous species of terrestrial wildlife, including the special-status bald eagle. Nesting bald eagles have been documented along the edge of Lewiston Lake, Whiskeytown Lake, and the Thermalito Diversion Pool. Suitable giant garter snake habitat exists within portions of the Thermalito Forebay and Afterbay and in immediately adjacent areas. The Thermalito Afterbay also supports a mixed Clark's and western grebe nesting colony. Changes in reservoir surface water elevation fluctuations have the potential to adversely affect these species. However, because no change in operation is expected at any of these reservoirs as a result of implementation of Alternative A, and the habitat types that these species are associated with are not expected to be affected, there would be **no impact** to special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. Changes in reservoir surface water elevation fluctuations have the potential to adversely affect the Clark's and western grebe nesting colony. However, because no change in operation is expected at the Thermalito Afterbay as a result of implementation of Alternative A, there would be **no impact** to these nesting colonies, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with the operation of these reservoirs. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because no change in operation is expected at any of these reservoirs as a result of implementation of Alternative A, there would be no conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Trinity River

Operational modeling indicates that Trinity River flows would meet or exceed the Trinity River Record of Decision (ROD) requirements with implementation of Alternative A. Project operations could change the timing of flows through the Clear Creek Tunnel, but not the amount supplied. Modeling results show little change from the existing flow schedule, and the small amount of change would rarely occur.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Modifications to the existing flow regime could have an adverse effect on the montane and valley foothill riparian habitats along the Trinity River. However, because the ROD requirements would be met or exceeded, and implementation of Alternative A would result in occasional small changes to the existing flow schedule, these habitat types would not be expected to be substantially adversely affected. Therefore, changes to the flow regime of the Trinity River resulting from implementation of Alternative A would have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The montane and valley foothill riparian habitats along the Trinity River support numerous wildlife species, including the special-status bald eagle, osprey, and willow flycatcher. The nearshore portion of the riverine habitat also supports numerous wildlife species, including the special-status foothill yellow-legged frog. Modifications of the existing flow regime could have an adverse effect on these habitat types and their associated wildlife species. However, because the ROD requirements would be met or exceeded, and implementation of Alternative A would result in occasional small changes to the existing flow schedule, these habitat types would not be expected to be substantially adversely affected. Therefore, changes to the Trinity River flow regime resulting from implementation of Alternative A would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes in Trinity River flows resulting from implementation of Alternative A. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Trinity River resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Klamath River downstream of the Trinity River

Operational modeling indicates that implementation of Alternative A would not affect the Klamath River flow regime.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Montane and valley foothill riparian habitats are located along the lower Klamath River. Modifications of the existing flow regime could have an adverse effect on these habitat types. However, implementation of Alternative A would not change the existing flow regime of the Klamath River. Therefore, there would be **no impact** to wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The montane and valley foothill riparian habitats along the lower Klamath River support numerous wildlife species, including the special-status bald eagle and osprey. The nearshore portion of the riverine habitat also supports numerous wildlife species. Modifications of the existing flow regime could have an adverse effect on these wildlife species. However, implementation of Alternative A would not change the existing flow regime of the Klamath River. Therefore, there would be **no impact** to special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Implementation of Alternative A would not change the existing flow regime of the lower Klamath River. Therefore, there would be **no impact** to native resident or migratory wildlife species, or to wildlife nursery sites, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with operational effects to the Klamath River resulting from implementation of Alternative A. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because the flow regime of the Klamath River is not expected to be affected by implementation of Alternative A, wildlife or wildlife habitat would not be adversely affected. Consequently, there would be no conflict with any HCPs, NCCPs, or local ordinances, and would result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Spring Creek

Operational modeling was not performed for Spring Creek. Spring Creek runoff is diluted by flows from Whiskeytown Lake through the Spring Creek Tunnel before it enters the Sacramento River. Those flows are diluted again by releases from Keswick Reservoir once they enter the Sacramento River.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Implementation of Alternative A would not change operation of Whiskeytown Lake or Keswick Reservoir, and therefore, would not be expected to affect the released flows that dilute Spring Creek runoff. Because no change in the dilution of Spring Creek runoff is expected as a result of implementation of Alternative A, there would be **no impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because implementation of Alternative A would have no impact on Spring Creek wildlife habitat, it would not be expected to adversely affect the wildlife species associated with that habitat. Therefore, implementation of Alternative would have **no impact** on special-status wildlife species on Spring Creek, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with Spring Creek dilution flows. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because no change in operation is expected at Spring Creek as a result of implementation of Alternative A, there would be no conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, result in **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento River

Operational modeling indicates that Sacramento River flows would meet or exceed the OCAP Biological Opinion requirements with or without the Project. When compared to Existing Conditions and the No Project/No Action Alternative, Alternative A operations would result in changes to the flow regime upstream of the location of Project diversions as a result Project-related operational changes at Shasta Lake. Systematic changes in flows downstream of each of the Project diversions would occur as a result of the combination of Shasta Lake operational changes and the diversion of up to 5,900 cfs at the Project intakes when diversions occur.

Modeling results indicate that there would be no change in the frequency or severity of flood events, and consequently no large change in the movement of sediment or timing of scour events, because the modeling inputs purposely avoided effects to the Sacramento River from regulation and diversion when the flow is between 15,000 and 25,000 cfs. For the Sacramento River upstream of the Project diversions, implementation of Alternative A would result in stage fluctuations of approximately -0.6 to 0.5 feet using the Bend Bridge location as the indicator, when compared to Existing Conditions and the No Project/No Action Alternative. September flows would vary in the amount of increases. Downstream of Project diversions, July and August flow changes would be negligible. Using Wilkins Slough as an indicator for this reach, there would be changes in the stage of approximately -2.3 to 2.8 feet if Alternative A is implemented, when compared to Existing Conditions and the No Project/No Action Alternative. The reduction in stage would mainly occur in the winter and spring months, when the water would be diverted from the Sacramento River to Sites Reservoir; higher stage values would occur in the summer and fall months because of the releases from the Sites Reservoir to the river. Fall flows from Shasta Lake to Project intakes would decrease, but Project releases would stabilize fall flows downstream of the intakes, especially in Dry years.

Modeling performed using SRH-1DV and SacEFT indicates that the coverage of the valley foothill riparian vegetation alliance along the Sacramento River would increase or would remain similar with implementation of Alternative A relative to Existing Conditions and the No Project/No Action Alternative. For bank swallows, SacEFT modeling indicates negligible effects resulting from peak flow during nesting season and a slight decrease in habitat potential and suitability with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Valley foothill riparian and backwater habitats are located along the Sacramento River. Modifications to the existing flow regime could alter the formation of off-channel habitats. New off-channel habitat is created during large fall and winter flow events, and existing off-channel backwater areas can fill in with sediment and vegetation if these flow events do not occur. However, modeling results indicate that the timing and magnitude of flood events, and consequently the conditions required for creating and maintaining these backwater habitats, would not be expected to change with implementation of Alternative A. Modifications to the existing flow regime could also affect the establishment of riparian habitat, or reduce the survival rate of early successional stages of riparian habitat that already exist. Elderberry shrubs are associated with riparian habitat, but are typically located higher up the slope of the bank rather than at the water’s edge. An increase in river stage has the potential to cause inundation of some shrubs. However, the shrubs likely to be affected are already subjected to seasonal inundation, and the minor increase in river stage during the winter months would be within the historical range of conditions. Operational modeling for Alternative A, including modeling that is specific to riparian habitat, indicates a minimal effect to riparian habitat resulting from the described changes in the flow regime. Therefore, elderberry shrubs are not likely to be adversely affected. Similarly, riparian habitat in general would not be expected to be adversely affected.

It should be noted that although modeling results indicate that there would be only slight changes to backwater or riparian habitat when compared to Existing Conditions or the No Project/No Action Alternative, Existing Conditions is not necessarily good for these species. Implementation of Alternative A is not expected to make these conditions worse, but also is not expected to improve them. Therefore, the impact of modifications of the existing flow regime of the Sacramento River resulting from implementation of Alternative A would have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The Sacramento River's backwater habitats support the western pond turtle, and are included in a recovery unit for the giant garter snake. The river's riparian habitat, which includes elderberry shrubs essential to the survival of the valley elderberry longhorn beetle, is known to support osprey, ringtail, and nesting bald eagles and western yellow-billed cuckoos. The largest known breeding population of bank swallows in California nests along the river. Riparian habitat along the Sacramento River may also support Swainson's hawks, long-eared owls, several special-status bat and songbird species, as well as willow flycatchers during migration. Modifications to the existing flow regime of the Sacramento River could have substantial adverse effects on these species.

Modifications to the existing flow regime could alter the formation of off-channel habitats, which could affect the western pond turtle and giant garter snake. However, modeling results indicate that the timing and magnitude of flood events, and consequently the conditions required for creating and maintaining these backwater habitats, would not be expected to change with implementation of Alternative A. Western pond turtles could also be affected by a rise in river stage during the breeding season, which could inundate eggs. Modeling results show, at most, a 4 to 6 inch increase in river stage during June, and minimal change in July or August. Because western pond turtles typically build nests away from the water's edge, an increase of 4 to 6 inches would not be expected to have a substantially adverse effect on this species.

Modifications to the existing flow regime could also affect the establishment of riparian habitat, or reduce the survival rate of early successional stages of riparian habitat that already exist, which in turn could adversely affect riparian-associated species. However, modeling that is specific to riparian habitat indicates a minimal effect to riparian habitat resulting from the described changes in the flow regime associated with implementation of Alternative A. Therefore, the special-status birds and mammals associated with riparian habitat would not be expected to be adversely affected.

Changes in the existing flow regime could result in changes to the frequency of the high flows required to cause sloughing of river banks, which are used by bank swallows, or could result in higher spring flows that have the potential to inundate nesting bank swallows. Modeling results indicate that that there would be no change in the frequency or severity of flood events, and up to a 2 to 4 inch increase in river stage with implementation of Alternative A. Therefore, minimal effects to bank swallow habitat are expected. River stage in June would be increased 4 to 6 inches; this stage increase would be unlikely to inundate bank swallow nests, as the lowest nests are typically located a greater distance from the water level. There would not be an increase in high flows that could cause nest failure. SacEFT modeling specific to the bank swallow indicates that there would be minimal effects to this species.

It should be noted that, although modeling results indicate that there would be only minimal change to backwater habitat and its associated wildlife species, to riparian habitat and its associated wildlife species, or to bank swallows and their habitat requirements associated with Alternative A, when compared to Existing Conditions or the No Project/No Action Alternative, Existing Conditions are not necessarily good for these species. Implementation of Alternative A is not expected to make these conditions worse, but also is not expected to improve them. Therefore, the impact of modifications of the existing flow regime of the Sacramento River resulting from implementation of Alternative A would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes to the Sacramento River flow regime. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Sacramento River resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Pump Installation at the Red Bluff Pumping Plant

The installation of the pump would occur within an existing bay at the existing Red Bluff Pumping Plant. The construction activities associated with installing a pump at the existing pumping plant, which would require the use of a crane, are expected to occur along existing construction or access roads. Dewatering of the afterbay would likely be required, and would occur during regularly scheduled maintenance periods or during the non-irrigation season.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Installation of the pump at the existing pumping plant is not expected to involve any ground-disturbing activity, and therefore, would not result in a loss or alteration in habitat suitability. There would, therefore, be **no impact** to wildlife habitat associate with construction activities at the Red Bluff Pumping Plant, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of the additional pump could increase the rate of diversion from the Sacramento River by up to 250 cfs. This small increase would not be expected to adversely affect wildlife habitat downstream of the diversion. Therefore, the modification of the existing flow regime resulting from the operation of an additional pump at the Red Bluff Pumping Plant with implementation of Alternative A would have a

less-than-significant impact on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of the additional pump could increase the amount of sediment that requires removal. However, sediment removal would occur during the regularly scheduled maintenance period for the canal and would involve the same maintenance activities conducted for Existing Conditions. Maintenance associated with the installation of a pump into an existing pumping plant would, therefore, have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Because pump installation, operation, and maintenance at the Red Bluff Pumping Plant would not be expected to adversely affect wildlife habitat, it would also not be expected to affect the special-status wildlife species associated with those habitat types. Therefore, installation of a pump at the Red Bluff Pumping Plant would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife may be directly or indirectly affected by the installation, operation, and maintenance of the additional pump. Construction activities, as well as maintenance activities associated with sediment removal, would include the use of heavy equipment, which could lead to increased disturbance to wildlife from noise. Pump operation could result in increased noise levels that may adversely affect wildlife. However, the addition of one pump would not be expected to impact wildlife above the existing level of disturbance already present from operation and maintenance of the other pumps in the pumping plant bay. Therefore, the human disturbance associated with installation and maintenance of this pump would be expected to have a **less-than-significant impact** on wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

The installation of an additional pump into an existing pumping plant bay that already has several pumps in it, associated with implementation of Alternative A, would not adversely affect wildlife or wildlife habitat, and consequently would not conflict with any HCPs, NCCPs, or local ordinances. There would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Clear Creek

Operational modeling indicates that Clear Creek flow requirements would be met or exceeded in all scenarios. With implementation of Alternative A, Clear Creek would have cooler temperatures resulting from the cooler temperatures in Whiskeytown Lake in Dry and Critical years.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Valley foothill riparian habitat is located along Lower Clear Creek. Modifications to the Clear Creek flow regime could have adverse effects on this habitat type. However, implementation of Alternative A would not change the existing flow regime of Clear Creek, and therefore, would have **no impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The valley foothill riparian habitat along Lower Clear Creek supports numerous terrestrial wildlife species, including the foothill yellow-legged frog. Bank swallows and willow flycatchers have been observed foraging over the riverine and adjacent habitats, and some bank swallow nesting has been documented. Modifications to the flow regime of Clear Creek could have adverse effects on these species. However, Implementation of Alternative A would not change the existing Clear Creek flow regime, and therefore, would have **no impact** to special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime of Clear Creek. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Implementation of Alternative A would not affect the Clear Creek flow regime and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Feather River

Operational modeling indicates that Feather River flows would meet or exceed the FERC Settlement Agreement's minimum flow requirements in all scenarios. The operational flexibility provided by implementation of Alternative A would result in a Feather River flow regime that would be less reactive to Delta conditions during summer and fall months. Consequently, when compared to Existing Conditions and the No Project/Action Alternative, flows in June through September in drier years would be improved. However, flows would generally be decreased during October, November, and December.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Valley foothill riparian and backwater habitats exist along the Feather River. Modifications to the existing flow regime have the potential to adversely affect these habitat types. However, implementation of Alternative A would allow the river to return to a flow regime that is more stable during summer and fall months. The higher flows that are released during summer months in Existing Conditions to improve Delta conditions have the potential to scour or inundate riparian habitat. Lower and more stabilized flows would reduce these risks. The lower summer flows associated with implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian habitat, and could be beneficial in drier years when flows would be higher than Existing Conditions or the No Project/No Action Alternative. The reduced summer flows would also not be likely to adversely affect the hydrology of backwater habitats. Because the modification of the existing flow regime of the Feather River resulting from implementation of Alternative A would not be expected to adversely affect riparian habitat, and would not be expected to reduce the habitat suitability of the riverine or backwater habitats, this change would have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The riverine and valley foothill riparian habitats of the Feather River support numerous species of terrestrial wildlife, including special-status species. Giant garter snakes exist in isolated backwater habitats, and the river is included in a portion of an identified recovery unit for this species. Bald eagles, Swainson's hawks, and bank swallows have been documented nesting along this river, and the western yellow-billed cuckoo has historically bred on the lower river. The riparian habitat also supports the State fully-protected ringtail and western pond turtles. Modifications to the existing flow regime have the potential to adversely affect these species. However, implementation of Alternative A would return the river to a flow regime that is more stable during summer and fall months. The higher flows that are released during summer months in Existing Conditions to improve Delta conditions have the potential to scour or inundate riparian habitat, as well as inundate portions of bank swallow colonies. Lower and more stabilized flows would reduce these risks. The lower summer flows associated with implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian habitat; consequently, riparian-associated species would not be expected to be adversely affected. The reduced summer flows would also not be likely to adversely affect the hydrology of backwater habitats used by the giant garter snake, and the resulting reduction in the velocity and temperature of the river flows could be beneficial to this species. Because the modification of the existing flow regime of the Feather River resulting from implementation of Alternative A would not be expected to adversely affect riparian habitat or riparian-associated species, and would not be expected to reduce the habitat suitability of the riverine or backwater habitats, this change would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

The valley foothill riparian habitat of the Feather River supports at least two large mixed heron/egret rookeries. Modifications to the existing flow regime have the potential to adversely affect these rookeries. However, the lower summer flows associated with implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian habitat, and could be beneficial in drier years when flows would be higher than Existing Conditions or the No Project/No Action Alternative. Consequently, these riparian-associated species would not be expected to be adversely affected. Because the modification of the existing flow regime of the Feather River resulting from implementation of Alternative A would not be expected to adversely affect riparian habitat or riparian-associated species, this change would have a **less-than-significant impact** on the mixed heron/egret rookeries, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated modification of the flow regime of the Feather River. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Feather River resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sutter Bypass

Implementation of Alternative A would result in the diversion of up to 5,900 cfs during winter flows. These diversions would occur at the T-C, GCID, and Delevan intake structures, all of which are located upstream of, and therefore would affect the hydrology of, the Sutter Bypass. The spills into the Bypass would consequently be reduced by up to 5,900 cfs, which would reduce the velocity and volume of water entering the Bypass, and could delay the point at which the weirs begin to spill.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Riparian and wetland habitats exist within the Sutter Bypass. Modifications of the existing flow regime of the Sutter Bypass could adversely affect these habitat types. The Sutter Bypass has water flowing through it year round. A reduction of the frequency, velocity, and volume of floodwaters entering the Bypass from the Sacramento River as a result of implementation of Alternative A would reduce the amount of flooding, which could impact wetland and riparian habitat by reducing the duration of inundation. However, the riparian and wetland habitats within the bypass are adapted to various degrees of inundation. Therefore, the modification of the existing flow regime of the Sutter Bypass that would result in reduced frequency, velocity, and volume of floodwaters entering the Bypass as a result of implementing Alternative A would be relatively minor and would have a **less-than-significant impact** on riparian and wetland habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Approximately 80 percent of the Sutter NWR is located in the Sutter Bypass. The agricultural, riparian, and wetland habitats within the Sutter Bypass support numerous species of terrestrial wildlife, including a large mixed heron and egret rookery and the special-status giant garter snake, Swainson’s hawk, white-tailed kite, bald eagle, western yellow-billed cuckoo, American white pelican, redhead, least bittern, western pond turtle, and State fully-protected ringtail. The open water habitat created during flooding can provide a similar value to migratory waterbirds as permanent wetlands. The flooding that occurs during high flow events can create deep water suitable for diving ducks. Raptor species forage in recently flooded areas. If the flooding is not substantial, low water levels provide shallow water habitat, which is valuable to wintering dabbling ducks, shorebirds, and wading birds. Modifications of the existing flow regime of the Sutter Bypass could adversely affect these species.

The Sutter Bypass has water flowing through it year round. A reduction of the frequency, velocity, and volume of floodwaters entering the Bypass from the Sacramento River as a result of implementation of Alternative A would reduce the amount of flooding that the refuge experiences, which at times can be up to 12 feet deep. This reduction in the frequency, velocity, and volume of water could benefit small mammals, reptiles, and amphibians because they would have an increased chance of reaching flood refugia before inundation. Therefore, the modification of the existing flow regime of the Sutter Bypass, although relatively minor, would result in reduced velocity and volume of floodwaters entering the Bypass as a result of implementing Alternative A, and would have a **potentially beneficial effect** to special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

The riparian habitat within the Sutter Bypass supports a large mixed heron and egret rookery. Because the relatively minor modification of the existing flow regime of the Sutter Bypass resulting from implementation of Alternative A would not be expected to have an adverse effect on riparian habitat or loss of the nesting colony, the change in flow regime would have a **less-than-significant impact** on the heron and egret rookery, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime of the Sutter Bypass. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Sutter Bypass resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Yolo Bypass

Operational modeling for Alternative A indicates that that there would be a minor reduction in the duration and magnitude of flows entering into the Yolo Bypass.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Riparian and wetland habitats exist within the Yolo Bypass. As floodwaters recede, mudflats are created and smaller areas of open water habitat may remain in the Bypass. A reduction of the frequency, velocity, and volume of floodwaters entering the Bypass as a result of implementation of Alternative A would reduce the amount of flooding, which could impact wetland and riparian habitat by reducing the duration of inundation. However, the riparian and wetland habitats within the bypass are adapted to various degrees of inundation. Therefore, the modification of the existing flow regime of the Yolo Bypass that would result in minor reductions in velocity and volume of floodwaters entering the Bypass as a result of implementation of Alternative A would have a **less-than-significant impact** on riparian and wetland habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The Yolo Bypass includes the Yolo WA. The agricultural, riparian, and wetland habitats within the Yolo Bypass support numerous species of terrestrial wildlife, including the special-status western pond turtle, American white pelican, bald eagle, Swainson's hawk, and greater sandhill crane. When the Bypass floods, the receding water creates mudflats that are used by many shorebird species. After floodwaters recede, smaller areas of open water habitat may remain in the Bypass that has the potential to support foraging waterbirds and raptors, as well as the western pond turtle. A minor reduction of the frequency, velocity, and volume of floodwaters entering the Bypass as a result of implementation of Alternative A would reduce the amount of flooding, which could impact wetland and riparian habitat by reducing the duration of inundation, and consequently impact the special-status species that use these habitat types. However, the riparian and wetland habitats within the bypass are adapted to various degrees of inundation. Therefore, the modification of the existing flow regime of the Yolo Bypass that would result in reduced velocity and volume of floodwaters entering the Bypass as a result of implementing Alternative A would have a **less-than-significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. The modification of the existing flow regime of the Yolo Bypass that would result in reduced velocity and volume of floodwaters entering the Bypass as a result of implementing Alternative A would have a **less-than-significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime of the Yolo Bypass. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Yolo Bypass resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

American River

Operational modeling indicates that implementation of Alternative A would have effects on the American River that are similar to those described for the Feather River. The operational flexibility provided by implementation of Alternative A would result in an American River flow regime that would be more consistent with hydrologic conditions, rather than reactive to Delta conditions. Consequently, when compared to Existing Conditions and the No Project/No Action Alternative, flows would generally be decreased during June through September with the largest reductions in July. However, when compared to the No Project/No Action Alternative, flows would be improved from June through September in drier years.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Valley foothill riparian and backwater habitats exist along the American River. Modifications to the existing flow regime have the potential to adversely affect these habitat types. However, implementation of Alternative A would return the river to a flow regime that is more stable during summer months. The higher flows that are released during summer months in Existing Conditions to improve Delta conditions have the potential to scour or inundate riparian habitat. Lower and more stabilized flows would reduce these risks. The lower and more stable summer flows resulting from implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian habitat, and could be beneficial in drier years from June through September when flows would be higher than the No Project/No Action Alternative. The reduced summer flows would also not be likely to adversely affect the hydrology of backwater habitats. Modification of the existing flow regime in the American River resulting from implementation of Alternative A would not be expected to adversely affect riparian habitat or reduce the habitat suitability of the riverine or backwater habitats, and would, therefore, have a **less-than-significant impact** on these wildlife habitats, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The riverine and valley foothill riparian habitats of the American River support numerous species of terrestrial wildlife, including special-status species. Giant garter snakes exist in backwater habitats, and the river is included in a portion of an identified recovery unit for this species. Western pond turtles and nesting bank swallows have been documented along this river. Modifications to the existing flow regime have the potential to adversely affect these species. However, implementation of Alternative A would return the river to a flow regime that is more stable during summer months. The higher flows that are released during summer months in Existing Conditions to improve Delta conditions have the potential to scour or inundate riparian habitat, as well as inundate portions of bank swallow colonies. Lower and more stabilized flows would reduce these risks. The lower summer flows resulting from implementation of Alternative A would not be likely to have a substantial adverse effect on established riparian habitat, and could be beneficial in dire years from June through September when flows would be higher than the No Project/No Action Alternative. Consequently, riparian-associated species would not be expected to be adversely affected. The reduced summer flows would also not be likely to adversely affect the hydrology of backwater habitats used by the giant garter snake, and the resulting reduction in the velocity and temperature of the summer river flows could be beneficial to this species. Because the modification of the existing flow regime in the American River resulting from implementation of Alternative A would not be expected to adversely affect riparian habitat or riparian-associated species, and would not be expected to reduce the habitat suitability of the riverine or backwater habitats, this change would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with flow regime changes on the American River. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the American River resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento-San Joaquin Delta

Operational modeling indicates that implementation of Alternative A would result in a flow reduction in the Delta in December and January, resulting in a 1 to 2 km shift in the position of X2. However, this shift would occur during Wet months when the X2 position is well within compliance of salinity standards for the Delta, and would, therefore, be within the recorded range of salinity tolerance for species present in the Delta. Modeling also indicates an improvement in salinity conditions in August through October, and increased inflows into the Delta during Critical years.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

The Sacramento-San Joaquin Delta contains sloughs, emergent wetlands, and saline wetlands. Modifications to the existing flow regime of the Delta could adversely affect these habitat types. However, because the modification of the flow regime associated with implementation of Alternative A would result in a shift in X2 that would be within the historical range of tolerance of these habitats, and because salinity conditions would be improved in August through October, as well as in Critical years, there would be a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The Sacramento-San Joaquin Delta supports numerous wildlife species, including the special-status giant garter snake in the vicinity of Sherman Island, bank swallows along Seven-Mile and Three-Mile sloughs, the California black rail, the greater sandhill crane in emergent wetlands, and the salt marsh harvest mouse in saline wetlands. Modifications to the existing flow regime of the Delta could adversely affect these species. However, because the modification of the flow regime associated with implementation of Alternative A would result in a shift in X2 that would be within the historical range of tolerance of these species, and because salinity conditions would be improved in August through October, as well as in Critical years, there would be a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with flow regime changes in the Delta. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of the Delta resulting from implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Suisun Bay

Operational modeling indicates that the diversions associated with implementation of Alternative A would increase electrical conductivity (EC), which is a measure of changes in salinity, in the Suisun Marsh in December. However, in Existing Conditions and the No Project/No Action Alternative, EC would be very low in December and the substantial increase in EC associated with Project operation would be within the historic range of species tolerance.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Suisun Bay and Marsh contains saline emergent wetlands. Modifications to the existing flow regime of the bay and marsh could adversely affect this habitat type. However, because the modification of the flow regime associated with implementation of Alternative A would result in an increase in EC that would be within the historic range of tolerance of this habitat type, there would be a **less-than-significant impact** on saline emergent wetlands, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Suisun Bay and Marsh support numerous wildlife species, including the special-status California clapper rail, California black rail, and the salt marsh harvest mouse. The majority of breeding California black rails is found in Suisun Marsh. Modifications to the existing flow regime of the bay and marsh could adversely affect these species. However, because the modification of the flow regime associated with implementation of Alternative A would result in an increase in EC that would be within the historic range of tolerance of these species, there would be a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes to the Suisun Marsh flow regime. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Anticipated changes to the flow regime of Suisun Bay associated with implementation of Alternative A would be within the historical range of operation and would not adversely affect wildlife or wildlife habitat. Consequently, these changes would not conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, have no impact, when compared to Existing Conditions and the No Project/No Action Alternative.

San Pablo Bay and San Francisco Bay

Implementation of Alternative A is not expected to affect the hydrology of San Pablo and San Francisco bays.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

San Pablo and San Francisco bays contain saline emergent wetlands. Modifications of the existing flow regime of these bays could adversely affect this habitat type. However, because no effect to the bays' hydrology is expected from implementation of Alternative A, there would be **no impact** to saline emergent wetlands, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

San Pablo and San Francisco bays support numerous wildlife species, including the special-status California clapper rail, California black rail, and salt-marsh harvest mouse. Modifications of the existing flow regime of these bays could adversely affect these species. However, because no effect due to implementation of Alternative A is expected within San Pablo or San Francisco bays, there would be **no impact** to special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

No Project-related human disturbance would be associated with changes to the flow regime of San Pablo and San Francisco bays. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Because implementation of Alternative A is not expected to affect the flow regime of San Pablo and San Francisco bays, there would be no conflict with any HCPs, NCCPs, or local ordinances, and would, therefore, be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

14.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Sites Reservoir Inundation Area and Sites Reservoir Dams

The construction of a 1.27-MAF Sites Reservoir requires the construction of Sites Dam, Golden Gate Dam, and seven saddle dams. Construction-related ground-disturbing activities, vegetation removal, and the subsequent filling of the reservoir, would result in the direct and permanent loss of wildlife habitats, or the direct conversion of wildlife habitats to lacustrine habitat (Table 14-7).

Table 14-7
Acres of Wildlife Habitat Subject to Direct Permanent Loss from the Construction and Filling of the 1.27-MAF Sites Reservoir and Associated Dams: Alternative A

Habitat	Permanent Loss (Acres)
Annual grassland	11,654.6
Blue oak woodland	353.5
Dryland grain and seed crops	206.9
Lacustrine	20.2
Pasture	61.0
Urban/disturbed	76.1
Valley foothill riparian	81.5
Valley oak woodland	3.4
TOTAL	**12,457.2**

In addition to the permanent loss of habitat, there would also be temporary disturbance of habitat associated with a construction disturbance area outside of the reservoir footprint. The construction disturbance area would be located on the northeast side of the reservoir in the vicinity of the proposed

Sites and Golden Gate dams, and could disturb as much as 1,000 acres of land. Disturbed areas would be restored to their original habitat type after construction is complete. The majority of wildlife habitat that would be disturbed in that area is annual grassland habitat, but disturbance of valley foothill riparian habitat could also occur.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland

Annual grassland habitat within the proposed footprint of Sites Reservoir and its dams provides foraging habitat for special-status species, such as the loggerhead shrike, northern harrier, tri-colored blackbird, and pallid bat. Annual grassland also provides burrowing and foraging habitat for the burrowing owl and American badger, and wintering habitat for the ferruginous hawk and prairie falcon. Annual grassland provides potential habitat for the western spadefoot, which was observed southwest of the reservoir footprint, but not within the footprint itself. Along the annual grassland/blue oak woodland edge, annual grassland provides foraging habitat for the golden eagle, long-eared owl, and white-tailed kite. The vernal pools within annual grassland provide foraging habitat for the long-billed curlew. Annual grassland also provides habitat for numerous general wildlife species. In the vicinity of Golden Gate Dam and within the potential construction disturbance area, there are two elderberry shrubs in the middle of annual grassland habitat. The permanent loss of 11,654.6 acres and the additional temporary disturbance of up to 1,000 acres of annual grassland habitat, resulting from the construction activities and filling of the reservoir associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Blue Oak Woodland

Blue oak woodland habitat within the proposed footprint of Sites Reservoir and its dams provides nesting and foraging habitat for special-status species, such as the golden eagle, Lawrence’s goldfinch, long-eared owl, and white-tailed kite, and wintering habitat for the prairie falcon. Blue oak woodland also provides roosting and foraging habitat for the pallid bat and western red bat, as well as burrowing and foraging habitat for American badger. Blue oak woodland also provides habitat for numerous general wildlife species. The permanent loss of 353.5 acres of blue oak woodland habitat resulting from the construction activities and filling of the reservoir associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Dryland Grain and Seed Crops

Dryland grain and seed crops habitat within the proposed footprint of Sites Reservoir and its dams may provide habitat for many species of rodents and birds that have adapted to this annual crop, and hawks, owls, and other predators that feed on the rodents, including the northern harrier. The permanent loss of 206.9 acres of dryland grain and seed crops habitat resulting from the construction activities and filling of the reservoir associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lacustrine

The 20.2 acres of existing lacustrine habitat within the proposed reservoir footprint consists of man-made ephemeral stock ponds. The filling of Sites Reservoir would replace these stock ponds with more than

12,000 acres of lacustrine habitat. The new reservoir would create shoreline and shallow water habitat, as well as open water habitat. The increase in open water habitat associated with implementation of Alternative A would have a **potentially beneficial effect** on many common avian species by providing winter rafting habitat, when compared to Existing Conditions and the No Project/No Action Alternative. This habitat type could also create nesting opportunities for a few of these species (Table 14-8). In addition, the reservoir could provide foraging habitat for bats.

Table 14-8
Avian Species Expected to Benefit from an Increase in Open Water Habitat within the Sites Reservoir Inundation Area

American coot	Cinnamon teal	Great blue heron*	Northern shoveler
American white pelican	Clark's grebe	Great egret	Osprey
American wigeon	Cliff swallow*	Greater scaup	Peregrine falcon
Bald eagle*	Common goldeneye	Green-winged teal	Pied-billed grebe
Barrow's goldeneye	Common loon	Herring gull	Redhead
Blue-winged teal	Common merganser*	Hooded merganser	Ring-billed gull
Bufflehead	Double-crested cormorant	Horned grebe	Ring-necked duck
California gull	Eared grebe	Killdeer*	Rock pigeon*
Canada goose	Eurasian wigeon	Lesser scaup	Ruddy duck
Canvasback	Forster's tern	Mallard	Spotted sandpiper
Caspian tern	Gadwall	Northern pintail	Western grebe

*Potential nesting opportunity for these species.

After filling, Sites Reservoir would be operated in a way that would cause frequent and often times severe drawdowns. The fluctuation of surface water elevation could impact wildlife that use the reservoir as a drinking source, as they would have to travel farther from the cover of adjacent habitat to reach the water. This increased travel distance can increase the risk of predation, especially for small mammals, reptiles, and amphibians. However, terrestrial wildlife within the area currently does not have access to a large permanent water source. Water sources around the rim of the proposed reservoir include seasonal wetlands, ephemeral streams, and stock ponds. Most stock ponds do not have year-round water. Wildlife could continue to use these existing water sources when the reservoir is drawn down. Therefore, the fluctuations of surface water elevations during operation of Sites Reservoir associated with implementation of Alternative A would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Pasture

Pasture habitat within the proposed footprint of Sites Reservoir and its dams provides potential wintering habitat for the special-status ferruginous hawk. When it is not overgrazed, pasture also provides potential habitat for ground-nesting birds and numerous general wildlife species. The permanent loss of 20.2 acres of pasture habitat resulting from construction activities and filling of the reservoir associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the footprint of Sites Reservoir and its dams provides marginal habitat for common wildlife species, including numerous non-native species. However, existing structures located within urban/disturbed habitat within the Sites Reservoir footprint provide roosting habitat for bats, including a pallid bat maternity colony observed during field surveys. The demolition of these structures would adversely affect the maternity colony if demolition occurs before young are weaned and would adversely affect all roosting bat species if they are not excluded prior to demolition.

Therefore, the permanent loss of 76.1 acres of urban/disturbed habitat resulting from the construction activities and filling of the reservoir associated with implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Foothill Riparian Habitat

Valley foothill riparian habitat within the proposed footprint of Sites Reservoir and its dams provides nesting and foraging habitat for special-status species, such as the bald eagle, long-eared owl, and yellow warbler, and provides roosting and foraging habitat for the western red bat. Valley foothill riparian also provides habitat for the western pond turtle, and potential habitat for the Swainson's hawk, which was observed adjacent to, but outside of, the footprint. When elderberry shrubs are present, valley foothill riparian provides habitat for the valley elderberry longhorn beetle. Valley foothill riparian also provides habitat for numerous general wildlife species. The permanent loss of 81.5 acres and the potential temporary disturbance of additional acreage of valley foothill riparian habitat, resulting from the construction activities and filling of the reservoir associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Valley Oak Woodland Habitat

Valley oak woodland habitat within the proposed footprint of Sites Reservoir and its dams has the potential to provide nesting and foraging habitat for special-status species, such as the Lewis' woodpecker, roosting and foraging habitat for the pallid bat and western red bat, and wintering habitat for the prairie falcon. Valley oak woodland provides burrowing and foraging habitat for the American badger, and potential habitat for the Swainson's hawk, which was observed in an area adjacent to the reservoir footprint, but not within the footprint. However, the valley oak woodland within the reservoir footprint represents a small isolated patch of marginal habitat. Therefore, the permanent loss of 3.4 acres of valley oak woodland habitat resulting from the construction activities and filling of the reservoir associated with implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Bald Eagle

Construction-related ground-disturbing activities and vegetation removal, and the subsequent filling of the proposed reservoir, would result in the direct and permanent loss of the valley foothill riparian habitat that is used as bald eagle nesting and foraging habitat. No nests occur within the proposed reservoir footprint, but the construction of Golden Gate Dam would result in the indirect take of an established bald eagle nest tree, which is located immediately adjacent to the footprint of the dam and within the construction disturbance area. Bald eagles tend to use the same nest for multiple years, and the nesting pair at this location has successfully reproduced in consecutive years. The disturbance or removal of this nest tree during the nesting season could result in the direct mortality of eggs or young, which would be a **significant impact**. If removed, the permanent loss of this nest tree would be a **significant impact** to bald eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

The conversion of valley foothill riparian habitat to lacustrine habitat as a result of filling of the reservoir would provide new foraging habitat and an increase in prey for bald eagles, and the lacustrine/blue oak woodland edge could provide new roosting habitat. However, during operation, recreational boating on the reservoir and its associated noise, as well as the noise and disturbance associated with campground use, could make potential nesting habitat unsuitable or result in nest abandonment. The disturbance to bald eagles caused by recreation activities would be a **potentially significant impact** to bald eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

Periodic maintenance activities, such as garbage removal, and maintenance of signs, culverts, and buoys, would not be expected to have a substantial adverse effect on bald eagles and would, therefore, have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Golden Eagle

Construction-related ground-disturbing activities and vegetation removal, and the subsequent filling of the proposed reservoir, would result in the direct and permanent loss of annual grassland, blue oak woodland, and valley oak woodland habitat that is used by the golden eagle as nesting and foraging habitat. Golden eagles were observed foraging within the proposed reservoir footprint. This foraging habitat would be converted to lacustrine habitat, which is not suitable foraging habitat for golden eagles. Therefore, the loss of foraging habitat would be a **potentially significant impact** to golden eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

Construction activities associated with the construction of Sites Dam could disturb an active golden eagle nest located adjacent to the construction footprint in Sites Canyon. Although the location of the nest does not have a direct line of sight to the dam construction disturbance area, and although the nest is already subject to traffic noise, construction activities associated with Sites Dam could have a **potentially significant impact** on these nesting golden eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation of the dam, the portion of the road that the nest is located along would be restricted to authorized vehicles only; public vehicle access would be eliminated. Operation- and maintenance-related traffic at the dam would have a **less-than-significant impact** on these nesting golden eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Elderberry Longhorn Beetle

Construction-related ground-disturbing activities and vegetation removal, and the subsequent filling of the proposed reservoir, would result in the direct and permanent loss of 672 elderberry stems. Valley elderberry longhorn beetle emergence holes were observed on 18 of the surveyed stems. Four elderberry shrubs, which were not surveyed for emergence holes, are located within the footprint of Sites Dam and would consequently experience direct loss during construction of the dam. Outside of the reservoir footprint, but within the potential construction disturbance area, two elderberry shrubs exist within the annual grassland. Emergence holes were documented on one of these shrubs. The permanent loss of these elderberry shrubs would be a **significant impact** to valley elderberry longhorn beetles, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Burrowing Owl

Construction-related ground-disturbing activities and vegetation removal, and the subsequent filling of the proposed reservoir, would result in the direct and permanent loss of annual grassland and blue oak woodland habitat. Burrowing owls were observed within the reservoir footprint at the annual grassland/blue oak woodland edge. These habitat types would be converted to lacustrine habitat, which is unsuitable habitat for burrowing owls. The conversion of these habitat types to lacustrine habitat would, therefore, have a **potentially significant impact** on burrowing owls, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Pond Turtle

Construction-related ground-disturbing activities and vegetation removal, and the subsequent filling of the proposed reservoir, would result in the direct and permanent loss of ponds and streams that are used by the western pond turtle. Pond turtles were observed within the reservoir footprint and at the Sites Dam site. This loss of habitat could adversely affect this species. In addition, construction activities and the subsequent filling of the reservoir could result in direct mortality to this species. During operation, the reservoir's lacustrine habitat has the potential to provide suitable pond turtle habitat along the shallow edges of the reservoir. However, the expected surface water elevation fluctuations associated with reservoir operation would reduce the potential habitat value and likely be unsuitable for this species. Therefore, the construction and operation of Sites Reservoir and Dams would have a **potentially significant impact** on western pond turtles, when compared to Existing Conditions and the No Project/No Action Alternative.

Because the reservoir's surface water elevation fluctuations would likely make the reservoir's lacustrine habitat unsuitable for pond turtles, the proposed maintenance activities (including law enforcement, garbage removal, and maintenance of signs, culverts, and buoys) would not be expected to have a substantial adverse effect on this species. Therefore, maintenance activities associated with Sites Reservoir and Dams would have a **less-than-significant impact** on western pond turtles, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion for impacts of dam construction on bald eagle nesting.

The proposed Sites Reservoir Inundation Area is used by a small resident deer herd. The herd makes small seasonal movements; it does not make large seasonal migrations to critical habitat areas. Construction activities within the reservoir footprint would not be expected to affect the movement of this herd. Construction activities at the dam sites would likely cause the herd to travel over the hillside rather than through the gap, but this change in travel route would not cause substantial interference to the herd's movements. Filling and operation of the reservoir would displace this herd into adjacent suitable habitat, and could restrict the herd's small seasonal movements. However, the deer herd would be able to travel around the rim of the reservoir, and could swim across the reservoir. Maintenance activities would not be expected to affect the movement of this herd. Therefore, the impact of interference to resident deer herd movement caused by the construction, operation, and maintenance of Sites Reservoir and Dams would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction and maintenance activities associated with the proposed Sites Reservoir and dams, as well as by recreation activities associated with reservoir operation. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Recreational use of the reservoir would include the use of watercraft such as powerboats, fishing boats, personal watercraft, and canoes. Watercrafts have been documented to adversely impact waterfowl, as they can cause disturbance of foraging and rafting activity. Boats can be a major cause of foraging disturbance for bald eagles. Human activities that are documented to cause disturbance to wildlife include power-boating and water skiing; wind surfing, rowing, and canoeing; wading and swimming; and activities along shorelines such as fishing, bird watching, and hiking. Disturbance of wildlife can result in increased energy expenditure during flight responses, displacement, and increased predation of eggs or young if nesting birds are flushed from their nests for an extended period of time. High-speed boating can also cause shoreline degradation, resulting in reduced habitat suitability for some species. Therefore, human disturbance associated with construction, maintenance, and recreation at Sites Reservoir and dams would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

The Primary Study Area is not included in any HCPs or NCCPs. The Colusa County Voluntary Oak Woodlands Management Plan provides guidelines for voluntary participation, and Project mitigation for oak woodlands would exceed those guidelines. Therefore, there would be no conflict with this plan, and consequently **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas and Associated Electrical Distribution Lines

The proposed Antelope Island, Lurline Headwaters, Stone Corral, Peninsula Hills, and Saddle Dam recreation areas all have a footprint that represents the total area within which land-based recreation could occur. However, only approximately 15 percent of each footprint would experience a permanent loss of habitat as a result of the construction of facilities, such as boat ramps, picnic areas, roads, restroom facilities, and campgrounds. The remainder of the acreage could experience impacts from activities that would occur during Project operation and maintenance, such as hiking, camping in undesignated areas, firewood collection, fuelbreak and vegetation maintenance, and off-road vehicle or mountain bike use. Three of the Recreation Areas would also have transmission lines associated with them, and the temporary construction disturbance area for the electrical distribution lines is included in addition to the recreation area footprint acreage. The total acreage of wildlife habitat within each recreation area is presented in Table 14-9.

Table 14-9
Permanent Wildlife Habitat Loss and Temporary Disturbance Due to the Construction of the Recreation Areas and Associated Electrical Distribution Lines: Alternative A

Habitat	Total Number of Acres Affected					TOTAL Disturbance	Permanent Loss[b]
	Saddle Dam[a]	Peninsula Hills[a]	Stone Corral	Antelope Island	Lurline Headwaters[a]		
Annual grassland	271.6	78.2	132.8	12.3	79.2	**574.1**	**86.1**
Blue oak woodland	0	301.3	102.3	36.9	156.2	**596.7**	**89.2**
Chamise-redshank chapparal	0	0			1.0	**1.0**	**0.2**
Lacustrine	1.2	0	0	0	0[c]	**1.2**	**0.2**
TOTAL	**272.8**	**379.5**	**235.1**	**49.2**	**236.4**	**1,173.0**	**175.7**

[a]Acreage includes construction disturbance area for associated electrical distribution line.
[b] Permanent loss is calculated as 15 percent of the total construction disturbance area.
[c]This facility has a small amount of lacustrine habitat, but the total amount is less than 0.1 acre.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland

Annual grassland habitat within the proposed footprint of each of the Recreation Areas does not contain vernal pools, but otherwise has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. However, the Saddle Dam Recreation Area contains seasonal wetlands that are considered to be part of the annual grassland habitat. The special-status long-billed curlew and tri-colored blackbird were observed using this habitat, and foraging golden eagles were observed. The potential disturbance of up to 574.1 acres and permanent loss of approximately 86 acres of annual grassland habitat resulting from construction and the recreation activities associated with the operation of the Alternative A Recreation Areas would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Blue Oak Woodland

Blue oak woodland habitat within the proposed footprint of four of the five Recreation Areas has similar value to wildlife as described in the impact assessment for Sites Reservoir and Dams, although portions of the blue oak woodland on Antelope Island and Lurline Headwaters have an understory of mixed chaparral. The special-status American badger and golden eagle were observed within this habitat. The potential disturbance of up to 596.7 acres and permanent loss of approximately 89 acres of blue oak woodland habitat resulting from construction and the recreation activities associated with operation of the Alternative A Recreation Areas would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Chamise-Redshank Chaparral

Chamise-redshank chaparral habitat is located within the construction disturbance area associated with the proposed Lurline Headwaters Recreation Area. This chaparral provides potential habitat for Bell's sage sparrow, which was observed west of the Sites Reservoir footprint. The construction disturbance area represents an area of potential temporary disturbance that would be returned to chaparral habitat after completion of the Project. Because of the above-ground nature of transmission line construction, impacts to this habitat could be avoided. The potential disturbance of up to 1.0 acre of chamise-redshank chaparral habitat resulting from transmission line construction activities associated with implementation of the Alternative A Recreation Areas would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lacustrine Habitat

The lacustrine habitat within the proposed footprint of two of the Recreation Areas is made up of man-made ephemeral stock ponds. The three ponds that exist within the footprint of the Saddle Dam Recreation Area are not located within an area designated for construction, but are spread out through the center of the recreation area footprint and could be subject to disturbance from recreation activities. The one pond that exists within the footprint of the Lurline Headwaters Recreation Area is located at the north edge of the recreation area footprint and is not located within an area designated for construction. The potential disturbance to the 1.2 acres of stock ponds could adversely impact terrestrial wildlife.

However, the inundation area of Sites Reservoir would be located immediately adjacent to these Recreation Areas, and implementation of Alternative A would provide over 12,000 acres of lacustrine habitat, including shoreline, shallow water, and open water habitat. The increase in adjacent lacustrine habitat could benefit the wildlife species that use these stock ponds. Therefore, the potential disturbance to these stock ponds resulting from recreation activities associated with operation of the Alternative A Recreation Areas would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Golden Eagle

The construction-related ground-disturbing activities, and the associated recreation activities that would occur during operation in the proposed Recreation Areas, would result in the direct and permanent loss or disturbance of annual grassland and blue oak woodland habitat that is used by golden eagles as nesting and foraging habitat. Golden eagles were observed foraging at the proposed Recreation Areas year round, and were observed nesting at Stone Corral, Lurline Headwaters, and Peninsula Hills recreation areas. The permanent loss or disturbance of annual grassland and blue oak woodland habitat resulting from construction and operation of the Recreation Areas would be a **significant impact** to golden eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

Nest tree removal during construction, and the potential disturbance to nesting golden eagles from recreation activities that would occur during Project operation, or from maintenance activities, could cause nest abandonment or direct mortality to eggs or young, and therefore, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion for the impacts of the Recreation Areas on nesting golden eagles.

Limited construction would occur within the proposed footprint of each recreation area. Permanent structures could include vault toilets, picnic tables, and boat ramps. Portions of the existing vegetation within the Recreation Areas could be cleared to provide hiking trails, campsites, and gravel parking areas. After construction is complete, it is possible that larger areas of disturbance, such as gravel parking lots or multiple-site campgrounds, could interfere with the movement of small mammals, reptiles, or amphibians due to the lack of vegetative cover. However, the surrounding native habitat would be preserved, and vegetation would be planted and maintained around these disturbed areas. These disturbed areas would not be expected to substantially interfere with the movement of resident wildlife species because those species would be able to travel around the areas of disturbance. Therefore, construction, operation, and maintenance of the Recreation Areas would have a **less-than-significant impact** on the movement of small mammals, reptiles, and amphibians, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, maintenance, and recreation activities associated with the proposed Recreation Areas. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Maintenance activities on roads, trails, and parking lots could involve grading or vegetation removal, which would involve the use of heavy equipment and cause increased disturbance from noise. Maintenance of the vault toilets would require large and noisy pumping trucks. Land-based recreation activities that occur outside of designated camping areas, hiking trails, or roads cause ground disturbance that could result in the loss of native vegetation and promote the establishment of non-native plant species, which can alter habitat suitability. The non-native landscaping that would be planted around campsites and parking areas, and the associated vegetation maintenance and weed control, including the potential use of herbicides, would alter habitat suitability. Recreational activity would result in the accumulation of garbage, which attracts non-native wildlife species and can increase human-wildlife conflicts. The availability of additional food can change the composition and population dynamics of native species, as more species such as raccoons, skunks, crows, and rodents would be attracted to the Recreation Areas. Reptiles and amphibians in and around the Recreation Areas could experience increased injury or mortality as a result of handling by humans. Unleashed dogs can also disturb, injure, or kill wildlife by flushing, chasing, or attacking. Dogs also have the potential to spread disease or parasites to other wildlife. Artificial nighttime lighting at the Recreation Areas could cause resident wildlife to avoid the area, and could adversely affect reptiles and amphibians that breed and forage nocturnally. Wildlife viewing and photography can disturb wildlife as a result of frequent encounters of a long duration and attempts to approach wildlife. The increased noise from human activity could disturb the special-status species that are found within the Recreation Areas, and could, for example, lead to golden eagle nest abandonment and the incidental loss of fertile eggs or young. The human disturbance associated with the construction, maintenance, and recreational use during Project operation of the Recreation Areas would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Road Relocations and South Bridge

Construction of the proposed road relocations would require a 100-foot-wide buffer on each side of the road, measured from the roadway centerline, which would result in the temporary disturbance of wildlife habitat. Disturbed areas would be restored to their original habitat type after construction is completed. The roads would be fenced on both sides, as most are now. The affected habitat types and total acreage impacted for each habitat type are listed in Table 14-10. Acreage for the proposed South Bridge is not included in this analysis because the bridge’s on-the-ground footprint (i.e., bridge piers) and its onstruction disturbance area would be within the footprint of Sites Reservoir; the acreage is, therefore, already accounted for in the permanent loss of habitat associated with the proposed reservoir.

Table 14-10
Permanent Wildlife Habitat Loss and Temporary Disturbance Due to the Construction of the Road Relocations and South Bridge: Alternative A

Habitat	Total Number of Acres Affected	Permanent Loss* (Acres)
Annual grassland	719.9	216.0
Blue oak woodland	195.8	58.7
Canal	0.6	0.2
Chamise-redshank chaparral	1.5	0.4
Dryland grain and seed crops	15.9	4.8
Lacustrine	0.5	0.2
Mixed chaparral	2.6	0.8
Urban/disturbed	9.7	2.9
Valley foothill riparian	4.2	1.3
TOTAL	**950.7**	**285.3**

*Permanent loss is calculated as 30 percent of the total construction disturbance area.

The permanent loss of wildlife habitat resulting from the proposed footprint of the roads and the required cut and fill would be approximately 285 acres. The majority of the habitat acreage affected by construction of the roads would be annual grassland habitat and blue oak woodland habitat.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland

Annual grassland habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The special-status long-billed curlew, prairie falcon, tri-colored blackbird, white-tailed kite, American badger, and pallid bat were observed within this habitat along the North Road and/or Southeast Road. The loggerhead shrike, white-tailed kite, golden eagle, northern harrier, tri-colored blackbird, and long-billed curlew were observed within this habitat type along the Eastside Road. The temporary disturbance of 719.9 acres, of which up to 285 acres could represent a permanent loss, of annual grassland habitat resulting from road construction activities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Blue Oak Woodland

Blue oak woodland habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The special-status Lewis' woodpecker, western red bat, and American badger were observed in this habitat along the North and/or Southeast Road. The temporary disturbance of 195.8 acres, all of which could represent a permanent loss, of blue oak woodland habitat resulting from road construction activities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Canal

The construction of a bridge would be required where the proposed footprint and construction disturbance area of the road relocations would cross existing canals. Because no loss of canal habitat or disturbance of the main channel of any canal would occur as a result of road construction associated with implementation of Alternative A, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Chamise-Redshank Chaparral

Chamise-redshank chaparral habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for the Recreation Areas. The temporary disturbance of 1.5 acres or potential permanent loss of chamise-redshank chaparral habitat, resulting from road construction activities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Dryland Grain and Seed Crops

Dryland grain and seed crops habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The special-status Swainson's hawk was observed foraging, and sandhill cranes were observed flying, over this habitat type along the Southeast Road. The temporary disturbance of 15.9 acres or potential permanent loss of dryland grain and seed crops habitat, resulting from road construction activities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lacustrine

The lacustrine habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for the Recreation Areas. The construction disturbance areas for Lurline Road and Com Road converge east of the Lurline Headwaters Recreation Area. At the point of convergence, the disturbance areas overlap with a pond that is located within blue oak woodland habitat. Several other stock ponds are located adjacent to, but outside of, the construction disturbance area of other road segments. The temporary disturbance of up to 0.5 acre of lacustrine habitat resulting from road construction activities associated with implementation of Alternative A would not be expected to adversely affect wildlife, and would, therefore, have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Mixed Chaparral

The mixed chaparral habitat within the proposed footprint and construction disturbance area of the road relocations has the potential to support numerous species of terrestrial wildlife, including Bell's sage sparrow, which was observed west of the Sites Reservoir footprint along a formerly proposed road route. The temporary disturbance of 2.6 acres or potential permanent loss of mixed chaparral habitat, resulting from road construction activities associated with implementation of Alternative A, would have a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. Although construction of the proposed South Bridge could provide roosting habitat for bats if niches are incorporated into the design, construction of the proposed roads could require the demolition of a few existing structures that may provide roosting habitat for bats. Therefore, the temporary disturbance of 9.7 acres or potential permanent loss of urban/disturbed habitat, resulting from road construction activities associated with implementation of Alternative A, would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Foothill Riparian

Valley foothill riparian habitat within the proposed footprint and construction disturbance area of the road relocations has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The special-status western pond turtle was observed within this habitat type along Stone Corral Creek. The temporary disturbance of 4.2 acres or potential permanent loss of valley foothill riparian habitat, resulting from road construction activities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Valley Elderberry Longhorn Beetle

There are more than 60 elderberry shrubs along Stone Corral Creek within 100 feet of Maxwell Sites Road, located approximately 0.5 to 0.75 mile northwest from the road's intersection with the proposed Eastside Road. There is also one shrub within 100 feet of the road located approximately 0.5 mile southeast of the same intersection. Although construction would not occur on Maxwell Sites Road, construction vehicles and equipment would use this road. The expected increase in recreational visitors to the area would also increase the use of this road. Traffic associated with maintenance activities is expected to be minimal, resulting in a **less-than-significant impact** on elderberry shrubs, when compared to Existing Conditions and the No Project/No Action Alternative.

The increase in construction and recreation traffic associated with construction and operation of Alternative A has the potential to adversely affect these elderberry shrubs by increasing the amount of dust in the area. Increased dust would have a **potentially significant impact** on elderberry shrubs, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Burrowing Owl

Construction-related ground-disturbing activities associated with the proposed road relocations would result in the permanent loss and temporary disturbance of annual grassland habitat. Burrowing owls were observed along the proposed North Road and Eastside Road in the vicinity of road cuts. Due to their proximity to the road, vehicle collisions with this species could increase due to increased recreation and maintenance traffic on existing and proposed new roads. The loss of annual grassland habitat during Project construction, as well as the increased traffic associated with operation and maintenance activities resulting from implementation of Alternative A, would be a **potentially significant impact** to burrowing owls, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion for the potential impact of roads on western burrowing owl movement.

In addition, construction of new roads can result in habitat fragmentation or reduced habitat connectivity. Improvement (such as from gravel to asphalt) or widening of existing roads can make it more difficult for small mammals, reptiles, or amphibians to cross them. However, each of the proposed new roads would be two-lane roads that, combined with their shoulders, are only approximately 60 feet wide. The roads would, therefore, not be expected to prohibit wildlife movement. Roadside fencing can also restrict wildlife movement. However, the fencing along existing roads and fencing that would be constructed along new roads consist of barbed wire fencing that does not obstruct the movement of these wildlife species. Construction of the roads associated with implementation of Alternative A would, therefore, have a **less-than-significant impact** on wildlife movement, when compared to Existing Conditions and the No Project/No Action Alternative.

Increased traffic associated with the operation and maintenance of the roads could result in increased mortality for individual wildlife species traveling across or basking on the roads. However, the mortality rate would not be expected to increase to a level that would adversely affect local populations. Therefore, the increased traffic associated with the operation and maintenance of the roads would have a **less-than-significant impact** on wildlife movement, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, operation, and maintenance of the roads and bridge. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting.

Road maintenance could include grading, vegetation removal, railing repairs, and repaving. Bridge maintenance activities could include safety inspections, redecking, and repainting. Many of these activities involve the use of heavy equipment and cause increased disturbance from noise. Depending on design, the completed bridge has the potential to support nesting birds and roosting bats, including the special-status pallid bat. Maintenance activities on the bridge have the potential to adversely affect these species, especially if it is conducted during the breeding season.

During Project operation, the bridge and portions of the roads would have permanent nighttime safety lighting. Bridge and road lighting could cause resident wildlife to avoid the area, and could adversely affect nocturnal wildlife such as bats, owls, and frogs. Project operation would result in increased traffic on the roads, as well as on the bridge in a location where traffic does not currently travel. Increased traffic could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Human disturbance associated with construction, operation, and maintenance of the South Bridge and roads would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Sites Pumping/Generating Plant, Sites Electrical Switchyard, Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

The construction of the proposed Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard would require ground-disturbing activities that would result in the direct and permanent loss of wildlife habitats (Table 14-11).

Table 14-11
Acres of Wildlife Habitat Subject to Direct and Permanent Habitat Loss from Construction of the Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard: Alternative A

Habitat	Permanent Loss (Acres)
Annual grassland	81.6
Lacustrine	0.2
Urban/disturbed	4.3
Valley foothill riparian	3.1
TOTAL	**89.2**

Additional acreage of temporary disturbance (9 acres) would occur as a result of a construction disturbance area for these proposed facilities. Disturbed areas would be restored to their original habitat type after construction is complete. The majority of wildlife habitat affected by these facilities and their construction disturbance areas would be annual grassland habitat.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland

Annual grassland within the proposed footprint of each of these facilities has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The permanent loss of 81.6 acres and the potential temporary disturbance of an additional 9 acres of annual grassland habitat, resulting from the construction of these facilities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lacustrine

The lacustrine habitat that is located within the proposed footprint of the Sites Reservoir Inlet/Outlet Structure consists of a man-made ephemeral stock pond. However, the existing Funks Reservoir is located adjacent to this structure and provides over to 220 acres of lacustrine habitat, including shoreline, shallow water, and open water habitat. Therefore, the loss of 0.2 acre of lacustrine habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the proposed footprint of these facilities (i.e., Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard) has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. Construction of the proposed outlet structure would require the demolition of a few existing structures that may provide roosting habitat for bats. Therefore, the permanent loss of 4.3 acres of urban/disturbed habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Foothill Riparian

Valley foothill riparian habitat within the proposed footprint of these facilities (i.e., Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and the Field Office Maintenance Yard) has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams, with the exception of elderberry shrubs, which are not present within the footprint of any of these facilities. The permanent loss of 3.1 acres of valley foothill riparian habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No special-status species were observed within the vicinity of the proposed footprint of the Sites Reservoir Inlet/Outlet Structure or associated facilities. Therefore, construction, operation, and maintenance activities associated with implementation of Alternative A in this area would be expected to have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

It is possible that the construction and operation of these proposed facilities could interfere with the movement of small mammals, reptiles, or amphibians. However, more than 90 percent of the disturbance would occur in annual grassland habitat, and the surrounding grassland habitat would be preserved. These facilities would not be expected to substantially interfere with the movement of resident wildlife species because those species would be able to travel around the areas of disturbance. Maintenance activities, including vehicle access to these facilities, would not be expected to substantially interfere with wildlife movement. Therefore, construction, operation, and maintenance of these facilities associated with implementation of Alternative A would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, operation, and maintenance of these facilities. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require frequent vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Pump operation could result in increased noise levels that may adversely affect wildlife. Therefore, the human disturbance associated with construction, operation, and maintenance of these facilities resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

The proposed footprint for the tunnel from the Sites Pumping/Generating Plant to the Sites Reservoir Inlet/Outlet Structure would be drilled and would not have any above-ground disturbance associated with it. Staging areas would occur at either end of the tunnel within the construction footprint of the Sites Pumping/Generating Plant and the Sites Reservoir Inlet/Outlet Structure. These staging areas are addressed in the impact analysis for those facilities. The tunnel would be operated remotely, and maintenance activities would not occur above ground. Therefore, construction, operation, and maintenance of the tunnel would have **no impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No special-status species were observed within the vicinity of the proposed construction footprint of the tunnel. Because no above-ground disturbance would occur during construction, operation would occur remotely, and maintenance activities would not occur above ground, these activities associated with the tunnel would be expected to have **no impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction and maintenance of the tunnel and inlet/outlet structure. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Therefore, the human disturbance associated with the construction, operation, and maintenance of these facilities resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The construction of the Holthouse Reservoir Complex would require the dredging of Funks Reservoir. The existing Funks Reservoir provides up to 228 acres of lacustrine habitat and more than three miles of associated shoreline. The reservoir would be drained for approximately two years, with construction activities occurring during months other than November through April.

Construction of the rest of the proposed Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would result in the direct and permanent loss of the following wildlife habitats, with the exception of the Holthouse to T-C Canal Pipeline, which would result in the temporary disturbance of wildlife habitat (Table 14-12).

Table 14-12
Permanent Wildlife Habitat Loss and Temporary Disturbance Due to the Construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard: Alternative A

Habitat	Temporary Disturbance[a] (Acres)	Permanent Loss (Acres)
Annual grassland	9.7	112.7
Canal	0.4	7.3
Dryland grain and seed crops	0	60.5
Fresh Emergent Wetland[b]	0	0.5
Irrigated row and field crops	14.2	151.8
Urban/disturbed	0	0.6
Valley foothill riparian	0	7.0
TOTAL	**24.3**	**340.4**

[a]Acreage represents temporary disturbance associated with the defined construction disturbance area of the Holthouse to T-C Canal Pipeline.

[b]Fresh Emergent Wetland includes alkaline wetland.

Additional acreage of temporary disturbance would occur as a result of a construction disturbance area for these proposed facilities. The construction disturbance areas for the Delevan Transmission Line and the Delevan and TRR pipelines are located adjacent to the footprint of these facilities. The construction disturbance area acreage for the Holthouse Reservoir Complex would be approximately 36 acres in size, but could overlap with the pipeline disturbance area. Disturbed areas would be restored to their original habitat type after construction is complete. The majority of wildlife habitat affected by these facilities and their construction disturbance area would be irrigated row and field crops, followed by annual grassland and dryland grain and seed crops habitat.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland

Annual grassland within the footprint of the proposed Holthouse Reservoir facilities has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. Northern harriers and white-tailed kites were observed foraging over this habitat within the footprint of the reservoir. The permanent loss of 112.7 acres and the potential additional temporary disturbance of annual grassland habitat, resulting from the construction of these facilities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Canal

Canal habitat within the proposed footprint of the Holthouse Reservoir facilities consists of a portion of the existing concrete-lined T-C Canal. Wildlife species observed using this habitat within the construction footprint include the double-crested cormorant, mallard, and river otter. Killdeer are usually present along the canal’s levee. A portion of the canal would be relocated, and the previous location would be converted to lacustrine habitat. The conversion of 7.3 acres of canal habitat to lacustrine habitat resulting from the construction of these facilities and the filling of the reservoir associated with implementation of

Alternative A would be a **less-than-significant** impact, when compared to Existing Conditions and the No Project/No Action Alternative.

Dryland Grain and Seed Crops

Dryland grain and seed crops habitat within the proposed footprint of the Holthouse Reservoir facilities has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The permanent loss of 60.5 acres and the potential additional temporary disturbance of dryland grain and seed crops habitat, resulting from the construction of these facilities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Fresh Emergent Wetland

The fresh emergent wetland wildlife habitat within the Holthouse Reservoir Complex footprint is represented by an alkaline wetland swale within the annual grassland. This wetland habitat has the potential to support numerous species of wildlife. Construction of the Holthouse Reservoir Complex would result in the permanent loss of 0.5 acre of this habitat type, and could result in the disruption of the water supply to this alkaline wetland. Therefore, the permanent loss of up to 0.5 acre of fresh emergent wetland habitat, and the potential disruption of its hydrology, resulting from construction of the Holthouse Reservoir Complex, would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Irrigated Row and Field Crops

Irrigated row and field crops habitat within the proposed footprint of the Holthouse Reservoir facilities provides foraging habitat for the northern harrier. The permanent loss of 151.8 acres, and the potential additional temporary disturbance of irrigated row and field crops habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lacustrine

The existing Funks Reservoir is used extensively by many water-dependent species of waterfowl and shorebirds, including the American bittern, American coot, black-necked stilt, canvasback, double-crested cormorant, great blue heron, killdeer, northern shoveler, wood duck, and five species of grebes. The projected two-year absence of lacustrine habitat and associated shoreline habitat at the reservoir during Project construction would eliminate habitat that has been available to these water-dependent avian species since 1976. However, the reservoir would be drained during the non-breeding season, and nearby East Park, Stony Gorge, and Indian Valley reservoirs, the Delevan and Sacramento NWRs, and the adjacent rice fields could be used during the period of construction. The lacustrine habitat would be restored after construction is complete. Therefore, Funks Reservoir dredging associated with implementation of Alternative A would have a **less-than-significant impact** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat that is located within the proposed footprint of the Holthouse Reservoir facilities consists of the existing Funks Dam maintenance road. The gravel road provides little habitat value for wildlife. Therefore, the permanent loss of 0.6 acre of urban/disturbed habitat resulting from the construction of the Holthouse Reservoir Complex associated with implementation of Alternative A would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Foothill Riparian

Valley foothill riparian habitat within the proposed footprint of the Holthouse Reservoir facilities has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams, with the exception of elderberry shrubs, which are not present within the footprint of this complex of facilities. Nesting great horned owls and red-tailed hawks were observed in this habitat within the footprint of the reservoir. The permanent loss of 7.0 acres of valley foothill riparian habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The existing Funks Reservoir is used by the special-status American white pelican, common loon, and long-billed curlew. The projected two-year absence of lacustrine habitat and associated shoreline habitat at the reservoir during Project construction would eliminate habitat that has been available to these water-dependent avian species since 1976. However, nearby East Park, Stony Gorge, and Indian Valley reservoirs could be used during the period of maintenance, and the lacustrine habitat would be restored after construction is complete. Operation and maintenance impacts would be expected to be the same as for the existing Funks Reservoir. Therefore, Funks Reservoir dredging associated with implementation of Alternative A would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Pond Turtle

Western pond turtles were observed downstream of Funks Reservoir along Funks Creek in an area that would be within the proposed footprint of the Holthouse Reservoir Complex. Construction activities and the subsequent filling of the reservoir would result in habitat loss and could result in direct mortality of this species. Therefore, construction activities and inundation associated with the Holthouse Reservoir Complex resulting from implementation of Alternative A would have a **potentially significant** impact on western pond turtles, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation of the reservoir, releases would be made downstream to the remaining Funks Creek channel to maintain flows. Operation and maintenance impacts would be expected to the same as for the existing Funks Reservoir. Therefore, operation and maintenance of the Holthouse Reservoir Complex would have a **less-than-significant impact** on the western pond turtle, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

The existing Funks Reservoir is used by a few pair of nesting western grebes annually. The projected two-year absence of lacustrine habitat and associated shoreline habitat at the reservoir during construction would eliminate habitat that has been available to these water-dependent grebes since 1976. However, the reservoir would be drained during the non-breeding season and nearby East Park, Stony Gorge, and Indian Valley reservoirs could be used during the period of construction. The lacustrine habitat would be restored after construction is complete. Therefore, Funks Reservoir dredging associated with implementation of Alternative A would have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

After Project construction is complete, it is possible that larger areas of disturbance associated with the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard could interfere with the movement of small mammals, reptiles, or amphibians. However, almost 80 percent of the disturbance would occur in annual grassland habitat and irrigated row and field crops. The surrounding grassland and field crop habitat would be preserved. The reservoir complex would not be expected to substantially interfere with the movement of resident wildlife species because those species would be able to travel around the areas of disturbance. Therefore, construction, operation, and maintenance of these facilities associated with implementation of Alternative A would have a **less-than-significant impact** on wildlife movement, when compared to Existing Conditions and the No Project/No Action Alternative.

Additionally, filling Holthouse Reservoir would effectively enlarge the surface area of Funks Reservoir. If emergent vegetation is present, the larger reservoir size and increased availability of shallow water habitat could benefit the western grebes that already nest at Funks Reservoir. This potential increase in available nesting habitat associated with implementation of Alternative A would have a potentially **beneficial effect** on nesting western grebes, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, operation, and maintenance of the proposed Holthouse Reservoir Complex. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require frequent vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Therefore, the human disturbance associated with construction, operation, and maintenance of the Holthouse Reservoir Complex resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Proposed modifications to the existing GCID Canal Facilities would require associated construction disturbance areas that would create a temporary disturbance to wildlife habitats (Table 14-13).

Table 14-13
Temporary Disturbance of Wildlife Habitat Due to Modifications of the Glenn-Colusa Irrigation District Canal Facilities: Alternative A

Habitat	Temporary Disturbance (Acres)
Canal (existing GCID Canal)	3.1
Urban/disturbed	1.6
TOTAL	**4.7**

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Canal

Canal habitat within the proposed construction disturbance area of the GCID Canal Facilities Modifications consists of a portion of the existing GCID Canal. The canal would be dewatered to line 200 feet of it, so the open water portion of that section would be lost during construction. However, construction would occur during the annual maintenance period when the canal is already dewatered. Therefore, the temporary disturbance of approximately three acres of canal habitat resulting from canal modifications associated with implementation of Alternative A would be a **less-than-significant** impact, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat that is located within the proposed construction disturbance area of the GCID Canal Facilities Modifications consists of roads and a railroad, which provide little habitat value for wildlife. Therefore, the temporary disturbance of almost two acres of urban/disturbed habitat resulting from the canal modifications associated with implementation of Alternative A would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Giant Garter Snake

Areas of giant garter snake habitat exist within 200 feet of the GCID Canal. Proposed construction activities have the potential to disturb giant garter snakes or cause direct mortality from excavation of hibernating snakes if work is conducted from October 1 through May 1. Construction activities associated with modification of the GCID Canal resulting from implementation of Alternative A would, therefore, have a **potentially significant impact** on the giant garter snake, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Proposed canal modifications would occur within the existing canal or siphon locations and would have small associated construction disturbance areas for a temporary period of time. After construction is complete, the areas would be returned to their original condition. Because construction activities would occur along a maintained canal and at a railroad track siphon, where disturbance is frequent, modifications to these facilities associated with implementation of Alternative A would be expected to have a **less-than-significant impact** on wildlife movement, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by the proposed construction activities associated with GCID Canal Modifications. Increased vehicle traffic associated with the transportation of personnel and materials to the site, as well as the noise associated with construction equipment and personnel, could cause temporary disturbance to wildlife. Therefore, the human disturbance associated with construction activities at the GCID Canal modifications resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

Construction of the proposed TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and GCID Canal Connection to the TRR facilities would require ground-disturbing activities that would result in the direct and permanent loss of wildlife habitats (Table 14-14).

Table 14-14
Permanent Wildlife Habitat Loss and Temporary Disturbance Due to the Construction of the Terminal Regulating Reservoir Facilities: Alternative A

Habitat	Temporary Disturbance* (Acres)	Permanent Loss (Acres)
Canal	0	0.9
Deciduous orchard	0	0.6
Dryland grain and seed crops	0	60.8
Pasture	0	11.7
Rice	13.6	120.9
Urban/disturbed	0.8	
TOTAL	**14.4**	**194.9**

*Acreage represents temporary disturbance associated with the defined construction disturbance area of the TRR to Funks Creek Pipeline.

Additional temporary disturbance of wildlife habitat would occur as a result of a construction disturbance area for these facilities. Construction disturbance associated with the proposed TRR to Funks Creek Pipeline would also be temporary. Two sides of the proposed reservoir would be surrounded by the construction disturbance area for the Delevan and TRR pipelines, which overlaps with the footprint of the reservoir. The construction disturbance area acreage would be approximately 19 acres in size, but could overlap with the pipeline disturbance area. Disturbed areas would be restored to their original habitat type after construction is complete. The majority of wildlife habitat affected by these facilities is rice habitat, followed by dryland grain and seed crops.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Canal

The existing GCID Canal is within the proposed footprint of the bay associated with the GCID Canal Connection to the TRR. The canal would still exist upstream and downstream of this bay, and the portion of the canal that would be within the proposed footprint of the connection would be expanded during the annual maintenance period for the canal when the canal is dewatered. This modification of the canal associated with implementation of Alternative A would not be expected to adversely affect wildlife, and therefore, would have a **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Deciduous Orchard

Deciduous orchards are used by numerous wildlife species. It is possible that the permanent loss of 0.6 acre of deciduous orchard habitat resulting from the construction of the TRR facilities could be avoided by revising the siting of the facilities. Due to the small amount of acreage that could be lost, and due to the possibility of avoiding this loss, the potential loss of deciduous orchard associated with construction of the TRR facilities would have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Dryland Grain and Seed Crops

Dryland grain and seed crops habitat within the proposed footprint of these facilities has the same habitat value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The permanent loss of 60.8 acres and the potential additional temporary disturbance of dryland grain and seed crops, resulting from the construction of these facilities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Pasture

Pasture habitat within the proposed footprint of these facilities has the same habitat value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The permanent loss of 11.7 acres of pasture habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative.

Rice

Rice habitat, especially when flooded, supports numerous species of wildlife. The special-status sandhill crane, black tern, Caspian tern, long-billed curlew, yellow-headed blackbird, long-eared owl, short-eared owl, and white-tailed kite were observed using this habitat within or adjacent to the proposed footprint of these facilities. The permanent loss of 120.9 acres and the potential additional temporary disturbance of rice habitat, resulting from the construction of these facilities associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the proposed footprint of these facilities consists of maintenance roads. These roads provide little habitat value for wildlife. Therefore, the temporary disturbance of 0.8 acre of urban/disturbed habitat resulting from the construction of these facilities associated with implementation of Alternative A would be a **less than significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No special-status species were observed within the vicinity of the proposed construction footprint of the TRR or associated facilities. Therefore, construction, operation, and maintenance activities associated with these facilities resulting from implementation of Alternative A would be expected to have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

After construction is complete, it is possible that larger areas of disturbance associated with these proposed facilities could interfere with the movement of small mammals, reptiles, or amphibians. However, all of the disturbance would occur in agricultural, urban/disturbed, or canal habitat. The surrounding area that includes these habitats would be preserved. These facilities would not be expected to substantially interfere with the movement of resident wildlife species because those species would be able to travel around the areas of disturbance. Therefore, construction, operation, and maintenance of these facilities associated with implementation of Alternative A would have a **less-than-significant impact** on wildlife movement, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, operation, and maintenance of these facilities. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Pump operation could result in increased noise levels that may adversely affect wildlife. Therefore, the human disturbance associated with construction, operation, and maintenance of these facilities resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

The proposed TRR Pipeline would be aligned parallel and adjacent to the western 3.5 miles of the proposed Delevan Pipeline, and would be completely within the construction disturbance area of the Delevan Pipeline. The TRR Pipeline Road would be located atop the length of the TRR Pipeline, and the Delevan Pipeline Electrical Switchyard would be located where the Delevan Pipeline would cross the existing PG&E transmission line. The construction of the pipelines would require ground-disturbing activities that would result in the temporary disturbance of wildlife habitats that would be restored to their original habitat type after construction is complete. The construction of the TRR Pipeline Road and Delevan Pipeline Electrical Switchyard would require ground-disturbing activities that would result in permanent habitat loss (Table 14-15).

Table 14-15
Permanent Wildlife Habitat Loss and Temporary Disturbance Due to the Construction of the Delevan and Terminal Regulating Reservoir Pipelines, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard: Alternative A

Habitat	Temporary Disturbance (Acres)	Permanent Loss (Acres)
Barren*	20.9	0.2
Canal	8.2	0.1
Deciduous orchard	173.2	3.7
Dryland grain and seed crops	190.1	0.2
Eucalyptus	46.2	0
Fresh emergent wetland	18.5	0
Irrigated row and field crops	196.3	3.8
Lacustrine	5.1	0
Pasture	240.0	0
Rice	1,358.9	0.3
Urban/disturbed	36.8	0
TOTAL	**2,294.2**	**8.3**

*Barren habitat includes fallowed agricultural fields

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Barren

Barren habitat within the construction disturbance area of the proposed Delevan and TRR pipelines consists of fallowed agricultural fields. The only special-status species that has the potential to use this type of barren habitat is the wintering mountain plover. This species was not observed within any of the Project facility sites, but is known to occur in southeast Colusa County. Depending on the time of year and duration of construction activities, the temporary disturbance of 20.9 acres of barren habitat and permanent loss of 0.2 acre resulting from construction of the Delevan and TRR pipelines, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard associated with implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Canal

The canal habitat within the construction disturbance area of the proposed Delevan and TRR pipelines is represented by the locations where the Delevan Pipeline would cross the GCID Canal and the CBD. The special-status American white pelican and yellow warbler were observed at the CBD.

At the GCID Canal crossing location, construction would include tunneling below the canal without disturbing the existing infrastructure. Because no loss of canal habitat would occur as a result of pipeline construction associated with implementation of Alternative A, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

At the CBD crossing location, construction would occur after the irrigation season ends and before winter rains begin. Construction would be staged at this crossing and would occur within half of the channel while an installed cofferdam bypasses flows on the other half of the channel. The temporary disturbance of the CBD would be short-term, would affect a small area of the CBD, and would not disrupt upstream and downstream passage or use of adjacent areas. Therefore, pipeline construction associated with implementation of Alternative A would have a **less-than-significant impact** on the CBD, when compared to Existing Conditions and the No Project/No Action Alternative.

Deciduous Orchard

Deciduous orchard habitat within the construction disturbance area of the proposed Delevan and TRR pipelines consists of almond trees. The temporary disturbance of 173.2 acres and permanent loss of 3.7 acres of deciduous orchard habitat resulting from the construction of the Delevan and TRR pipelines, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Dryland Grain and Seed Crops

Dryland grain and seed crops habitat within the construction disturbance area of the proposed Delevan and TRR pipelines has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The temporary disturbance of 190.1 acres and permanent loss of 0.2 acre of dryland grain and seed crops habitat resulting from the construction of the Delevan and TRR pipelines, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Eucalyptus

The eucalyptus habitat within the construction disturbance area of the proposed Delevan and TRR pipelines is located along the sides of an unlined irrigation canal, and consequently functions in a capacity similar to riparian habitat for many wildlife species. Eucalyptus habitat provides roosts, perches, and nest sites for numerous bird species, including raptors. The temporary disturbance of 46.2 acres of Eucalyptus habitat resulting from the construction of the Delevan and TRR pipelines associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Fresh Emergent Wetland

The fresh emergent wetland habitat within the construction disturbance area of the proposed Delevan and TRR pipelines, which includes alkaline wetlands, has the potential to support numerous species of wildlife, including the special-status giant garter snake, sandhill crane, black tern, northern harrier, short-eared owl, tri-colored blackbird, white-tailed kite, and yellow-headed blackbird. All of these species were observed along the pipeline disturbance area in adjacent habitat types. The temporary disturbance of 18.5 acres of fresh emergent wetland habitat resulting from the construction of the Delevan and TRR pipelines associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Irrigated Row and Field Crops

Irrigated row and field crops habitat within the construction disturbance area of the proposed Delevan and TRR pipelines has the same value to wildlife as described in the impact assessment for the Holthouse Reservoir Complex. The temporary disturbance of 196.3 acres and permanent loss of 3.8 acres of irrigated row and field crops habitat resulting from the construction of the Delevan and TRR pipelines, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Lacustrine

The lacustrine habitat within the construction disturbance area of the proposed Delevan and TRR pipelines represents a large pond, which has the same value to wildlife as described in the impact assessment for lacustrine habitat within the Recreation Areas. This pond is located in proximity to the fresh emergent wetlands of the adjacent Delevan NWR, and therefore, may provide habitat for numerous wildlife species. The temporary disturbance of 5.1 acres of lacustrine habitat resulting from pipeline construction activities associated with implementation of Alternative A would have a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Pasture

Pasture habitat within the construction disturbance area of the proposed Delevan and TRR pipelines has the same habitat value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The special-status golden eagle and prairie falcon were observed within this habitat type along the pipeline disturbance area. The temporary disturbance of 240.0 acres of pasture habitat resulting from pipeline construction activities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Rice

Rice habitat within the construction disturbance area of the proposed Delevan and TRR pipelines has the same value to wildlife as described in the impact assessment for the TRR, TRR Pumping/Generating Plant, and GCID Canal Connection to the TRR. The special-status western pond turtle was observed along an irrigation canal associated with rice habitat. The black tern, long-billed curlew, Caspian tern, sandhill crane, long-eared owl, short-eared owl, white-tailed kite, and yellow-headed blackbird were observed in rice fields or adjacent habitats within this construction disturbance area. The temporary disturbance of 1,358.9 acres and permanent loss of 0.3 acre of rice habitat resulting from pipeline, road, and electrical switchyard construction activities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the construction disturbance area of the proposed Delevan and TRR pipelines consists of roads and several structures. The structures would not be demolished, and the roads provide little habitat value for wildlife. Therefore, the permanent loss of 36.8 acres of urban/disturbed habitat resulting from pipeline construction activities associated with implementation of Alternative A would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Bank Swallow

Construction of the proposed Delevan and TRR pipelines would require the creation of trenches that would have steep cut banks made of sandy loam soils. Due to the proximity of the trench to the Sacramento River and to known breeding populations of bank swallows, the banks of the trenches could attract nesting bank swallows. Nesting bank swallows within the construction area would be at high risk of injury or death. Therefore, the construction of the pipelines associated with implementation of Alternative A could have a **potentially significant impact** on bank swallows, when compared to Existing Conditions and the No Project/No Action Alternative.

Giant Garter Snake

The USFWS confirmed that giant garter snakes use the rice fields and fresh emergent wetlands within the construction disturbance area of the proposed Delevan Pipeline. Giant garter snakes are also known to occur in the CBD, which could have construction-related impacts where the pipeline crosses the CBD. The pipeline would take approximately two years to build, and would be conducted outside of a November through April timeframe for protection of the giant garter snake. The pipeline would likely be constructed in sections, so that loss of habitat would occur in stages, rather than for the entire length of the pipeline all at once. Because dredged material from the underground footprint of the pipeline would potentially be spread over the entire width of the construction disturbance area, total loss of habitat would occur temporarily within the disturbance area. Fallowing of rice fields would not only temporarily remove giant garter snake habitat, but could also have adverse effects on the reproduction, recruitment, and survival of this species that could continue beyond the two-year construction schedule. The temporary loss of fresh emergent wetland habitat, as well as the extensive temporary loss of rice habitat resulting from construction activities associated with implementation of Alternative A, would have a **significant impact** on the giant garter snake, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Pond Turtle

Construction of the proposed Delevan Pipeline could temporarily disturb existing canal habitat within the construction disturbance area. Western pond turtles were observed within the disturbance area along an irrigation canal. Although the area would be restored after construction is complete, construction activities could result in the direct mortality of this species. Therefore, construction of the Delevan

Pipeline associated with implementation of Alternative A would have a **potentially significant impact** on western pond turtles, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Yellow-Billed Cuckoo

Construction of the proposed Delevan and TRR pipelines, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard would temporarily disturb existing deciduous orchards within the construction disturbance area. The special-status western yellow-billed cuckoo uses deciduous orchards when the orchards are located near riverine and riparian habitat. However, the orchards within the construction disturbance area of these pipelines are located approximately 11 miles west of the Sacramento River, and therefore, do not represent suitable habitat for this species. Therefore, construction of the Delevan and TRR pipelines associated with implementation of Alternative A would have a **no impact** on western yellow-billed cuckoos, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Construction of the proposed pipelines would require an open trench. Exposed pipeline trenches could trap small mammals, amphibians, or reptiles moving through the area, including the special-status giant garter snake. Nocturnal wildlife would have a high risk of falling into the trenches. Wildlife could be injured during the fall into the trench, and once trapped would have no access to food, water, or shelter. Trapped wildlife would also be at risk of predation. The open trench associated with construction of the pipelines resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction and maintenance of the proposed pipelines, road, and electrical switchyard. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Therefore, the human disturbance associated with construction and maintenance of the pipelines, road, and electrical switchyard resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Delevan Transmission Line

The Delevan Transmission Line would parallel, and be completely within the construction disturbance area of, the proposed Delevan Pipeline, with the exception of the westernmost 3.5 miles. Because the impacts of the eastern approximately nine miles of the proposed transmission line route construction disturbance area are already accounted for in the impact assessment for the Delevan Pipeline, only the temporary ground disturbance of the remaining 3.5 miles of the transmission line are analyzed here. Disturbed habitats would be restored to their original habitat type after construction is complete. The construction disturbance area of the Delevan Transmission line would result in the temporary disturbance of wildlife habitats (Table 14-16).

Table 14-16
Temporary Disturbance of Wildlife Habitat from Construction of the Delevan Transmission Line: Alternative A

Habitat	Number of Acres Affected for the Entire Length of the Transmission Line	Number of Acres Affected for the Section of the Transmission Line Outside of the Delevan Pipeline Construction Disturbance Area
Annual grassland	69.5	69.5
Barren*	0.5	0.5
Canal	1.5	1.2
Dryland grain and seed crops	25.6	1.5
Deciduous orchard	0.4	0
Eucalyptus	0.3	0
Fresh emergent wetland	2.1	0
Irrigated row and field crops	9.4	0
Lacustrine	1.0	0
Pasture	24.5	0
Rice	143.0	0
Urban/disturbed	1.1	0
Valley foothill riparian	1.1	1.1
TOTAL	**280.0**	**73.8**

*Barren habitat includes fallowed agricultural fields.

Although the proposed transmission line would be an above-ground feature and have no associated permanent ground disturbance, the footings of the transmission towers would result in the permanent loss of wildlife habitat. Based on a worst-case scenario, the total permanent habitat loss associated with the footings would be approximately 2.5 acres of a combination of rice and annual grassland habitat.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland

Annual grassland within the construction disturbance area of the proposed Delevan Transmission Line has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The temporary disturbance of 69.5 acres and the potential permanent loss of up to 2.5 acres of annual grassland habitat, resulting from the construction of the transmission line associated with implementation of Alternative A, would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Barren

Barren habitat within the construction disturbance area of the proposed Delevan Transmission Line consists of fallowed agricultural fields. During Project construction, additional agricultural fields would be temporarily fallowed. The only special-status species that has the potential to use this type of barren habitat is the wintering mountain plover. This species was not observed within any of the Project facility sites, but is known to occur in southeast Colusa County. Depending on the time of year and duration of construction activities, the temporary disturbance of 0.5 acre of barren habitat resulting from construction of the Delevan Transmission Line associated with implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Canal

The canal habitat within the construction disturbance area of the proposed Delevan Transmission Line is represented by the location where the construction disturbance area crosses the T-C Canal. The transmission line would be aligned above and across the canal, but would not disturb existing infrastructure. Because no loss of canal habitat or disturbance of the main channel would occur as a result of transmission line construction associated with implementation of Alternative A, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Dryland Grain and Seed Crops

Dryland grain and seed crops within the construction disturbance area of the proposed Delevan Transmission Line have the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. The temporary disturbance of 1.5 acres of dryland grain and seed crops resulting from the construction of the transmission line associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Foothill Riparian

Valley foothill riparian habitat within the construction disturbance area of the proposed Delevan Transmission Line has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams, with the exception of elderberry shrubs, which are not present within the disturbance area. The temporary disturbance of 1.1 acres of valley foothill riparian habitat resulting from the construction of the Delevan Transmission Line associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

No special-status species were observed within the vicinity of the construction disturbance area for the proposed Delevan Transmission Line, and on-the-ground disturbance would be limited to tower footings. Therefore, construction activities associated with these facilities resulting from implementation of Alternative A would be expected to have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Transmission lines can provide perch sites for birds, but the length of the transmission line that would be aligned from the Sacramento River to the proposed Sites Electrical Switchyard also has the potential to create conflicts with birds. Raptors and other birds may collide with the conductors (i.e., wires) on the transmission line towers during their construction and operation; however, the construction activities associated with the towers are not expected to interfere with bird movement. The eastern end of the transmission line would be located adjacent to the Delevan NWR, and could, therefore, disrupt a migratory corridor by causing collisions. The potential disruption of a migratory corridor, as well as the increased risk of collisions resulting from the construction and operation of the Delevan Transmission Line associated with implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, operation, and maintenance of the proposed transmission lines. Construction activities would include the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials, which could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Transmission line towers are often used by nesting osprey and other raptors. If an osprey nest were established, maintenance activities could disturb this species during incubation or before young have fledged. Therefore, the human disturbance associated with construction, operation, and maintenance of the transmission line resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Delevan Pipeline Intake Facilities

Construction activities associated with the proposed Delevan Pipeline Intake Facilities, which includes a fish screen and pumping/generating facility located on the Sacramento River, would result in the direct and permanent loss of wildlife habitats (Table 14-17).

Additional acreage of temporary disturbance would occur as a result of a construction disturbance area for these proposed facilities. The construction disturbance area for the Delevan Pipeline is located adjacent to these facilities and could potentially be used as a staging area. Disturbed areas would be restored to their original habitat type after construction is complete. The wildlife habitat that would be most affected by this construction disturbance area would be deciduous orchard habitat.

Table 14-17
Permanent Wildlife Habitat Loss Due to the Construction of the Delevan Pipeline Intake Facilities: Alternative A

Habitat	Permanent Loss (Acres)
Canal	0.6
Deciduous orchard	11.1
Riverine	1.6
Urban/disturbed	4.2
Valley foothill riparian	1.6
TOTAL	**19.1**

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Canal

Canal habitat within the footprint of the proposed Delevan Pipeline Intake Facilities consists of a small irrigation canal, and has the same value to wildlife as described in the impact assessment for Holthouse Reservoir and Dam. The permanent loss of 0.6 acre of canal habitat resulting from construction activities associated with implementation of Alternative A would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Deciduous Orchard

Deciduous orchard habitat within the footprint of the proposed intake facilities, which consists of walnut orchards, is located immediately adjacent to the Sacramento River. Deciduous orchards with a riverine/riparian edge are used by numerous wildlife species, including the special-status western yellow-billed cuckoo. The permanent loss of 11.1 acres of deciduous orchard habitat resulting from the construction of the Delevan Pipeline Intake Facilities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Riverine

Riverine habitat within the footprint of the proposed Delevan Pipeline Intake Facilities consists of a portion of the Sacramento River. The construction disturbance area would be located immediately downstream of the existing Maxwell Irrigation District (ID) Pumping Plant. The Sacramento River supports numerous wildlife species, including the special-status bank swallow, American white pelican, and bald eagle. The permanent loss of 1.6 acres of riverine habitat associated with construction of the Delevan Pipeline Intake Facilities resulting from implementation of Alternative A would have a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the footprint of the proposed Delevan Pipeline Intake Facilities consists of small maintenance buildings and associated access roads. Construction of the intake facilities would require the demolition of the maintenance buildings, which could provide roosting habitat for bats. Therefore, the permanent loss of 4.2 acres of urban/disturbed habitat resulting from the construction of the Delevan Pipeline Intake Facilities associated with implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Valley Foothill Riparian

Valley foothill riparian habitat within the footprint of the proposed Delevan Pipeline Intake Facilities has the same value to wildlife as described in the impact assessment for Sites Reservoir and Dams. There is one elderberry shrub within the construction footprint and a second elderberry shrub adjacent to the footprint. The State fully-protected ringtail was observed using this habitat within the footprint of the intake facilities. This riparian habitat has the potential to support the special-status western yellow-billed cuckoo, Swainson's hawk, western pond turtle, long-eared owl, and the yellow warbler. The permanent loss of 1.6 acres of valley foothill riparian habitat resulting from the construction of the Delevan Pipeline Intake facilities associated with implementation of Alternative A would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Bank Swallow

Construction of the proposed Delevan Pipeline Intake Facilities would result in the loss of approximately 660 linear feet (0.1 mile) of river bank. This section of the bank supports riparian habitat. There are no steep barren banks that are suitable for bank swallow excavation. Bank swallow colonies have been documented near this location in previous years, but the lack of barren habitat and the geologic control in this section of the river makes it unsuitable for excavation, and therefore, unsuitable nesting habitat, for the bank swallow. Therefore, the habitat loss associated with the construction of the Delevan Pipeline Intake Facilities resulting from implementation of Alternative A would have **no impact** on bank swallows, when compared to Existing Conditions and the No Project/No Action Alternative.

Ringtail

The State fully-protected ringtail was observed within the riparian habitat that would be removed during construction of the proposed Delevan Pipeline Intake Facilities. The loss of 1.6 acres and 660 linear feet of this habitat type would further reduce the connectivity of the riparian corridor at this location, which could reduce the value of the adjacent riparian habitat to the ringtail. The loss of 1.6 acres of riparian habitat resulting from the construction of the Delevan Pipeline Intake Facilities associated with implementation of Alternative A would be a **potentially significant impact** to the ringtail, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance activities would occur within the footprint of the facilities and would not further disrupt habitat connectivity. However, noise and night-time lighting associated with these activities could affect habitat quality for the ringtail and would have a **potentially significant impact**.

Valley Elderberry Longhorn Beetle

One elderberry shrub exists within the riparian habitat that would be displaced as a result of construction of the proposed Delevan Pipeline Intake Facilities. Protocol-level surveys were conducted on this elderberry shrub, and no emergence holes were found. A second elderberry shrub is located adjacent to the footprint of the proposed facility, within an orchard on the edge of an irrigation canal that is aligned parallel to an access road. This road may be used during construction, operation, and maintenance activities; consequently, the shrub could be adversely affected. This second elderberry shrub has not been surveyed.

Although no emergence holes were found on the surveyed shrub, the loss of this elderberry shrub and the possible disturbance of a second shrub during construction associated with implementation of Alternative A would be a **significant impact** to the valley elderberry longhorn beetle, when compared to Existing Conditions and the No Project/No Action Alternative.

Western Yellow-Billed Cuckoo

The 1.6 acres of riparian habitat that would be lost as a result of construction of the proposed Delevan Pipeline Intake Facilities are located immediately adjacent to walnut orchards, of which 11.2 acres would be lost. Both of these habitat types are used by the western yellow-billed cuckoo along the Sacramento River. During a 2010 survey, cuckoos were detected along the river 4.5 miles upstream and 1.5 miles downstream of the footprint of the proposed Intake Facility. It is possible that the habitat within the construction footprint is also used by this species, although it was not detected during Project surveys or during the 2010 survey at this location. The loss of riparian and deciduous orchard habitat along the Sacramento River resulting from construction of the Delevan Pipeline Intake Facilities associated with implementation of Alternative A would be a **potentially significant impact** to the western yellow-billed cuckoo, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would occur within the footprint of the facilities and would not be expected to adversely affect the surrounding riparian or orchard habitat. Noise levels associated with maintenance activities, such as sediment removal, are expected to be similar to the levels associated with the proposed pumps, as well as the existing Maxwell ID pumps, and would not be expected to substantially adversely affect this species. Therefore, maintenance activities associated with these facilities would have a **less-than-significant impact** on the western yellow-billed cuckoo.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

The valley foothill riparian habitat that exists along the banks of the Sacramento River provides a travel corridor for numerous terrestrial wildlife species, including the fully-protected ringtail. Gaps in the connectivity of this corridor create higher risks of predation for wildlife that travel through these areas. Therefore, the removal of 660 linear feet of valley foothill riparian habitat along the Sacramento River associated with construction of the proposed Delevan Pipeline Intake Facilities resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation and maintenance activities would not be expected to result in additional ground disturbance or placement of facilities, and therefore, would have a **less-than-significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Refer to the **Impact Wild-2** discussion for the potential impact of noise and night-time lighting on the ringtail.

Wildlife and wildlife habitats may be directly or indirectly affected by Project-related construction, operation, and maintenance of the intake facilities. Construction activities would include sheet pile driving and the use of heavy equipment, and would result in increased traffic from the transportation of personnel and materials. These activities could lead to increased mortality from vehicles and increased disturbance from noise and artificial lighting. Operation and maintenance would require vehicle access to these facilities, and may require nighttime safety lighting, which can adversely affect many wildlife species, especially nocturnal species. Pump operation could result in increased noise levels that may adversely affect wildlife. Therefore, the human disturbance associated with construction, operation, and maintenance of these facilities resulting from implementation of Alternative A would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Project Buffer

Within the Proposed Take Line, the following activities are expected to occur: fence construction, the demolition of existing structures, and fuelbreak maintenance. The acreage of wildlife habitats included within the Proposed Take Line buffer is presented in Table 14-18.

Table 14-18
Acres of Wildlife Habitat Within the Project Buffer[a]: Alternative A

Habitat	Acres within Project Buffer
Annual grassland	8,083.1
Barren[b]	2.9
Blue oak woodland	4,180.1
Canal	15.8
Chamise-redshank chapparal	1.9
Deciduous orchard	77.8
Dryland grain and seed crops	134.3
Irrigated row and field crops	151.2
Lacustrine	17.2
Pasture	15.7
Rice	21.1
Riverine	0.1

Table 14-18
Acres of Wildlife Habitat Within the Project Buffer[a]: Alternative A

Habitat	Acres within Project Buffer
Urban/disturbed	35.4
Valley foothill riparian	63.4
TOTAL	**12,800.0**

[a]Calculated by subtracting the acreage of permanent disturbance associated with each proposed Project facility that is surrounded by the Project Buffer, the acreage of existing Funks Reservoir, and the acreage of the portion of the existing GCID Canal that is surrounded by the Project Buffer, from the total acreage of land that would be acquired for the Project.

[b]Barren includes fallow/idle agricultural fields.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Annual Grassland, Barren, Blue Oak Woodland, Canal, Chamise-Redshank Chaparral, Lacustrine, and Valley Foothill Riparian

The above-listed wildlife habitat types within the Project Buffer have the same value to wildlife as described for other Project features, and would not be altered or converted to other habitat types. Construction and maintenance activities associated with fence building would have a negligible impact on these habitat types because the footprint of the fence posts would be small and a large portion of the Project Buffer is already fenced. However, the potential creation and maintenance of a fuelbreak would require vegetation clearing that, if maintained around the entire perimeter of the Project Buffer, could result in a substantial adverse effect due to the loss of wildlife habitat. Therefore, the potential loss of wildlife habitat associated with construction and maintenance of the Project Buffer fuelbreak resulting from implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Deciduous Orchard, Dryland Grain and Seed Crops, Irrigated Row and Field Crops, Pasture, and Rice

The above-listed agricultural habitat types within the Project Buffer have the same value to wildlife as described for other Project features, but would not be maintained as agricultural lands after Project construction is complete. These agricultural lands would be converted to natural wildlife habitat, likely to annual grassland habitat. Although some wildlife species would benefit from this conversion, other wildlife species may be adversely affected. Therefore, the loss of 211.4 acres of agricultural habitat types that would be converted to natural habitat types within the Project Buffer as a result of implementation of Alternative A would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Urban/Disturbed

The urban/disturbed habitat within the Project Buffer consists of roads and structures. Construction activities within the Project Buffer would include the demolition of existing structures that may provide roosting habitat for bats. After demolition activities cease, the urban/disturbed habitat would be converted to natural wildlife habitat, likely to annual grassland habitat. This habitat conversion may benefit several wildlife species. However, potential loss of bat roosting habitat associated with the demolition of structures within the Project Buffer resulting from implementation of Alternative A would be a

potentially significant impact, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Activities associated with fence construction and maintenance could result in the temporary disturbance of special-status wildlife species. Demolition of existing structures during construction has the potential to result in the loss of roosting habitat for special-status bats. The creation of a fuelbreak would result in the loss of habitat that may be used by special-status wildlife species, and maintenance of the fuelbreak could disturb those species. Therefore, construction and maintenance activities that would occur within the Project Buffer would have a **potentially significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

The potential construction of barbed wire fencing around the perimeter of the Project Buffer in the few areas where fencing does not already occur would not be expected to interfere with wildlife movement. Fencing already occurs around most, if not all, of the property lines, and the fence design would allow wildlife to go under, through, or over the fencing. Periodic fence maintenance would not be expected to interfere with wildlife movement. The construction and maintenance of a fuelbreak would eliminate vegetative cover within the footprint of the fuelbreak, but would not be expected to substantially interfere with wildlife movement. Therefore, the construction and maintenance of fencing and the fuelbreak within the Project Buffer associated with implementation of Alternative A would have a **less-than-significant impact** on wildlife movement, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-4: Indirect Effects on Common Wildlife from Human Disturbance

Although signs would be posted to prevent recreationists from using the Project Buffer lands, it is likely that unauthorized hiking, biking, or other recreational activity would occur within the take line. In addition, the construction crews required to demolish existing structures or build fences would cause a temporary disturbance to wildlife. Maintenance activities associated with fencing and the fuelbreak could also disturb wildlife. Therefore, human disturbance associated with Project Buffer activities would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-5: Conflict with the Provisions of an Adopted HCP, NCCP, or Other Approved Local or Regional HCP, or Conflict with any Local Policies or Ordinances Protecting Biological Resources, such as a Tree Preservation Policy or Ordinance

Refer to the **Impact Wild-5** discussion for Sites Reservoir Inundation Area and Sites Reservoir Dams.

Summary of Alternative A Impacts to Wildlife Habitats

Construction, operation, and maintenance of Alternative A would result in the permanent loss of 13,572.6 acres, and the temporary disturbance of an additional 5,357.9 acres of wildlife habitat (Table 14-19).

Table 14-19
Acres of Wildlife Habitat Subject to Alternative A Construction Impacts[a]

Habitat Type	Acreage	
	Permanent Loss[b]	Temporary Disturbance[c]
Annual grassland	12,151.8	2,091.4
Barren	0.2	21.4
Blue oak woodland	501.4	644.5
Canal	9.1	14.1
Chamise-redshank chaparral	0.6	1.9
Deciduous orchard	15.4	175.1
Dryland grain and seed crops	333.2	214.5
Eucalyptus	0	46.2
Fresh emergent wetland[d]	0.5	18.5
Irrigated row and field crops	155.6	225.7
Lacustrine	20.8	2,264.0
Mixed chaparral	0.8	1.8
Pasture	72.7	241.2
Rice	122.9	1,383.6
Riverine	1.6	0
Urban/disturbed	88.1	46.9
Valley foothill riparian	94.5	4.7
Valley oak woodland	3.4	0
TOTAL	**13,572.6**	**5,357.9**

[a]Calculated acreage does not include acres associated with the Project Buffer because the location and extent of disturbance is not yet specified.

[b]Total permanent wildlife habitat loss acreage includes the defined footprints of Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and the Delevan Pipeline Intake Facilities. Total permanent loss acreage also includes the estimated permanent loss from construction of facilities within the footprint of the Recreation Areas, within the construction disturbance area for the Road Relocations, and from construction of the transmission tower footings associated with the Delevan Transmission Line.

[c]Total temporary disturbance acreage includes the footprint of the Recreation Areas (minus the acreage of estimated permanent loss) and the footprint of the existing Funks Reservoir, as well as the defined construction disturbance areas for the Road Relocations and South Bridge (minus the acreage of estimated permanent loss), Delevan Pipeline, TRR Pipeline, Holthouse to T-C Canal Pipeline, TRR to Funks Creek Pipeline, Delevan Transmission Line, and GCID Canal Facilities Modifications. Total temporary disturbance acreage also includes the estimated construction disturbance areas (outside of the facility footprints) for Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Tunnel from Sites Pumping Generating Plant to Sites Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Intake Facilities.

[d]Fresh Emergent Wetland includes alkaline wetlands.

14.3.7 Impacts Associated with Alternative B

14.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**), would be the same as described for Alternative A for the Extended Study Area.

14.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B operations on wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**) would be the same as described for Alternative A for Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, Thermalito Complex, Trinity River, Klamath River, Spring Creek, Clear Creek, Feather River, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

For the remaining facilities, the indirect impacts to native plants from human disturbance (**Impact Wild-4**) and conflicts with conservation plans (**Impact Wild-5**) would also be the same as described for Alternative A.

Operational differences for Alternative B, when compared to Alternative A for Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, the Sacramento River, Sutter Bypass, and Yolo Bypass, are discussed below.

Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake

Operational modeling results for Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, are similar to those described for Alternative A as Alternative B would also result in improved storage conditions. However, Alternative B operations would result in more variable reservoir surface water elevation fluctuations than Alternative A.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

With implementation of Alternative B, these reservoirs would experience more variability in surface water elevation fluctuations, when compared to Alternative A. However, these fluctuations would still be less severe than when compared to Existing Conditions or the No Project/No Action Alternative. Therefore, operational changes at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake associated with implementation of Alternative B that would result in improved storage and reduced water level fluctuations would have a **beneficial effect** on wildlife habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to special-status wildlife species.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-1** discussion. That discussion is also applicable to interference with wildlife movement.

Sacramento River

Operational modeling indicates that Sacramento River flows associated with implementation of Alternative B would experience changes similar to those described for Alternative A. However, Alternative B would divert up to 3,900 cfs during winter flows (rather than the 5,900 cfs diversion that would occur with Alternative A during winter flows). The reduced rate of diversion would consequently require a longer duration of diversion, lasting from February through May.

Modeling performed using SRH-1DV and SacEFT indicates that the coverage of the valley foothill riparian vegetation alliance along the Sacramento River would increase or remain similar with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative. The only exception is that SacEFT indicates a slight increase in the number of years with post-initiation scour risk for Fremont Cottonwood seedlings with implementation of Alternative B, when compared to the No Project/No Action Alternative. For bank swallows, SacEFT modeling indicates negligible effects that would result from peak flow during nesting season and a slight decrease in habitat potential and suitability with implementation of Alternative B, when compared to the Existing Conditions and the No Project/No Action Alternative. The decrease in habitat potential and suitability resulting from implementation of Alternative B would be slightly greater than the decrease resulting from implementation of Alternative A.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Despite the change in the rate and duration of diversion, operational modeling for Alternative B, including modeling that is specific to riparian habitat, indicates that minimal effects would occur to riparian habitat resulting from the described changes in the flow regime. Therefore, riparian habitat downstream of the intakes would not be expected to be adversely affected. Modifications of the existing flow regime of the Sacramento River resulting from implementation of Alternative B would have a **less-than-significant impact** on riparian habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Despite the change in the rate and duration of diversion, operational modeling for Alternative B, including modeling that is specific to riparian habitat, indicates that minimal effects would occur to riparian habitat resulting from the described changes in the flow regime. Therefore, riparian habitat downstream of the intakes would not be expected to be adversely affected, nor would the special-status birds or mammals associated with riparian habitat. SacEFT modeling specific to the bank swallow also indicates that there would be minimal effects to this species. Therefore, modifications of the existing flow regime of the Sacramento River resulting from implementation of Alternative B would have a

less-than-significant impact on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Sutter Bypass

Implementation of Alternative B would divert up to 3,900 cfs during winter flows; in comparison, Alternative A would result in the diversion of up to 5,900 cfs during winter flows. The reduced rate of diversion would require a longer duration of diversion.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Alternative B, when compared to Alternative A, would reduce the velocity and volume of floodwaters entering the Bypass from the Sacramento River, but diversions would be reduced by 2,000 cfs. Although the rate of diversion would be reduced, the duration of diversion would be longer, and therefore, could result in a greater reduction of water volume than described for Alternative A. This reduction in the frequency, velocity, and volume of water entering the Bypass would have the same effects on riparian and wetland habitats as described for Alternative A. Therefore, the relatively minor modification of the existing flow regime of the Sutter Bypass associated with implementation of Alternative B that would result in reduced magnitude and duration of floodwaters entering the Bypass would have a **less-than-significant impact** on riparian and wetland habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Alternative B's reduction in the frequency, velocity, and volume of water entering the Bypass would have the same effects on wildlife species as described for Alternative A. Therefore, the relatively minor modification of the existing flow regime of the Sutter Bypass associated with implementation of Alternative B that would result in reduced magnitude and duration of floodwaters entering the Bypass would be a **potentially beneficial effect** to special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild Impact-3** discussion for Alternative A. The relatively minor change in the flow regime with implementation of Alternative B would have a **less-than-significant impact** on wildlife nursery sites, when compared to Existing Conditions and the No Project/No Action Alternative.

Yolo Bypass

Operational modeling for Alternative B indicates that that there would be a minor reduction in the duration and magnitude of flows entering into the Yolo Bypass.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

The relatively minor reduction in the frequency, velocity, and volume of water entering the Bypass associated with implementation of Alternative B would have the same effects on riparian and wetland habitats as described for Alternative A. The modification of the existing flow regime of the Yolo Bypass associated with implementation of Alternative B that would result in minor reductions in the frequency, velocity, and volume of floodwaters entering the Bypass would, therefore, have a **less-than-significant impact** on riparian and wetland habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The relatively minor reduction in the velocity and volume of water entering the Bypass associated with implementation of Alternative B would have the same effects on riparian and wetland habitats as described for Alternative A, and would, therefore, not adversely affect the associated species. The minor modification of the existing flow regime of the Yolo Bypass associated with implementation of Alternative B that would result in the reduced frequency, velocity, and volume of floodwaters entering the Bypass, would, therefore, have a **less-than-significant impact** on special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. The minor modification of the existing flow regime of the Yolo Bypass that would result in the reduced frequency, velocity, and volume of floodwaters entering the Bypass as a result of implementing Alternative B would have a **less-than-significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

14.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to terrestrial biological resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure

- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

Although the footprint of the Recreation Areas would be the same for Alternatives A and B, the associated electrical distribution line alignment would differ as a result of the change in location of Golden Gate Dam. With implementation of Alternative B, 2.9 fewer acres of annual grassland would be affected by the Recreation Area Electrical Distribution Line construction disturbance area. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**) as described for Alternative A.

In addition, the road relocations associated with Alternative B differ from those for Alternative A, mostly due to changes to the saddle dam access roads. An additional 2.5 acres of wildlife habitats would be affected by Alternative B roads. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**) as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included in the Project Buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**) as described for Alternative A.

For the remaining facilities, the effects of human disturbance on wildlife (**Impact Wild-4**) and conflicts with habitat plans (**Impact Wild-5**) would also be the same as described for Alternative A. However, for Alternative B, the footprint and/or construction disturbance area of Sites Reservoir and Dams, the Delevan Transmission Line, and the Delevan Discharge Facilities differ from Alternative A. These changes would affect different acreages of wildlife habitat. The differences between these facilities and their impacts on terrestrial biological resources are described below.

Sites Reservoir Inundation Area and Sites Reservoir Dams

Alternative B includes the construction of a 1.81-MAF Sites Reservoir, which requires the construction of Sites Dam, Golden Gate Dam, and nine saddle dams. For Alternative B, Sites Dam would have a larger footprint and Golden Gate Dam shifts location, when compared to Alternative A. Construction-related ground-disturbing activities and vegetation removal, and the subsequent filling of the reservoir, would result in the direct and permanent loss of the same wildlife habitats as described in Alternative A, but more acreage would be lost with the construction and filling of the larger reservoir (Table 14-20).

Table 14-20
Permanent Wildlife Habitat Loss Due to the Construction and Filling of the 1.81-MAF Sites Reservoir and Associated Dams: Alternative B Compared to Alternative A

Habitat	Permanent Loss (Acres) Alternative A	Permanent Loss (Acres) Alternative B	Additional Loss Associated with Alternative B when Compared to Alternative A
Annual grassland	11,654.6	13,196.9	1,542.3
Blue oak woodland	353.5	739.7	386.2
Dryland grain and seed crops	206.9	206.9	0
Lacustrine	20.2	21.8	1.6
Pasture	61.0	61.0	0
Urban/disturbed	76.1	78.8	2.7
Valley foothill riparian	81.5	97.5	16.0
Valley oak woodland	3.4	3.5	0.1
TOTAL	**12,457.2**	**14,406.1**	**1,948.9**

The construction disturbance area for the 1.81-MAF Sites Reservoir would be the same as described for the 1.27-MAF Sites Reservoir. The construction disturbance area could disturb as much as 1,000 acres of land, with the majority of disturbed habitat consisting of annual grassland habitat.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

Construction of the Alternative B reservoir and dams would result in the additional permanent loss of nearly 1,950 acres of wildlife habitat, when compared to Alternative A. The two habitat types most affected by the increased acreage would be annual grassland and blue oak woodland. The permanent loss and temporary disturbance of wildlife habitat resulting from the construction activities and filling of the reservoir associated with implementation of Alternative B would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The impacts of Alternative B on special-status wildlife species would be the same as described for Alternative A, with the exception of the impact on bald eagles. Construction of the larger Alternative B Golden Gate Dam would result in the direct take of an established bald eagle nest and nest tree because the tree is located within the proposed footprint of the dam. The disturbance or removal of this nest tree during the nesting season could result in the direct mortality of eggs or young, and the permanent loss of this nest tree would be a **significant impact** to bald eagles, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

Refer to the **Impact Wild-2** discussion. That discussion is also applicable to interference with wildlife movement.

Delevan Transmission Line

The design of the Delevan Transmission Line associated with Alternative B differs from that of Alternative A. Because there would be no pumping/generating plant associated with the Delevan Pipeline Discharge Facility, there would be no transmission line aligned from the Sacramento River to the existing PG&E or WAPA transmission line. There would, however, still be a transmission line aligned approximately three miles from the Sites Electrical Switchyard to the existing PG&E or WAPA transmission line. The construction disturbance area of the Delevan Transmission Line for Alternative B would result in the temporary disturbance of wildlife habitats, but at a much smaller scale than described for Alternative A (Table 14-21).

Table 14-21
Temporary Disturbance of Wildlife Habitat Due to the Construction of the Delevan Transmission Line: Alternative B Compared to Alternative A

Habitat	Temporary Disturbance (Acres) for the Entire Length of the Delevan Transmission Line for Alternative A	Temporary Disturbance (Acres) for the Section of the Alternative A Transmission Line outside of the Construction Disturbance area of the Delevan Pipeline	Temporary Disturbance (Acres) for the Entire Length of the Delevan Transmission Line for Alternative B
Annual grassland	69.5	69.5	54.6
Barren*	0.5	0.5	0
Canal	1.5	1.2	0.6
Dryland grain and seed crops	25.6	1.5	0
Deciduous orchard	0.4	0	0
Eucalyptus	0.3	0	0
Fresh emergent wetland	2.1	0	0
Irrigated row and field crops	9.4	0	0
Lacustrine	1.0	0	0

Table 14-21
Temporary Disturbance of Wildlife Habitat Due to the Construction of the Delevan Transmission Line: Alternative B Compared to Alternative A

Habitat	Temporary Disturbance (Acres) for the Entire Length of the Delevan Transmission Line for Alternative A	Temporary Disturbance (Acres) for the Section of the Alternative A Transmission Line outside of the Construction Disturbance area of the Delevan Pipeline	Temporary Disturbance (Acres) for the Entire Length of the Delevan Transmission Line for Alternative B
Pasture	24.5	0	0
Rice	143.0	0	0
Urban/disturbed	1.1	0	0
Valley foothill riparian	1.1	1.1	1.1
TOTAL	**280.0**	**73.8**	**56.3**

*Barren habitat includes fallowed agricultural fields.

The footings of the transmission towers would result in the permanent loss of wildlife habitat. Based on a worst-case scenario, the total permanent habitat loss associated with the footings would be approximately 0.5 acre of annual grassland habitat, which is less than the 2.5-acre loss associated with Alternative A.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

The reduced length of the Alternative B Delevan Transmission Line would result in the temporary disturbance of approximately 17 fewer acres of wildlife habitat than Alternative A, and would result in the permanent disturbance of approximately two fewer acres. The habitat type most affected by this decreased acreage would be annual grassland. Despite the reduction in the number of acres affected, the total permanent loss and temporary disturbance of annual grassland and valley foothill riparian habitat resulting from construction of the Alternative B transmission line would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

The impacts of Alternative B on special-status wildlife species would be the same as described for Alternative A.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

In contrast to Alternative A, the shortened Alternative B transmission line would not extend to the Sacramento River and would not be located adjacent to the Delevan NWR. In addition, the shortened transmission line would reduce the potential for avian collision, when compared to Alternative A. However, the remaining risk of collision and the potential disruption of a migratory corridor associated with the Alternative B transmission line would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Discharge Facility

For Alternative B, the Delevan Pipeline would be operated as a release-only pipeline. The associated Delevan Pipeline Discharge Facility would, therefore, not include a fish screen or any of the facilities needed for pumping and generating operations that were described for Alternative A. The ground-disturbing activities associated with the construction of the Delevan Pipeline Discharge Facility would result in the direct and permanent loss of wildlife habitats (Table 14-22), but habitat loss would occur at a smaller scale than described for the Intake Facilities for Alternative A.

Table 14-22
Direct and Permanent Wildlife Habitat Loss Due to the Construction of the Delevan Pipeline Discharge Facility: Alternative B Compared to the Alternative A Delevan Pipeline Intake Facilities

Habitat	Permanent Loss (Acres) by Alternative A	Permanent Loss (Acres) by Alternative B
Canal	0.6	0.1
Deciduous orchard	11.1	3.9
Riverine	1.6	0.1
Urban/disturbed	4.2	2.0
Valley foothill riparian	1.6	1.6
TOTAL	**19.1**	**7.7**

Additional acreage of temporary disturbance would occur as a result of a construction disturbance area for these facilities. The construction disturbance area for the Delevan Pipeline would be located adjacent to these facilities and could potentially be used as a staging area. Disturbed areas would be restored to their original habitat type after construction is complete. The wildlife habitat that would be affected by this construction disturbance area would be deciduous orchard habitat.

Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS

The smaller proposed Delevan Pipeline Discharge Facility would result in the permanent loss of approximately 12 fewer acres of wildlife habitat than Alternative A. The habitat type most affected would be deciduous orchard. Despite the reduction in the number of acres affected, the total permanent loss of wildlife habitat resulting from construction of the Alternative B discharge facility would be a **significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS

Construction of the proposed Delevan Pipeline Discharge Facility would result in the loss of approximately 140 linear feet (0.03 mile) of river bank, as compared to the loss of 660 linear feet (0.1 mile) associated with the Alternative A Intake Facilities. Despite the reduced Alternative B impact on the river bank, the number of acres of valley foothill riparian habitat that would be lost would be the same as described for Alternative A. This loss of river bank and riparian habitat would reduce the connectivity of the riparian corridor at this location, which could reduce the value of the habitat to the ringtail and western yellow-billed cuckoo. Despite the reduced number of acres of deciduous orchard habitat loss associated with Alternative B, the loss of this habitat, combined with the loss of riparian habitat, could adversely affect the western yellow-billed cuckoo. Despite the reduced size of the footprint of the Delevan Pipeline Discharge Facility, the shift in its location would result in the take of a second elderberry shrub that is located adjacent to the footprint of the Delevan Pipeline Intake Facilities and could adversely affect the valley elderberry longhorn beetle. Therefore, the Alternative B discharge facility would have a **potentially significant impact** on these special-status wildlife species, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wild-3: Substantial Interference with the Movement of any Native Resident or Migratory Wildlife Species, or with Established Native Resident or Migratory Wildlife Corridors, or Impede the Use of Native Wildlife Nursery Sites

The valley foothill riparian habitat that exists along the banks of the Sacramento River provides a travel corridor for numerous terrestrial wildlife species, including the fully-protected ringtail. Gaps in the connectivity of this corridor create higher risks of predation for wildlife that have to travel through these areas. Therefore, the removal of 140 linear feet of valley foothill riparian habitat along the Sacramento River associated with construction of the proposed Delevan Pipeline Discharge Facility resulting from implementation of Alternative B would have a **potentially significant impact** on terrestrial wildlife, when compared to Existing Conditions and the No Project/No Action Alternative.

Summary of Alternative B Impacts to Wildlife Habitats

Construction, operation, and maintenance of Alternative B would result in the permanent loss of 15,508.3 acres, and the temporary disturbance of an additional 5,341.4 acres, of wildlife habitat (Table 14-23).

Table 14-23
Acres of Wildlife Habitat[a] Subject to Alternative B Construction Impacts

Habitat Type	Acreage	
	Permanent Loss[b]	Temporary Disturbance[c]
Annual grassland	13,694.4	2,079.4
Barren	0.2	20.9
Blue oak woodland	887.5	644.3
Canal	8.6	13.5
Chamise-redshank chaparral	0.6	1.9
Deciduous orchard	8.2	174.0
Dryland grain and seed crops	331.2	213.0
Eucalyptus	0	46.2
Fresh emergent wetland	0.5	18.5
Irrigated row and field crops	155.6	225.7
Lacustrine	22.4	226.4
Mixed chaparral	0.8	1.8
Pasture	72.7	241.2
Rice	121.2	1,383.6
Riverine	0.1	0
Urban/disturbed	88.6	46.9
Valley foothill riparian	110.2	4.1
Valley oak woodland	3.5	0

Table 14-23
Acres of Wildlife Habitat[a] Subject to Alternative B Construction Impacts

Habitat Type	Acreage	
	Permanent Loss[b]	Temporary Disturbance[c]
TOTAL	**15,508.3**	**5,341.4**

[a]Calculated acreage does not include acres associated with the Project Buffer because the location and extent of disturbance is not yet specified.
[b]Total permanent habitat loss acreage includes the footprint of Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and the Delevan Pipeline Discharge Facilities. Total permanent loss acreage also includes the estimated permanent loss from construction within the footprint of the Recreation Areas, within the construction disturbance area for the Road Relocations, and from construction of the transmission tower footings associated with the Delevan Transmission Line.
[c]Total temporary disturbance acreage includes the footprint of the Recreation Areas (minus the acreage of estimated permanent loss) and the footprint of the existing Funks Reservoir, as well as the defined construction disturbance areas for the Road Relocations (minus the acreage of estimated permanent loss), Delevan Pipeline, TRR Pipeline, Holthouse to T-C Canal Pipeline, TRR to Funks Creek Pipeline, Delevan Transmission Line, and GCID Canal Facilities Modifications. Total temporary disturbance acreage also includes the estimated construction disturbance areas (outside of the footprints) for Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Tunnel from Sites Pumping Generating Plant to Sites Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Modifications, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Discharge Facilities.

14.3.8 Impacts Associated with Alternative C

14.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**), would be the same as described for Alternative A for the Extended Study Area.

14.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C operations on wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**) would be the same as described for Alternative A for Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Lake Natoma, Thermalito Complex, Trinity River, Klamath River, Spring Creek, Clear Creek, Feather River, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

Because Alternative C includes the three Project intake locations that were described for Alternative A, the operational impacts associated with Alternative C, as they relate to wildlife habitat (**Impact Wild-1**), special-status wildlife species (**Impact Wild-2**), and wildlife movement (**Impact Wild-3**), as well as the potential impacts from human disturbance (**Impact Wild-4**), or conflicts with habitat plans (**Impact Wild-5**), would be the same as described for Alternative A for Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, Sacramento River, Sutter Bypass, and Yolo Bypass.

14.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction, operation, and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to terrestrial biological resources:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Delevan Transmission Line and Delevan Pipeline Intake Facilities included in Alternative C are the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to botanical resources as described for Alternative A.

The Alternative C design for the Sites Reservoir Inundation Area and Dams, Electrical Distribution Lines associated with the Recreation Areas, and Road Relocations and South Bridge are the same as described for Alternative B. These facilities would require the same construction, operation, and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to terrestrial biological resources as described for Alternative B.

The boundary of the Project Buffer is the same for Alternatives A, B, and C, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A.

Summary of Alternative C Impacts to Wildlife Habitats

Construction, operation, and maintenance of Alternative C would result in the permanent loss of 15,536.72 acres, and the temporary disturbance of an additional 5,329.4 acres, of wildlife habitat (Table 14-24).

Table 14-24
Acres of Wildlife Habitat[a] Subject to Alternative C Construction Impacts

Habitat Type	Acreage	
	Permanent Loss[b]	**Temporary Disturbance[c]**
Annual grassland	13,694.7	2,091.5
Barren	0.2	21.4
Blue oak woodland	887.5	6443.
Canal	9.1	14.1
Chamise-redshank chaparral	0.6	2.1
Deciduous orchard	15.4	175.1
Dryland grain and seed crops	333.2	214.5
Eucalyptus	0	46.2
Fresh emergent wetland	0.5	18.5
Irrigated row and field crops	155.6	225.7
Lacustrine	22.4	226.6
Mixed chaparral	0.8	1.8
Pasture	72.7	241.2
Rice	122.9	1,383.6
Riverine	1.6	0
Urban/disturbed	90.8	46.9
Valley foothill riparian	110.2	4.1
Valley oak woodland	3.5	0
TOTAL	**15,521.7**	**5,357.6**

[a]Calculated acreage does not include acres associated with the Project Buffer because the location and extent of disturbance is not yet specified.

[b]Total permanent habitat loss acreage includes the footprint of Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, and the Delevan Pipeline Intake Facilities. Total permanent loss acreage also includes the estimated permanent loss from construction within the footprint of the Recreation Areas, within the construction disturbance area for the Road Relocations, and from construction of the transmission tower footings associated with the Delevan Transmission Line.

[c]Total temporary disturbance acreage includes the footprint of the Recreation Areas (minus the acreage of estimated permanent loss) and the footprint of the existing Funks Reservoir, as well as the defined construction disturbance areas for the Road Relocations (minus the acreage of estimated permanent loss), Delevan Pipeline, TRR Pipeline, Holthouse to T-C Canal Pipeline, TRR to Funks Creek Pipeline, Delevan Transmission Line, and GCID Canal Facilities Modifications. Total temporary disturbance acreage also includes the estimated construction disturbance areas for Sites Reservoir and Dams, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Tunnel from Sites Pumping Generating Plant to Sites Inlet/Outlet Structure, Sites Electrical Switchyard, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, GCID Canal Connection to the TRR, TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and Delevan Pipeline Intake Facilities.

14.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 14-25 for the impacts that have been identified as significant or potentially significant.

Table 14-25
Summary of Mitigation Measures for
NODOS Project Impacts to Terrestrial Biological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Wild-1: A Substantial Adverse Effect, Including Alteration of Habitat Suitability, on any Wildlife Habitat, Especially Riparian Habitat or Other Sensitive Natural Communities Identified in Local or Regional Plans, Policies, Regulations, or by DFG or USFWS	All Primary Study Area Project Facilities (construction)	Significant or Potentially Significant	Mitigation Measure Wild-1a: Implement a Combination of Habitat Protection, Enhancement, Restoration, or Conservation Easement Measures, in Consultation with USFWS	Less than Significant
	Sites Reservoir, Road Relocations, Sites Outlet Structure, Delevan Pipeline Intake/Discharge Facilities, Project Buffer (construction)	Potentially Significant	Mitigation Measure Wild-1b: Implement Bat Exclusion Measures Prior to Demolition of Existing Structures	Less than Significant
Impact Wild-2: A Substantial Adverse Effect, Including Mortality, Either Directly or Through Habitat Modifications, on any Species Identified as a Candidate, Sensitive, or Special-Status Species in Local or Regional Plans, Policies, or Regulations, or by DFG or USFWS				
Impact Wild-2a: Bald Eagle	Sites Reservoir and Dams (construction operation)	Significant	Mitigation Measure Wild-2a: Obtain Permit for Bald Eagle Nest Tree Removal, Remove Nest Tree Outside of Breeding Season, and Create Suitable Habitat	Less than Significant
Impact Wild-2b: Bank Swallow	Delevan/TRR Pipelines (construction)	Potentially Significant	Mitigation Measure Wild-2b: Implement Protective Actions to Prevent Bank Swallows from Nesting in the Cut Banks of Project Construction Trenches	Less than Significant
Impact Wild-2c: Giant Garter Snake	Delevan Pipeline, GCID Canal Facilities Modifications (construction)	Significant	Mitigation Measure Wild-2c: Conduct Pre-Construction Surveys for Giant Garter Snakes and Implement Protective Actions. Conduct Project Construction Activity Between May 1 and October 1 in Giant Garter Snake Habitat. Compensate for Temporary Disturbance of Habitat According to USFWS Guidelines	Less than Significant

Table 14-25
Summary of Mitigation Measures for
NODOS Project Impacts to Terrestrial Biological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Wild-2d: Golden Eagle	Sites Reservoir and Dams (construction), Recreation Areas (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure Wild-2d: Implement Avoidance and Minimization Measures at Historic or Active Golden Eagle Nest Sites. Conduct Satellite Telemetry Studies Pre- and Post-Construction to Determine Territory Size. Prepare a Golden Eagle Protection Plan and a Golden Eagle Monitoring Plan. Mitigate for Loss of Annual Grassland Foraging Habitat	Significant and Unavoidable
Impact Wild-2e: Ringtail	Delevan Intake/Discharge Facilities (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure Wild-2e: Implement Protective Actions to Minimize Impacts to the Ringtail, and Restore Connectivity of Riparian Corridor	Less than Significant
Impact Wild-2f: Valley Elderberry Longhorn Beetle	Sites Reservoir and Dams (construction), Road Relocations (construction, operation), Delevan Pipeline Intake/Discharge Facilities (construction)	Significant	Mitigation Measure Wild-2f: Implement Protective Actions to Avoid or Minimize Impacts to Elderberry Plants. Where Avoidance is not Possible, Transplant or Replace Plants, According to USFWS Guidelines	Less than Significant
Impact Wild-2g: Western Burrowing Owl	Sites Reservoir and Dams (construction), Road Relocations (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure Wild-2g: Conduct Pre-Construction Surveys for Western Burrowing Owls. If Owls are Found, Implement Protective Actions	Less than Significant
Impact Wild-2h: Western Pond Turtle	Sites Reservoir and Dams (construction, operation), Holthouse Reservoir Complex (construction), Delevan Pipeline (construction)	Potentially Significant	Mitigation Measure Wild 2h: Conduct Pre-Construction Surveys and Provide a Biological Monitor During Project Construction for the Western Pond Turtle. If Found, Turtles shall be Captured and Relocated by a Qualified Biologist	Less than Significant
Impact Wild-2i: Yellow-Billed Cuckoo	Delevan Pipeline Intake/Discharge Facilities (construction)	Potentially Significant	Mitigation Measure Wild-2i: Conduct Pre-Construction Surveys for the Western Yellow-Billed Cuckoo and Schedule Construction Activities to Avoid Impacts to Nest Sites	Less than Significant

Table 14-25
Summary of Mitigation Measures for
NODOS Project Impacts to Terrestrial Biological Resources

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Wild-3: Substantial interference with the movement of any native resident or migratory wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites	Delevan Pipeline (construction), Delevan Transmission Line (construction and operation), Delevan Pipeline Intake/Discharge Facilities (construction)	Potentially Significant	Mitigation Measure Wild-3a: During Project Construction, Backfill Trenches within 72 hours of Pipeline Installation and Provide an Escape Ramp for Trapped Wildlife Mitigation Measure Wild-3b: Construct Transmission Lines and Associated Equipment Following Suggested Practices for Avian Protection on Power Lines Mitigation Measure Wild-3c: Restore Riparian Habitat Connectivity	Less than Significant
Impact Wild-4: Indirect effects on common wildlife from human disturbance	All Primary Study Area Project Facilities (construction, operation, and maintenance)	Potentially Significant	Mitigation Measure Wild-4: Implement Avoidance and Minimization Measures.	Less Than Significant

Note:
LOS = Level of Significance

Mitigation Measure Wild-1a: Implement a Combination of Habitat Protection, Enhancement, Restoration, or Conservation Easement Measures, in Consultation with USFWS

For all three action alternatives, the acreage of permanent habitat loss within the Recreation Areas and the Road Relocations, as well as the temporary habitat disturbance within the construction disturbance areas for most facilities, was estimated. Because these acres are estimated, it may be possible to avoid impacts to certain habitat types.

A Habitat Evaluation Procedures assessment of the Primary Study Area was conducted under the lead of USFWS. A determination of appropriate mitigation measures for the habitat types that would be adversely affected within the Primary Study Area shall be made using the results of the HEP assessment, as well as through consultation with USFWS pursuant to the Fish and Wildlife Coordination Act. Mitigation measures could include but not be limited to protection, enhancement, restoration, or conservation easement.

Mitigation Measure Wild-1b: Implement Bat Exclusion Measures Prior to Demolition of Existing Structures

Prior to structure demolition, structures shall be inspected by a qualified biologist to determine if bats are present, and if present, to determine if the structure is being used as a day, night, or maternity roost. If a roost is present, appropriate bat exclusion measures shall be implemented at least five to seven days prior to structure demolition outside of the maternity season, which can range from mid-April through August 31, and outside of the winter months when bats could be hibernating. Bat exclusion measures could include one-way devices such as polypropylene netting, plastic sheeting, or tube-type excluders that would be placed at all active entry points. If a roost is present in a structure located outside of a reservoir inundation area, possible avoidance measures could include retaining the structure.

Mitigation Measure Wild-2a: Obtain Permit for Bald Eagle Nest Tree Removal, Remove Nest Tree Outside of Breeding Season, and Create Suitable Habitat

A permit to remove or relocate an eagle nest shall be obtained from USFWS. The bald eagle nest tree shall be removed outside of the breeding season, which ranges from January through July, to avoid direct impacts. Dam construction activities shall not occur during the breeding season until the nest tree is removed. After construction is complete, the filling of Sites Reservoir and Holthouse Reservoir would create new fish-bearing lacustrine habitat in an area that is surrounded by suitable bald eagle nest trees. Following inundation, releases downstream of Golden Gate Dam would restore flows to Funks Creek to maintain fisheries and bald eagle habitat.

Mitigation Measure Wild-2b: Implement Protective Actions to Prevent Bank Swallows from Nesting in the Cut Banks of Project Construction Trenches

Construction of the pipelines shall begin in May due to giant garter snake restrictions. May falls within the bank swallow breeding season (ranging from mid-March through July). Protective action shall be taken to prevent bank swallows from attempting to nest within the cut banks of the pipeline trenches. Actions shall include the placement of a mesh net on all cut banks during the bank swallow nesting season, and implementation of **Mitigation Measure Wild-3a** to ensure that trenches are backfilled within 72 hours of pipeline installation.

Mitigation Measure Wild-2c: Conduct Pre-Construction Surveys for Giant Garter Snakes and Implement Protective Actions. Conduct Project Construction Activity Between May 1 and October 1 in Giant Garter Snake Habitat. Compensate for Temporary Disturbance of Habitat According to USFWS Guidelines

Protective actions shall be taken to avoid or minimize impacts to the giant garter snake. Protective actions and mitigation measures shall comply with the USFWS's Programmatic Biological Opinion (USFWS, 1997) and could include the following actions:

- Preconstruction surveys shall be conducted within 24 hours prior to the start of construction in giant garter snake habitat. If a snake is encountered during construction, activities shall cease until corrective measures have been completed. Any sightings shall be reported to USFWS.
- Exclusion fencing shall be placed around construction areas within giant garter snake habitat to ensure that snakes do not enter the area. Exclusion fencing shall also be used around any agricultural irrigation ditches within 200 feet of the disturbance area.
- Construction activity within giant garter snake habitat shall be conducted between May 1 and October 1. If work outside of this time period is necessary, USFWS's Sacramento Fish and Wildlife Office shall be contacted to determine which additional protection measures are necessary.
- Construction personnel shall receive USFWS-approved environmental awareness training so that workers can recognize giant garter snakes and their habitats.
- Clearing shall be confined to the defined construction disturbance area.

- Rice fields shall be fallowed prior to the start of construction, and any dewatered habitat shall remain dry for at least 15 consecutive days after April 15 and prior to excavating or filling of the dewatered habitat.
- Construction between May and September in wetlands shall be restricted to prevent inadvertent mortality of giant garter snakes.
- A trained biological monitor shall be onsite during construction activities to inspect around the work equipment and within the trench and surrounding disturbance area each day before work begins.
- **Mitigation Measure Wild-3a** shall be implemented to avoid potential entrapment of a snake in the pipeline trench.
- After construction is complete, habitat shall be restored to pre-Project conditions.

Temporary disturbance to giant garter snake habitat would typically be mitigated at a ratio of 1:1. However, construction activity for the Delevan Pipeline is scheduled to occur during three giant garter snake seasons (season is from May 1 through October 1). Any disturbance lasting longer than two seasons is considered to be a permanent loss of habitat and shall be mitigated at a ratio of 3:1, with some of the mitigation compensated for through restoration of the area after Project construction is complete. If Project construction is conducted outside of the May 1 through October 1 active season, mitigation at a ratio of 6:1 could be required.

Disturbance to fresh emergent wetland habitat could, and shall to the extent feasible, be avoided by reducing the use of the construction buffer in areas of this habitat type, or altering the footprint of the road. Mitigation for rice habitat would already be partially compensated for by implementation of the mitigation for loss of wildlife habitat types described above.

Mitigation Measure Wild-2d: Implement Avoidance and Minimization Measures at Historic or Active Golden Eagle Nest Sites. Conduct Satellite Telemetry Studies Pre- and Post-Construction to Determine Territory Size. Prepare a Golden Eagle Protection Plan and a Golden Eagle Monitoring Plan. Mitigate for Loss of Annual Grassland Foraging Habitat

Golden eagle nests were observed within the footprint of three of the five proposed Recreation Areas during field surveys. Subsequent surveys documented that the nest at Lurline Headwaters Recreation Area no longer exists, the nest at Peninsula Hills Recreation Area is still active, and the nest at Stone Corral Recreation Area is falling apart, but is still active. An active golden eagle nest also exists outside, but in the vicinity, of the Sites Dam footprint.

Construction activities shall be modified to ensure that nesting golden eagles are protected. To avoid impacts to nesting golden eagles at Peninsula Hills, construction of the recreation area would be deferred. To avoid or minimize possible impacts to nesting golden eagles in other construction areas, some or all of the following measures shall be implemented:

- A bird detraction program shall be implemented near historic golden eagle nest sites to discourage eagles from returning to those sites.
- Construction near recently active nest sites shall start outside the active nesting season. The nesting period for golden eagles is between March 1 and August 15.

- If groundbreaking activities begin during the nesting period, a qualified biologist shall perform a pre-construction survey 14 to 30 days before the start of each new construction phase to search for golden eagle nest sites in appropriate habitat within 0.5 mile of proposed activities. If active nests are not identified, no further action is required and construction may proceed.
- If active nests are identified, a minimum 0.5 mile buffer zone around active golden eagle nests shall be implemented. Buffer zones shall remain until young have fledged. For activities conducted with agency approval within this buffer zone, a qualified biologist shall monitor construction activities and the eagle nest(s) to monitor eagle reactions to activities. If activities are deemed to have a negative effect on nesting eagles, the biologist shall immediately inform the construction manager that work should be halted, and CDFG and USFWS will be consulted.
- For golden eagles that begin nesting within the buffer zone after start of construction, the same avoidance and minimization measures as described for active eagle nests found before start of construction (0.5 mile buffer) shall be implemented. A buffer of less than 0.5 mile may be used if there is a visual barrier, such as a hill or dense trees, between the construction activity and the nest.

After construction is complete, it is possible that golden eagles will nest within the constructed Recreation Areas. In this situation, the following avoidance and minimization measures shall be implemented:

- After construction, golden eagle nesting sites shall be surveyed and monitored within and adjacent to the Recreation Areas to ensure that recreational activities do not disrupt eagle nest sites. Surveys shall be performed at the beginning of, and continue through, the nesting season. Consistent with avoidance guidelines, recreational access and other disruptive activities shall be suspended within 0.5 mile of active golden eagle nests until the young eagles have fledged.

The filling of Sites Reservoir would result in the loss of more than 11,600 acres (Alternative A) and almost 13,200 acres (Alternatives B and C) of annual grassland that provides foraging habitat for golden eagles. To assess the impact of this loss of foraging habitat, the following measures shall be implemented prior to the start of Project construction:

- A Golden Eagle Monitoring Plan shall be prepared.
- Satellite telemetry studies shall be conducted for three to five years prior to the start of construction to establish the number of golden eagles and the size of their territories.
- Surveys shall be conducted by permitted biologists.
- A Golden Eagle Protection Plan shall be prepared.

After construction is complete, at least five years of telemetry studies (to be determined during consultation with USFWS) shall be conducted to determine the effect of habitat loss. The loss of the annual grassland habitat shall be mitigated during consultation with USFWS; mitigation may include the preservation of annual grassland habitat located near the Primary Study Area that could provide foraging habitat for golden eagles, or could consist of restoring a historic foraging site that is no longer used because of an impact.

Mitigation Measure Wild-2e: Implement Protective Actions to Minimize Impacts to the Ringtail, and Restore Connectivity of Riparian Corridor

The fully-protected ringtail was observed within the riparian habitat that would be removed during construction of the Delevan Pipeline Intake/Discharge Facilities. The removal of riparian habitat within the footprint of the facilities would further reduce connectivity of the riparian corridor at that location. Implementation of **Mitigation Measure Wild-3c** would restore that connectivity. To minimize potential direct impacts to the ringtail, riparian vegetation removal shall not occur during the early pup-rearing season, which ranges from May 1 through June 15. Efforts to restore riparian corridor connectivity could include other habitat enhancements, such as providing ringtail nesting cavities and planting food sources.

Mitigation Measure Wild-2f: Implement Protective Actions to Avoid or Minimize Impacts to Elderberry Plants. Where Avoidance is not Possible, Transplant or Replace Plants, According to USFWS Guidelines

There are two elderberry shrubs located within the potential construction disturbance area for Sites Reservoir and Dams that could be completely avoided by establishing and maintaining a 100-foot-wide or wider buffer around them. Construction crews shall be briefed regarding the need to avoid these plants, and signs shall be posted during construction to avoid the buffer area. After Project construction is complete, this area would not be affected by Project operation or maintenance.

The elderberry shrub immediately adjacent to the footprint of the Delevan Pipeline Intake/Discharge Facility is located on the edge of an irrigation canal that is situated along an existing access road. Because of its proximity to the road, it would not be possible to establish a 100-foot-wide buffer. It would also not be possible to establish a 100-foot-wide buffer for the shrubs located immediately adjacent to the existing Maxwell Sites Road. Consultation with USFWS would be initiated for possible approval to encroach on the buffer. Otherwise, appropriate mitigation measures shall be implemented.

The elderberry shrubs within the footprint of Sites Reservoir, Sites Dam, and Golden Gate Dam, as well as the one shrub within the footprint of the Delevan Pipeline Intake/Discharge Facility, would not be avoided by Project construction, and therefore, shall be transplanted or replaced, depending on the likelihood of survival post-transplantation. Transplantation procedures shall comply with USFWS's 1999 Conservation Guidelines for the Elderberry Longhorn Beetle (USFWS, 1999b). If transplantation is not feasible, USFWS general guidelines require replacement of elderberry plants in designated mitigation areas. Elderberry plants are typically replaced at a ratio of 2:1 for stems greater than one inch in diameter at ground level with no adult emergence holes, 3:1 for stems where emergence holes are documented in less than 50 percent of the shrubs, and 5:1 for stems greater than one inch in diameter with emergence holes.

Mitigation measures already required for the loss of riparian habitat pursuant to the mitigation for loss of wildlife habitat types described above could potentially compensate for the native planting requirement for elderberry plant mitigation.

Mitigation Measure Wild-2g: Conduct Pre-Construction Surveys for Western Burrowing Owls. If Owls are Found, Implement Protective Actions

Pre-construction surveys shall be conducted in annual grasslands within the footprint of Sites Reservoir and within the construction disturbance area of the Road Relocations to determine if burrowing owls are present. These surveys shall be conducted within 30 days of ground-disturbing construction activities or the start of the filling of reservoir. Surveys shall be conducted by a qualified biologist in compliance with the Burrowing Owl Survey Protocol and Mitigation Guidelines (CBOC, 1993). If burrowing owl burrows are found, protective measures shall be implemented.

Protective measures may include avoidance of occupied burrows during the nesting season, which is from February 1 through August 31, with the peak of the season occurring from April 15 through July 15. Any unoccupied burrows located within the immediate construction area shall be excavated using hand tools, and then filled to prevent reoccupation.

If destruction of occupied burrows is unavoidable, such as within the footprint of Sites Reservoir, burrow entrances shall be altered, outside of the nesting season, to allow resident owls to exit but not re-enter the burrow. Owls shall be excluded from burrows by installing one-way doors in burrow entrances. One-way doors shall be left in place for at least 48 hours to ensure owls have left the burrow before the start of construction. Other possible mitigation could include the creation of artificial burrows in adjacent suitable habitat.

Loss of annual grassland habitat shall be compensated for with implementation of the mitigation for loss of wildlife habitat types described above.

Mitigation Measure Wild-2h: Conduct Pre-Construction Surveys and Provide a Biological Monitor During Project Construction for the Western Pond Turtle. If Found, Turtles shall be Captured and Relocated by a Qualified Biologist

Before construction activities begin, a qualified biologist shall conduct western pond turtle surveys along creeks and other ponded areas within the footprint of Sites Reservoir, Sites Dam, and Holthouse Reservoir, as well as along the irrigation canals within the construction disturbance area of the Delevan Pipeline. Adjacent upland areas shall also be examined for evidence of nests or individual turtles. A Project biologist shall be responsible for conducting the survey and relocating any turtles found within footprints or construction disturbance areas. If a nest is observed, a biologist with appropriate permits and prior approval from CDFG shall move eggs to a suitable location or facility for incubation. However, some individuals may be undetected or enter sites after surveys are conducted, and could be subject to mortality. A biological monitor shall, therefore, be present during Project construction to minimize take.

Mitigation Measure Wild-2i: Conduct Pre-Construction Surveys for the Western Yellow-Billed Cuckoo and Schedule Construction Activities to Avoid Impacts to Nest Sites

The yellow-billed cuckoo breeding season ranges from mid-June through August. To minimize direct impacts to this species, riparian and orchard vegetation removal within the footprint of the Delevan Pipeline Intake/Discharge Facility shall occur outside of these dates. If construction activities are scheduled to occur during the breeding season, preconstruction surveys shall be conducted in riparian and orchard habitat within the construction disturbance area of the Delevan Pipeline Intake/Discharge Facility to confirm that cuckoos are not actively nesting in or near the area. If active nests are identified, a minimum 500-foot construction buffer shall be established around any nest sites. All construction shall be avoided where active nests are discovered until the cuckoos have finished nesting.

Loss of valley foothill riparian and deciduous orchard habitat shall be compensated for with implementation of the mitigation for loss of wildlife habitat types described above.

Mitigation Measure Wild-3a: During Project Construction, Backfill Trenches within 72 hours of Pipeline Installation and Provide an Escape Ramp for Trapped Wildlife

Pipeline trenches shall be backfilled within 72 hours of pipeline installation to prevent potential impacts to trapped wildlife. The trench shall be inspected for wildlife before it is filled. At the end of each day, a ramp shall be placed at the end of the trench at an approximate 45 degree slope to allow trapped wildlife to escape. In addition to a ramp, the trench shall be covered to prevent wildlife from falling in.

Mitigation Measure Wild-3b: Construct Transmission Lines and Associated Equipment Following Suggested Practices for Avian Protection on Power Lines

Transmission lines, poles, and associated equipment shall be properly fitted with wildlife protective devices to isolate and insulate structures to prevent injury or mortality to wildlife, especially avian species. Protective measures shall follow the guidelines provided in Suggested Practices for Avian Protection on Power Lines (APLIC, 2006), and shall include insulating hardware or conductors against simultaneous contact, using poles that minimize impacts to birds, and increasing the visibility of conductors or wires to prevent or minimize bird collisions.

Mitigation Measure Wild-3c: Restore Riparian Habitat Connectivity

After the Delevan Pipeline Intake/Discharge Facilities are constructed, riparian habitat connectivity shall be restored to provide a travel corridor for terrestrial wildlife. The entire length of the land side of the new levee associated with the facilities shall be planted with riparian vegetation. Where the levee approaches SR 45, fencing shall be installed to protect wildlife from vehicles. Vegetation shall be monitored, and irrigated if necessary, to ensure survival.

Mitigation Measure Wild-4: Implement Avoidance and Minimization Measures

Measures to avoid or minimize human disturbance impacts associated with Project construction and maintenance activities shall include the following:

- Provide worker awareness training to all construction personnel prior to the start of construction activities; such training shall explain how to avoid impacts to sensitive species or habitats.
- Require construction personnel to comply with applicable federal, State, and local laws and regulations regarding prevention and control of noise during Project construction.
- Equip construction equipment engines with adequate mufflers, intake silencers, and engine enclosures.
- Turn off construction equipment during prolonged periods of nonuse to eliminate noise.
- Maintain all equipment appropriately, and train equipment operators regarding good practices to reduce noise levels.
- Minimize light pollution to the greatest extent practicable. Measures may include, but not be limited to, light hoods/shields, directional lighting, or minimum required brightness.
- Conduct pre-construction surveys in habitat types for special-status species. If found, protective actions shall be taken to passively relocate wildlife as needed.

- Use exclusion fencing or equivalent to prevent wildlife from entering the Project construction area. Fencing shall be removed after construction is complete.
- A biological monitor shall be on-site during Project construction in habitat associated with special-status species.
- Removal of trees and other vegetation shall occur outside of the breeding/nesting season of associated special-status species, and shall be completed prior to the start of reservoir filling to minimize impacts to tree- or shrub-nesting species. If Project construction must occur during the breeding/nesting season, a USFWS or DFG-approved buffer shall be established around the sensitive areas.
- Demolition of structures and bridge maintenance shall occur outside of the breeding/roosting season. If Project construction or maintenance must occur during this period, exclusionary devices shall be installed during late fall or winter to prevent roosting in structures.
- Maintenance of transmission lines or towers shall not be conducted during the nesting season in proximity to an active raptor nest.
- Food-related garbage items, such as wrappers, cans, bottles, or food scraps, shall not be left at the Project construction sites.
- Persons associated with the Project shall not be permitted to have pets of any kind within the Project construction sites.

Measures to avoid or minimize human disturbance impacts associated with Project recreation activities shall include the following:

- Implement adequate signage, fencing, and leash laws in areas of public access to minimize potential harassment of wildlife, including handling, by people and pets.
- Retain or plant screening vegetation along the margins of developed areas to reduce indirect impacts from lights and noise and the effects of human disturbance.
- Retain mature trees and minimize use of non-native landscaping.
- Design recreational areas with physical barriers to limit impacts to adjacent habitat.
- Revegetate areas of disturbed soil.
- Establish boat speed limits and designate no wake zones in sensitive areas to minimize disturbance of lacustrine wildlife and erosion of shoreline habitat.
- Provide adequate numbers of wildlife-proof garbage containers and maintain a pick-up schedule of at least once per week during the recreation season.
- For exterior lighting, use light shields or downward directed lighting to minimize the impacts of artificial light.

Measures to avoid or minimize impacts from human disturbance impacts associated with increased traffic during Project construction shall include the following:

- Restrict all movement of construction vehicles outside of the right-of way to pre-designated access or public roads.

- Enforce an approved speed limit on Project right-of way and access roads, unless otherwise posted, for all Project personnel.

Implementation of **Mitigation Measures Wild-1a, Wild-1b, Wild-2a, Wild-2b, Wild-2c, Wild-2e, Wild-2f, Wild-2g, Wild-2h, Wild-2i, Wild-3a, Wild-3b, Wild-3c,** and **Wild-4** would reduce the level of significance of Project impacts to **less than significant.**

Implementation of **Mitigation Measure Wild-2d** would result in Project impacts remaining **significant and unavoidable.**

15. Wetlands and Other Waters of the United States

15.1 Introduction

This chapter provides a description of the wetlands and other waters of the United States (U.S.) for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. *Wetlands*, which are waters of the U.S., are areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions. Wetlands generally include swamps, marshes, bogs and similar areas. *Other waters of the U.S.* include all waters that are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide.[1]

The regulatory setting for wetlands and waters of the U.S. is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially impacts, where appropriate. Project-related impacts to the water quality in wetlands or waters of the U.S. are described in Chapter 7 Surface Water Quality.

15.2 Environmental Setting/Affected Environment

15.2.1 Extended Study Area

15.2.1.1 Methodology

This section describes the Extended Study Area with respect to jurisdictional waters pursuant to the Clean Water Act Section 404, including wetlands and other waters of the U.S. In the Extended Study Area, CVP and SWP water deliveries are made to urban users, agricultural users, to Level 4 wildlife refuges, and to San Luis Reservoir. Only San Luis Reservoir and Level 4 wildlife refuges are described for the Extended Study Area, because no wetlands or other waters of the U.S would be involved in water deliveries to urban or agricultural lands.

Information describing existing wetland or waters resources for San Luis Reservoir is based on research conducted for the Bay Delta Conservation Plan.

To describe the extent of wetlands and other waters of the U.S. potentially affected in wildlife refuges, GIS was used to examine the 11 selected Wildlife Refuges and Wildlife Areas for the National Wetland Inventory (NWI) (USFWS, 1999) perennial wetlands they contain. A comparison of the 1999 wetland mapping with mapping available in 2011 shows no change in attributes for the 11 selected wildlife refuges. Using the ArcView 9.3 GIS program (ESRI, 2010), polygons were obtained for perennial wetland areas within outlines of wildlife refuges receiving Level 4 CVP and SWP water deliveries

[1] For more detail regarding the definition of waters of the U.S., the reader is referred to the program definitions document at http://water.epa.gov/lawsregs/lawsguidance/cwa/wetlands/regs_index.cfm

(Figure 1-7 in Chapter 1 Introduction).Acreages of the resulting areas were calculated using GIS to provide an estimate of wetlands and other waters of the U.S. that could potentially receive an alternate source of Level 4 water supply if one of the alternatives is implemented. Categories of NWI wetland types selected were all freshwater non-tidally influenced wet areas: Palustrine – all categories; Riverine – Lower Perennial/Emergent, Intermittent-Streambed/Vegetated, and Unconsolidated Shore/Vegetated categories.

15.2.1.2 Wetlands and Waters of the U.S.

San Luis Reservoir

Existing acreage, capacity, water levels, and extent of fluctuation of San Luis Reservoir are described in Chapter 6 Surface Water Resources. San Luis Reservoir's drawdown zone fluctuates between 45 and 90 vertical feet. Within this drawdown zone, temporary narrow strips of herbaceous, often weedy, wetland vegetation or riparian wetland vegetation, such as willow scrub, become established for part of the year in temporary narrow bands and fragmented patches. Where rivers or streams enter the reservoir, more established riparian wetland patches can be found adjacent to the stream.

Wildlife Refuges

The approximate extents of various types of wetlands that exist in the 11 selected Wildlife Refuges and Wildlife Areas are listed in Table 15-1. Acres of other waters of the U.S. (ponds, lakes, streams) that receive Level 4 water deliveries within the 11 selected Wildlife Areas and Refuges are listed in Table 15-1. The "Riverine" portions may or may not receive Level 4 water. The "Other" category represents wetland types that are undefined by the NWI.

15.2.2 Secondary Study Area

15.2.2.1 Methodology

For this discussion, jurisdictional waters whose flows, quantity, seasonality, or quality may be affected by Project operations include only the mainstems of the Sacramento, Trinity, American, and Feather rivers, plus Clear Creek near Shasta Lake. The following facilities would also be potentially affected: Trinity Lake, Lewiston Lake, Klamath River downstream of the Trinity River, Whiskeytown Lake, Shasta Lake, Spring Creek, Keswick Reservoir, Lake Oroville, Thermalito Complex, Folsom Lake, Lake Natoma, Suisun Bay, Sacramento-San Joaquin Delta (and its wetlands), San Pablo Bay and San Francisco Bay.

The Yolo and Sutter bypasses are also considered as “other waters of the U.S.”, even though they are farmed part of the year, due to their hydrological connection with the Sacramento River system. Waters of the U.S. in the Secondary Study Area were quantified by measuring the length (in miles) of the centerline of each river’s main channel, or areas (in acres) of lakes or reservoirs, using GIS software (ESRI, 2006). Acreages for the Suisun Bay and Marsh were obtained from the Delta Atlas (DWR, 1995) and from the DWR geodetic branch for the Legal Delta. Acreages for San Pablo and San Francisco bays were estimated using the measuring tool in the ArcView 9.3 GIS program (ESRI, 2010) on the map of the Secondary Study Area.

15.2.2.2 Wetlands and Waters of the U.S.

The above-listed potentially affected waters of the U.S. in the Secondary Study Area include both rivers that drain mountain and foothill areas, and the lakes or reservoirs that feed or regulate the creeks and rivers. The Sacramento River conveys water from these areas down the center of the Sacramento Valley and into the Delta at its confluence with the San Joaquin River. The Colusa Basin Drain, a natural drainage feature that parallels the Sacramento River on the west side, intercepts westside tributaries and agricultural runoff between Stony Creek and Colusa. All westside tributary streams to the Sacramento River between Red Bluff and Colusa, with the exception of Stony Creek, are intermittent.

Although the area drained by the Sacramento River contains ponds and several kinds of wetlands (including seasonal wetlands, alkaline wetlands, vernal pools, and emergent wetlands), these wetlands are located in upland landscapes and are not hydrologically connected to the main channel of the Sacramento River. The exceptions are small areas of emergent wetland in some of the Sacramento River's off-channel habitats, such as oxbows or cutoffs, in the Red Bluff-to-Colusa reach.

Emergent wetlands usually remain wet throughout the year. They contain vegetation that is rooted under water and stems that emerge above the surface. Typical species include cattails and bulrush. Emergent wetlands are not common along the smaller drainages, but do occur occasionally along drainage canals, larger streams, and pond edges. Extensive wetlands, mostly within tidal influence, occur in the Delta and Suisun Marsh around the north edge of Suisun Bay.

For potentially affected waterways, the flow, hydrograph, diversions, impoundments, main tributaries, pattern of riparian vegetation, and any adjacent wetland areas are described in Chapter 6 Surface Water Resources, Chapter 7 Surface Water Quality, and Chapter 8 Fluvial Geomorphology and Riparian Habitat.

The extent of potentially affected streams and waterways are represented by length in miles of the main channel in Table 15-2; the extent of lakes and reservoirs are represented by acres in Table 15-3; and the extent of wetlands in acres in Table 15-4.

Table 15-2
Potentially Affected Waters of the U.S. in the Secondary Study Area: Rivers and Streams

River or Creek	Miles	Notes
Sacramento River	278.7	Downstream of Shasta Lake
Trinity River	121.3	Between Spring Creek Tunnel and Klamath River confluence
Clear Creek	16.1	Reach between Sacramento River and Whiskeytown Lake
Spring Creek	0.7	Downstream of tunnel (measured from Google Earth)
American River	23.3	Downstream of Folsom Lake
Feather River	66.7	Downstream of Lake Oroville

15.2.3 Primary Study Area

15.2.3.1 Methodology

Wetlands and other waters of the U.S. were evaluated within the proposed Sites Reservoir Inundation Area during 1998 and 1999 (DWR, 2000). Wetlands and other waters of the U.S. within proposed Project facility locations such as the Recreation Areas, Road Relocations, Funks Reservoir, and the Delevan Pipeline were evaluated during 2001 and 2002 (DWR, 2005). Project facilities proposed after 2005 were evaluated during 2010 (Eastside Road Extension) and 2011 (Delevan Pipeline Intake/Discharge Facilities and Holthouse Reservoir Complex). Potential wetland features were initially mapped using GIS, based in part on interpretation of aerial photography flown in 1997 for this project (scale: 1:12,000). Preliminary wetland assessments were then made by a field review of hydrologic conditions, plant species composition, and soil characteristics, pursuant to USACE 1987 guidance (USACE, 1987). All potential wetlands were field-mapped using GPS and assigned to a wetland feature type; wetland acreages were then calculated using ArcView 3.2 and ArcGIS 9.3 software (ESRI 2001, 2010). For all Project facilities locations, the jurisdictional status of the wetlands has not been determined or verified by the USACE. One exception is the GCID Canal Facilities, which are not evaluated in this chapter because Project-related modifications would occur within the confines of existing canal facility structures.

Other waters of the U.S. include ponds, small reservoirs, and tributaries. Other waters of the U.S. were first identified and measured using aerial photography, then field-verified where feasible. Acreages were calculated using GIS and Excel. Tributaries were classified by two general width categories (less than 15 feet wide, greater than 15 feet wide) in the proposed Sites Reservoir footprint (DWR, 2000). Due to changes in measurement guidelines, four width categories (0 to 5, 5 to 10, 10 to 15, and greater than 15 feet wide) were evaluated at all other Project facility locations (DWR, 2005). Agricultural canals and ditches visible on aerial imagery were included in the inventory of existing tributary features, but were not field-verified as to extent of wetland vegetation occurring within the ditch or canal, or whether the canal had a direct hydrological connection with a natural stream.

Although the extent of the wetland/other waters of the U.S. surveys conducted within the Sites Reservoir Inundation Area overlaps with portions of the Project Buffer, most of the area within the buffer has not yet been inventoried for waters or wetlands. Wetlands and other waters of the U.S. lying outside of Project facility footprints, but within the Project Buffer, were evaluated at a general level only, using 2009 NAIP aerial imagery and GIS. Results of field surveys or GIS inventories which had already been conducted on much of the land within this buffer as part of Project surveys were used to describe and evaluate wetlands and other waters of the U.S. within the buffer. A survey of this Project component for wetlands and other waters of the U.S. would be conducted prior to Project construction.

15.2.3.2 Wetlands and Waters of the U.S.

Table 15-5 shows presence or absence of wetland features and other waters of the U.S. in the parts of the Primary Study Area that would be occupied by the footprints of the proposed Project facilities, as well as the Delevan Pipeline construction disturbance area. The affected areas are described below. Acres of wetlands and other waters of the U.S. in the Primary Study Area are shown in Table 15-6.

Sites Reservoir Inundation Area, Dams, Recreation Areas, Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Site Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard

The proposed Sites Reservoir inundation area (approximately 14,000 acres) includes most of the Antelope Valley and the drainages of Antelope Creek, Stone Corral Creek, and Funks Creek. All streams within the reservoir footprint and within the proposed roads and recreation areas are ephemeral with little or no flow from June through October. These streams, and especially their smaller tributaries, may rise rapidly with significant rainfall events; however, they may also dry out between events and remain dry for long periods during the winter months.

The majority of the proposed reservoir inundation area is currently used for livestock production. The vegetation consists mostly of non-native annual grasslands with sporadic riparian species along the banks of the creeks and drainages. Several large valley oaks and cottonwoods occur along Antelope Creek, with willows scattered along the smaller drainages. Most of the banks of the creeks are heavily degraded by cattle trampling and trails. Smaller drainages have little to no wetland species associated with them and contain annual weedy species up to the ordinary high water mark. Approximately 148 miles of drainages (including Antelope, Grapevine, Stone Corral, Lurline and Funks creeks) occur within the proposed inundation area. Sixteen acres of small stock ponds occur on drainages throughout the area.

Approximately 153 acres of seasonal wetlands occur throughout the proposed reservoir inundation area. Most are dry by early summer and are associated with low-lying areas of clay or clay loam soils. A small amount of alkaline wetlands, vernal pools, and emergent wetlands also occur within the proposed reservoir inundation area, including Salt Lake.

Golden Gate Dam would be located on Funks Creek and Sites Dam on Stone Corral Creek. Both are active creek channels cutting through steep hillslopes with no other streams or wetlands. The Sites Inlet/Outlet Structure, Pumping/Generating Plant, Tunnel, Electrical Switchyard, Asphalt Batch Plant, and Field Office Maintenance Yard, as well as a 1000-acre construction disturbance area for all of these Project facilities, would be located in the rolling annual grassland east of the reservoir footprint. In this heavily grazed area, a few intermittent streams drain into Funks Creek as it winds through the area just west of existing Funks Reservoir. No other streams, vernal pools or other wetlands occur in this grassland except for scattered disturbed agricultural ponds.

Proposed recreation areas are mostly sited along hilltops and hillsides above the proposed reservoir inundation area. These areas are mostly dominated by various upland vegetation types, such as grasslands and oak savannas. However, all have several drainages that traverse the areas with sporadic riparian and wetland features. Lurline Creek and its associated small wetlands are located along the Lurline Recreation Area access road. Some of the proposed distribution line routes serving the recreation areas cross intermittent streams and, in the case of the Saddle Dam Recreation Area, traverse through areas with vernal pools and other seasonal wetlands.

Wetlands and other waters of the U.S. coinciding with proposed road relocations vary by route segment. Several road segments are located mostly in annual grasslands, but similar to the proposed recreation area distribution lines, cross numerous ephemeral drainages and occasional small seasonal wetlands.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The 228-acre existing Funks Reservoir is bounded primarily by annual grasslands composed of mostly weedy non-native species. Very few trees or wetlands occur along the water's edge. Approximately five acres of seasonal wetlands occur along drainages above the reservoir water's edge. One vernal pool occurs in the grasslands near the upstream end of the reservoir, although it supports very few native vernal pool plant species. The portion of Funks Creek immediately upstream of the reservoir supports a thin line of riparian and other associated trees, and very small patches of wetland vegetation within its bed. In addition, Funks Creek supports an approximately 0.7-acre area of riparian habitat downstream of the existing dam.

The approximately 365-acre area proposed for the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard is composed mostly of annual grassland and agricultural fields. A 13-acre Alkaline Seasonal Wetland complex is located adjacent to and southeast of the Holthouse facilities. The source of water for the wetland complex appears to be seeps located at its southern edge, as well as runoff from both the nearby orchard to the east and the adjacent agricultural land to the north. Underlying soils are predominantly Hillgate and Capay clays and clay loams, with lesser amounts of Corval, Altamont, and other clay soils (NRCS, 1999), which have a very slow infiltration rate, and high water retention capacity typical of clays. Funks Creek flows through the northern third of this area and supports a thin swath of riparian vegetation, including large trees, along its 0.9 mile length, as well as a 1.7-acre area of riparian wetland in its bed near the outlet downstream of the Funks Reservoir Dam.

Table 15-5
Presence of Wetlands and Other Waters of the U.S. at each Proposed Project Facility[a]

Project Facility	Wetland Type					Other Waters of the U.S. Type						Notes
	Alkaline	Emergent	Riparian	Seasonal	Vernal Pool	Pond	Streams 0-5 Feet Wide	Streams 5-10 Feet Wide	Streams 10-15 Feet Wide	Streams <15 Feet Wide	Streams >15 Feet Wide

[a]Proposed Project Facility includes the facility footprints of the proposed Project facilities, as well as the Delevan Pipeline construction disturbance area.
[b]The Project Buffer does not include facility footprints, but may overlap with portions of construction disturbance areas.

Table 15-6
Acre Summary of Wetlands and Other Waters of the U.S. in the Primary Study Area

	Acres												
	Wetland Type						Other Waters of the U.S. Type						
	Alkaline[a]	Emergent	Riparian	Seasonal	Vernal Pool	TOTAL WETLAND ACRES	Pond[b]	Streams 0-5 Feet Wide	Streams 5-10 Feet Wide	Streams 10-15 Feet Wide	Streams <15 Feet Wide (Reservoir Only)	Streams >15 Feet Wide (All Project Facilities)	TOTAL OTHER WATERS OF THE U.S.
TOTAL ACRES for Primary Study Area (Project facility footprints) and subject to potential impacts[c]	**36.54**	**2.41**	**25**	**182.41**	**5.81**	**252.17**	**29.66**	**5.87**	**15.09**	**13.28**	**77**	**116.32**	**227.56**

[a]20 acres of Alkaline wetlands include at least 19.5 acres that are adjacent to the footprint rather than within, but would be subject to indirect impacts; 0.5 acre is within footprint.

[b]Includes 6.1 acres for Salt Lake; all remaining ponds are stockponds.

[c]Total acreage does not include acreage associated with the Project Buffer, which has not been surveyed or mapped.

Note:

Primary Study Area is defined here as the non-overlapping set of largest proposed facility footprints, except for the Delevan Pipeline, which also includes a wider construction disturbance area, and the Holthouse Reservoir Complex, where alkaline wetlands include the area adjacent to as well as within the footprint.

GCID Canal Facilities Modifications

This Project facility consists of modifications to the GCID Canal facilities that are contained completely within the existing canal structures. Because this Project component would not generate any ground disturbance or effects on any wetlands or other waters of the U.S., it will not be discussed further in this chapter.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir

The 218-acre footprint for this reservoir and associated facilities is located east of the GCID Canal in an area occupied entirely by agricultural fields, mostly rice. The footprints of these facilities cross no streams and contain no wetlands; the only waterways located in this area are agricultural canals.

Delevan Pipeline, Delevan Transmission Line, Terminal Regulating Reservoir Pipeline, and Delevan Pipeline Electrical Switchyard

The proposed Delevan Pipeline and associated Delevan Transmission Line routes are located primarily within the valley floor and bordered by agricultural fields for most of their length. Approximately 2.7 miles west of the Sacramento River, the pipeline/transmission route would cross the Colusa Basin Drain, a large canal that collects agricultural field irrigation water and water intercepted from small streams west of the Sacramento River, conveying it southward to its terminus at the Sacramento River in northeastern Yolo County. The pipeline/transmission line route would also cross a fourteen-acre site of disturbed alkaline wetlands approximately three miles west of the Sacramento River. The Delevan National Wildlife Refuge is located immediately south of the proposed pipeline/transmission line route. The wildlife refuge contains several wetlands and ponds. Numerous canals occur adjacent to or intersect the proposed pipeline/transmission line route. Associated with these canals are adjacent wet areas, wetland vegetation, and some riparian vegetation. Several of these drainages follow historic channels.

Toward its west end, the pipeline and transmission line routes would diverge. The Delevan Pipeline would cross the GCID Canal at the southwest corner of the proposed TRR, and would terminate at the T-C Canal (within the proposed Holthouse Reservoir). The TRR Pipeline would parallel the Delevan Pipeline between these two canals, and the Delevan Pipeline Electrical Switchyard would be located within this section of the pipeline route. Lands between these two canals contain agricultural fields and previously tilled annual grassland. The Delevan Transmission Line route would continue west across both of the canals and would terminate at the proposed Sites Electrical Switchyard and Sites Pumping/Generating Plant. Lands along this portion of the route contain agricultural fields and previously tilled annual grassland, with a small area of alkaline/saline soils.

Delevan Pipeline Intake/Discharge Facilities

The proposed intake and discharge facility site is located east of SR 45, along the bank of the Sacramento River at approximately RM 158.5. The proposed intake would encompass an approximately 19-acre area, mostly on the land side of the river levee, with a small strip on the water side. The proposed discharge facility would occupy a small fraction of the same area, when compared to the proposed intake facility. A few riparian trees, such as valley oaks, Fremont cottonwoods, and black walnuts, occur at the site between the levee and the river's edge. Emergent wetland vegetation occurs in one shallow area along the riverbank. Large tracts of mature mixed riparian growth occur upstream and downstream; however, the area where the new intake and discharge facilities would be located consists mostly of agricultural land (orchards) in the area west of the levee. The intake facility would extend out into the Sacramento River 40 feet and would occupy a small portion of the river's 400- to 500-foot width at this location. The discharge facility would not extend into the river.

Project Buffer

The Project Buffer surrounds all Project facilities, with the exception of the Delevan Pipeline, Delevan Transmission Line, and portions of the roads. Numerous ephemeral streams draining into the Sites Reservoir footprint are located within the Project Buffer, especially in the hills above the western side and south end of the reservoir. Within the Project Buffer are also scattered stockponds and, off the reservoir's northeast edges, portions of the seasonal wetland complexes typical of that part of the Primary Study Area. The Project Buffer also includes smaller segments surrounding the TRR and associated facilities, and the Delevan Pipeline Intake/Discharge facilities at the Sacramento River. Waters of the U.S. within the Project Buffer at both of the latter sites consist only of agricultural canals, except for a short stretch of river edge at the Delevan Pipeline Intake/Discharge facilities.

Sacramento River

Between Red Bluff and Hamilton City, the Sacramento River meanders within a broad floodplain; whereas, from Hamilton City to Colusa, the river meanders between setback levees on both sides. Upstream of Hamilton City, the river is fed by numerous tributary streams; Stony Creek is the only major tributary downstream.

Historically, this reach supported a wide corridor of riparian forest, with valley oaks on the higher terraces. Today, it is estimated that only five to10 percent of California's original riparian forest remains (RHJV, 2011). Along the Sacramento River, approximately 11 percent of the original riparian forest and valley oak woodland remain (SRCAF, 2003). Vegetation consists of large to small patches of willow scrub, cottonwood riparian forest, mixed riparian forest, valley oak riparian forest, and woodland. Marsh and emergent wetlands occur sporadically along sloughs and backwaters. Much of the adjacent lands that historically supported large areas of permanent or seasonal wetlands have been converted to agriculture. Small tributaries are mostly channelized and drain into larger canals, such as the Colusa Basin Drain.

Other Local Creeks and Water Bodies

Funks Creek

Funks Creek originates at approximately 850 feet elevation in blue oak savanna in the foothills west of Antelope Valley. It flows southeast as an intermittent natural stream, where it is joined by Grapevine Creek. As it flows through the foothills and Antelope Valley, its banks are generally eroded to near-vertical slopes, the gravel bed is highly disturbed and compacted by cattle, and it is bordered by annual grassland vegetation. Little to no riparian vegetation occurs throughout much of this reach, although occasional cottonwoods, willows, or non-native species occur along the banks.

Along the north end of Antelope Valley, Funks Creek receives underground drainage from Salt Lake. Salt Lake is a 28-acre area of impounded water and seasonal alkaline wetlands formed by warm salt springs that occur upslope.

As Funks Creek cuts through the Golden Gate gap and enters the west side of the Sacramento Valley, the stream channel becomes wider although flows are still intermittent. The banks and channel have an occasional grouping of riparian trees and shrubs. Occasional wetlands occur, mainly small patches of emergent wetland or stock ponds. Approximately one mile downstream of the Golden Gate gap, Funks Creek is impounded by Funks Reservoir. This reservoir is fed mainly from waters of the T-C Canal. Downstream of the reservoir, Funks Creek is bordered by agricultural lands, and much of this reach is channelized before emptying into Stone Corral Creek. The banks are bordered by levee roads and sparsely vegetated with non-native weedy species. Occasional native or non-native riparian trees and shrubs occur along the bank, as well as small patches of emergent wetland. This portion of Funks Creek likely has some flow year round due to leakage from the dam at Funks Reservoir. A large wetland area fed by waters from agricultural canals and Funks Creek occurs upstream of the confluence of Funks Creek and Stone Corral Creek.

Stone Corral Creek

Stone Corral Creek originates at approximately 700 feet elevation in the foothills west of Antelope Valley. As the intermittent stream flows into the grasslands of Antelope Valley, the channel is narrow and the banks are eroded by streamflows to near-vertical slopes. Willows and small wetlands occur sporadically along this section of the creek. The much larger Antelope Creek flows into Stone Corral Creek from the south near the town of Sites. As Stone Corral Creek flows through the gap in the foothills and into the western Sacramento Valley, riparian vegetation increases for a few miles downstream of the community of Sites. Native and non-native species, including valley elderberries, occur along the banks.

Other Local Streams

Grapevine Creek runs along a valley west of the proposed Sites Reservoir and is a tributary to Funks Creek. It has fairly well-developed, but sporadic, riparian vegetation along its entire length. Valley elderberries are common in some areas. It is fed by numerous small ephemeral drainages.

Antelope Creek flows from the south through Antelope Valley and merges with Stone Corral Creek near the town of Sites. It is fed by numerous intermittent drainages and supports sporadic short stretches of riparian vegetation consisting of large valley oaks, Fremont cottonwoods, willows, and valley elderberries. The largest concentration of riparian habitat in the proposed reservoir occurs along Antelope Creek in the southern portion of the reservoir footprint.

Lurline Creek originates in the hills east of Antelope Valley. A small amount of seasonal wetlands and ponds occur within the basin where it originates. Narrow strips of mature willow riparian occur along stretches of the creek as it flows through the low grassy foothills.

15.3 Environmental Impacts/Environmental Consequences

15.3.1 Regulatory Setting

Wetlands and other waters of the U.S. are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

15.3.1.1 Federal Plans, Policies, and Regulations

- Clean Water Act
  - Section 401 – Discharge into Navigable Waters
  - Section 404 – Discharge of Dredged or Fill Material

- Rivers and Harbors Act of 1899
- Natural Communities Conservation Planning Act
- Executive Order 11990: Protection of Wetlands
- No Net Loss of Wetlands Policy
- Comprehensive Conservation Plans for National Wildlife Refuges

15.3.1.2 State Plans, Policies, and Regulations

- Porter-Cologne Water Quality Control Act
- Suisun Marsh Preservation Agreement
- Suisun Marsh Protection Act and Suisun Marsh Protection Plan
- Delta Vision Strategic Plan
- Delta Protection Act of 1992
- California Wetlands Conservation Policy

15.3.1.3 Regional and Local Plans, Policies, and Regulations

- Yolo Bypass Wildlife Area Land Management Plan

15.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for biological resources:

Would the Project:

- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact to wetlands if it would result in any of the following:

- A substantial change in the use or quality (extent in acres or miles) of “other waters of the U.S.”, (including but not limited to lakes, rivers or streams tributary to navigable rivers, natural ponds) through direct removal, filling, obstruction, hydrological interruption, or other means. A substantial effect (significant impact) would be permanent impacts to any streams, including canals or ditches that are determined by the U.S. Army Corps of Engineers (USACE) to be jurisdictional.
- A substantial adverse effect on federally protected wetlands, as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, discharge of pollutants, or other means. A substantial effect (significant impact) would be any permanent adverse impact to any wetland.

Level of significance for flow-related impacts to wetlands and other waters of the U.S. was determined by comparing modeling results for different scenarios of the proposed operation of the alternatives (Appendix 6B and Chapter 6 Surface Water Resources). Project-related changes to the flow regime outside the range of historical variation were considered significant.

It should also be noted that any "no impact" statements in this chapter are subject to USACE jurisdictional determinations. Such jurisdictional determinations could affect the significance conclusions.

Impacts to riparian vegetation are evaluated in Chapter 13 Botanical Resources.

15.3.3 Impact Assessment Assumptions and Methodology

15.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to wetland and other waters of the U.S.:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge facilities would be required.
- Borrow areas would be located within the Sites Reservoir footprint or outside the Primary Study Area from commercial sources.
- Frequent Sites Reservoir water level fluctuations would create a barren draw-down zone.

15.3.3.2 Methodology

The methodology used to determine the extents of wetlands and other waters of the U.S. potentially affected in the Extended Study Area, the extent of jurisdictional waters whose flows, quantity, seasonality, or quality may be affected by Project operations in the Secondary Study Area, and the extent of wetlands and other waters of the U.S. within the Primary Study Area is described in Sections 15.1.1.1, 15.1.2.1, and 15.1.3.1, respectively.

The Extended and Secondary study area impact assessments relied on hydrologic and operational modeling performed using CALSIM II, which provided monthly river flows, and reservoir water surface elevations derived from monthly river flows and end-of-month reservoir storages, for the period of simulation extending from water year 1922 through 2003 (82-year simulation period). Detailed discussion of the CALSIM II model is provided in Appendix 6B. These modeling results were used in combination with professional judgment to assess the potential impacts of Project operations on wetlands and other waters of the U.S.

Within the Primary Study Area, the footprints of proposed Project facilities were compared to the existing extents of wetlands and other water of the U.S. to determine direct impacts, as well as indirect impacts to immediately adjacent wetlands and other waters of the U.S.

15.3.4 Topics Eliminated from Further Analytical Consideration

Because the effects of population growth associated with the No Project/No Action Alternative would be addressed in the agricultural, municipal, and industrial water use discussions, and those issues are not relevant to jurisdictional waters and wetlands, population growth is not addressed.

The effects of operation and maintenance activities on wetlands and other water of the U.S. within the Primary Study Area are not discussed for wetlands or other waters of the U.S. that would experience permanent loss as a result of construction activities and/or inundation.

15.3.5 Impacts Associated with the No Project/No Action Alternative

15.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use and San Luis Reservoir

Impact Wet-1: A Permanent Change in the Use or Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to waters of the U.S. has been addressed in those environmental documents. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on waters of the U.S. in the Extended Study Area, when compared to Existing Conditions.

Project operational modeling indicates that Level 4 Refuge water supply would be met every year with or without the Project. Therefore, the continued reliability of Level 4 water supply **would not have a substantial adverse effect** on wildlife refuge waters, when compared to Existing Conditions.

Project operational modeling indicates that, at San Luis Reservoir, the No Project/No Action Alternative would result in the same or slightly lower water levels than for Existing Conditions during most water years. During Dry and Critical years, San Luis Reservoir water levels would be the same or slightly higher than Existing Conditions. These negligible fluctuations in surface water elevations are not expected to change the habitats, water quality, or other characteristics of this reservoir. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on waters of the U.S. at San Luis Reservoir, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. The continued reliability of Level 4 wildlife refuge water supply associated with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on wildlife refuge jurisdictional wetlands, when compared to Existing Conditions.

Refer to the **Impact Wet-1** discussion. Due to the negligible fluctuations in surface water elevations expected at San Luis Reservoir with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse effect** on jurisdictional wetlands that may be present at that location, when compared to Existing Conditions.

15.3.5.2 Secondary Study Area – No Project/No Action Alternative

<u>Construction, Operation, and Maintenance Impacts</u>

Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, Thermalito Complex, and Lake Natoma

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake, which are the reservoirs upstream of Lewiston Lake and Whiskeytown Lake, Keswick Reservoir, the Thermalito Complex, and Lake Natoma, indicates that the No Project/No Action Alternative would result in the same or only slight changes in water levels and degrees of water level fluctuations when compared to Existing Conditions. Therefore, for these facilities, changes in water level fluctuations **would not have a substantial adverse effect** on the extent of these waters of the U.S, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the negligible fluctuations in surface water elevations expected at the listed lakes and reservoirs with implementation of the No Project/No Action Alternative,

there would not be a substantial adverse effect on jurisdictional wetlands that may be present at these locations, when compared to Existing Conditions.

Trinity River and Klamath River Downstream of the Trinity River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling results for Trinity River flows downstream of Lewiston Lake for the No Project/No Action Alternative indicate significant decreases in flow during wet water years during the months of March and April, when compared to Existing Conditions. Modeling also shows a significant increase in flows in above-normal water years in the month of February. No significant changes in flows are indicated during below-normal, dry, or critical water years. Because there would be significant changes in flows under some conditions, the No Project/No Action Alternative would have a **potentially substantial adverse effect** on waters of the U.S. on the Trinity River, when compared to Existing Conditions; these impacts would be expected to transfer to the Klamath River downstream of the Trinity River.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Because no marshes, vernal pools, or other similar wetlands have been identified along the edges of the Klamath and Trinity rivers, due to the steep slopes and rapid flows in these rivers, the No Project/No Action Alternative **would not have a substantial adverse effect** on jurisdictional wetlands along these rivers, when compared to Existing Conditions.

Spring Creek

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling was not performed for Spring Creek. However, if the No Project/No Action Alternative is implemented, Whiskeytown Lake and Keswick Reservoir are expected to continue to operate as regulating reservoirs, and therefore, would not be expected to affect the released flows that dilute Spring Creek runoff. Because no change in the dilution of Spring Creek runoff is expected, **there would not be a substantial adverse effect** on waters of the U.S. at Spring Creek, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the lack of fluctuation in flows expected in Spring Creek with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse**

effect on jurisdictional wetlands that may be present at that location, when compared to Existing Conditions.

Sacramento River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

On the Sacramento River, Project operational modeling indicates that, if the No Project/No Action Alternative is implemented, flows downstream of Keswick Reservoir, at Bend Bridge, downstream of RBDD, and downstream of Hamilton City would experience minimal changes. Flows downstream of Keswick Reservoir would experience a decrease in November flows in dry years. Impacts to Sacramento River waters of the U.S. **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the negligible fluctuations in flows expected in the Sacramento River with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse effect** on the few jurisdictional wetlands that may be present along the river, mostly in backwater or side-channel areas, when compared to Existing Conditions.

Clear Creek

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

If the No Project/No Action Alternative is implemented, Project operational modeling indicates an overall small change in Clear Creek flows (flows downstream of Whiskeytown). This would be due to almost no change in wet, above-normal, below-normal, and dry water year flows, but large increases in flows in critically dry years. The large changes in critically dry years could result in an impact to waters of the U.S. in Clear Creek that **would not have a substantial adverse effect**, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the net small fluctuation in flows expected in Clear Creek with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse effect** on the few jurisdictional wetlands that may be present along this Creek (mostly in backwater or side-channel areas), when compared to Existing Conditions.

Feather River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling for the Feather River (flows downstream of the Thermalito Complex) for the No Project/No Action Alternative indicates August-September increases in wet years and an August increase in above-normal years. In below-normal years, there would be increases in October and June, and decreases in November and February. In dry years, flows would decrease in August, October, and January-March, and increases in December and June. Critically-dry years would result in decreases in November-December and July, and increases in August-September. Because there would be substantial changes in flows under many conditions, the No Project/No Action Alternative **would have a potentially substantial adverse effect** on waters of the U.S. on the Feather River, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Because no marshes, vernal pools, or other similar wetlands have been identified along the edges of the Feather River, due to steep slopes and rapid flow, the No Project/No Action Alternative **would not have a substantial adverse effect** on jurisdictional wetlands along this river, when compared to Existing Conditions.

Sutter Bypass

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling for the Sutter Bypass for the No Project/No Action Alternative indicates the following alterations compared to existing flow regimes:

- Moulton Weir Spills into Sutter Bypass – small overall change; decrease in spills in December of wet years; large increase in December of dry years
- Ord Ferry Spills into Sutter Bypass – almost no overall change, but large decrease in December in wet years and large increase in December in critical years
- Colusa Weir into Sutter Bypass – overall decrease in November; very large decrease in dry years; major changes in below normal years; large January increase in dry and critical years
- Tisdale Weir into Sutter Bypass – very small overall change; increase in February in below-normal years; decrease in November in dry water-years

Because there would be substantial changes in flows into Sutter Bypass during several water-year conditions compared to existing flow regimes, the No Project/No Action Alternative **would have a**

potentially substantial adverse effect on waters of the U.S. in the Sutter Bypass, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Because there would be substantial changes in flows into Sutter Bypass during several water-year conditions compared to existing flow regimes, the No Project/No Action Alternative **would have a potentially substantial adverse effect** on jurisdictional wetlands that may exist in parts of the Sutter Bypass, when compared to Existing Conditions.

Yolo Bypass

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling indicates that, if the No Project/No Action Alternative is implemented, the Yolo Bypass would experience only a slight overall change in monthly flow compared with existing flow conditions, but in below-normal and dry years there would be a large late-fall decrease in flows. Therefore, the No Project/No Action Alternative's large decreases in critically dry years **would have a substantial adverse effect** to waters of the U.S. in the Yolo Bypass, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Because there would be substantial changes in flows into Sutter Bypass during Dry and Below Normal water year conditions compared to existing flow regimes, the No Project/No Action Alternative **would have a potentially substantial adverse effect** on jurisdictional wetlands that may exist in parts of the Yolo Bypass, when compared to Existing Conditions.

American River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling for the American River (flows downstream of Nimbus Dam) indicates that, if the No Project/No Action Alternative is implemented, there would be an overall decrease in flows in all months except for December. There would also be a large decrease in September of above-normal years and in September-October of below-normal years, and in August-September in critically dry years. Due to such large changes in seasonal flows with the No Project/No Action Alternative when compared to Existing Conditions, **there would be a substantial adverse effect** on waters of the U.S. in the American River.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the decreases in flows expected in the American River with implementation of the No Project/No Action Alternative, **there would be a potentially substantial adverse effect** on the few jurisdictional wetlands that may be present along the river (mostly in backwater or side-channel areas), when compared to Existing Conditions.

Sacramento-San Joaquin Delta

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

If the No Project/No Action Alternative is implemented, Project operational modeling indicates an overall minimal change in Delta monthly outflow, when compared to existing flows. It also indicates a decrease in August outflows in wet years, a decrease in October flows, and an increase in July flows in below-normal years. Therefore, with the No Project/No Action Alternative, **there would not be a substantial adverse effect** to Delta waters of the U.S, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the minimal fluctuations in flows expected in the Delta with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse effect** on jurisdictional wetlands present at that location, when compared to Existing Conditions.

Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling indicates a negligible change in the X2 position if the No Project/No Action Alternative is implemented. Therefore, **there would not be a substantial adverse effect** from the No Project/No Action Alternative to waters of the U.S. in the Delta and Suisun, San Pablo, San Francisco Bays, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the negligible change in flows or the salinity gradient expected in the Suisun, San Pablo, or San Francisco Bays with implementation of the No Project/No Action Alternative, **there would not be a substantial adverse effect** on jurisdictional wetlands present at those locations, when compared to Existing Conditions.

15.3.5.3 Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Projects included within the No Project/No Action Alternative are not located within the Primary Study Area, and therefore, **would not have a substantial adverse effect** on waters of the U.S. in that area, when compared to Existing Conditions. However, current land use practices in the Primary Study Area would continue. On grazing lands in and surrounding the Sites Reservoir footprint, existing levels of ongoing impacts, such as discharge, use by cattle, erosion, obstruction from debris, and other by-products of rural life are expected to continue at their current levels. In agricultural lands to the east of the Golden Gate Dam site, canals, channelized creeks, and the Sacramento River across from Moulton Weir are expected to continue to experience similar flows and uses as they currently do (i.e., Existing Conditions). Therefore, **there would not be a substantial adverse effect** from the No Project/No Action Alternative to waters of the U.S. in the Primary Study Area, when compared to Existing Conditions.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion.

15.3.6 Impacts Associated with Alternative A

15.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Wildlife Refuge Water Use

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

To meet the established requirement to supply the target of 555,515 acre-feet of water to the wildlife refuges (Level 4), pursuant to CVPIA, the refuges would be supplying the same amount of water to their wetlands regardless of the Project operations. Therefore, there would be **no impact** on waters of the U.S., when compared to Existing Conditions or the No Project/No Action Alternative, within the wildlife refuges from differences in the source of their water supply as a result of Project operations.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

As indicated in the **Impact Wet-1** discussion, the wildlife refuges would be supplying the same amount of water to their wetlands regardless of the Project operations. Therefore, the perennial wetland resources in the eleven potentially affected wildlife refuges and wildlife areas would experience **no impact** on federally protected wetlands, when compared to Existing Conditions and the No Project/No Action Alternative, from differences in the source of their water supply as a result of Project operations.

San Luis Reservoir

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling indicates that Project operations would result in larger and more frequent fluctuations in water levels in San Luis Reservoir, in certain types of water years. This effect would slightly exceed the existing height or extent of the draw-down zone at San Luis Reservoir in some very dry years. Because the fluctuations would remain very close to the historic range of variability, and because operating the Project would not introduce pollutants, fill material, or obstructions to this water body, the impact of Project operations on the waters of San Luis Reservoir is considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Although small wetlands occur at some seeps in drainages feeding San Luis Reservoir, these small wetlands in the drawdown zone have their own water sources and are independent of water levels in the reservoir. Therefore, **no impact** to wetlands would occur as a result of the increased San Luis Reservoir fluctuations associated with the Project, when compared to Existing Conditions and the No Project/No Action Alternative.

15.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, and American River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling in all of the above waters indicates that Project operations would not result in water levels higher or lower than historic levels. For lakes and reservoirs, Project operations would cause no discernible differences in water levels, mostly reducing the extent of fluctuation extremes. For rivers in general, a total of 668 miles of rivers downstream of dams would be potentially affected; however, this impact would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative. For the Feather and American rivers in particular, Project operation would have the indirect effect of dampening the extremes of flows to make the rivers' flows more closely resemble natural conditions, correlating with local hydrological conditions. Because water levels would remain within historic ranges of variation, and would have a steadying effect on the artificially fluctuating water levels that occur during Existing Conditions, the impact of the Project operation on all of the above waters would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the minimal fluctuations in flows expected in the above-listed waters with implementation of Alternative A, there would be a **less-than-significant impact** on jurisdictional wetlands present at those locations, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling using the Sacramento River Ecological Flow tool (SacEFT) (Appendix 8B) indicates that Project operations would indirectly result in changes in river flows downstream of the GCID Canal, Red Bluff Pumping Plant, and proposed Delevan Pipeline intakes for Sites Reservoir. However, the changes would be slight when compared to Existing Conditions. There would be no change in the frequency or severity of flood event flows. These slight changes in flows would represent a **less-than-significant impact** on the waters of the Sacramento River, when compared to Existing Conditions and the No Project/No Action Alternative.

Pump Installation at the Red Bluff Pumping Plant

The construction activities associated with pump installation at the Red Bluff Pumping Plant, and its operation and maintenance, would not affect levels of waters other than the Sacramento River immediately downstream of the pumping plant. Transportation of necessary equipment to install the pump (including a crane) would occur along existing construction or access roads. Dewatering of the afterbay would likely be required, and could occur during regularly scheduled maintenance periods or during the non-irrigation season. Therefore, construction and maintenance is not expected to involve any disturbance that would result in a loss or alteration of the river environment. Operations of the pump would increase the rate of diversion from the river by up to 250 cfs. An increase of such a small amount is not expected to adversely affect the aquatic environment downstream of the diversion. Therefore, the modification of the existing flow regime resulting from the operation of an additional pump at the Red Bluff Pumping Plant would have a **less-than-significant impact** on Sacramento River waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Minimal fluctuations in flows are expected in the Sacramento River with implementation of Alternative A from the installation, operation, and maintenance of a pump at the existing Red Bluff Pumping Plant. Because changes in flows would be minimal, there would be a **less-than-significant impact** on jurisdictional wetlands present along the edges of the river (most likely in backwater or slough locations), when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento-San Joaquin Delta and Suisun Bay

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling indicates that Project operations would increase the flow through the Delta in summer and fall, and in very dry years. This change in flow is not contrary to the Biological Opinion for delta smelt. Therefore, there would be a **less-than-significant impact** on waters of the U.S. in the Delta, when compared to Existing Conditions and the No Project/No Action Alternative.

In December and January, Project operations would result in a reduction in flows through the Delta, which would result in a 1 to 2 kilometer westward movement of the salinity/freshwater edge line, or "X2", increasing salinity in Suisun Bay in early spring. This shift would be located substantially to the west of the mandated standard location of X2, and would fall within the historical range of species tolerance. Similarly, modeling indicates that the diversions associated with the Project would substantially increase electrical conductivity (EC) (which is a measure of changes in salinity) in the Suisun Marsh in December. However, this would occur when EC is at its lowest annual level, and this increase would fall within the historical range of species tolerance. Modeling also indicates an improvement in salinity conditions in August through October, and increased inflows into the Delta during critically dry years. Because the salinity changes would be within historic ranges of variation, there would be a **less-than-significant impact** on Delta-Suisun Bay waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Because alterations in flows and salinities expected in the Delta-Suisun Bay with implementation of Alternative A would be within the historical range of species tolerance in winter, and actually improved during Dry conditions, there would be a **less-than-significant impact** from Alternative A on jurisdictional wetlands present in the Delta and Suisun Marsh, when compared to Existing Conditions and the No Project/No Action Alternative.

San Pablo Bay and San Francisco Bay

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers,

Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Project operational modeling indicates that the effect of Project operations would not reach as far as San Pablo or San Francisco Bay, and would, therefore, result in **no impact** on these waters, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion.

15.3.6.3 Primary Study Area – Alternative A

<u>Construction, Operation, and Maintenance Impacts</u>

An evaluation of the potential construction, operation, and maintenance impacts to wetlands and other waters of the U.S. resulting from implementation of Alternative A is discussed below.

Sites Reservoir Inundation Area and Sites Dams

Ground disturbance associated with dam construction, as well as inundation of the 1.27-MAF Sites Reservoir, would have a permanent adverse impact on existing wetlands and other waters of the U.S. due to removal and replacement by standing water, sterile subsoil, or permanent facilities. The acres of wetlands or other waters of the U.S. that would be affected by the1.27-MAF Sites Reservoir and its associated dams are listed in Table 15-7. Ponds are considered separately from wetlands or tributary streams.

Table 15-7
Direct Loss of Wetlands and Other Waters of the U.S. due to the Construction of the 1.27-MAF Sites Reservoir Inundation Area and Dams

Wetland or Other Waters of the U.S. Type	Number of Acres Affected	Number of Miles Affected*
Alkaline	19.2	
Emergent	2.4	
Riparian	21.5	
Seasonal	153.1	
Vernal pool	4.3	
Total Wetlands	**200.6**	
Tributaries 0 to 15 Feet Wide (smaller tributaries)	77.0	123.0
Tributaries >15 Feet Wide (major tributaries)	82.0	25.0
Total Other Waters of the U.S.	**159.0**	**148.0**
TOTAL PONDS	**20.2**	
Salt Lake	6.1	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

During construction of the dams, a cofferdam would be installed upstream of the Sites and Golden Gate damsites around the dams' construction work areas to retain storm flows entering the reservoir basin from Funks Creek and Stone Corral Creek. Funks Creek flows would not be maintained between the Golden Gate damsite and the existing Funks Reservoir during the construction period. The reach of Funks Creek that would be temporarily dewatered during construction would be approximately 1.4 miles long. However, Funks Creek flows would be maintained downstream of Funks Reservoir during the entire construction period. Therefore, the temporary dewatering of Funks Creek upstream of Funks Reservoir would be a **less-than-significant impact** on waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Diverted Funks Creek flows would pass through a pipe at the Sites Dam site and would continue downstream into Stone Corral Creek. Construction of the dams, as well as the filling of Sites Reservoir, would result in the direct permanent loss of a total of 148 miles (175 acres) of waters of the U.S. These waters consist of 25 miles (82 acres) of major tributaries, 123 miles (77 acres) of smaller tributaries, and 20 acres of ponds (Table 15-7) (DWR, 2000). Major tributaries are considered to be stream reaches more than 15 feet in width; minor tributaries are less than 15 feet wide. Most of the streams are associated with Antelope, Grapevine, Funks, and Stone Corral creeks. The streams are mostly very minor ephemeral drainages, and the more major tributaries are also quite disturbed. However, the loss of these streams, especially the 82 acres of major tributaries, could be considered a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation, releases from Sites and Golden Gate dams would maintain flows of up to 10 cfs from October through May in Stone Corral and Funks creeks, respectively, to mimic the ephemeral nature of these streams. Because these flows would be maintained close to natural levels, the impact to waters of the U.S. would be **less than significant**.

Periodic maintenance activities, and debris and vegetation removal from the dam embankments, could result in temporary increases in sedimentation or organic matter in downstream Stone Corral and Funks creeks. However, Best Management Practices (BMPs) should minimize this effect, resulting in a **less-than-significant** impact on waters of the U.S.

Ponds

Due to their disturbed and artificial nature, and because stock ponds are generally not jurisdictional (USACE, 2011a), the permanent loss of 28 small stock ponds due to construction and filling of Sites Reservoir would have *no impact* ***on waters of the U.S, when compared to Existing Conditions and the No Project/No Action Alternative. Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means***

Seasonal Wetlands

Construction and operation of the 1.27-MAF reservoir would result in the permanent loss of approximately 153 acres of seasonal wetlands through initial inundation and repeated water level fluctuations. These 97 wetlands are mostly small areas associated with low-lying swales, valley bottoms, or shallow drainages, especially in clay-dominated soils. More than half of these wetlands are smaller than one acre in size; 29 are between one and five acres, and eight are larger than five acres. Seasonal wetlands lost to inundation include nearly 12 acres associated with Salt Lake; some of these may be at least partially saline. Because the wetlands of the western edge of the Sacramento Valley are already much reduced in number, the loss of these potentially jurisdictional seasonal wetlands (especially because they include some partly alkaline or saline features) would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Alkaline Wetlands

Construction and inundation of a 1.27-MAF Sites Reservoir would result in the permanent direct loss of more than 19 acres of alkaline wetlands, all associated with the six-acre saline spring-fed Salt Lake impoundment. These seasonal wetlands are separate from the 12 acres of seasonal (non-alkaline) wetlands discussed above. More than 15 acres are located in the same drainage as Salt Lake (directly upstream or downstream), and four additional acres of alkaline wetland are located in the adjacent drainage to the east. This unique habitat includes muds so high in mineral salts that no vegetation becomes established; salt- and alkali-tolerant species are supported in narrow strips around its edges. The saline/alkaline wetland surrounding Salt Lake represents the single largest wetland within the Sites Reservoir footprint. No alkaline wetlands were mapped in any other portions of the reservoir footprint. Although historically abundant in the western edges of the Sacramento Valley, the alkaline (or saline/ alkaline) wetland type is no longer common in the Project region due to extensive conversion of land to large-scale agricultural fields. Loss of the Salt Lake pond (6 acres) and alkaline wetland complex (19 acres), totaling 25 acres, would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Vernal Pools

If Alternative A is implemented, the construction and inundation of Sites Reservoir would also permanently destroy more than four acres of vegetated vernal pools, many of which are either artificially created impoundments or highly disturbed/degraded by long-term heavy grazing. These 16 vernal pools are distributed throughout the reservoir footprint in Antelope Valley. The largest pool (more than 1.3 acres) is associated with Salt Lake. The remaining features are all smaller than one acre in size. Most of the vernal pools within the reservoir footprint are highly degraded. However, because vernal pools of the western edge of the Sacramento Valley are already much reduced in number, the loss of these vernal pools within the Sites Reservoir Inundation Area (especially because they include some partly alkaline or saline features) would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Emergent Wetlands

Approximately 2.4 acres of emergent wetlands would be permanently lost through construction and inundation of Sites Reservoir if Alternative A is implemented. These wetlands consist of two areas impounded by Peterson Road in the north part of the reservoir footprint; one (1.6 acres in size) is spring-fed. Although these features are small and disturbed by cattle, such wetlands are sensitive features and part of a large swale complex draining the coast range foothills, and their loss would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Riparian Wetlands

More than 21 acres of riparian wetlands were mapped and identified within the reservoir footprint for Alternative A. These riparian wetlands would be permanently lost through construction and filling of Sites Reservoir. Most of these 15 mapped areas are one acre or smaller in size, and consist of sparse wetland vegetation within disturbed intermittent stream channels. However, the loss of these riparian wetlands due to construction and inundation could be considered a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

The recreation areas at Sites Reservoir would include the five proposed recreation area footprints and the electrical distribution lines[2] needed to supply electricity to four of the recreation areas (Antelope Island would not have electricity). The construction of boat ramps, picnic tables, fire rings, gravel roads, vault toilets, and garbage dumpsters within the recreation areas would result in direct impacts to existing wetlands and other waters of the U.S. Waters could be permanently lost or adversely affected due to development of facilities at the sites.

Indirect impacts to wetlands or other waters of the U.S. could include siltation, erosion, and habitat degradation due to mechanical disturbance from incidental or accidental off-road driving, foot traffic, and other disturbance by visitors and their pets that could occur during Project operation and maintenance.

Because the exact location and area affected by construction is not currently known, total loss of existing ponds and other waters of the U.S. from recreation area footprints is expected. The maximum acres of wetlands or other waters of the U.S. expected to be lost or affected within each recreation area are listed in Table 15-8. This loss represents the maximum acreage; the actual direct loss of waters would likely be less, and most of the impacts would be indirect.

Impacts to waters from the distribution lines that would serve the recreation areas would all be temporary impacts of disturbance during the construction period only, with very small areas permanently occupied by the poles during Project operation.

[2] The roads to each of the recreation areas are addressed in the Road Relocations and South Bridge discussion.

Table 15-8
Direct Loss of Wetlands and Other Waters of the U.S.
Due to the Construction of the Recreation Areas

Wetland or Other Waters of the U.S. Type	Number of Acres/Miles Lost by Recreation Area					All Recreation Areas
	Saddle Dam	Peninsula Hills	Stone Corral	Antelope Island	Lurline Headwaters	
Seasonal Wetlands	13.30 acres	0	0	0	0	13.30 acres
Total Wetlands	**13.30 acres**	**0**	**0**	**0**	**0**	**13.30 acres**

Total Ponds	**1.24 acres**	**0**	**0**	**0**	**0.04 acre**	**1.28 acres**

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

Approximately three acres (10.5 miles) of streams could be permanently lost or permanently degraded by construction and operation of the five recreation areas. These waters consist mostly of numerous short sections of intermittent small natural tributaries (mostly less than five feet in width) in all five areas. No streams greater than 10 feet wide would be lost or affected. In some recreation areas, the majority of these small stream segments are located at upper ends of very steep drainage channels that are very unlikely to be included in facility development. However, in the Stone Corral Recreation Area, some tributaries to Stone Corral Creek are on gentler slopes and could be directly affected. This is also true of the several tributaries to Funks Creek in the Peninsula Hills Recreation Area and some of the tributaries to Hunters Creek in the Saddle Dam Recreation Area. The streams in the Saddle Dam Recreation Area connect the many seasonal wetlands in that vicinity. In addition, because headwaters are involved in almost every case, all of the streams are vulnerable to impacts of erosion and siltation due to construction and other upslope human activities that would occur in the recreation areas during Project operation and maintenance. Despite the ephemeral nature of most of these streams, loss or adverse effects to streams within the recreation areas would be considered a substantial effect on waters of the U.S. The combined length of more than ten miles, and the connection of several streams with wetland features, mostly in the Saddle Dam Recreation Area, would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

The corridor for the distribution lines that would serve the recreation areas would cross 0.06 acre (0.11 mile) of streams, which could result in minor temporary impacts during construction and potential direct impacts from placement of electrical poles. However, poles could be placed to avoid these stream crossings. Operation of these distribution lines would be an unmanned activity and have no associated on-the-ground disturbance. Maintenance activities, including equipment inspections and vegetation maintenance, could also be performed to avoid any effects to these stream crossings. Due to the minor extent of streams that could be affected and the ease of avoiding the streams, this would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Ponds

Approximately 1.2 acres of ponds (a total of five ponds) could be destroyed or substantially disturbed by construction of three of the recreation areas. Indirect disturbance from recreational use during Project operation, as well as from maintenance activities, including road grading and vegetation control, could also occur. All are stock ponds that are smaller than one acre in size, and vary in the amount of emergent or other wetland vegetation they support. Most have little to no vegetation because they are very disturbed by cattle trampling. No ponds would be affected by construction within the corridors of the distribution lines that would serve any of the recreation areas. Direct loss, disturbance during construction, or indirect disturbance from operation and maintenance activities, of 1.2 acres of stockponds would constitute **no impact** to waters of the U.S. due to their small size, disturbed state, minimal vegetation, and agricultural stockpond status (USACE, 2011a), when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Seasonal Wetlands

Approximately 13 acres of seasonal wetlands could be permanently lost or otherwise affected by construction, operation, and maintenance of the recreation facilities within the Saddle Dam Recreation Area. This acreage includes approximately 0.2 acre of seasonal wetlands within the north end of the construction disturbance area for the electrical distribution line that would serve this recreation area. Although not mapped as alkaline wetlands, these seasonally wet areas are at or near the headwaters of some of the watersheds feeding off-site alkaline wetlands. It is possible that some of the wetlands in the Saddle Dam Recreation Area could support alkaline wetland species, and these habitats could be lost or affected by construction, operation, or maintenance activities in this area. Although a portion of these 13 acres would probably not be affected or may be subjected to only temporary or short-term impacts during construction, it is expected that they would be lost or adversely affected by use of recreational facilities during operation or during maintenance activities, including road grading and vegetation control. Because seasonal wetlands are potentially jurisdictional wetlands, their loss or disturbance would be a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

The Road Relocations and South Bridge would include portions of the existing Huffmaster, Maxwell Sites, Sites Lodoga, and private property roads; new access roads to facilities, such as recreation areas and dams; connections between existing and new roads; and an approach to a new bridge (Figure 3-1 in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives).

The 200-foot-wide construction buffer includes the surface areas of paved roads, gravel roads, the associated shoulders and cut-and-fill slopes, and some additional area. Both sides of the roads are proposed to be fenced. Because exact locations of construction-related activities are not known, construction of the roads is expected to result in direct permanent loss of existing waters of the U.S. within the entire construction disturbance area. An unknown portion of these impacts would actually be temporary if the waters were avoided or restored after construction. However, once a stream is severely disturbed or impacted, its hydrology may be permanently altered, resulting in a permanent impact even if the feature still exists after construction. The maximum extent (in acres and miles) of wetlands or other waters of the U.S. that would be affected by construction of the Road Relocations and South Bridge is shown in Table 15-9.

Table 15-9
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Road Relocations and South Bridge

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost*
Alkaline wetlands	1.14	
Emergent wetlands	0.04	
Seasonal wetlands	4.21	
Vernal pools	0.03	
Total Wetlands	**5.42**	
Tributaries 0 to 5 Feet Wide	2.05	6.0
Tributaries 5 to 10 Feet Wide	4.02	4.44
Tributaries10 to 15 Feet Wide	1.15	0.80
Tributaries > 15 Feet Wide	2.22	0.58
Total Other Waters of the U.S.	**9.44**	**11.8**
Total Ponds	**0.484**	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

A total of more than 9.4 acres (or approximately 11.8 miles) of streams could suffer permanent adverse impacts from road construction. These streams consist mostly of numerous short sections of intermittent small tributaries (many smaller than five feet in width) in all road segments, with substantial additions from some larger stream crossings in a few segments. The largest potential impacts to other waters of the U.S. are the crossings by Eastside Road, where it would cross Funks Creek (>15 feet wide) and its tributaries. One Funks Creek tributary crossing in this segment, and another in the Stone Corral Road segment, support riparian trees. The next largest losses of streams are the crossings of creeks that are five to 10 feet wide by Saddle Dam Road and Lurline Road. Streams crossed by Saddle Dam Road (the North Road segment) are tributaries to Hunters Creek, and streams crossed by Lurline Road (the Huffmaster Road to Lurline Road segment) are tributaries to Antelope or Lurline creeks off the southeast end of the reservoir. Although most stream crossings would be very small, the collective loss of these streams would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Vehicle use associated with operation of the roads would be confined to the defined road and shoulder areas due to continuous roadside fencing and/or guardrails. Therefore, operation of the roads would be expected to result in a **less-than-significant impact** on waters of the U.S.

Disturbance from maintenance activities, such as road repair, embankment erosion repair, and vegetation control, could result in increased sedimentation and organic matter entering adjacent streams. However, BMPs should minimize this effect, resulting in a **less-than-significant** impact on waters of the U.S.

Ponds

Construction of the Road Relocations and South Bridge could also result in the direct loss of nearly 0.5 acre of ponds, in locations between Golden Gate Dam and Funks Reservoir, and also along the Lurline Road to the Communication Tower segment of Com Road, off the southeast edge of the Sites Reservoir footprint. One small pond would also be intersected by the construction disturbance area of the Road 69 segment, east of Eastside Road. Indirect disturbance could also occur during operation or maintenance of the roads. No other ponds would be crossed by any other segment of the roads. These ponds are all very small stockponds, artificially created (dammed) and disturbed, with minimal associated vegetation, except for some vegetation associated with the pond at the head of Lurline Road. Their loss or disturbance would constitute **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Seasonal Wetlands

If Alternative A is implemented, approximately 4.2 acres of seasonal wetlands could be permanently lost or otherwise impacted by construction of the Road Relocations and South Bridge and the associated cut and fill areas. More than one acre would be lost within the Saddle Dam Road, and approximately two acres along Road 69 approaching its intersection with Saddle Dam Road. Comprised of four separate crossings, these wetlands are located approximately one to two miles directly north of the Salt Lake complex of alkaline wetland features. Although not mapped as alkaline wetlands, the wetlands intersected by these road segments are at or near headwaters of some of the watersheds feeding alkaline wetlands off the northeast edge of the Sites Reservoir footprint. It is possible that some of the seasonal wetlands crossed by the Saddle Dam Road and intersected by the Road 69 widening could support alkaline wetland species, and portions of these habitats could be lost or affected by construction in this area. Approximately 0.8 acre of seasonal wetlands would also be permanently lost due to construction of the Sulphur Gap Road (Maxwell Sites Road to Lurline Road segment) portion of the route. Indirect disturbance could also occur during operation or maintenance of the roads. No mapped seasonal wetlands would be lost or directly affected in any of the other parts of the road relocations. Although seasonal wetlands can be considered jurisdictional features, these small wetlands can be easily avoided by relocation of the route, so their loss is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Alkaline Wetlands

If Alternative A is implemented, construction of the Road Relocations and South Bridge could result in the direct loss of approximately 1.14 acres of alkaline wetlands along the Road 69 at T-C Canal to Saddle Dam Road segment of the North Road, located northeast of the Sites Reservoir footprint. At this location, the construction disturbance area overlaps with closely adjacent seasonal and alkaline wetlands and has high potential for impacts to these wetlands. Indirect disturbance could also occur during operation or maintenance of the roads. No other alkaline wetlands are crossed by other segments of the Road Relocations and South Bridge. In this part of the Sacramento Valley, remnant alkaline wetlands have mostly disappeared due to agriculture, so loss of any remaining alkaline wetlands would be a potentially substantial adverse effect; however, because these features are relatively easily avoided by rerouting the road corridor, their loss is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Vernal Pools

If Alternative A is implemented, construction of the Road Relocations and South Bridge could also result in the direct loss of 0.03 acre of vernal pools along the North Road (Road 69 at T-C Canal to Saddle Dam Road segment), located northeast of the Sites Reservoir footprint. This small acreage would result from an overlap of the construction disturbance area with a series of ten small vernal pools ranging from 12 to 20 feet in diameter. Indirect disturbance could also occur during operation or maintenance of the roads. No other vernal pools would be crossed by other segments of the Road Relocations and South Bridge. Because these five small vernal pools represent half of all the vernal pool features mapped in this part of the Primary Study Area, and vernal pools are a sensitive resource, loss of or impact to these vernal pools near Road 69 would be a potentially substantial adverse effect; however, because these features are relatively easily avoided by rerouting the road corridor, their loss is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Emergent Wetlands

Alternative A construction of the Road Relocations and South Bridge could result in the direct loss of 0.04 acre of emergent wetlands along the North Road (Road 69 at T-C Canal to Saddle Dam Road segment), located northeast of the Sites Reservoir footprint. This small acreage would result from an overlap of the construction disturbance area with a stream channel aligned south of Road 69, approximately 0.5 west of the T-C Canal. This 390-foot-long emergent wetland is in a stream channel, and is therefore, also a riparian wetland. It is associated with other waters of the U.S. Indirect disturbance could also occur during operation or maintenance of the roads. Its loss or disturbance resulting from road construction would be a potentially substantial adverse effect; however, because these features are relatively easily avoided by rerouting the road corridor, their loss is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

The Sites Reservoir Inlet/Outlet Structure and four adjacent facilities would be located between Logan Ridge (location of the dams) and Funks Reservoir. The footprints of these facilities represent the area of permanent disturbance; temporary disturbance would also occur within the construction disturbance area. Because exact locations of construction-related activities are not known, construction of the Inlet/Outlet facility group is expected to result in the direct permanent loss of existing waters of the U.S. within the entire combined footprint. A portion of these impacts would be temporary if the wetland or waters were avoided or restored after construction. However, once a wetland or stream is severely disturbed or impacted, its hydrology may be permanently altered, resulting in permanent impact even if the feature still exists after construction. The acres of each type of waters of the U.S. that would be lost or adversely affected within the Sites Inlet/Outlet facility group footprint are summarized in Table 15-10. No wetlands exist at the Sites Inlet/Outlet facility group location. The construction disturbance area for this facilities group lies within the approximately 1,000-acre construction disturbance area for the Sites Reservoir/dam facilities. Construction-related ground disturbance for the Inlet/Outlet structure facilities occurring in this construction disturbance area would be temporary, and disturbed areas would be returned to their original condition following completion of construction.

Table 15-10
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Sites Reservoir Inlet/Outlet Structure, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, and Field Office Maintenance Yard

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost*
Seasonal wetlands	0	
Total Wetlands	**0**	
Tributaries 0 to 5 Feet Wide	0.31	0.61
Tributaries 5 to 10 Feet Wide	0.58	0.49
Tributaries10 to 15 Feet Wide	0	0
Tributaries > 15 Feet Wide	0.53	0.08
Total Other Waters of the U.S.	**1.42**	**1.19**
Total Ponds	**0.2**	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

If Alternative A is implemented, approximately 1.4 acres (or approximately 1.2 miles) of streams could experience permanent adverse impacts from the construction of these facilities. Some of these streams consist of sections of intermittent small tributaries that are smaller than five feet in width within the Field Office Maintenance Yard footprint. However, crossings of Funks Creek and its tributaries by the Sites Reservoir Inlet/Outlet Structure account for larger areas of impact to waters of the U.S., because these streams are 15 feet or larger in width. The largest potential impacts to other waters of the U.S. would be the crossings at the center of the Inlet/Outlet Structure, where the facility would cross Funks Creek (greater than 50 feet wide). One Funks Creek tributary crossing in this segment supports riparian trees. The Inlet/Outlet Structure would also cross the northwest end of Funks Reservoir, which is from 60 to 130 feet wide and accounts for approximately 1.3 acres of waters. Although the acreage of disturbed streams is small, the permanent disturbance to Funks Creek during construction of the Sites Reservoir Inlet/Outlet Structure would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Ponds

Construction of the Outlet concrete and excavation components of the Sites Reservoir Inlet/Outlet Structure facility group would result in the direct loss of approximately 0.2 acre of one pond, located west of Funks Reservoir. This pond is a stockpond, artificially created (dammed) as part of the nearby ranching operation, very disturbed, and devoid of associated vegetation. Its loss or disturbance would have **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

No wetlands occur within the footprint of these facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

The Holthouse Reservoir Complex includes the existing Funks Reservoir, the proposed Holthouse Reservoir, and these connected facilities: the dam, spillway and stilling basin, pumping plant, electrical switchyard, T-C Canal discharge dissipater, Funks bypass pipeline, and discharge pipeline to the T-C Canal. The footprints of these facilities represent the ground area they would occupy once built plus the temporary disturbance area within the construction disturbance area of the Holthouse to T-C Canal discharge pipeline. The construction disturbance area for the remainder of the Holthouse Reservoir facilities is expected to be located within adjacent agricultural land. Construction of the proposed facilities within the Holthouse Reservoir Complex would result in the direct permanent loss of wetlands or other waters of the U.S. within the entire combined footprint. The number of acres of each type of other waters of the U.S. that would be lost or adversely affected within the Holthouse Reservoir Complex proposed footprint is summarized in Table 15-11.

Table 15-11
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard[a]

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost[b]
Alkaline wetlands	Direct: 0.5 Possible Indirect: 13.0 to 40.0	
Total Wetlands	**Direct: 0.5 Possible Indirect: 13.0 to 40.0**	
Tributaries 0 to 5 Feet Wide	0	0
Tributaries 5 to 10 Feet Wide	0.30	0.29
Tributaries 10 to 15 Feet Wide	0.46	0.26
Tributaries > 15 Feet Wide	5.04	0.87
Total Other Waters of the U.S.	**5.8**	**1.4**
Total Ponds	**0**	

[a]Acreage of existing Funks Reservoir not included,

[b]Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

A total of nearly six acres (or approximately 1.4 miles) of tributaries would be permanently lost through construction of these facilities and inundation of Holthouse Reservoir. Some (one acre/0.6 mile) of these streams consist of agricultural ditches (between eight and 32 feet wide) that traverse the agricultural areas between the T-C Canal and north of Funks Creek within the Holthouse Reservoir and Dam footprints. Loss of these ditches, which were dug through upland areas to irrigate nearby fields, would constitute **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. However, inundation of Funks Creek by the Holthouse Reservoir and Dam accounts for more substantial areas of impact to waters of the U.S., because Funks Creek downstream of the existing dam outlet ranges from 40 to 120 feet or more in width. One of the largest potential impacts to other waters of the U.S. is the inundation of the two-acre riparian area supported by Funks Creek downstream of the existing dam outlet, where Funks Creek averages more than 80 feet wide. The remaining length (approximately 0.8 mile or five acres) of the Funks Creek channel supports a narrow strip of mature riparian trees that would be lost to construction of these facilities. The permanent loss to this stretch of Funks Creek waters resulting from construction and inundation would be a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Ponds

The proposed dredging of the existing Funks Reservoir would involve draining the reservoir for two years. This dredging would represent special maintenance to return the facility to original design capacity, which is beyond the annual maintenance that is already conducted. Funks Reservoir is an impoundment of Funks Creek (in part); Funks Creek is considered a water of the U.S.; Funks Reservoir is, therefore, also considered to be jurisdictional waters of the U.S. The two-year drainage and dredging would be temporary, but may be considered a hydrological interruption, which would be a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

After dredging activities are complete, Funks Reservoir would continue to impound Funks Creek and would become hydrologically connected to the proposed Holthouse Reservoir. Current periodic maintenance required for the existing Funks Reservoir is expected to continue after the Funks Reservoir dredging and its connection to Holthouse Reservoir.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Alkaline Wetlands

Approximately 0.5 acre of alkaline wetlands would be directly impacted by construction of the Holthouse Reservoir Complex. The footprint of the Holthouse to T-C Canal Pipeline would overlap with the northwest end, or headwaters, of one of the shallow alkaline wetland swales that contribute to a 13-acre alkaline wetland. Loss of this portion of the alkaline wetland swale would be a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

A 13-acre alkaline and saline wetland complex lies immediately southeast of the Holthouse Reservoir Complex, located within a 40-acre area that supports an upland (grassland) matrix. This wetland type is rare and sensitive, being potential habitat for several rare plant and invertebrate species (Silveira, pers. comm., 2011). Although it would not be directly impacted by the construction and operation of the Holthouse Reservoir Complex, there is potential during operation for the pressure from the weight of the water behind the dam, and possibly the belowground portion of the dam and discharge pipeline, to affect the underground hydrologic regime supporting this wetland. No groundwater studies have been conducted to evaluate this potential. From inspection of field data on the location of seeps, comparison of current (2009) and historical (1958) aerial photos, and consultation of geology fault-trace maps, it appears that the wetland's water source is likely ancient marine groundwater rising up from the south or southeast. The direction of the bedding dips, and the direction of the faults, would direct underground water up from the south and east. If this is the case, the presence of a dam and reservoir to the west and north would not interfere with the wetland's water source (Gordon et. al, pers. comm., 2011). Because it is not known if the presence and operation of the Holthouse facilities would intercept and cut off the wetland area's underground water supply and dry up the wetland, or might redirect or pressure more water into the area and increase inundation, converting the area into a perennial marsh, these possible effects would be considered a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

In addition to the underground water supply being possibly increased or decreased, overland flow from the uplands along the wetland's western border, particularly to the vernal swale at the wetland area's northwestern corner, would be cut off. This could occur from construction of the Holthouse to T-C Canal Pipeline, which would be located less than 200 feet from the swale and would directly impact the swale's headwater area. The pipeline and dam would be located approximately 300 and 700 feet, respectively, from the hillslope along the wetland's western edge. It is not known to what extent the wetland depends on waters entering from within or from the surface of this upland strip. Thus, this rare and sensitive habitat could be subject to drying or inundation effects from the presence of the proposed Holthouse Reservoir Complex. This indirect hydrological interruption effect would represent a **potentially significant impact** to wetlands, when compared to Existing Conditions and the No Project/No Action Alternative.

Seasonal Wetlands The proposed dredging of the existing Funks Reservoir would involve deepening the bottom and making the sides steeper, which would eliminate the shallow-water areas around its edges. This could result in the desiccation or alteration of the hydrology of the 3.8-acre seasonal wetland area at Funks Reservoir's south end. If this wetland's water supply is not interrupted, it may not be affected; however, the down-cutting of the reservoir edge along the wetland's northern edge may result in desiccation when the lake is not full because its water could abruptly fall into the steeper-sided reservoir basin. The alteration of this wetland could represent a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. No other wetlands have been mapped around the immediate edges of Funks Reservoir. Other seasonal wetlands and a vernal pool in the general area are located more than 500 feet away from the reservoir edge and would be unlikely to be affected by the dredging of Funks Reservoir.

Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Electrical Switchyard, and GCID Canal Connection to the Terminal Regulating Reservoir

The TRR and its associated facilities would be located near the intersection of the existing GCID Canal and the proposed Delevan Pipeline. The waters of the U.S. that could be impacted by these facilities are all agricultural canals. Their acreage and lengths are shown in Table 15-12. No wetlands or ponds would be affected by TRR construction.

Table 15-12
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Terminal Regulating Reservoir, TRR Pumping/Generating Plant, TRR Electrical Switchyard, and the GCID Canal Connection to the TRR

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost*
Total Wetlands	**0**	
Tributaries 0 to 5 Feet Wide	0.37	0.74
Tributaries 5 to 10 Feet Wide	0.78	0.77
Tributaries 10 to 15 Feet Wide	0.63	0.43
Tributaries > 15 Feet Wide	0.61	0.26
Total Other Waters of the U.S.	**2.39**	**2.19**
Total Ponds	**0**	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

All 2.4 acres (or approximately 2.2 miles) of waters that would be permanently lost to construction of the TRR and its associated facilities consist of agricultural canals. It is likely that these canals would be determined to be non-jurisdictional (USACE, 2011a), and their loss would, therefore constitute **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. No ponds exist at the TRR facility group location; therefore, there would be **no impact** to ponds at that location, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

No wetlands occur within the footprint of these facilities. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

The Delevan Transmission Line analysis for Alternative A includes only the 150-foot-wide construction disturbance area extending between the Sacramento River and the Sites Reservoir Inlet/Outlet Structure to the west of Funks Reservoir[3]. The Delevan Transmission Line construction disturbance area includes all areas needed for transmission line construction activities. This 150-foot-wide corridor would experience mostly temporary disturbance during construction. Once construction is complete, the only Project facility that would generate a permanent impact would be the transmission line tower footings. The total permanent habitat loss associated with the tower footings, with a worst-case scenario of 70 transmission towers with a concrete pad for a base over the entire length of the transmission line, would equal approximately 2.5 acres of agricultural fields and some open grassland, with intermittent streams scattered within the grasslands. Because no additional access or maintenance roads or other infrastructure is proposed, the land between the towers would revert back to its original use. Thus, the impact on much of the acreage within the easement would be temporary for this Project facility. Because there is flexibility in siting the individual tower footings, the likelihood of a tower footing being constructed within or adjacent to any waters of the U.S. is low.

The acres of each type of wetlands and other waters of the U.S. that would be lost or adversely affected within the Delevan Transmission Line easement are summarized in Table 15-13.

Table 15-13
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Delevan Transmission Line East of the Sites Electrical Switchyard

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost*
Alkaline wetlands	Direct/Permanent: 0.04 Temporary: 2.2	
Vernal pools	Indirect/Temporary: 0.4	
Total Wetlands	Permanent: < 0.1 Temporary: 2.6	
Tributaries 0 to 5 Feet Wide	0.09	0.22
Tributaries 5 to 10 Feet Wide	0.41	0.41
Tributaries10 to 15 Feet Wide	0.44	0.30
Tributaries > 15 Feet Wide	1.77	0.32
Total Other Waters of the U.S.	2.72	1.26
Total Ponds	1.9 acres	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Stream

A total of more than 2.7 acres (or approximately 1.26 miles) of streams could be adversely affected through construction of the tower footings and other construction activities. Because no towers are likely to be placed in or adjacent to waterways, the impact would be temporary. If the water was redirected back into the farmer's irrigation system so that the water would still be available for surrounding fields,

[3] The impacts on wetlands and other waters of the U.S. of the 50-foot-wide easements for the electrical distribution lines that would serve the Recreation Areas are discussed in that analysis.

temporary disruption of these waters by construction of the transmission line would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

East of the GCID Canal, all of these waters (approximately 1.5 acres or 0.8 mile) consist of agricultural canals, mostly between five and 20 feet in width. Where canals are found by the USACE to be non-jurisdictional, as is normally the case (USACE, 2011a), Project effects to canals would constitute **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. West of the GCID Canal, the streams are natural drainages through open grassland or dryland grain fields. In this area, 1.2 acres (0.47 mile) of streams would be at least temporarily impacted by the Delevan Transmission Line construction. Except for where the line would cross Funks Creek, these ephemeral drainages average six feet wide. Because the transmission tower spans can be from 1,200 to 1,300 feet, flexibility in tower footing placement would decrease the likelihood of any tower footing being constructed on or immediately adjacent to any waters of the U.S. Because these drainage features are relatively easily avoided by rerouting the transmission line corridor, their loss or disturbance is unlikely and would be a **less than significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Ponds

A five-acre pond located approximately 3.5 miles west of the Sacramento River could be impacted by the Delevan Transmission Line. This pond is part of an agricultural operation and has no associated natural vegetation. It is likely that tower footings could be constructed to one side of this pond rather than impact it. Because this pond is relatively easily avoided by rerouting the transmission line corridor, its loss or disturbance is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Alkaline Wetlands

Construction of the Delevan Transmission Line could result in direct loss or long-term disturbance of 0.04 acre and temporary disturbance to a maximum of 2.2 acres of disturbed alkaline wetlands in one parcel located approximately three miles west of the Sacramento River. This land is located north of the Delevan NWR, north of the existing road. It is highly disturbed, having been disked in the past, and is currently being managed as a private duck hunting club, with imported tules and other freshwater emergent wetland vegetation. The extent of permanent loss would equal the area of one tower footing (worst case, approximately 1,600 square feet, or 0.04 acre). Because this area is relatively easily avoided by repositioning the towers, this loss would be unlikely, and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Vernal Pools

Although the Delevan Transmission Line construction disturbance area would not be aligned through any vernal pools, it is aligned adjacent to a mapped 0.4-acre vernal pool located west of the GCID Canal. Because the construction disturbance area would be located less than 25 feet south of this vernal pool, the potential exists for direct or indirect impacts to this vernal pool if construction activities are not confined within the defined area. The construction disturbance area would also pass between two small vernal pools in the median strip of I-5, passing approximately 200 feet south of one and 330 feet north of another; each is approximately 0.1 acre in size. Keeping all construction activities within the construction disturbance area would avoid disruption or disturbance to any of these adjacent or nearby pools, so loss or disturbance of the pools would be unlikely, and a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

The pipeline analysis for Alternative A includes the 1,500-foot-wide construction disturbance area that would extend between the Sacramento River and the Holthouse Dam. This includes the portion of the Delevan Pipeline route that would extend from the river to the TRR, the TRR Pipeline route, and the portion of the Delevan Pipeline route that would parallel the TRR Pipeline from the TRR to Holthouse Reservoir and Dam. The latter portion of the pipeline route also includes a permanent gravel maintenance road and electrical switchyard above the pipelines. Once construction is complete, there would be no major pipeline facilities that would generate permanent ground impact; most of the land over the buried pipeline would revert back to its original use. The exceptions would be regularly spaced aboveground facilities, such as blow-off structures, air valve structures, and an outlet and energy dissipater structure. The 20-foot-wide gravel inspection road from the TRR to Holthouse Reservoir and Dam, as well as the electrical switchyard, would generate permanent ground disturbance. The pipeline construction disturbance area would traverse many agricultural canals and some agricultural ponds; some of these might be avoidable. The acres of each type of wetlands and other waters of the U.S. that would be lost or adversely affected within the pipeline, maintenance road, and electrical switchyard construction disturbance area are summarized in Table 15-14.

Table 15-14
Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

Wetland or Other Waters of the U.S. Type	Number of Acres Lost or Disturbed	Number of Miles Lost or Disturbed*
Alkaline wetlands	Indirect: 14.0	
Vernal pools	Indirect: 0.4	
Total Wetlands	**Direct/Permanent: 0** **Indirect: 14.4**	
Tributaries 0 to 5 Feet Wide	0.26	0.46
Tributaries 5 to 10 Feet Wide	8.77	9.16
Tributaries10 to 15 Feet Wide	10.6	6.77
Tributaries > 15 Feet Wide	22.3	7.48
Total Other Waters of the U.S.	**41.9**	**23.9**
Total Ponds	**5.0 acres**	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers,

Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

A total of approximately 42 acres (or approximately 24 miles) of waters could be permanently lost or adversely affected through construction of the buried pipelines and other activities associated with construction of the Delevan and TRR pipelines, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard. All affected waters consist of agricultural canals between three and 30 feet in width. If the water was redirected back into the farmers' irrigation systems so that the water would still be available for surrounding fields, temporary or even permanent disruption of most of these canal waters by the pipelines would not represent a hydrological interruption and would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, because the pipelines' small and regularly spaced above-ground structures (i.e., blow-off structures, air valve structures, and an outlet and energy dissipater structure) could be sited to avoid waters, they would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Ponds

No ponds would be affected by construction of the TRR Pipeline, TRR Pipeline Road, or Delevan Pipeline Electrical Switchyard. The five-acre pond located approximately 3.5 miles west of the Sacramento River would be affected by construction of the Delevan Pipeline (refer to the Delevan Transmission Line discussion for additional description of the pond). The pipeline would pass directly through this pond, resulting in the loss of the entire pond. Because this is an agricultural (human-made) pond, it is possible that it could be restored to its original condition after construction is completed, in which case the effects to this pond would be a **less-than-significant-impact** on waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. If the pond's hydrological integrity cannot be restored post construction, then its loss would represent a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. In addition, because the pipelines' small and regularly spaced above-ground structures (i.e., blow-off structures, air valve structures, and an outlet and energy dissipater structure) could be sited to avoid ponds, they would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Construction of the Delevan Pipeline could have a long-term direct adverse impact on two wetland types due to the direct removal of the soil and the replacement of soil over the buried pipeline, and/or by construction access roads, spoils piles, or other mechanical disturbance or displacement within the 1,500-foot-wide construction disturbance area. For wetlands, mechanical disruption of the hydrological regime would result in the permanent destruction of the feature; once disturbed or disrupted, wetland features rarely return to their former ecological integrity.

Alkaline Wetlands

No alkaline wetlands would be affected by construction of the TRR Pipeline, TRR Pipeline Road, or Delevan Pipeline Electrical Switchyard. Construction of the Delevan Pipeline could result in the direct loss or long-term disturbance of a maximum of 14 acres of disturbed alkaline wetlands in one parcel located approximately three miles west of the Sacramento River. This land is located north of the Delevan NWR, north of the existing road along the south end of the Gunnersfield duck club. (Refer to the Delevan Transmission Line discussion for further description of the managed wetland.) Direct disturbance of the duck club managed freshwater wetland would be unavoidable during pipeline construction, which in this case might be temporary. If the managed freshwater wetland could be restored to its full water-containment capacity and use after construction, the pipeline construction would represent a **less-than-significant impact** to these waters, when compared to Existing Conditions and the No Project/No Action Alternative. If it is not possible to restore the impermeable clay bottom of the managed freshwater wetland, then the wetland properties of the parcel would be lost and the pipeline construction would have a **potentially significant impact** on waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

The pipeline construction disturbance area is located near a federally protected wetland complex. The Delevan NWR wetlands are separated from the disturbance area by two roads and a canal located along the south edge of the pipeline's construction disturbance area. Because construction activities would occur north of these three barriers, the NWR wetlands would not be adversely affected by sedimentation, mechanical disturbance or other effects of construction activities including traffic, equipment operation, and other aspects of pipeline installation. Because construction would occur north of three effective barriers, there should be **no impacts** to the refuge wetlands, when compared to Existing Conditions and the No Project/No Action Alternative.

Vernal Pools

No vernal pools would be affected by construction of the TRR Pipeline, TRR Pipeline Road, or Delevan Pipeline Electrical Switchyard. The Delevan Pipeline construction disturbance area would pass through three small vernal pools located within the median strip of I-5; each is approximately 0.1 acre in size. The northern two pools are discussed in the Delevan Transmission Line analysis. Although these pools could easily be avoided during transmission line construction, they and the third southernmost pool would be more difficult to avoid during pipeline construction, which would affect a wider swath of land. Because most of the vernal pools formerly present in this part of Colusa County have been converted to agricultural fields, the loss of these few remaining pools would be **potentially significant**, when compared to Existing Conditions and the No Project/No Action Alternative. However, if the pipeline construction occurs completely underground, as proposed, impacts to these pools would be indirect.

The Delevan Pipeline construction disturbance area is located adjacent to a mapped 0.1-acre vernal pool that is located south of the road in the Delevan NWR. Because all construction activities would occur north of the Gunnersfield southern boundary road, there would be **no impact** on this NWR vernal pool, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Intake Facilities

The Delevan Pipeline Intake Facilities are associated with the Delevan Pipeline for Alternatives A and C. Construction of these facilities could result in a combination of temporary disruption, long-term disturbance, and permanent loss of existing agricultural canals and natural waters (Sacramento River).

The Sacramento River would be considered traditionally navigable waters (parts are still navigable and have been navigable in the past) or permanent (contains water year-round) waters of the U.S.(USACE, 2011b).The acres of each water type that would be lost as a result of construction of the Delevan Pipeline Intake Facilities are listed in Table 15-15. No ponds exist where the Delevan Pipeline Intake Facilities would be constructed.

Table 15-15
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Delevan Pipeline Intake Facilities

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost*
Total Wetlands	**0**	**0**
Tributaries 0 to 5 Feet Wide	0.05	0.13
Tributaries 5 to 10 Feet Wide	0	0
Tributaries 10 to 15 Feet Wide	0	0
Tributaries > 15 Feet Wide	0.25	0.10
Sacramento River	1.6	0.12
Total Waters of the U.S.	**1.9**	**0.35**
Total Ponds	**0**	

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

Construction of the Delevan Pipeline Intake Facilities would impact approximately two acres (0.35 mile) of potential waters of the U.S. These acres include agricultural canals, but also include 1.6 acres (0.12 mile) of the Sacramento River. Agricultural canals and ditches are generally not jurisdictional (USACE, 2011a), so canal disturbance from intake facility construction would most likely result in **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

For the Sacramento River, construction activities would create temporary disturbance of this portion of the river, where a cofferdam would extend approximately 40 feet into the river channel. Due to its temporary nature, construction disturbance to this part of the river would represent a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

The completed intake facility would permanently extend into the river channel. However, the existing Maxwell ID Pumping Plant is located in a narrow section of the river and consequently acts as a local flow control point (Reclamation, 2012). Therefore, the portion of the Delevan Pipeline Intake Facilities that would extend into the river would not obstruct the Sacramento River and would have a **less-than-significant impact** on waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

During operation, there is potential for ongoing erosional, biotic, and other effects of intake and release. Therefore, the operation of this facility represents a **potentially significant impact** on permanent waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities, including periodic sediment removal from the forebay, would be conducted when the forebay is dewatered and would not be expected to contribute to increased sedimentation of the Sacramento River. Therefore, there would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Riparian Wetlands

No loss of mapped wetlands of any type would result from construction of the Delevan Pipeline Intake Facilities on the Sacramento River. However, small amounts of emergent riparian wetland vegetation in shallow areas along the river's edge could be disturbed or lost to construction activities. The affected area is approximately 0.06 mile long (350 feet) and includes sparse herbaceous growth along the water's edge. This vegetation is variable, influenced by fluctuations in the river; its loss would therefore be temporary and would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Project Buffer

The area within the Project Buffer for Alternative A includes many small streams and a few ponds around the Sites Reservoir footprint, canals around the TRR facilities, and canals and a short river stretch around the Intake facilities. The outer perimeter of the Project Buffer would be fenced.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Ground-disturbing activities that would occur within the Project Buffer outside of existing developed land include fence construction, the creation of a fuelbreak, and the demolition of existing structures. Fence posts could be strategically placed to avoid waters. Their construction would therefore have a **less-than-significant impact** on waters of the U.S. The fuelbreak would consist of permanently disturbed unvegetated land around the perimeter of the Buffer. The exposed soil within the fuelbreak has the potential to contribute sediments to downslope streams. Although any single stream crossing within the fuelbreak would not contribute a significant amount of sediment to waters of the U.S., the total number of stream crossings within the entire Project Buffer could contribute an amount of sediment that could result in a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. Ground disturbance associated with the demolition of existing structures could result in temporary increases in sediment transport to adjacent waters of the U.S. However, this disturbance would be temporary, and lands would be revegetated following demolition. Therefore, structure demolition would have a **less-than-significant impact** on waters of the U.S.

Project and outer perimeter fencing would prevent any ground disturbance and human activity within the Project Buffer during operation. In addition, grazing would also no longer occur within the Project Buffer.

Project operation would, therefore, have **no impact** on waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities associated with fence repair would not be expected to affect waters of the U.S., and would, therefore, have a **less-than-significant impact** on waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. Fuelbreak maintenance would result in the removal of any vegetation growth, and therefore, could contribute sediment to downslope streams. The total number of stream crossings that would occur within the entire Project Buffer during maintenance of the fuelbreak could contribute an amount of sediment that could result in a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Demolition of existing structures, as well as activities associated with the construction, operation, and maintenance of fences and a fuelbreak, would have the same impact on wetlands as described for other waters of the U.S.

One probable indirect effect that could occur within the Project Buffer during operation would be conversion of some of the more disturbed shallow seasonal wetlands or vernal pools in the area around the Sites Reservoir footprint to non-native weedy grasslands once cattle-grazing is removed, because this is a common outcome in many wetland or vernal pool landscapes in California (Marty, 2007). The net effect of lack of any direct impacts, but with the indirect effects of cessation of grazing, would most likely be a **less-than-significant impact** to some of the wetlands within the reservoir facilities' Project Buffer.

Summary of Alternative A Impacts to Wetlands and Waters of the U.S.

A summary of the acreages of wetlands and other waters of the U.S. that would be affected by construction, operation, and maintenance of Project facilities as a result of Alternative A implementation are presented in Table 15-16.

Table 15-16
Affected Acres of Wetlands and Other Waters of the U.S. for all Project Facilities: Alternative A

Project Facility	Wetland Type						Waters of the US Type							Notes
	Alkaline	Emergent	Riparian	Seasonal	Vernal Pool	TOTAL WETLAND ACRES	TOTAL PONDS[b] ACRES	Streams 0-5 Feet Wide	Streams 5-10 Feet Wide	Streams 10-15 Feet Wide	Streams <15 Feet Wide	Streams >15 Feet Wide	TOTAL OTHER WATERS OF THE U.S. ACRES

Delevan Pipeline Intake Facilities						**0**		0.1				1.9	**2.0**	Includes Sacramento River
Project Buffer[d]														Area includes some wetlands and streams
TOTAL ACRES for Primary Study Area (Project Facility Footprints) and Subject to Potential Impacts[e]	**37.0**	**2.4**	**23.5**	**170.6**	**5.1**	**238.7**	**35.3**	**6.0**	**15.1**	**13.3**	**77**	**116.3**	**227.8**	

[a]The northwest 0.5 acre of swale feeding the marsh is within proposed footprint, but hydrologically connected to a 20-acre (estimated minimum area) marsh/swale/vernal pool complex. Wetlands themselves equal 13 acres; entire complex with connecting upland watersheds equal 20 to 40 acres.

[b]Ponds counted separately from streams.

[c]Includes 6.1 acres for Salt Lake. All other pond acreages are stockponds.

[d]Acres of wetlands and other waters of the U.S. types are unknown because the Project Buffer was added after surveys were conducted; consequently, wetland/WUS features were not mapped.

[e]Total acreage does not include acreage associated with the Project Buffer, which has not been surveyed or mapped.

Note:

Primary Study Area is defined as the Project facility footprints except for the Delevan Pipeline, which also includes a wider construction disturbance area, and for Holthouse Reservoir Complex, where alkaline wetlands potentially affected include acres adjacent to dam footprint as well as overlapping with the footprint.

15.3.7 Impacts Associated with Alternative B

15.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to jurisdictional waters of the U.S. (**Impact Wet-1)** and federally protected wetlands (**Impact Wet-2**), would be the same as described for Alternative A for the Extended Study Area.

15.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B operations to jurisdictional waters of the U.S. (**Impact Wet-1)** and federally protected wetlands (**Impact Wet-2**) would be the same as described for Alternative A for Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, *Clear Creek*, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, the American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River, as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

Operational differences for Alternative B, when compared to Alternative A, for the Sacramento River are discussed below.

Sacramento River

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Operational modeling using SacEFT (Appendix 8B) indicates that Project operations would indirectly result in changes in river flows downstream of the diversions for Sites Reservoir. For Alternative B, there would not be any diversion from the Sacramento River at the east end of the Delevan Pipeline (as there would be for Alternatives A and C). Operational modeling indicates that Sacramento River flows associated with implementation of Alternative B would experience changes similar to those described for Alternative A. However, Alternative B would divert up to 3,900 cfs during winter flows (rather than the 5,900 cfs diversion that would occur with Alternative A during winter flows). The reduced rate of diversion would consequently require a longer duration of diversion, lasting from February through May. Despite the increased duration of diversion, minor changes in flows are expected. These minor changes would represent a **less-than-significant impact** on the waters of the Sacramento River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Refer to the **Impact Wet-1** discussion. Due to the minimal fluctuations in flows expected in the Sacramento River with implementation of Alternative B, there would be a **less-than-significant impact** on jurisdictional wetlands present along the edges of the river (most likely in backwater or slough locations), when compared to Existing Conditions and the No Project/No Action Alternative.

15.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to wetlands and other waters of the U.S.:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The footprints of the Recreation Areas for Alternative B are the same as Alternative A, but the electrical distribution lines that would serve the Alternative B Saddle Dam Recreation Area would have a different alignment than was evaluated for Alternative A. However, the two Alternatives' distribution lines would cross equivalent extents of very small tributary drainages, distributed the same over the various stream widths, and would, therefore, have the same impacts on jurisdictional waters of the U.S. (**Impact Wet-1**) and federally protected wetlands (**Impact Wet-2**), as described for Alternative A.

Despite the larger reservoir size and increased number of dams with implementation of Alternative B, the impacts of Sites Reservoir and Dams to jurisdictional waters of the U.S. (**Impact Wet-1**) would be the same for Alternative B as described for Alternative A.

The boundary of the Project Buffer would be the same for Alternatives A and B, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on jurisdictional waters of the U.S. (**Impact Wet-1**) and federally protected wetlands (**Impact Wet-2**), as described for Alternative A.

The remaining facilities, and their impacts associated with implementation of Alternative B, are described below.

Sites Reservoir Inundation Area and Dams

Ground disturbance associated with dam construction and borrow areas, as well as inundation by a 1.81-MAF Sites Reservoir, would have a long-term direct adverse impact on existing wetlands and other waters of the U.S. due to direct removal of wetlands or waters and replacement by standing water, sterile subsoil, or permanent facilities. Construction of the associated dams would result in the complete loss of existing waters and wetlands within their footprints. Alternative B includes nine saddle dams as well as Golden Gate Dam and Sites Dam. The acres of each wetland or waters type that would be affected by the 1.81-MAF Sites Reservoir and its associated dams are listed in Table 15-17. Ponds are considered separately from wetlands or tributary streams.

Table 15-17
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the 1.81-MAF Sites Reservoir Inundation Area and Dams

Wetland or Other Waters of the U.S. Type	Number of Acres Affected	Number of Miles Affected*
Alkaline	19.2	
Emergent	2.4	
Riparian	23.0	
Seasonal	164.9	
Vernal pool	4.7	
Total Wetlands	**214.2**	
Tributaries 0 to 15 Feet Wide (smaller tributaries)	77	123
Tributaries > 15 Feet Wide (major tributaries)	82	25
Total Other Waters of the U.S.	**159**	**148**
Total Ponds	**20.7**	
Salt Lake	6.1	

*Only streams are indicated.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Seasonal Wetlands

Approximately 164 acres (11 acres more than for Alternative A) of seasonal wetlands would be permanently lost through initial inundation and repeated water level fluctuations within Sites Reservoir. These 113 wetlands (16 more than for Alternative A) are mostly small areas associated with low-lying swales, valley bottoms, or shallow drainages especially in clay-dominated soils. More than half are smaller than one acre in size; 30 are between one and five acres, and 10 (two more than for Alternative A) are larger than five acres. The impacts to seasonal wetlands associated with Salt Lake are the same as described for Alternative A. The loss of all of these seasonal wetlands (especially because they include some partly alkaline or saline features) would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Vernal Pools

The construction and inundation of Sites Reservoir and Dams would result in the direct and permanent loss of approximately 4.7 acres of vernal pools (0.7 acre more than for Alternative A), many of which are either artificially created impoundments or highly disturbed/degraded by long-term heavy grazing. These 17 vernal pools (one more than for Alternative A) are distributed throughout the reservoir footprint in Antelope Valley. The largest (larger than 1.3 acres) is associated with Salt Lake. The remaining features are all smaller than one acre in size. Because the vernal pools of the western edge of the Sacramento Valley are already much reduced in number, the loss of these vernal pools (especially because they include some partly alkaline or saline features) would be a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Emergent Wetlands

The impact of Alternative B on emergent wetlands would be the same as described for Alternative A.

Riparian Wetlands

More than 23 acres of riparian wetlands were mapped and identified within the reservoir footprint for Alternative B. Most of these 16 mapped areas are one acre or smaller in size, and consist of sparse wetland vegetation within disturbed intermittent stream channels. The loss of these riparian wetlands would be considered a **potentially significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

The road relocation construction disturbance area would differ slightly to serve different sets of dams, but the two Alternatives' routes would cross equivalent extents of very small tributary drainages. They both would impact approximately 12 miles (or 9.5 acres) of waters of the U.S., distributed the same over the various stream widths. However, Alternative B would result in a slightly greater impact, affecting 0.3 mile (0.1 acre) more waters than Alternative A. This increase is due largely to some substantial crossings of creeks associated with salt springs in the area south of the Saddle Dam Recreation Area; only Alternative B's road route traverses this sensitive area of wetlands and waters on its way to Saddle Dams 1 and 2. For Alternative B, the combined length of almost 12 miles and the connection of several streams with wetland features near the Saddle Dam Recreation Area would result in a **potentially significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Ponds

The impact of roads on ponds for Alternative B would be the same as described for Alternative A.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

Seasonal Wetlands

For Alternative B, the impacts of the road relocations on wetlands would be similar to Alternative A, exceeding Alternative A only by 0.17 acre more of impacts to seasonal wetlands along the road south of the Saddle Dam Recreation Area, for a total of 5.6 acres of seasonal wetlands lost to construction activities. As described for Alternative A, although seasonal wetlands can be considered jurisdictional features, these small wetlands can be easily avoided by relocation of the route, so their loss is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Transmission Line

If Alternative B is implemented, the affected wetlands and waters acreage from construction of the Delevan Transmission Line would be less than half of the total for Alternative A because there would be no transmission line alignment from the Sacramento River to the PG&E transmission line. Only the portion of the transmission line that would connect the Sites Pumping/Generating Plant to the PG&E or WAPA transmission line would be constructed (a total of up to three miles, compared to more than 12 miles for Alternative A) (Figure 3-1 in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives). Construction of this part of the transmission line would impact small tributary streams, but no wetlands or ponds.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

West of the GCID Canal, 1.2 acres (0.47 mile) of streams through open grassland or dryland grain fields would be at least temporarily impacted by the Delevan Transmission Line construction. Except for where the line would cross Funks Creek, these ephemeral drainages average six feet wide. Because the transmission tower spans could be from 1,200 to 1,300 feet, flexibility in tower footing placement would decrease the likelihood of any tower footing being constructed on or immediately adjacent to any waters of the U.S. Because these drainage features are relatively easily avoided by rerouting the transmission line corridor, their loss or disturbance is unlikely and would be a **less-than-significant impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

No wetlands occur within the construction disturbance area of the Alternative B Delevan Transmission Line. Therefore, there would be **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline Discharge Facility

The Delevan Pipeline Discharge Facility is associated with the Delevan Pipeline for Alternative B. Construction of this facility could result in a combination of temporary disruption, long-term disturbance, and permanent loss of existing agricultural canals and natural waters (Sacramento River). The Sacramento River would be considered traditionally navigable waters (parts are still navigable and have been navigable in the past) or at least permanent (contains water year-round) waters of the U.S. (USACE, 2011b). Construction of the Discharge Facility would impact fewer acres of tributaries (agricultural canals) and a smaller area of the Sacramento River than construction of the Delevan Pipeline Intake Facilities described for Alternative A. No ponds exist where the Delevan Pipeline Discharge Facilities would be constructed. The acres of each wetland or water type that would be lost from the construction of the Delevan Pipeline Discharge Facility are listed in Table 15-18.

Table 15-18
Direct Loss of Wetlands and Other Waters of the U.S. Due to the Construction of the Delevan Pipeline Discharge Facility

Wetland or Other Waters of the U.S. Type	Number of Acres Lost	Number of Miles Lost*
TOTAL Wetlands	**0**	**0**
Tributaries 0 to 5 Feet Wide	0	0
Tributaries 5 to 10 Feet Wide	0	0
Tributaries 10 to 15 Feet Wide	0	0
Tributaries > 15 Feet Wide	0.05	0.02
Sacramento River	0.09	0.03
Total Other Waters of the U.S.	**0.14**	**0.05**
Total Ponds	**0**	**0**

*Only streams are indicated.

Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means

Streams

Construction of the Discharge Facility would directly impact approximately 0.14 acre (0.05 mile) of potential waters of the U.S. These acres consist of an agricultural canal, but also include 0.09 acre (0.03 mile) of the Sacramento River. Agricultural canals and ditches are generally not jurisdictional (USACE, 2011a), so disturbance to this canal would most likely represent **no impact** to waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative. For the Sacramento River, construction activities would create temporary disturbance in a small portion of the river where the cofferdam would extend approximately 5 to 10 feet out into the channel. Due to its temporary nature, discharge facility construction disturbance to this part of the river would represent a **less-than-significant impact** to waters of the U.S. However, due to the potential for ongoing erosional, biotic, and other effects of release as a result of Project operation, the operation of this facility represents a **potentially significant impact** on permanent waters of the U.S., when compared to Existing Conditions and the No Project/No Action Alternative

Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means

No loss of mapped wetlands of any type would result from construction of the Delevan Pipeline Discharge Facility on the Sacramento River. Very small amounts of emergent riparian wetland vegetation along the river's edge could be disturbed or lost to construction activities. The affected area is approximately 0.02 mile long (140 feet) and includes intermittent sparse herbaceous growth at the base of a steep slope below riparian forest. This vegetation is variable, influenced by fluctuations in the river; its loss would therefore be temporary and would be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Summary of Alternative B Impacts to Wetlands and Other Waters of the U.S.

A summary of the acreages of wetlands and other waters of the U.S. that would be affected by construction, operation, and maintenance of Project facilities as a result of implementing Alternative B are presented in Table 15-19.

Table 15-19
Affected Acres of Wetlands and Other Waters of the U.S. for all Project Facilities: Alternative B

Project Facility	Wetland Type							Other Waters of the US Type						Notes
	Alkaline	Emergent	Riparian	Seasonal	Vernal Pool	TOTAL WETLAND ACRES	TOTAL POND ACRES[b]	Streams 0-5 Feet Wide	Streams 5-10 Feet Wide	Streams 10-15 Feet Wide	Streams <15 Feet Wide	Streams >15 Feet Wide	TOTAL OTHER WATERS OF THE U.S. ACRES	
Sites Reservoir Inundation Area (1.81 MAF) and Dams	19.2	2.4	23.0	164.9	4.7	**214.2**	26.8[c]				77	82	**159.0**

TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, and TRR Electrical Switchyard						**0**		0.4	0.8	0.6		0.6	**2.4**	All agricultural canals
Delevan Transmission Line (entire length)	2.2				0.7	**2.9**	1.9	0.1	0.4	0.4		1.8	**2.7**	Some natural streams, some canals
Delevan Pipeline (entire length), TRR Pipeline, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard	14.0				0.4	**14.4**	5.1	0.3	8.8	10.6		22.3	**42.0**	All agricultural canals
Delevan Pipeline Discharge Facility						**0**		0.1				1.9	**2.0**	Includes Sacramento River
Project Buffer[d]														Area includes some wetlands and streams
TOTAL ACRES for Primary Study Area (Project Facility Footprints) and Subject to Potential Impacts[e]	**37.0**	**2.4**	**25**	**182.4**	**5.8**	**252.6**	**35.8**	**6.0**	**15.1**	**13.3**	**77**	**116.3**	**227.8**	

[a]The northwest 0.5 acre of swale feeding marsh is within proposed footprint, but hydrologically connected to a 20-acre (estimated minimum area) marsh/swale/vernal pool complex. Wetlands themselves equal 13 acres; entire complex with connecting upland watersheds equal 20 to 40 acres.

[b]Ponds counted separately from streams.

[c]Includes 6.1 acres for Salt Lake. All other pond acreages are stockponds.

[d]Acres of wetlands and other waters of the U.S. types are unknown because the Project Buffer was added after surveys were conducted; consequently, wetland/WUS features were not mapped.

[e]Total acreage does not include acreage associated with the Project Buffer, which has not been surveyed or mapped.

Note:

Primary Study Area is defined as the Project facility footprints except for the Delevan Pipeline, which also includes a wider construction disturbance area corridor, and for Holthouse Reservoir complex, where Alkaline wetlands potentially affected include acres adjacent to dam footprint as well as overlapping with the footprint.

15.3.8 Impacts Associated with Alternative C

15.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to jurisdictional waters of the U.S. (**Impact Wet-1)** and federally protected wetlands (**Impact Wet-2**), would be the same as described for Alternative A for the Extended Study Area.

15.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C operations, as they relate to jurisdictional waters of the U.S. (**Impact Wet-1)** and federally protected wetlands (**Impact Wet-2**), would be the same as described for Alternative A for Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, *Clear Creek*, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, the American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

Because Alternative C includes the three Project intake locations that were described for Alternative A, the impacts associated with Alternative, as they relate to the jurisdictional waters of the U.S. (**Impact Wet-1)** and federally protected wetlands (**Impact Wet-2**) of the Sacramento River, would be the same as described for Alternative A.

15.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to wetlands and other waters of the U.S.:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road

- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C design of the Delevan Transmission Line and Delevan Pipeline Intake Facilities is the same as described for Alternative A. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to wetlands and other waters of the U.S. as described for Alternative A.

The Alternative C design of the Sites Reservoir Inundation Area and Dams, Recreation Facilities and Associated Distribution Lines, and Road Relocations and South Bridge is the same as described for Alternative B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore result in the same construction, operation, and maintenance impacts to wetlands and other waters of the U.S. as described for Alternative B.

The boundary of the Project Buffer would be the same for all three alternatives, but because the footprints of some of the Project facilities that are included in the Project Buffer would differ between the alternatives, the acreage of land within the Project Buffer would also differ. However, these differences in the size of the area included within the buffer would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on jurisdictional waters of the U.S. (**Impact Wet-1**) and federally protected wetlands (**Impact Wet-2**), as described for Alternative A.

Summary of Alternative C Impacts to Wetlands and Other Waters of the U.S.

A summary of the acreages of wetlands and other waters of the U.S. that would be affected by construction, operation, and maintenance of Project facilities as a result of implementing Alternative C are presented in Table 15-20.

Table 15-20
Affected Acres of Wetlands and Other Waters of the U.S. for all Project Facilities: Alternative C

	Wetland Type						Waters of the US Type							
Project Facility	**Alkaline**	**Emergent**	**Riparian**	**Seasonal**	**Vernal Pool**	**TOTAL WETLAND ACRES**	**TOTAL POND ACRES[b]**	**Streams 0-5 Feet Wide**	**Streams 5-10 Feet Wide**	**Streams 10-15 Feet Wide**	**Streams <15 Feet Wide**	**Streams >15 Feet Wide**	**TOTAL OTHER WATERS OF THE U.S. ACRES**	**Notes**
Sites Reservoir Inundation Area (1.81 MAF) and Dams	19.2	2.4	23.0	164.9	4.7	**214.2**	26.8[c]				77	82	**159.0**

[a]The northwest 0.5 acre of swale feeding marsh is within proposed footprint, but hydrologically connected to a 20-acre (estimated minimum area) marsh/swale/vernal pool complex. Wetlands themselves equal 13 acres; entire complex with connecting upland watersheds equal 20 to 40 acres.

[b]Ponds counted separately from streams.

[c]Includes 6.1 acres for Salt Lake. All other pond acreages are stockponds.

[d]Acres of wetlands and other waters of the U.S. types are unknown because the Project Buffer was added after surveys were conducted; consequently, wetland/WUS features were not mapped.

[e]Total acreage does not include acreage associated with the Project Buffer, which has not been surveyed or mapped.

Note:

Primary Study Area is defined as the Project facility footprints except for the Delevan Pipeline, which also includes a wider construction disturbance area corridor, and for Holthouse Reservoir complex, where Alkaline wetlands potentially affected include acres adjacent to dam footprint as well as overlapping with the footprint.

PRELIMINARY – SUBJECT TO CHANGE

15.4 Mitigation Measures

It should be noted that some of the wetlands identified as being adversely affected by the construction of various Project facilities have been identified as jurisdictional wetland types in a preliminary wetland delineation study. Other Project facilities have not been field-delineated, and the preliminary wetland delineation still needs to be verified by the USACE. In addition, some irrigation canals and drainage ditches mapped within Project facility footprints could be considered jurisdictional.

All jurisdictional determinations shall be made as part of a formal wetland delineation process; DWR and Reclamation shall provide information to support a CWA 404(b)(1) analysis. Final determination of jurisdictional status and associated Project impacts to such jurisdictional wetlands would be decided by USACE. If as a result of a wetland delineation and jurisdictional determination, the USACE determines that the Project would impact jurisdictional waters and wetlands, avoidance, minimization, and mitigation measures shall be implemented pursuant to USACE guidance to ensure that the Project would result in no-net-loss of waters of the U.S. and that impacts would be reduced to less-than-significant levels. Impact avoidance shall be achieved by placing all structures, heavy equipment, spoils piles, staging areas, and construction access roads at least 200 feet away from the wetland or water feature where feasible. Impact minimization shall be achieved through use of BMPs, a Stormwater Pollution Prevention Plan, protective fencing, erosion control, and/or protective berms or wattles during construction, operation, and maintenance of Project facilities. Compensatory mitigation may consist of:

- Obtaining credits from a mitigation bank;
- Making a payment to an in-lieu fee program that would conduct wetland, stream, or other aquatic resource restoration, creation, enhancement, or preservation activities; or
- Aquatic resource restoration, establishment, enhancement, and/or preservation activities within the same watershed as the Project impacts (off-site mitigation) where on-site mitigation would not be possible.

Mitigation measures are provided below and summarized in Table 15-21 for the impacts that have been identified as significant or potentially significant.

Mitigation Measure Wet-1a: Implement Compensatory Mitigation Measures for Streams pursuant to USACE Determination within the Watershed in which the Impacts Occur

Compensatory mitigation for streams shall be provided for each significant impact identified by the USACE determination according to ratios determined by the USACE for the appropriate category and degree of severity of loss or impact. Mitigation shall occur within the watershed in which the impacts occur:

- Sites Reservoir & Dams, Recreation Areas - Funks/Hunter/Antelope/Grapevine/Stone Corral Creek watersheds.
- Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility – Sacramento River adjacent to facility location.
- Road Relocations, Funks Reservoir, Holthouse Reservoir Complex, Sites Inlet/Outlet Structure and associated facilities, Field Office Maintenance Yard, Electrical Switchyard –Funks Creek watershed.

Table 15-21
Summary of Mitigation Measures for
NODOS Project Impacts to Wetlands and Other Waters of the U.S.

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Wet-1: A Permanent Change in the Use, Quality (Extent in Acres or Miles) of "Other Waters of the U.S.", (Including, but not Limited to, Lakes, Rivers, Streams Tributary to Navigable Rivers, Natural Ponds, Canals, or Ditches) that are Determined by the USACE to be Jurisdictional, through Direct Removal, Filling, Obstruction, Hydrological Interruption, or other Means				
Impact Wet-2a: Seasonal Wetlands	Sites Reservoir & Dams, Recreation Areas, Funks Reservoir	Potentially Significant	Mitigation Measure Wet-2a: Conserve, enhance, restore, or create seasonal wetlands, or implement other compensatory mitigation measures per USACE determination within the watershed in which the impacts occur.	Less than Significant
	Project Buffer	Potentially Significant	Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs	Less than Significant
Impact Wet-1a: Streams	Sites Reservoir & Dams, Recreation Areas, Road Relocations, Sites Inlet/Outlet Structure, Field Office Maintenance Yard, Funks Reservoir, Holthouse Reservoir Complex, Delevan Pipeline Intake Facilities, Delevan Pipeline Discharge Facility	Potentially Significant	Mitigation Measure Wet-1a: Implement compensatory mitigation measures for streams per USACE determination within the watershed in which the impacts occur.	Less than Significant
	Project Buffer	Potentially Significant	Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs	Less than Significant
Impact Wet-1b: Canals	Subject to USACE determination	Potentially Significant	Mitigation Measure Wet-1b: Reroute canals to ensure continued hydrological connection, or implement other compensatory mitigation measures per USACE determination.	Less than Significant
Impact Wet-1c: Ponds	Funks Reservoir, Delevan Pipeline	Potentially Significant	Mitigation Measure Wet-1c: Restore pond to original condition, or implement other compensatory mitigation measures per USACE determination within the same hydrologic unit in which the pond occurs.	Less than Significant

Table 15-21
Summary of Mitigation Measures for
NODOS Project Impacts to Wetlands and Other Waters of the U.S.

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact Wet-2: A Permanent Adverse Effect to Federally Protected Wetlands (as Defined by Section 404 of the Clean Water Act [Including, but not Limited to, Marsh, Vernal Pool, Coastal]) through Direct Removal, Filling, Hydrological Interruption, Discharge of Pollutants, or Other Means				
Impact Wet-2b: Alkaline Wetlands	Sites Reservoir & Dams, Holthouse Reservoir Complex, Delevan Pipeline	Potentially Significant	Mitigation Wet-2b: Conserve, enhance, restore, or create alkaline wetlands, or implement other compensatory mitigation measures per USACE determination within the watershed in which the impacts occur.	Less than Significant
	Project Buffer	Potentially Significant	Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs	Less than Significant
Impact Wet-2c: Vernal Pools	Sites Reservoir & Dams, Delevan Pipeline	Potentially Significant	Mitigation Measure Wet-2c: Conserve, enhance, restore, or create vernal pools equivalent to the type of vernal pools adversely impacted, or implement other compensatory mitigation measures per USACE determination.	Less than Significant
	Project Buffer	Potentially Significant	Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs	Less than Significant
Impact Wet-2d: Emergent Wetlands	Sites Reservoir & Dams	Potentially Significant	Mitigation Measure Wet-2d: Conserve, enhance, restore, or create emergent wetlands, or implement other compensatory mitigation measures per USACE determination within the watershed in which the impacts occur.	Less than Significant
	Project Buffer	Potentially Significant	Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs	Less than Significant
Impact Wet-2e: Riparian Wetlands	Sites Reservoir & Dams	Potentially Significant	Mitigation Measure Wet-2e: Conserve, enhance, restore, or create comparable riparian wetlands in the inner coast range foothills, or implement other compensatory mitigation measures per USACE determination.	Less than Significant
	Project Buffer	Potentially Significant	Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs	Less than Significant

Note:
LOS = Level of Significance

Mitigation Measure SW Qual-1c(1): Implement Soil Stabilization and Sediment Control BMPs

During Project construction activities, on-site monitoring shall be performed to identify runoff impacts. Appropriate soil stabilization BMPs; such as hydroseeding and application of other soil binders; installation of culverts, pipelines, and lined ditches to divert stormwater around disturbed soil areas; dust suppression through application of water to unpaved access roads; and placing cover material over material stockpiles; shall be implemented to reduce potentially significant construction impacts from erosion to a less-than-significant level. Sediment control BMPs, such as installation of fiber rolls and straw bales, settling/desilting basins, and other control measures, shall be implemented to reduce potentially significant construction impacts to wetlands and waters of the U.S. through sedimentation to a less-than-significant level. Details of these BMPs are described in Section WM-3 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure Wet-1b: Reroute Canals to Ensure Continued Hydrological Connection, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination

For impacts to canals, mitigation shall include re-routing the canals to ensure continued hydrological connection to traditional waters of the U.S. Loss of emergent wetland habitat from within canals shall be mitigated for in other ways, as recommended by the USACE.

Mitigation Measure Wet-1c: Restore Ponds to Original Condition, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination within the Same Hydrologic Unit in which the Ponds Occur

The pond located 3.5 miles west of the Sacramento River within the Delevan Pipeline construction disturbance area should be restored after construction is completed to its current condition as an agricultural pond. If restoration is not possible, compensatory mitigation measures, pursuant to USACE determination, shall be implemented within the Hunters Creek-Logan Creek watershed downstream of their confluence.

Mitigation Measure Wet-2a: Conserve, Enhance, Restore, or Create Seasonal Wetlands, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination within the Watershed in which the Impacts Occur

For the seasonal wetlands located along the edge of Funks Reservoir, alter the extent of dredging so that the slope of the reservoir bottom is more tapered at this point.

Mitigation Measure Wet-2b: Conserve, Enhance, Restore, or Create Alkaline Wetlands, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination within the Watershed in which the Impacts Occur

The local saline spring areas further upslope in same geological formation as the springs that feed Salt Lake shall be enhanced. These springs are located outside of the Sites Reservoir footprint but in the creases of the foothills due north of Salt Lake. Some of them may be able to be expanded, and could possibly be partially protected from grazing impacts with the installation of protective fencing.

A conservation agreement shall be entered into with Reclamation to manage and protect the entire alkaline wetland area southeast of Holthouse Reservoir. Management shall include burning and grazing regimes similar to those used effectively on the Sacramento NWR.

A purchase or conservation agreement shall be entered into with the utilities or other landowners to protect and manage other saline/alkaline wetland habitats in parcels east of the T-C Canal, north of the Primary Study Area. Protected areas might include a potential alkaline wetland area southeast of the Colusa Generating Station located along the T-C Canal.

For the Holthouse Reservoir alkaline wetlands, a hydrogeologic study shall be conducted to determine the direction and sources of water supplying the seeps, swales, and main wetland area, to better inform evaluation of potential effects of placing the dam and reservoir in proximity of the wetland's west edge. The study shall include testing of the wetland area's water and soils, and may allow for development of minimization measures.

Mitigation Measure Wet-2c: Conserve, Enhance, Restore, or Create Vernal Pools Equivalent to the Type of Vernal Pools Adversely Impacted, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination

For vernal pools, the type of vernal pools conserved elsewhere shall be equivalent to the type lost from the Primary Study Area – most likely, claypan and alkaline vernal pools. Consultation with vernal pool experts shall occur to ensure ecological equivalence.

Mitigation Measure Wet-2d: Conserve, Enhance, Restore, or Create Emergent Wetlands, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination within the Watershed in which the Impacts Occur

[Text to be developed]

Mitigation Measure Wet-2e: Conserve, Enhance, Restore, or Create Comparable Riparian Wetlands in the Inner Coast Range Foothills, or Implement other Compensatory Mitigation Measures pursuant to USACE Determination

For the two-acre riparian wetland and waters of Funks Creek lost to Holthouse Reservoir, a comparable area in the inner coast range foothills shall be selected for restoration and conservation.

Implementation of **Mitigation Measures Wet-1a, Wet-1b, Wet-1c, Wet-2a, Wet-2b, Wet-2c, Wet-2d, Wet-2e**, and **SW Qual-1c(1),** would reduce Project impacts to wetlands and other waters of the U.S. to **less than significant**.

16. Geology, Minerals, Soils, and Paleontology

16.1 Introduction

This chapter describes the geologic, minerals, soils, and paleontologic setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for geology, minerals, soils, and paleontological resources are discussed briefly in this chapter, and are presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary and Extended study areas were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate. Because none were identified for minerals, no mitigation is included in this chapter for that resource.

16.2 Environmental Setting/Affected Environment

16.2.1 Extended Study Area

16.2.1.1 Geology

Of the 48 contiguous states, California contains the highest and the lowest elevations only 80 miles apart, plus a variety of rocks, structures, and mineral resources equaled by few areas in the world (Norris and Webb, 1990).

California's landscapes are extremely varied, ranging from the broad nearly flat floor of the Great Valley to the jagged glaciated Sierra Nevada. Eleven geomorphic provinces[1] are recognized (Figure 16-1): the Sierra Nevada, the Klamath Mountains, the Cascade Range, the Modoc Plateau, the Basin and Range, the Mojave Desert, the Colorado Desert, the Peninsular Ranges, the Transverse Ranges, the Coast Ranges, and the Great Valley.

California's geologic diversity, in part, is attributed to its location astride two major tectonic plates: the North American Plate and the Pacific Plate. The active San Andreas Fault, heading north out of the Gulf of California, westward along the Transverse Ranges, then northwestward within and west of the Coast Ranges up to Cape Mendocino, separates the North American Plate from the Pacific Plate. Active faulting is an important feature of California's structural pattern. The San Andreas Fault has been crucial in California's geologic history since at least the Miocene epoch (approximately 23 million years ago [MYA]). The ground surface at the fault has moved as much as 350 miles. Other important faults are the Calaveras and Hayward in the San Francisco Bay area, the Nacimiento in the southern Coast Ranges, the San Jacinto of the Peninsular Ranges, the Sierra Nevada in eastern California, and the Garlock, which separates the Mojave Desert from the Sierra Nevada and the Basin and Range.

[1] The geomorphic provinces are topographic-geologic groupings based primarily on landforms and late Cenozoic structural and erosional history.

The oldest rocks found in California are metamorphic rocks as much as 1.8 billion years old, which occur in the San Gabriel and San Bernardino mountains and in the Mojave and Basin and Range provinces. During the Paleozoic era (approximately 600 MYA), most of California was below sea level and thick sequences of marine sediments were deposited. These sediments ranged from near-shore limestone in the east to deeper-water deposits composed of volcanic detritus[2] from offshore islands mixed with oceanic crustal materials. Marine conditions continued into the Mesozoic era (beginning approximately 260 MYA) but with active subduction[3] as the Pacific Plate plunged under the North American Plate. The sea withdrew to the west and mountains developed in eastern California accompanied by some granitic intrusive activity. With some pauses or interruptions, subduction continued through the latter part of the Mesozoic era when granitic intrusions were again voluminous and very widespread.

Granitic rocks from the Mesozoic era are by far the most abundant igneous rocks in California and are exposed in most provinces. Sedimentation continued offshore in deep marine basins from material stripped off the rising mountains to the east and from volcanic material derived from a chain of offshore volcanic islands; these sediments later become known as the Franciscan Complex. Marine sedimentation decreased in the Cenozoic era (beginning approximately 70 MYA), confined primarily in and west of the San Joaquin Valley and in scattered locations in Southern California. Subduction slowed considerably later in the Cenozoic era, but compressive forces continued, raising the Coast Ranges and eventually closing off the Central Valley from the Pacific Ocean. Beginning in the Eocene epoch and continuing to the Pleistocene, the Central Valley inland basin gradually filled in with continental deposits. During the Pleistocene epoch[4] (approximately 2.6 MYA), extensive glaciation sculpted the Sierra Nevada and other mountain ranges, and large inland lakes developed west of the Sierra Nevada.

16.2.1.2 Minerals

California's geology has resulted in a wealth of mineral resources, including industrial, metallic, and nonmetallic minerals. These minerals are important to the state's economy. California ranks second in the U.S. in non-fuel mineral production; in 2005, over 30 non-fuel mineral commodities – valued at $3.7 billion – were produced from 820 California mines (CGS, No Date).California's major mineral resources include sand, gravel, crushed stone, building stone, gold, silver, iron, evaporite[5] minerals, and clay.

Sand and gravel are California's most valuable industrial minerals. Most sand and gravel is mined from alluvial deposits, which include sediment from streams and alluvial fans. Other important industrial minerals are crushed stone and limestone.

Gold, silver, and iron are the major metallic minerals mined in California. The most productive gold mining areas include the Sierra Nevada, the Klamath Mountains, and the Mojave Desert. Silver is mined in the Sierra Nevada and iron is mined in the Mojave Desert region. Copper and zinc were mined extensively in the past century, particularly in the Klamath Mountains and the Sierran foothills; production has decreased substantially in recent decades.

Other economically important nonmetallic minerals include borates, which are mined in southern California, and gypsum and clay minerals.

---

[2] Volcanic detritus is loose fragments, such as sand or gravel, which has been worn away from rock.

[3] Subduction is a geologic process in which one edge of one crustal plate is forced below the edge of another.

[4] An epoch is the shortest division of geologic time.

[5] Evaporite is a nonclastic sedimentary rock composed primarily of minerals produced from a saline solution as a result of extensive or total evaporation of the solvent. Examples include gypsum, anhydrite, rock salt, primary dolomite, and various nitrates and borates.

Oil has been found in 18 counties in California, primarily in the San Joaquin Valley and Southern California. Small amounts of oil are also produced in the northern California near Eureka. Natural gas is generally formed with oil; however, natural gas is produced in the Sacramento Valley without any recoverable oil resources.

Ultramafic[6] rocks, possibly containing localized veins of asbestos, occur widely throughout California (CGS, 2000a).

16.2.1.3 Soils

California has over 700 distinct soil series map units.[7] California soil types vary extensively. In the mountains of northern California, where precipitation is higher and vegetation abundant, soil depths are generally deeper with a greater abundance of clay. At lower elevations, such as the Sacramento Valley, rich alluvial soils predominate, supporting an extensive agricultural region. Soils within the southern California coastal plains and adjacent mountains are more clastic (i.e., clay-poor) due to lower precipitation and less vegetation. Soil development east of the Sierra Nevada and the desert portions of Southern California is less extensive.

16.2.1.4 Paleontology

Table 16-1 shows the fossil locations and number of fossils found in a database search of the Extended Study Area. Fossils found in the Extended Study Area range from microfossils (fossils of single-celled organisms) to large megafossils (fossils of larger organisms, ranging from small invertebrates to large mammals). Several counties contain more fossil localities than there are actual fossils on record. Typically, these localities represent sites where fossils have been discovered, but the specimens have yet to be added to the database. Because no impacts to paleontological resources are anticipated in the Extended Study Area, a full paleontological inventory review of the Extended Study Area was not conducted.

Table 16-1

[6] Ultramafic rocks are igneous rocks that form in high temperature environments well below the surface of the earth. By the time they are exposed at the surface by uplift and erosion, ultramafic rocks may be partially to completely altered to serpentinite, a type of metamorphic rock in which small amounts of chrysotile asbestos are common.

[7] The soil series is the lowest category of the national soil classification system. The name of a soil series or the phase of a soil series is the most common reference term used in soil map unit names. The name of a soil series is also the most common reference term used as a soil map unit component. The purpose of the soil series category is closely allied to the interpretive uses of the system, though map unit components provide the interpretive applications within soil survey for most detailed purposes. Soil series are the most homogeneous classes in the system of taxonomy (NRCS, 2011).

16.2.2 Secondary Study Area

16.2.2.1 Geology

The Secondary Study Area occurs primarily in the eastern portion of the Coast Range Geomorphic Province and the northwestern portion of the Great Valley Geomorphic Province (Figure 16-1). Additionally, portions of the Klamath Mountains, Cascades, Modoc Plateau, Basin and Range, and the Sierra Nevada geomorphic provinces are within the Secondary Study Area. These are described below.

Coast Range Geomorphic Province

The Coast Range Geomorphic Province is characterized by a series of north-northwest trending ranges and valleys; few are continuous for more than 100 miles. The province extends approximately 600 miles from Point Arguello northward to the Klamath Range (Norris and Webb, 1990) and varies in width from a few miles to 70 miles.

The Coast Ranges are complex and consist of many types of rocks ranging in age from Jurassic (206 MYA) to Tertiary (present time). The Franciscan Formation is composed of metamorphosed sedimentary and igneous rocks. It represents the basement rocks of the Coast Ranges to the west of the project area. The general structural trend is northwest.

The eastern portion of the Coast Range is composed of a thick sequence of Upper Mesozoic (65 to 145 MYA) sedimentary rocks known as the Great Valley Sequence (GVS). The section consists principally of sedimentary rocks that are folded and faulted, and are not affected by other than mild metamorphism. The GVS is divided into several formations that are generally based upon particle size. Although the naming system for these formations has been subject to many revisions (e.g., Blake et al., 1992; Dickinson and Rich, 1972; Rich, 1971; Ingersoll, 1979), for this study, the pertinent formations of the GVS (from oldest to youngest) include the Stony Creek, Lodoga, Boxer, Venado, Cortina, and Yolo. Quaternary (1.8 MYA to Present) units in the Coast Range include stream deposits consisting of clay, silt, sand, gravel, cobbles, and boulders found in recent stream channels. Stream deposits are derived from the older components of the Franciscan Complex and the GVS. Hillside deposits occur along slopes or at their bases. It consists of soil, but contains a sizable fraction of angular rock fragments and some organic material. Landslide deposits are similar to hillside deposits, but are more defined and generally deeper. Landslide deposits tend to occur on steeper slopes.

Great Valley Geomorphic Province

The Great Valley Geomorphic Province is a nearly flat alluvial plain extending from the Tehachapi Mountains in the south to the Klamath Mountains in the north; to the Sierra Nevada in the east and the Coast Ranges in the west. The valley consists of the San Joaquin River drainage to the south of the Sacramento-San Joaquin Delta, and the Sacramento River drainage to the north. This northwest-trending trough has been filled with a thick (several miles deep) (Wahrhaftig and Birman, 1965) accumulation of sediments eroded from the adjacent ancestral Sierra Nevada and Klamath Mountain ranges from the Jurassic to the Present. It has a long stable eastern shelf supported by subsurface granite and a short western flank with basin sediments. The western edge has eroded to form a series of northwest-trending eastward-dipping ridges of sandstone and conglomerate separated by valleys underlain by siltstone and mudstone.

Rock units on the surface in the Great Valley Geomorphic Province close to the Secondary Study Area range in age from Miocene to Recent (23.8 MYA to Present).

The Lovejoy basalt is a dense and very hard extrusive volcanic rock (i.e., lava flow). The basalt originated approximately 23 million years ago from an unknown volcanic center near the eastern margin of the Sierra Nevada. Lovejoy exposures are found in the Orland Buttes on the west side of the Central Valley and as far south as Vacaville. Extensive outcrops of the Lovejoy are located in the Oroville area.

The Tehama Formation occurs as thin, discontinuous, and deeply weathered stream-transported fan deposits throughout the western edge of the Sacramento Valley that were derived from the erosion of the Coast Ranges and Klamath Mountains. Eastward, the deposits thicken and merge, forming a broad thick plain that contains pale green to tan semi-consolidated sand, tuffaceous[8] sand, and silt with lenses of gravel. The Tehama Formation is the primary groundwater aquifer of the Sacramento Valley west of the Sacramento River. The Nomlaki Tuff Member occurs near the bottom of the Tehama Formation and has been age-dated at approximately 3.3 million years. It consists of white, tan, or pink dacite pumice tuff and lapilli tuff that is approximately 30 feet thick along the west side of the valley. Most of the tuff is believed to have been deposited as an ash fall from a major volcanic eruption east of the project region.

The Red Bluff Formation occurs primarily in the northern portion of the Sacramento Valley, where it overlies the Tehama Formation. Its largest area is in the vicinity of the City of Red Bluff where it is approximately 50 feet thick. It consists largely of gravels with minor amounts of interbedded sands. The upper surface usually consists of a hardpan soil. In the Red Bluff area, rock fragments are metamorphic and igneous types, indicating that the sediments were transported from the north Coast Ranges and Klamath Mountains. The formation was probably deposited during a period when glaciers were active in the adjacent mountain areas. Streams draining the glacial areas were heavily choked with coarse debris and suspended fine-grained material. The suspended clay and silt particles filled the voids after deposition of the gravel so that most of the Red Bluff gravels are not very permeable. The Red Bluff remnants represent an extensive Pleistocene (1.8 MYA to 11,600 years ago) nearly level erosional surface that once covered much of the northern Sacramento Valley.

The Riverbank Formation consists of weathered reddish gravel, sand, and silt. It is differentiated from the younger Modesto Formation by its terraces being higher topographically and by its more developed soil profile. The upper layer is unconsolidated, but compact dark brown to red alluvium and forms the lower of the Riverbank terraces. The lower layer is a red semi-consolidated gravel, sand, and silt. Its surface is higher topographically and more dissected than the upper layer and has a stronger soil profile.

The Modesto Formation consists of the lowest distinct alluvial terraces lying above the Holocene (11,600 years ago to Present) stream deposits. It includes tan and light gray gravelly sand, silt, and clay. The upper layer is unconsolidated and unweathered, and it forms the lowest terraces approximately ten feet thick over older alluvial deposits. The lower layer can be slightly weathered and forms terraces that are higher than the upper layer. Soils on the lower layer contain clay and are red.

Recent stream channel deposits, floodplain, and flood basin deposits make up the remainder of rock types that crop out in the Sacramento Valley. Stream channel and floodplain deposits consist of well-sorted sand, gravel, and silt adjacent to the major streams. Flood basin deposits are the finest grained materials, consisting mostly of clay and silt. The deposits are thin and poorly permeable. Flood basin deposits in the project area occur in the Colusa Basin along the west side of the Sacramento River from approximately Princeton southward.

The Tuscan and Laguna formations, important water-bearing formations beneath the Sacramento Valley, crop out along the eastern portion of the Sacramento Valley. Further discussion of these formations is included in Chapter 10 Groundwater Resources.

Klamath Mountains Geomorphic Province

The Klamath Mountain Geomorphic Province is divided into four north-south trending terranes[9]. From east to west, these terranes are the Eastern Klamath, Central Metamorphic, Western Paleozoic and

[8] Tuffaceous sand is a rock composed of compacted volcanic ash varying in size from fine sand to coarse gravel.

[9] Terranes are areas having a preponderance of a particular rock or rock groups.

Triassic, and Western Jurassic. The terranes increase in age from west to east, except for the Central Metamorphic Terrane, which is slightly older than the Eastern Klamath Terrane. The rock units generally dip to the east, with the older eastern units overlying the younger western units. To varying degrees, these rock units are exposed throughout the 40-mile reach of the mainstem Trinity River. Older gold-bearing stream channel deposits, as well as recent channel deposits, occur along rivers and creeks.

Cascades Geomorphic Province

The Cascades Geomorphic Province, from southern British Columbia to south of Lassen Peak, is a volcanic terrane ranging in age from Pliocene to Holocene. The province has been divided into the Western Cascade series and the High Cascade series. The Western Cascade series consists of Miocene-aged basalts, andesites, and dacite flows interlayered with rocks of explosive origin, including rhyolite tuff, volcanic breccia, and agglomerate. This series is exposed at the surface in a belt 15 miles wide and 50 miles long from the Oregon border to the town of Mount Shasta. Early High Cascade rocks formed very fluid basalt and andesite that extruded from fissures to form low shield volcanoes. Large composite cones like Mount Shasta and Mount Lassen had their origins during the Pleistocene. Mount Lassen was the only active volcano in California in the 20th century. Mount Shasta was last active in the 18th century when steam and ash erupted from the summit cone (Norris and Webb, 1990).

Modoc Plateau Geomorphic Province

The Modoc Plateau Geomorphic Province consists of a high plain of irregular volcanic rocks of basaltic origin. The numerous shield volcanoes and extensive faulting on the plateau give the area more relief than may be expected for a plateau. The Modoc Plateau averages 4,500 feet in elevation and is considered a small part of the Columbia Plateau, which covers extensive areas of Oregon, Washington, and Idaho.

Basin and Range Geomorphic Province

The Basin and Range Geomorphic Province, located east of the Modoc Plateau and the Sierra Nevada, extends eastward into western Utah. It is characterized as north-south trending mountain ranges separated by low wide alluvial valleys derived from eroded materials from the adjacent mountain ranges. In general, the drainage is internal (i.e., no outlet to the sea) with saline lakes occupying low spots. One area, the Sierra Valley, drains westward into the Middle Fork Feather River. Rocks range from metamorphic rocks of pre-phanerozoic age (approximately 1.8 billion years ago to Recent) lakebed and stream deposits. Paleozoic and early Mesozoic sedimentary and metamorphic rocks constitute the bulk of the bedrock. The topography of the Basin and Range is a result of crustal extension within this part of the North American Plate. The crust has been stretched up to 100 percent of its original width, and underneath the Basin and Range, it is of the thinnest in the world.

Sierra Nevada Geomorphic Province

The Sierra Nevada Geomorphic Province is comprised principally of Cretaceous granitic pluton[10], remnants of Paleozoic and Mesozoic metavolcanic and metasedimentary rocks, and Cenozoic volcanic and sedimentary rocks. The Paleozoic and Mesozoic metavolcanic and metasedimentary rocks were intruded by the granitic plutons approximately 77 to 225 MYA, resulting in local uplift and deformation of the overlying older rock. Regional uplift and rapid erosion of most of the overlying metamorphic rocks closely followed intrusion of the plutons, exposing the underlying granitic rocks. Continued uplift and

---

[10] Plutons are masses of igneous rock that have solidified below the surface of the earth.

erosion, accompanied by volcanic activity and alpine glaciation, resulted in the present pattern of deep-walled valleys that characterize the Sierra Nevada.

16.2.2.2 Minerals

The mineral resources within the Secondary Study Area are the same as was described for the Extended Study Area. The exceptions are iron and gypsum, which are mined in southern California, but are not found in the Secondary Study Area.

The Stony Creek Fan in Glenn County has an estimated aggregate material availability of 160 million cubic yards (DWR, 2002).

Ultramafic rocks, possibly containing localized veins of asbestos, occur in the Coast Ranges, Klamath Mountains, and the Sierra Nevada (CGS, 2000a). Chromite was mined intermittently from ultramafic rocks in Glenn County in the vicinity of the town of Chrome. Mining activity ceased in the 1940s.

16.2.2.3 Soils

Soils in the western portion (i.e., the Coast Range foothills) of the Secondary Study Area are a byproduct of erosion of the underlying sedimentary rocks. Typical foothill soils are shallow to deep, generally well-drained, and fine- to medium-textured. Soil depth on steep slopes is moderate to very thin; slightly weathered sandstone and intensely weathered mudstones can be encountered within just a few inches of the surface. Soil depth increases on the gentler slopes, generally reaching its maximum thicknesses along valley bottoms. These deeper soils are more developed, moderately drained, and finer-grained; organic material is more common in the low-lying deeper soils.

Soils in the central portion (i.e., the Sacramento Valley) of the Secondary Study Area are a byproduct of the underlying weathered alluvial deposits. Most valley soils are alluvial silt loams, clays, and sands deposited by the Sacramento River and tributaries draining the west side of the valley. These soils are typically very deep to moderately deep, poorly drained, and fine-textured. The majority of the alluvial soils on the valley floor has high agricultural productivity and is designated as Prime Agricultural[11] soils. Some soils are limited in their ability to support many forms of agriculture because of alkali problems and/or drainage problems caused by the presence of a cemented hardpan or dense clay layer. These poorly drained soils are particularly well suited for growing rice.

Soils in the northern and eastern portions of the Secondary Study Area (i.e., the Klamath, Cascades, and Sierra Nevada) are a byproduct of the underlying metamorphic, volcanic, and intrusive rocks. In general, they are more clay-rich than the alluvial soils of the Sacramento Valley.

16.2.2.4 Paleontology

Table 16-2 shows the fossil locations and number of fossils found in the Secondary Study Area. As in the Extended Study Area, the recovered fossils range from microfossils to the bones of large mammals. Several counties contain more fossil localities than actual fossils because not all fossils from known localities have been added to the database at this time (the localities have been listed, but the specimens from those sites have yet to be entered into the database). Construction activities in the Secondary Study Area are limited to the installation of a new pump at the Red Bluff Pumping Plant, and maintenance activities are limited to the dredging of the intakes; neither operation will involve excavation into

[11] Prime Agricultural means that the soil meets the physical and chemical criteria for Prime Farmland or Farmland of Statewide Importance, as determined by the USDA Natural Resources Conservation Service (NRCS).

sediments with the potential to yield fossils. Because these activities are not expected to affect paleontological resources, a full paleontological inventory review of the Secondary Study Area was not conducted.

Table 16-2

16.2.3 Primary Study Area

16.2.3.1 Geology

Table 16-3 lists the Coast Range rock units and the Sacramento Valley rock units within the Primary Study Area. Figure 16-2 is a generalized geologic map of the Primary Study Area (CGS, 2000b). Detailed mapping of the rock units within the Sacramento Valley (Helley and Harwood, 1985) is shown in Figure 16-3.

Sites Reservoir Inundation Area, Sites Reservoir Dams, and Recreation Areas

Sites Reservoir and its dams would be located in sedimentary rocks of the GVS. The GVS is composed of Jurassic-Cretaceous marine sandstones, siltstones, and mudstones trending north by northwest and dipping steeply to the east. Older sedimentary rocks of the GVS occur to the west, and younger sedimentary rocks occur to the east.

Within the footprint of the Sites Reservoir, the GVS is primarily composed of the Boxer Formation. The Boxer Formation consists of thinly bedded mudstones with thin to medium sandstone/siltstone. The mudstone of the Boxer Formation is more erodible than the sandstone, thus forming the broad gentle relief of the Antelope Valley. The saddle dam foundations along the northeastern portion of the reservoir would be sited in the Boxer Formation.

The prominent ridge along the eastern shore of Sites Reservoir is formed from the contact between the underlying Boxer Formation and the more resistant Cortina Formation. The Cortina Formation consists of a greater proportion of sandstone, with moderate to thick mudstone interlayers. The basal member of the Cortina Formation, the Venado Sandstone, is the geologic unit in which the Golden Gate Dam and the Sites Dam foundations would be built.

Younger deposits of Late Quaternary (8,000 year ago to Present) deposits occur within the Sites Reservoir footprint, primarily along the stream valleys of Stone Corral Creek, Antelope Creek, Funks Creek, and Grapevine Creek in Antelope Valley. The deposits are composed primarily of fine-grained sands, silts, and clays derived from the surrounding Boxer Formation. Larger fragments of igneous and metamorphic rock occur in the deposits and are derived from upland areas west of the valley. They generally occur as stream channel and floodplain deposits; minor colluvium deposits occur on higher gentler slopes away from the streams. Floodplain deposits typically contain beds of sandy gravel and silty sand. Stream channel deposits consist of sandy silt and gravel inset into either the floodplain or terrace deposits. In general, the deposits are rather thin (less than 30 to 50 feet) with a maximum thickness reached adjacent to the downcut stream channels on the eastern side of Antelope Valley.

The five recreation areas would be located on either the Boxer Formation or the Cortina Formation.

Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard

The Sites Generating/Pumping Plant would be sited on the eastern slope of a prominent ridge composed of sandstones and mudstones of the Cortina Formation. Quaternary alluvium covers the alignment trace of the intake canal. The tunnel alignment would be in mostly Cortina Formation mudstones and sandstone, except for its western opening which would be in mudstones of the Boxer Formation. The Inlet/Outlet Structure would be sited in the Boxer Formation. The Sites Electrical Switchyard would be sited in sandstone of the Cortina Formation. The Field Office Maintenance Yard would be sited primarily in sandstone with occasional thin beds of mudstone of the Lodoga Formation.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Bedrock within and surrounding the existing Funks Reservoir is composed primarily of thinly bedded mudstones of the Yolo Member of the Cortina Formation. Due west of Funks Reservoir, the Sites member of the Cortina Formation is older geologically, and occurs as a more resistant ridge of thin to medium bedded sandstone and siltstones. Typically, the mudstone members are more susceptible to weathering and erosion, forming broad low valleys or swales between the more resistant sandstone. A more resistant outcrop of sandstone occurs near the downstream portion of Funks Reservoir in the vicinity of the existing Funks Dam. The Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would be sited in thinly bedded mudstones of the Yolo Member of the Cortina Formation. Younger deposits of the Late Quaternary (8,000 year ago to Present) occur on top of the bedrock around and inundated by Funks Reservoir; the Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would also be sited on these deposits.

Glenn-Colusa Irrigation District Canal

Geologic units along the alignment trace of the GCID Canal consist of (from youngest to oldest) the Basin Deposits, Upper and Lower Modesto Formation, and Upper and Lower Riverbank Formation. Descriptions of these geologic units are included in Section 16.2.2.1.

The GCID Canal headworks are located on the Lower Riverbank Formation. From approximately one mile south of the headworks to Stony Creek, the Canal then crosses the Lower Modesto Formation. Between Stony Creek and Willows, the Canal crosses the Upper and Lower Modesto Formation and the Riverbank Formation, as well as basin deposits. From Willows south to the Funks Reservoir, the Canal crosses primarily basin deposits and isolated deposits of Upper Modesto Formation and Upper Riverbank Formation.

Tehama-Colusa Canal

Geologic units along the alignment of the T-C Canal consist of (from youngest to oldest) the Basin Deposits, Upper and Lower Riverbank Formation, Upper and Lower Modesto Formation, Red Bluff Formation, Tehama Formation, and Cortina Formation. Descriptions of these geologic units are included in Section 16.2.2.1.

From Willow Creek to Funks Reservoir, the Canal crosses primarily deeply weathered mudstones, siltstones, and minor thin beds of sandstone of the Cortina Formation between drainage divides and younger alluvium or basin deposits at stream crossings.

Delevan Pipeline and Delevan Transmission Line

Geologic units along the alignment of the Delevan Pipeline consist of (from youngest to oldest) recent Sacramento River stream deposits, Basin Deposits, Lower Riverbank Formation, Lower Modesto Formation, and Cortina Formation. Descriptions of these geologic units are included in Section 16.2.2.1.

Terminal Regulating Reservoir, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, Delevan Pipeline Electrical Switchyard, Terminal Regulating Reservoir Pumping/Generating Plant, and Terminal Regulating Reservoir Electrical Switchyard

Geologic units underneath and adjacent to the proposed location of the TRR, GCID Canal Connection to the TRR, TRR Pipeline, TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, TRR Pumping/Generating Plant, and TRR Electrical Switchyard consist of Basin Deposits and the Lower Riverbank Formation. Descriptions of these geologic units are included in Section 16.2.2.1.

Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility

Geologic units underneath the proposed location of the Delevan Pipeline Intake Facilities and Delevan Pipeline Discharge Facility consist of recent Sacramento River stream deposits, Lower Modesto Formation, and the Tehama Formation. Descriptions of these geologic units are included in Section 16.2.2.1. The stream deposits and Lower Modesto Formation are relatively thin (less than 20 feet) and are underlain by the more resistant Tehama Formation. The Tehama Formation is less readily erodible and defines the western edge of the Sacramento River channel.

Road Relocations and South Bridge

Geologic units underneath the proposed location of the road relocations consist of the Boxer and Cortina Formations of the GVS (Section 16.2.2.1). Additionally, these older deposits are occasionally overlain by younger sedimentary deposits of Late Quaternary (8,000 year ago to Present).

Project Buffer

Geologic units underneath the portion of the Project Buffer that would surround Sites Reservoir and the inlet/outlet facilities, as well as the Holthouse Reservoir Complex, consist primarily of the Boxer and Cortina formations of the GVS (Section 16.2.2.1), with smaller portions of Basin Deposits, upper and lower members of both the Riverbank and Modesto formations, and Red Bluff Formation.

Geologic units underneath the portion of the Project Buffer that would surround the TRR facilities consist of Lower Riverbank Formation, Basin Deposits, and Red Bluff Formation.

Geologic units underneath the portion of the Project Buffer that would surround the Delevan Pipeline Intake/Discharge Facilities consist of Lower Modesto Formation and recent Sacramento River stream deposits.

16.2.3.2 Minerals

With the exception of an inactive dimensional stone quarry to the east of the proposed Sites Dam location, no known economic mineral resources occur in Primary Study Area. No locally important mineral resources exist within the Primary Study Area (Glenn County, 1997 and Colusa County, 1989).

Natural gas production occurs widely in the Primary Study Area with large gasfields in the Sacramento Valley, such as the Willows-Beehive Bend Field. Between 1948 and 1972, 10 exploratory wells were drilled within the footprint of the proposed Sites Reservoir; all 10 wells were “dry holes” (i.e., produced no natural gas). Approximately 10 exploratory wells (all “dry holes”) were also drilled near the alignment of the Delevan Pipeline.

Ultramafic rocks possibly containing localized veins of asbestos are not found within the Primary Study Area or in watersheds draining into the Primary Study Area (CGS, 2000a).

16.2.3.3 Soils

The soils in the Primary Study Area have been mapped by the U. S. Department of Agriculture, Soil Conservation Service (now the NRCS), and are described in the soil surveys of Colusa and Glenn counties (NRCS, 2006 and Begg, 1965). In addition, the NRCS provides soil data in GIS format and software (Soil Data Viewer) for detailed analysis of soil properties.

The Primary Study Area includes two physiographic provinces: the Sacramento Valley and the Coast Range foothills (NRCS, 2006).

Floodplains extending along both sides of the Sacramento River slope gently away from the river to the Butte Sink to the east and Colusa Basin to the west. Frequent overflows under natural conditions have deposited loamy soils high in content of silt and fine sand. A levee system combined with Shasta Reservoir upstream helps to control Sacramento River waters so that floodplains are no longer flooded on a regular basis.

The soils on the floodplains along the Sacramento River are very fertile and are among the best soils in the Sacramento Valley. Several sloughs originally disseminated from the Sacramento River into the Butte Sink and Colusa Basin. Water flow was stopped by construction of levees on the Sacramento River. These sloughs, particularly the Sycamore Slough, carried river sediments several miles from the river, creating the very productive Vina soils. West from the floodplains along the Sacramento River, the Colusa Basin extends north and south through the Primary Study Area. Overflows containing clayey sediments from the Sacramento River and foothill streams regularly filled the Colusa Basin. Because of the construction of levees on the Sacramento River, only sediments from the foothill streams now reach the basin. The basin is mostly leveled for rice production. Salts in the clayey sediments from the foothill streams were deposited in the basin soils, particularly Willows soils, and reclamation of the soils has been ongoing since early in the 20th century. Most basin soils have been reclaimed to several feet. The very deep clay deposits that are characterized by extremely slow permeability and a shallow water table hamper further reclamation.

Alluvial fans exist along the west side of the Sacramento Valley. They originate at the base of the foothills, at elevations of 200 to 400 feet, and gently descend to the east for several miles to the Colusa Basin. Under natural conditions, streams from the foothills flooded these alluvial fans, depositing fertile loamy soils. Many of the streams have been diverted from their natural channels, and levees have been constructed in some areas to control flooding.

Most of the foothill region is drained by streams flowing east to the Sacramento Valley. These streams occasionally carry heavy volumes from high rainfall events, and cause flooding in the Sacramento Valley along the west-side alluvial fans and in the Colusa Basin. Increased runoff has scoured and lowered the stream channels of many foothill streams. Some streams have been diverted or channelized in the Sacramento Valley. The foothill streams eventually find their way to the Colusa Basin and to the Colusa Basin Drain. Occasionally, the flow exceeds the capacity of the south-flowing Colusa Basin Drain, and widespread flooding occurs in the basin.

The Coast Range foothills range from approximately 200 to 2,500 feet in elevation. The lower foothills have rolling slopes in many areas and have clayey soils and very few oak trees. In most foothill areas, the soils are strongly sloping and are shallow or moderately deep over sandstone and mudstone of the Great Valley Sequence. Most small valleys in the foothills have gently sloping clayey soils and some areas of loamy soils.

The NRCS has mapped 61 soil types within the Primary Study Area. Appendix 16A provides the soil map unit name, the county in which it occurs, a map unit description, and several soil properties, such as erosion potential, shrink/swell potential, corrosion of steel potential, and corrosion of concrete potential. Soil property values were derived using the NRCS Soil Data Viewer software.

Sites Reservoir Inundation Area (1.27 MAF and 1.81 MAF)

Thirty-four soil types occur within the proposed Sites Reservoir footprint for Alternative A (1.27 MAF). Of these, 13 soil types make up approximately 92 percent of the total area (Table 16-4). The remaining 21 soil types make up less than eight percent of the total area.

Table 16-4
Major Soil Types at Sites Reservoir (Alternative A)

Soil Type	Acreage	Percent of Total	Cumulative Percent of Total
Capay clay	2,961.7	24.25	24.25
Altamont-Sehorn complex	2,315.8	18.96	43.20
Sehorn-Altamont complex	1,872.8	15.33	58.54
Corval loam	1,529.4	12.52	71.06
Altamont silty clay	841.4	6.89	77.94
Corning clay loam	348.9	2.86	80.80
Millsholm-Contra Costa association	311.4	2.55	83.35
Altamont-Contra Costa clays	193.8	1.59	84.94
Hillgate loam	191.2	1.57	86.50
Clear Lake clay	176.5	1.44	87.95
Zamora silty clay	174.2	1.43	89.37
Myers clay	172.4	1.41	90.78
Millsholm-Rock outcrop association	160.1	1.31	92.09

Thirty-six soil types occur within the proposed Sites Reservoir footprint for Alternatives B and C (both are 1.81 MAF). Of these, 15 soil types make up approximately 93 percent of the total area (Table 16-5). The remaining 21 soil types make up less than seven percent of the total area.

Table 16-5
Major Soil Types at Sites Reservoir (Alternatives B and C)

Soil Type	Acreage	Percent of Total	Cumulative Percent of Total
Capay clay	3,070.7	21.49	21.49
Altamont-Sehorn complex	2,633.9	18.43	39.92
Sehorn-Altamont complex	2,441.7	17.09	57.01
Corval loam	1,608.8	11.26	68.27
Altamont silty clay	902.7	6.32	74.58
Millsholm-Contra Costa association	527.7	3.69	78.28
Corning clay loam	357.3	2.50	80.78
Altamont-Contra Costa clays	324.6	2.27	83.05
Millsholm-Rock outcrop association	315.1	2.21	85.25
Myers clay	214.8	1.50	86.76
Hillgate loam	192.9	1.35	88.11
Altamont soils	192.5	1.35	89.45
Zamora silty clay	178.6	1.25	90.70
Clear Lake clay	176.5	1.24	91.94
Nacimiento-Contra Costa association	164.9	1.15	93.09

Sites Reservoir Dams

Fourteen soil types occur within the footprints of the Sites Dam, Golden Gate Dam and associated small saddle dam, and the six northern saddle dams for Alternative A. The Sites Dam location is predominantly underlain by the Millsholm-Contra Costa association soil type (14.3 acres) and a smaller amount of Corval loam (1.0 acre). The Golden Gate Dam and associated small saddle dam locations are underlain entirely by the Millsholm-Rock outcrop association soil type (41.0 acres). The six northern saddle dam locations are underlain primarily by Nacimiento-Contra Costa association (15.2 acres), Capay clay (11.0 acres) and Altamont soils (5.6 acres) with lesser amounts of Zamora silty clay (2.8 acres), Sehorn-Millsholm association (1.0 acre), and Millsholm very rocky sandy loam, Willows clay, Tehama clay loam, Altamont-Contra Costa clays, and Myers clay (each less than 0.5 acre).

The same fourteen soil types occur within the footprints of the Sites Dam, Golden Gate Dam, and nine northern saddle dams for Alternatives B and C. The Sites Dam location is predominantly underlain by the Millsholm-Contra Costa association soil type (18.1 acres) and a smaller amount of Corval loam (1.2 acres). The Golden Gate Dam location is underlain by the Millsholm-Rock outcrop association soil type (15.1 acres), the Capay clay (10.8 acres), the Corval loam (10.4 acres), and lesser amounts of Millsholm-Contra Costa association (0.6 acre) and Sehorn-Altamont complex (0.05 acre) soil types. The nine northern saddle dam locations are underlain primarily by Nacimiento-Contra Costa association (37.1 acres), Capay clay (20.0 acres), Altamont soils (17.0 acres), Sehorn-Millsholm association (8.1 acres), Altamont-Contra Costa clay (3.2 acres) and Sehorn-Altamont complex (3.0 acres) with lesser amounts of Zamora silty clay (2.6 acres), and Tehama clay loam, Willows clay, Millsholm-Rock outcrop association, and Sehorn-Millsholm-Gullied land complex (each less than 1.6 acres).

Soil cover at the proposed Sites and Golden Gate damsites is very thin and is derived from the interbedded sandstone and siltstones of the Venado Sandstone. Soil cover at the seven (Alternative A) and nine (Alternatives B and C) saddle damsites is moderately deep with gradual transition into the mudstones and siltstones of the Boxer Formation.

Recreation Areas

The Recreation Areas would be underlain predominantly by Sehorn-Altamont complex (302.9 acres), Millsholm-Contra Costa association (264.8 acres), Nacimiento-Contra Costa association (217.0 acres), Millsholm-Contra Costa complex (129.1 acres), Altamont-Sehorn complex (119.5 acres), and Capay clay (96.0 acres) soils. The remaining 74.1 acres would be underlain by five other soil types in lesser amounts.

Road Relocations and South Bridge

The Road Relocations and South Bridge (including a 200-foot-wide construction disturbance area) would be underlain by 43 different soil types. Total affected area is approximately 1,329 acres. The predominant soil types are Millsholm-Contra Costa association (273.1 acres), Sehorn-Altamont complex (234.9 acres), and Capay clay (210.7 acres). The remaining 610.6 acres are composed of 40 other soil types with acreages ranging from 79.5 acres to 0.1 acre.

Sites Pumping/Generating Plant, Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure, Sites Reservoir Inlet/Outlet Structure, Sites Electrical Switchyard, and Field Office Maintenance Yard

The Sites Pumping/Generating Plant would be located within the footprint of the proposed Inlet/Outlet Structure. The Tunnel would be entirely underground with openings in the outlet and inlet structures. The Inlet/Outlet Structure would be underlain predominantly by Millsholm-Rock outcrop association (34.7 acres), Corval loam (24.1 acres), and Sehorn-Altamont complex (15.0 acres) soils, with lesser amounts of Capay clay (8.7 acres), and Millsholm-Contra Costa association (7.6 acres) soils. Nearly 10 acres of Inlet/Outlet structure would be located in the footprint of the existing Funks Reservoir; no NRCS soils data are available for that area. The Sites Electrical Switchyard would be underlain by the Millsholm-Rock outcrop association. The Field Office Maintenance Yard would be underlain almost entirely by the Millsholm-Rock outcrop complex (18.0 acres) with a small portion by Capay clay (0.3 acre).

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

No NRCS soils data are available for the footprint of the existing Funks Reservoir. The proposed Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard would be underlain predominantly by Capay clay (129.2 acres) and Capay clay loam (74.0 acres) soils with lesser amounts of Hillgate clay loam (62.2 acres), Altamont-Sehorn complex (39.8 acres), Corval clay loam (36.1 acres), and Altamont silty clay (18.9 acres).

Terminal Regulating Reservoir, Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, and Terminal Regulating Reservoir Electrical Switchyard

The TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, and TRR Electrical Switchyard would be underlain by Capay clay loam (114.2 acres) and Hillgate clay loam (90.6 acres) soils, with 4.7 acres of Corval clay loam.

Glenn-Colusa Irrigation District Canal Facilities Modifications

The three modifications are primarily within the footprint of the existing GCID Canal; soil data within the footprint is unavailable (i.e., noted as water on soil map). At the railroad siphon location, Myers clay is present on both sides of the Canal. At the new headgate location, Hillgate loam is present on both sides of the Canal. The 200-foot canal lining feature is entirely within the footprint of the existing GCID Canal.

Delevan Pipeline, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

The Delevan Pipeline would be underlain predominantly by Willows silty clay (96.5 acres) and Hillgate clay loam (51.8 acres) with lesser amounts of Capay clay loam (28.0 acres), Corval clay loam (23.2 acres), Moonbend silt loam (8.5 acres), Corbiere silt loam (6.4 acres), and Vina loam (2.1 acres).The construction disturbance area for the Delevan Pipeline (totaling approximately 2,365 acres) would be underlain predominantly by Willows silty clay (1,175.6 acres), Hillgate clay loam (379.8 acres), Capay clay loam (277.3 acres), Corval clay loam (247.3 acres), Moonbend silt loam (101.3 acres), and Corbiere silt loam (84.9 acres). Six other soil types make up the remaining 86 acres in lesser amounts.

The TRR Pipeline, TRR Pipeline Road, and Delevan Pipeline Electrical Switchyard would be underlain predominantly by Hillgate clay loam (6.5 acres) with a lesser amount of Capay clay loam (2.1 acres). The construction disturbance area for these three facilities would be entirely within the construction disturbance area of the Delevan Pipeline.

Delevan Transmission Line

The Delevan Transmission Line route would be located within the construction disturbance area of the Delevan Pipeline, except for a four-mile portion extending west of the proposed TRR. This discussion addresses only that portion of the transmission line outside of the Delevan Pipeline construction disturbance area. The proposed Delevan Transmission Line route (west of the TRR) would be underlain predominantly by Altamont silty clay (23.6 acres), Corval loam (9.5 acres), Millsholm-Rock outcrop association, (8.3 acres), Capay clay (5.8 acres), and Altamont-Sehorn complex (5.4 acres). Seven other soil types make up the remaining 20.6 acres in lesser amounts.

Delevan Pipeline Intake Facilities (Alternative A and C)

The proposed Delevan Pipeline Intake Facilities would be underlain by Vina loam (17.4 acres). A portion of the facility (1.7 acres) would extend into the river; no NRCS soils data are available for that area.

Delevan Pipeline Discharge Facility (Alternative B)

The proposed Delevan Pipeline Discharge Facility would be underlain by Vina loam (7.64 acres). A portion of the facility (0.1 acre) would extend into the river; no NRCS soils data are available for that area.

Project Buffer

The Project Buffer would surround all Primary Study Area Project facilities, with the exception of the Delevan Pipeline, Delevan Transmission Line, portions of the roads, and the GCID Canal Facilities Modifications. The soil types underlying the Project Buffer are, therefore, similar to soils described above for the facilities that it would surround.

16.2.3.4 Paleontology

Methodology

Geological maps and geological literature were reviewed to provide the physiographic and geological context for the Primary Study Area. Internet queries and two standard online databases were also used to determine the relative potential for paleontological resources to be found in each of the rock units described below. The databases are the University of California Museum of Paleontology at Berkeley (UCMP, n.d.), and the Paleobiology Database (n.d.), managed by a consortium of academic institutions and supported, in part, by the National Science Foundation. The results of the search of paleontological site records are presented in Appendix 16B.

The following tasks were completed to establish the paleontologic sensitivity and distribution of rock units (including unconsolidated sediments) exposed within the Primary Study Area:

- The study area was defined and its physiographic and geologic context was described.
- A stratigraphic inventory (i.e., a review of the composition and relative positions of the rocks) of the area was completed, and the mapped geologic units within the Primary Study Area were identified.
- A paleontological records review of the area was completed to identify previously recorded fossil resources and the context of their discovery.

The mapped geologic units were assigned levels of paleontological sensitivity based on the fossil remains previously documented within that unit and on other relevant geological and paleontological data.

The paleontological sensitivity of the Primary Study Area was assessed by identifying the geological units that might yield fossils, and therefore, have paleontological potential using the approach described above. A description of the geological units is provided above; Appendix 16C presents the results of the review of the available geological literature focused on paleontological sensitivity assessment.

The distribution of stratigraphic units was determined through geologic mapping and used as a proxy for paleontological sensitivity. The features of the proposed project were then laid out on the geological map, and the Project facilities that have the potential to cross units of varying paleontological sensitivity (high, moderate, unknown, low, or no sensitivity) were delineated.

Paleontological Inventory of the Primary Study Area

Guidelines for paleontological resources assessments (SVP, No Date) call for the inventory of all geological units within one mile of the ground-disturbing activities associated with any project (Appendix 16C) to ensure that both surficial geologic units and geologic units that would be encountered in the subsurface are adequately analyzed. These geological units are then evaluated for paleontological sensitivity. During the preparation of this chapter, several data gaps were identified that complicate characterization of the paleontological sensitivity of the Primary Study Area. These include the following:

- Geologic maps at the necessary level of detail for this analysis tend to group all pre-Tertiary formations into the same category.
- There are few published geological studies of the GVS and overlying Neogene and Quaternary sediments within the limits of the project.
- There are proportionately few paleontological studies of these same rocks.

Older rocks referred to as the GVS occur only on the western portion of the Primary Study Area in the foothills of the North Coast Ranges. In the Sacramento Valley, much younger Pliocene (approximately 5.3 to 2.6 MYA) and Quaternary (2.6 MYA to present) sediments are found.

The results of the search of paleontological site records are summarized in Table 16-6. A comprehensive list of sites recorded in Glenn and Colusa counties is provided in Appendix 16B. Although the Primary Study Area includes only the Project area plus a one-mile buffer, all localities were recorded for each formation because the paleontological sensitivity of a geologic unit is based on the abundance of fossils within the entire unit (though local variations in the rock are taken into account).

Table 16-6
Results of Paleontological Records Search by Geological Unit for the Primary Study Area

Formation, Member, or Unit Name[a]		Number of Localities on Record[a]	
		UCMP Database	Paleobiology Database
Great Valley Sequence rocks (marine sediments older than 65 million years)			
1	Boxer	2[b]	0
2	Antelope Shale	13	2
3	Fiske Creek	1[b]	0
4	Julian Rocks	0	0
5	Brophy Canyon	0	0
6	Cortina	0	0
7	Venado Sandstone	9	0
8	Yolo	3	0
9	Sites	5[b]	0
10	Funks	4	1
11	Rumsey	0	0
12	Guinda	16	0
13	Forbes	25	6
14	Dobbins Shale	1	0
15	Hoodoo Hills	0	0
Late Neogene and Quaternary Sediments (younger than approximately 5.7 million years)			
1	Tehama (sites in Colusa, Glenn, and Tehama Counties only)	6	0
2	Red Bluff	2[c]	0
3	Victor[d]	1	0
4	Riverbank	9	2
5	Modesto	5	0

[a]Includes names that are no longer in use, but which may still be attached to fossil collection records (Appendix 16C).
[b]Limited to microfossil collections.
[c]Collections from the early 20th Century may now be attributed to a different unit, most likely the Tehama Formation.
[d]Name superseded, but collections from the early 20th Century may still bear this designator.

Note:
UCMP = University of California Museum of Paleontology at Berkeley

Source: UCMP, n. d.; PaleoBiology Database, n.d. (Appendix 16B)

Many of the recorded paleontological localities in the GVS are microfossil samples (chiefly small plankton fossils, including foraminifera and diatoms). The use of microfossils in age dating, correlation, and in paleoenvironmental studies is well documented. However, rocks bearing only microfossils are not typically assigned high or even moderate levels of paleontological sensitivity because these fossils are very abundant and found in many different sedimentary units, and therefore are not scientifically significant as individuals. Also, although microfossils usually possess scientific significance as an assemblage, isolated specimens or samples of microfossils normally have little scientific use.

Cretaceous Marine Units

The databases consulted (UCMP, n.d.; PaleoBiology Database, n.d.) included references to paleontological sites in 10 of the 15 Cretaceous geological units comprising the GVS. Of these, three (the Boxer, Fiske, and Sites formations) are known to yield only microfossils (chiefly foraminifera and radiolaria). The remaining seven of the GVS units in the Primary Study Area yield scientifically significant megafossils.

The comparative lack of marine sedimentary units that have yielded megafossils is consistent with the inferred paleoenvironments represented by these units. They are deep-ocean sediments consisting of muds of the abyssal ocean floor and trench, and sandstones of deep submarine fans. The depth of water during deposition of the GVS has been calculated as greater than 13,000 feet (Ingersoll, 1979). At that depth, few animals can be expected to be incorporated into the paleontological record due to a combination of geochemical and ecological factors, including low probability of preservation due to both the low density of animals at abyssal depths (the deep sea floor), and the fact that seawater at such depths dissolves calcite shells. In considering the paucity of fossil record from the GVS, Haggart and Ward (1984) observed that many paleontologists have had difficulty correlating Cretaceous strata of the GVS due to the lack of large fossils. Therefore, most studies have relied on microfossils to determine the relative age and stratigraphic position of these units, and most records for the GVS in the databases consulted (UCMP, n.d.; PaleoBiology Database, n.d.) consist of these microfossil assemblages.

Changes in the species composition of microfossils that lived at shallow depths have been the principal means of assigning strata to different ages within the Cretaceous period. However, with more intensive collecting, Haggart and Ward (1984) demonstrated that megafossils, primarily mollusks, can be found in at least the Santonian and Campanian strata (85.8 to 70.6 MYA) on the west side of the Sacramento Valley. Some of these fossils have been instrumental in clarifying the timing of deposition of the upper portion of the GVS (Haggart and Ward, 1984). The paleontological records of the seven GVS units that yield megafossils are discussed in Table 16-7.

Table 16-7
Great Valley Sequence Units in the Primary Study Area that Yield Megafossils

Antelope Shale: The gastropod *Paosia* (*Trajanella) colusaensis* was recovered from rocks that are likely from either the Antelope Shale or the overlying Venado Sandstone (Squires, 2004). The specimens were from near the town of Sites and are donated specimens, so the exact locale for this collection is uncertain. The gastropods *Paosia californica* and *Turitella petersoni* are from the upper part of the Antelope Shale (Brown and Rich, 1961). Similar to the Venado Sandstone above it, many of the invertebrates are thought to be shallow water fauna redeposited in submarine deposits, which may compromise some of their scientific value because the original context or depositional setting of the specimens would be in doubt.
Venado Sandstone: Similar to the Antelope Shale, many of the invertebrates found in the Venado are thought to have been redeposited in submarine deposits. The UCMP database notes that the collections there include important specimens of the Cenomanian to early Turonian (99.6 to 89.3 MYA) bivalve *Yaadia leana*.

Table 16-7
Great Valley Sequence Units in the Primary Study Area that Yield Megafossils

Yolo Formation: The Turonian (93.5 to 89.3 MYA) Yolo Formation has yielded mollusks of the genus *Turridea* (Oqvist, n.d.) as well as an array of ammonites (Squires, 2004). Also present in this unit is the gastropod *Paosia californica* (Squires, 2004).
Funks Formation: The texanitid ammonites (a type of cephalopodl) are relatively rare in Cretaceous sediments of the Pacific Coast, and the Funks Formation is important because it has yielded more than two dozen specimens of *Protexanites thompsoni* (Jones, 1966), a member of this group. The type site is approximately one mile north of Putah Creek, well south of the current Primary Study Area.
Guinda Formation: The gastropod *Paosia californica* and the bivalve *Cucullaea melhaseana* have been recovered from this unit (Squires, 2004). The uppermost portions of this formation yield specimens of the index fossil *Bostrychoceras elongatum*, an ammonite (Haggart and Ward, 1984).
Dobbins Shale: The lower half of the Dobbins Shale contains the ammonite *Bostrychoceras elongatum*, establishing that the species' range continued into this unit from the underlying Guinda Formation. Uppermost portions of the Dobbins Shale contain abundant specimens of the pelecypod *Inoceramus schmidti*, a lower Campanian (83.5 to 70.6 MYA) index fossil (Haggart and Ward, 1984).
Forbes Formation: The transition between the Dobbins Shale and the overlying Forbes Formation contains the important ammonite *Baculites chicoensis*, which allows correlation of this unit of the GVS with the upper member of the Chico Formation on the east side of the Sacramento Valley (Haggart and Ward, 1984).

Pliocene and Quaternary Terrestrial Units

Tehama Formation

The diverse fossil assemblage from the Pliocene (5.3 to 2.6 MYA) Tehama Formation (including the outdated Victor and Red Bluff Formations [Appendix 16C]) documents conditions in California not long before the beginning of the environmental changes accompanying the Pleistocene (2.6 to 0.01 MYA) ice ages, and the animals living in those environments. Recent discovery of the remains of a giant tortoise (*Geochelone*) from the Tehama Formation near Red Bluff (Sierra College, 2007) adds to the list of animals from the Tehama Formation that already included several records of the giant tortoise, as well as *Pliomastodon* (mastodon); *Mammut* (mammoth); *Equus simplicidens, Pliohippus, and Nannippus* (horses); *Camelops hesternus* (North American camel); Megalonichidae and *Mealonyx* (ground sloth);*Platygonus* (a pig-like animal); *Canis* (dog); *Odocoileus* (a genus of deer); *Thomomys* (pocket gopher); *Neotoma* (wood or pack rat); *Peromyscus* (deer mice); *Reithrodontomys* (harvest mice); *Osteichtheyes* (fish); and the hyena-like dog *Borophagus diversidens*.

Riverbank Formation

A variety of Pleistocene age (2.6 to 0.01 MYA) fossils were identified in extensive gravel pit excavations in east Sacramento (Hansen and Begg, 1970). They report a variety of Rancholabrean fossils (from about 125,000 to 10,000 years B.P.) collected from two gravel quarries in the Riverbank Formation. These fossils include: *Archoplites* (sunfish), two bird species, *Bison antiquus* (bison), *Camelops hesternus* (camel), *Canis dirus* (dire wolf), *Canis latrans* (coyote), *Clemmys marmorata* (pond turtle), *Colubridae* (colubrid snake), *Cyprinidae* (carp), *Equus* (horse), *Mammuthus* (mammoth), *Microtus* (meadow mouse or vole), *Neotoma* (wood rat), *Odocoileus* (deer), *Paramylodon harlani* (ground sloth), *Perognathus* (pocket mouse), *Scapanus latimanus* (mole), *Spermophilus* cf. *S. beecheyi* (ground squirrel), *Sylvilagus* (rabbit), *Thomomys bottae* (pocket gopher), as well as remains of trees such as *Pseudotsuga* (Douglas fir), *Platanus* (sycamore), and *Salix* (willow)

A variety of fossils of extinct large mammals were collected by Hilton et al. (2000), including *Glossotherium harlani* and *Paramylodon harlani* (ground sloths), *Bison antiquus* (bison), *Equus* sp.

(horse), *Camelops hesternus* (camel), *Sciurus* sp. (squirrel), and *Mammuthus* sp. (mammoth), as well as plant fossils during the excavations for a large sports arena north of Sacramento. These fossils were found in excavations approximately 13 to 30 feet below the ground surface. These fossils were attributed to the Riverbank Formation.

Dundas and Cunningham (1993) also collected Pleistocene-age ground sloth (*Glossotherium harlani*) and Columbian mammoth (*Mammuthus columbi*) remains from the Riverbank Formation in the Extended Study Area.

Modesto Formation

Similar to the Riverbank Formation, the Modesto Formation is represented by a variety of deposits, mainly river deposits, but also terrestrial sediment such as dune fields and sand sheets. The fossil record of the Late Pleistocene Modesto Formation is, therefore, similar to the Riverbank Formation, although the taxa represented in the Modesto are generally from a more recent time period. The extinct North American camel is well represented in collections from the Modesto. Other vertebrates that have been recovered from the Modesto Formation include Jefferson's ground sloth (*Megalonyx*), mammoth (*Mammuthus*), and an extinct species of bison.

Sensitivity Criteria

The paleontological sensitivity of a rock unit is determined by the likelihood that it will yield identifiable, unique, or scientifically important fossils. Well-developed and documented fossil-bearing formations are less likely to yield a unique paleontological resource, but the resources may nevertheless retain scientific importance.

An individual fossil specimen may be considered unique or significant if it is (1) identifiable, (2) complete, (3) well preserved, (4) useful in determining the age of the formation, (5) useful in interpreting the ancient environment, (6) a member of a rare species, or (7) a skeletal element different from, or a specimen more complete than, those now available for its species. The value or importance of different fossil groups varies, depending on the age and depositional environment of the rock unit that contains the fossils, their rarity, the extent to which they have already been identified and documented, and the ability to recover similar materials under more controlled conditions (such as part of a research project).

The following tasks were completed to establish the paleontological sensitivity of each rock unit potentially exposed in the Primary Study Area:

- Designated certain unit names as not applicable (n/a) because they duplicate other names being used, or because they are otherwise no longer used by geologists
- Considered the scientific significance of the fossil finds from the unit
- Assessed the potential paleontological productivity of each rock unit exposed within one mile of the proposed project features, based on available documentation
- Considered the potential for a rock unit exposed at the project feature site to contain a unique paleontological resource

Paleontological Sensitivity of Sediments in the Primary Study Area

The paleontological sensitivity of any part of the Primary Study Area depends almost entirely on its geology. Table 16-8 presents a summary of the paleontological sensitivity for the rock units that may be affected by proposed project features in the Primary Study Area.

Table 16-8
Paleontological Sensitivity of the Rock Units Within One Mile of Any Proposed Primary Study Area Project Facility

Formation, Member, or Unit Name Attributed[a]		Sensitivity[b]	Remarks
Great Valley Sequence Rocks (Upper Cretaceous; Older than 65 Million Years)			
1	Boxer	low	-
2	Antelope Shale	moderate	-
3	Fiske Creek	low	Temporally equivalent with the Boxer formation
4	Julian Rocks	low	Temporally equivalent with the Boxer formation
5	Brophy Canyon	low	Temporally equivalent to the lower Boxer formation
6	Cortina	low	-
7	Venado Sandstone	moderate	-
8	Yolo	moderate	-
9	Sites	moderate	-
10	Funks	moderate	-
11	Rumsey[c]	moderate	-
12	Guinda[c]	moderate	-
13	Forbes[c]	moderate	-
14	Dobbins Shale[a]	moderate	-
15	Hoodoo Hills[a]	n/a	Name no longer in use
Pliocene and Quaternary Sediments (Younger than Approximately 5.7 Million Years)			
1	Tehama	high	-
2	Red Bluff	low	-
3	Victor	n/a	Name no longer in use
4	Riverbank	moderate	Surficial sediments affected by soil development are not paleontologically sensitive; most fossil sites are from near the Sacramento River or its major tributaries
5	Modesto	moderate	Surficial sediments affected by soil development are not paleontologically sensitive. Includes unnamed Pleistocene units; most fossil sites are from near the Sacramento River or its major tributaries

[a]Some of these names are outdated and no longer in use, but nevertheless fossil localities are recorded as occurring within them. Databases are not updated when the geological nomenclature is revised.

[b]Sensitivity ratings were assigned based on the guidelines outlined by the SVP (n.d.), and by *Instructional Memorandum 2008-009* (USDI BLM, 2008). They are:

- High: A geologic unit known to be paleontologically productive and to contain fossil assemblages that include scientifically important species.
- Moderate: A geologic unit that is known to yield scientifically significant fossil specimens, but may not be paleontologically productive in any given area.
- Low: A geologic unit that is known to yield few identifiable fossils.

[c]These units do not outcrop within the Primary Study Area; however, they were included in this analysis because they may be encountered in the subsurface and, given the nature of the nomenclature of the Great Valley Sequence, to ensure all fossils within the Primary Study Area have been adequately analyzed.

The paleontological record of the GVS consists largely of microfossils. None of the GVS units are known to have an abundance of paleontological resources because they were deposited in a deep ocean setting; however, rare macrofossils such as bivalves, ammonites, and gastropods have been found in these units.

Although uncommon in the GVS, these fossils are important for dating the geologic units they are found in and for comparing geologic units throughout the Great Basin. The Venado, Yolo, Sites, Funks, Rumsey, Guinda, and Forbes formations, and the Dobbins shale, are considered to have a “moderate” paleontological sensitivity rating (Table 16-8). If large fossils, including invertebrate fossils, are encountered during Project construction, they would likely be scientifically significant.

Neither the Modesto nor the Riverbank formations within the Primary Study Area are assigned “high” paleontological sensitivity. These formations have yielded important fossils; however, the recorded paleontological sites are located primarily near the Sacramento River and along its major tributaries. The paleontological productivity of the geologic units deposited at higher elevations in the Primary Study Area does not appear to be substantial. Therefore, the paleontological sensitivity of the Modesto and Riverbank formations is considered “moderate.”

16.3 Environmental Impacts/Environmental Consequences

16.3.1 Regulatory Setting

Geology, minerals, soils, and paleontological resources are regulated at the federal, State, and local levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

16.1.1.1 Federal Plans, Policies, and Regulations

- Clean Water Act Section 402, National Pollutant Discharge Elimination System Program
- National Pollutant Discharge Elimination System General Permit for Stormwater Discharges from Construction Sites
- Antiquities Act of 1906
- Archaeological Resources Protection Act of 1979
- Omnibus Public Land Management Act of 2009

16.1.1.2 State Plans, Policies, and Regulations

- California Environmental Quality Act, *Guidelines for the Implementation of CEQA* (Public Resources Code Section 15023, Appendix G)
- Porter-Cologne Water Quality Control Act
- California Department of Fish and Game Code 1602
- California Water Code, Division 3: Dams and Reservoirs
- Surface Mining and Reclamation Act of 1975
- Seismic Hazards Mapping Act of 1990
- Asbestos Airborne Toxic Control Measure for Surfacing Applications (amended 2000)
- Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations

- Regulatory Design Codes for Buildings, Highways, and Other Structures
- Nonpoint Source Implementation and Enforcement Policy
- *California Public Resources Code* Chapter 1.7 Archaeological, Paleontological, and Historical Sites Section 5097.5

16.1.1.3 Regional and Local Plans, Policies, and Regulations

- Glenn County General Plan
- Colusa County General Plan

16.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for geology, minerals, soils, and paleontological resources:

Would the Project:

- Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the Project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse?
- Result in substantial soil erosion or the loss of topsoil?
- Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?
- Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?
- Result in the loss of availability of a locally important mineral resource recovery site delineated on a local General Plan, Specific Plan, or other land use plan?
- Expose people (working on the Project or the public) during Project construction or operation to naturally occurring asbestos?
- Directly or indirectly destroy of a unique paleontological resource or site or unique geologic feature?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Effects on a geologic unit or soil unit from Project construction, operation, and maintenance.
- Project construction, operation, and maintenance effects on soil erosion and loss of topsoil.
- Risks to life and property from Project construction, operation, and maintenance on expansive soil.

- Project construction, operation, and maintenance effects on soils that are incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the wastewater disposal.
- Loss of availability of a known mineral resource that would be of value to the region and the residents of the state.
- Loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan.
- Expose people to naturally occurring asbestos during Project construction, operation, or maintenance
- Project construction, operation, and maintenance effects on paleontological resources.

Paleontological resources impacts would include damage or destruction of a scientifically significant fossil, the removal of a scientifically significant fossil from its stratigraphic context, or any other action that reduces the amount of information available to future researchers. The probability that excavations would cause such impacts is proportional to the paleontological sensitivity of the geologic units. Excavations within high-sensitivity geologic units have a high potential to adversely impact paleontological resources. Excavations within moderate-sensitivity sediments have a lower potential to adversely impact paleontological resources, and that potential is frequently limited to specific portions of the unit. Low-sensitivity sedimentary units have a very low, but non-zero, chance of impacting paleontological resources. Excavations that do not impact paleontological resources—or that only impact non-significant fossils, such as microfossils—are not considered to impact paleontological resources. Impacts to sediment of moderate to high paleontological sensitivity, or to scientifically important fossils, would constitute significant impacts in the absence of mitigation.

16.3.3 Impact Assessment Assumptions and Methodology

16.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to geologic, mineral, soil, and paleontological resources:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect

effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.

- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge Facilities would be required.
- Erosion is the wearing away of soil and rock by processes such as mechanical or chemical weathering, mass wasting, and the action of waves, wind, and underground water. Excessive soil erosion can eventually lead to damage of building foundations and roadways. At the Project facility sites, areas that are susceptible to erosion are those that would be exposed during the construction phase and along the reservoir shoreline where soil is subjected to wave action. Typically, the soil erosion potential is reduced once the soil is graded and covered with concrete, structures, asphalt, or slope protection. However, some runoff and soil erosion may occur at discharge points from covered areas.
- Effects to paleontological resources would only occur during disturbance of fossil-bearing geologic units, which are typically associated with the construction phase of any project. No impacts would occur during Project operation activities or maintenance of Project facilities because no excavations within fossil-bearing geologic units would occur in association with operations or maintenance activities. Maintenance for several of the Project components would include dredging of built-up sediment, but such excavation activities would not affect paleontologically sensitive sediment. Paleontological resources are considered to be affected only if they are removed from the sediment or otherwise mechanically damaged, which would only occur during excavations during the Project construction phase.

16.3.3.2 Methodology

A combination of data, published reports, and professional experience with initial investigations for the proposed Project was used to evaluate the Project alternatives for potential impacts due to geology, soils, and minerals. The Extended and Secondary study area impact assessments primarily relied on data and publications (both printed and web-based) from the California Geological Survey and the United States Geological Survey. Professional experience with initial investigations included geological mapping within the Primary Study Area and core-drilling at the proposed damsites.

Expansive soils are characterized by a shrink-swell characteristic[12]. Expansive soils are largely comprised of clays, which expand in volume when water is absorbed and shrink when dried. Soil materials at the Project facility sites are composed of a wide variety of soil types. Using the NRCS Soil Data Viewer, the shrink-swell potential was derived for all of the soil types present at Project facility sites.

The Society of Vertebrate Paleontology Standard Procedures for the Assessment and Mitigation of Adverse Impacts to Paleontological Resources (SVP, 2010) provide guidelines that establish standard methods for assessing potential impacts to fossils and mitigating these impacts. For the paleontological resources impacts assessment, the paleontological sensitivity and distribution of rock units (including unconsolidated sediments), established during the analysis of the existing environment (refer to Appendix 16C), within the impacts area was considered, as well as the type of excavation or other

[12] "Shrink-swell" is the cyclical expansion and contraction that occurs in fine-grained clay sediments from wetting and drying. Structures located on soils with this characteristic may be damaged over a long period of time, usually as the result of inadequate foundation engineering or the placement of structures directly on expansive soils.

subsurface disturbance. The features of the Project were laid out on a map showing the distribution of rocks having varying paleontological sensitivity. Impacts were identified for those Project facilities that have the potential to cross units of varying paleontological sensitivity (high, moderate, unknown, low, or no sensitivity).

16.3.4 Topics Eliminated from Further Analytical Consideration

No Project facilities or topics that are included in the significance criteria listed above for geology, soils, or minerals were eliminated from further consideration in this chapter.

Within the Primary Study Area, operation and maintenance activities associated with Project facilities would not require excavations; the impacts of these activities are, therefore, not discussed for paleontological resources.

16.3.5 Impacts Associated with the No Project/No Action Alternative

16.3.5.1 Geology and Soils

<u>Extended, Secondary, and Primary Study Areas – No Project/No Action Alternative</u>

Construction, Operation, and Maintenance Impacts

Agricultural Water Use; Municipal and Industrial Water Use; Wildlife Refuge Water Use; and San Luis Reservoir; Trinity Lake; Lewiston Lake; Trinity River; Klamath River downstream of the Trinity River; Whiskeytown Lake; Spring Creek; Shasta Lake; Sacramento River; Keswick Reservoir; Clear Creek; Lake Oroville; Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Geo/Soils-1: Effects on a Geologic Unit or Soil Unit from Project Construction, Operation, and Maintenance

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to geology and soils have been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger human population would require additional development to occur, which could affect, and/or be affected by, local geology and soils. These impacts that would occur as a result of the population growth and development would be managed at the local level (e.g., cities and counties) in accordance with those agencies' regulations. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

It is possible that one or more of the projects that are included in the No Project/No Action Alternative could affect or be affected by existing site-specific geologic and/or soils[13] conditions. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would

[13] Potential impacts relating to geology or soils can be a combination of the two resources. Therefore, geology impacts and soils impacts have been combined as "Geo/Soils" impacts.

be required to mitigate for significant impacts. In addition, the Project would not be constructed if this alternative is implemented. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

Impact Geo/Soils-2: Project Construction, Operation, and Maintenance Effects on Soil Erosion and Loss of Topsoil

Refer to the **Impact Geo/Soils-1** discussion. That discussion is also applicable to effects on soil erosion and loss of topsoil.

Impact Geo/Soils-3: Risks to Life and Property from Project Construction, Operation, and Maintenance on Expansive Soil

Refer to the **Impact Geo/Soils-1** discussion. That discussion is also applicable to expansive soils.

Impact Geo/Soils-4: Project Construction, Operation, and Maintenance Effects on Soils that are Incapable of Adequately Supporting the Use of Septic Tanks or Alternative Wastewater Disposal Systems where Sewers are not Available for the Wastewater Disposal

Refer to the **Impact Geo/Soils-1** discussion. It is possible that one or more of the projects that are included in the No Project/No Action Alternative would include septic tanks or alternative wastewater disposal systems sited on soils that are incapable of supporting such systems. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. In addition, the Project would not be constructed if the No Project/No Action Alternative is implemented. Therefore, **there would not be a substantial adverse effect**, when compared to Existing Conditions.

16.3.5.2 Minerals

Extended and Secondary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, Wildlife Refuge Water Use, and San Luis Reservoir, Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay); Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; and San Francisco Bay

Impact Min-1: Loss of Availability of a Known Mineral Resource that would be of Value to the Region and the Residents of the State

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Extended and Secondary study areas. If the No Project/No Action Alternative is implemented, mineral resources would continue to be excavated, stockpiled, imported, or exported, and projected population growth could increase the rate of use of these resources. However, County General Plans and other regulations identify local mineral resources and specify measures to protect those resources from depletion. In addition, the Project would not be constructed if this alternative is implemented. Therefore, implementation of the No Project/No Action

Alternative **would not have a substantial adverse effect** on mineral resources in the Extended and Secondary study areas, when compared to Existing Conditions.

Impact Min-2: Loss of Availability of a Locally Important Mineral Resource Recovery Site Delineated on a Local General Plan, Specific Plan, or Other Land Use Plan

Refer to the **Impact Min-1** discussion as it relates to the Extended and Secondary study areas. That discussion is also applicable to mineral resource recovery sites.

Impact Min-3: Expose People to Naturally Occurring Asbestos during Project Construction, Operation, or Maintenance

Refer to the **Impact Geo/Soils-1** discussion as it relates to the Extended and Secondary study areas. Ultramafic rocks (which when converted to the metamorphic rock, serpentinite, can contain asbestos), occur in certain areas within the Extended and Secondary study areas. It is possible that one or more projects included in the No Project/No Action Alternative could mine, expose, or use serpentinite and cause naturally occurring asbestos to become airborne. However, any project being considered for implementation would be subject to CEQA and/or NEPA review and would be required to mitigate for that impact. In addition, the Project would not be constructed if this alternative is implemented. Therefore, **there would not be a substantial adverse effect** from the airborne emission of naturally occurring asbestos in the Extended and Secondary study areas, when compared to Existing Conditions.

Primary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Impact Min-1: Loss of Availability of a Known Mineral Resource that would be of Value to the Region and the Residents of the State

According to the Land Use Element of the Colusa County General Plan and Aggregate Resource Management Plan for Glenn County, identified mineral resource areas are located outside of the Primary Study Area. Therefore, continued land use activities, as well as projected population growth, within the counties of the Primary Study Area would not affect mineral resources. In addition, the projects included in the No Project/No Action Alternative do not occur within the Primary Study Area, and the Project would not be constructed if this alternative is implemented. Implementation of the No Project/No Action Alternative would not result in the loss of availability of any known mineral resource, or interfere with any existing commercial mining activity and therefore **would not have a substantial adverse effect** on mineral resources, when compared to Existing Conditions.

Impact Min-2: Loss of Availability of a Locally Important Mineral Resource Recovery Site Delineated on a Local General Plan, Specific Plan, or Other Land Use Plan

Refer to the **Impact Min-1** discussion. That discussion is also applicable to mineral resource recovery sites.

Impact Min-3: Expose People to Naturally Occurring Asbestos during Project Construction, Operation, or Maintenance

Rocks containing naturally occurring asbestos are not present in the Primary Study Area, nor are they present in the watershed draining into the Primary Study Area. Therefore, continued land use activities, as well as projected population growth, within the counties of the Primary Study Area would not expose people to naturally occurring asbestos in these counties. In addition, the projects included in the No

Project/No Action Alternative do not occur within the Primary Study Area, and the Project would not be constructed if this alternative is implemented. Implementation of the No Project/No Action Alternative would not expose people in Glenn and Colusa counties to naturally occurring asbestos, and therefore, **would not have a substantial adverse effect**, when compared to Existing Conditions.

16.3.5.3 Paleontology

Extended and Secondary Study Areas – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts
