North-of-the-Delta Offstream Storage Preliminary Administrative Draft Environmental Impact Report

Prepared by

California Department of Water Resources

December 2013

North-of-the-Delta Offstream Storage Preliminary Administrative Draft Environmental Impact Report

This preliminary administrative draft of the NODOS Environmental Impact Report (EIR) has not been reviewed or approved for adequacy in meeting CEQA and NEPA requirements. The California Department of Water Resources (DWR) is releasing this document to provide decision-makers, stakeholders, and the public with up-to-date and detailed information on the investigation.

Release of this material does not constitute the initiation of formal public review of the Draft EIR as provided by CEQA Guidelines Section 15087. Although comments are welcome and may be considered in preparation of the Draft EIR, DWR will not respond to comments received on this document.

Please note the following reading guidance for this preliminary administrative draft. Refer to the summary Table of Contents for a list of chapters and appendixes. At this time, a detailed Table of Content, List of Abbreviations and Acronyms, Index, and Chapter 37, References, are not included. Abbreviations and acronyms are defined at first use in each chapter, and references are included in a References section at the end of each chapter and appendixes when necessary. Some chapters/appendixes include figures and tables at the end of the chapters/appendixes.

Executive Summary

ES.1 Introduction

The Preliminary Administrative Draft Environmental Impact Report/Environmental Impact Statement (EIR/EIS) has been prepared by the California Department of Water Resources (DWR) and the U.S. Department of the Interior (DOI), Bureau of Reclamation, Mid-Pacific Region (Reclamation) to address the potential effects of the proposed North-of-the-Delta Offstream Storage (NODOS) Project. DWR is serving as the State lead agency for compliance with the California Environmental Quality Act (CEQA), and Reclamation is serving as the federal lead agency for compliance with the National Environmental Policy Act (NEPA). The EIR/EIS contains a description of the proposed Project, potential alternatives to the proposed Project, describes the environmental setting, identifies the potential direct and cumulative impacts that could result from implementation of each of the proposed Project's alternatives, and proposes mitigation measures for impacts found to be significant.

The proposed Project would be located in Antelope Valley, approximately 10 miles west of the town of Maxwell, in both Glenn and Colusa counties. Other proposed Project facilities would be located in Tehama, Glenn, and Colusa counties (Figure 1-2 in Chapter 1 Introduction). DWR and Reclamation developed three variations of the preferred alternative (described as "action alternatives" in the resource chapters) to meet the purpose, need, and objectives of the proposed Project.

ES.1.1 Purpose and Need and Project Objectives

ES.1.1.1 Purpose Statement and Project Objectives

The purpose of the proposed Project is to build offstream surface storage located north of the Delta. The proposed Project's primary objectives are to:

- Improve water supply reliability for agricultural, urban, and environmental uses
- Increase survival of anadromous and endemic fish populations
- Improve environmental and drinking water quality in the Delta
- Provide flexible hydropower generation to support integration of renewable energy sources

The secondary objectives for the proposed Project, based on opportunities that were identified during formulation of alternatives that met the primary objectives, are to:

- Develop additional recreation opportunities
- Provide incremental flood damage reduction opportunities

ES.1.1.2 Needs and Project Objectives

The NODOS Project identified six needs and opportunities that are the basis of the primary and secondary objectives. The NODOS Project also identified one additional need: operational flexibility. Following is a description of the needs and opportunities identified by the NODOS Project.

<u>Water Supply Reliability for Agricultural, Urban, and Environmental Uses</u>

Water supply reliability requires the delivery of specified amounts of water at predictable locations and times. A review of DWR's SWP Delivery Reliability Reports since 2002 (2002, 2005, 2007, 2009, and 2011) indicates declining SWP reliability. Average SWP delivery has been reduced by almost

500,000 acre-feet during the period from 2002-2011. The CVP has experienced similar reductions in delivery. During prolonged droughts or multiple dry years, water supplies are reduced, and the effects of climate change are predicted to further diminish water supply. The loss of water in storage reduces the ability of the SWP and CVP to deliver the amount of water requested by their contractors, reducing the reliability of these systems to provide needed water. The additional storage provided by the proposed Project could be used to augment some of the storage capacity at existing facilities. Greater improvements to water supply reliability could be achieved if operation of the proposed Project is integrated with other storage facilities, especially during drier periods.

Survival of Anadromous and Endemic Fish Populations

Populations of anadromous and endemic fish species within the Sacramento Valley river system and Bay-Delta are declining. The primary causes of the anadromous fish species decline have been identified as barriers to historic habitat, habitat degradation, predation from introduced species, reduced instream flows, and increased water temperatures (NMFS, 2009). Several potential causes of fish species declines in the Bay-Delta have been identified, including a combination of reduced habitat suitability (such as changing salinity), reduced food sources, entrainment, invasive species, predation, and toxins (Baxter et al., 2010). Onstream dams block many of the native anadromous species from their historic spawning areas. This impact of dams is partially mitigated with cold water releases that keep the water downstream of the dams cold enough to provide limited spawning and rearing habitat. The reliability of cold water in these streams can be increased and temperatures for anadromous fish can be improved by both maintaining additional water in storage year to year and releasing additional water at specific times to improve temperatures. Additional water in storage from the proposed Project would provide a source of additional water within the SWP and CVP systems that could be used to facilitate several ecosystem restoration and enhancement actions to improve conditions for fish populations in the Delta and Sacramento River watershed.

Water Quality

The CVP and SWP systems currently meet water quality requirements by releasing additional water from upstream reservoirs. Additional water in storage from new proposed Project storage could improve Delta water quality by providing high-quality supplemental flows dedicated to Delta outflow during periods when Delta water quality is impaired. Water quality improvements would benefit drinking water quality for urban customers, irrigation users, and the Bay-Delta ecosystem.

Flexible Hydropower Generation

California's renewable energy goal is to increase the portion of energy produced by renewable sources in the State to 33 percent by 2020. Although energy from the proposed Project may not, by law, count as having been produced by a renewable electrical generation facility, operation of the Project may nonetheless provide general if unrecognized benefits in the reduction of greenhouse gas emissions by matching renewable sources with reliable and flexible generation sources to cover short-term gaps in generation, such as when winds diminish in wind generation-intensive areas. The proposed Project would be built with pumping/generating plants capable of producing hydropower. Electricity would be generated when water is released from the proposed Sites Reservoir into the proposed Holthouse Reservoir and from the proposed Holthouse Reservoir to the proposed Terminal Regulating Reservoir and into the Sacramento River. The proposed Project is also capable of daily pump-back operations. In pump-back operations mode, water would be released from the proposed Sites Reservoir into the proposed Holthouse

Reservoir during on-peak hours to generate electricity and water would be pumped back into the proposed Sites Reservoir during the off-peak hours to complete the pump-back operations cycle. Additional storage provided by the proposed Project could facilitate flexible hydropower generation, which could be quickly ramped up or down to complement wind or solar generation to meet power demands and support reliable operation of the power grid.

Additional Recreation Opportunities

The planning of any reservoir north of the Delta provides an opportunity to develop new recreational facilities and provide additional opportunities for recreation activities such as fishing, swimming, camping, boating, and hiking. The proposed Project would provide up to five new recreation areas.

Incremental Flood Damage Reduction

Offstream storage can provide incremental flood damage reduction improvements to areas located immediately downstream of the reservoir that are prone to flooding. The proposed Project would not dam a major stream, but would dam two small ephemeral creeks that are known to cause local flood damage. The proposed Project would therefore provide local flood damage reduction.

Operational Flexibility

Operational flexibility was identified as a need by both the CALFED Program and the NODOS Project. Operational flexibility can be defined as the ability of water systems to adapt and respond to changing or uncertain conditions. Water in storage is a metric of operational flexibility; increased water in storage provides increased operational flexibility for a system by allowing system operators and water managers to do more. Water managers employ the flexibility of the systems they manage to accomplish a variety of water management objectives. As noted above in the discussion of Project objectives, additional water in storage can be used to deliver more water to users, improve ecosystem conditions within the system, or improve water quality. In this sense, operational flexibility has a direct relationship with water management generally, and with meeting water management objectives specifically.

California’s water management challenges include growing drought impacts, declining ecosystems, diminishing water quality, increasing climate change impacts to the State’s hydrology, increasing flood risk, and aging infrastructure (DWR, 2009). The California Water Plan Update (DWR, 2009) notes that, “the entire system—water and flood management, watersheds, and ecosystems – has lost its resilience and is changing in undesirable ways.” This loss of resiliency is the result of decreased operational flexibility.

Additional water in new storage, such as additional water in a new offstream storage reservoir located north of the Delta, would contribute to increased system flexibility. From a system perspective, operational flexibility can be assessed by evaluating the additional water in storage that can be used to meet existing and future water demands. To achieve this kind of flexibility, additional storage would be most effective when operationally integrated with existing SWP and CVP facilities. Supplemental north of Delta storage would provide the ability to increase the water in storage in existing system reservoirs such as Shasta Lake, Lake Oroville, Trinity Lake, and Folsom Lake. The additional water in new offstream storage and increasing water levels in existing reservoirs can meet a larger set of system objectives. For example, water users and ecosystem needs immediately downstream of existing reservoirs need additional water in those reservoirs to meet those needs; additional water in new offstream storage alone would not improve the system’s ability to meet needs below existing reservoirs without integration.

The total improvement in flexibility is both additional water in existing reservoirs and additional water in new offstream storage.

ES.1.2 NODOS Study Authorizations

DWR received authorization to study NODOS Project beginning in 1996. Reclamation received feasibility study authority for the NODOS Project in 2003. The specific federal and State authorities for study of NODOS Project are summarized in Table ES-1.

Table ES-1
Summary of Federal and State Authorities for the NODOS Project

Federal Authorities	State of California Authorities
• Public Law 108-7. Consolidated Appropriations Resolution, 2003 • Public Law 108-137. Energy and Water Development Appropriations Act, 2003 • Public Law 108-361. CALFED Bay-Delta Authorization Act, 2004	• Proposition 204. The Safe, Clean, Reliable Water Supply Act of 1996 • Budget Act, 1997-1998 • Proposition 50. Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002 • Proposition 84. 2006 Safe Drinking Water Bond Act

ES.1.3 Purpose and Intended Uses of this EIR/EIS

The purpose of this EIR/EIS is to present the process and overall findings of the NODOS environmental evaluations. This EIR/EIS, and the associated Draft Feasibility Report, is intended to be used by DWR and Reclamation when considering approval of the proposed Project. It will also provide information for DWR, Reclamation, National Marine Fisheries Service (NOAA Fisheries), U.S. Fish and Wildlife Service (USFWS), and the California Department of Fish and Wildlife (CDFW) to support compliance with the federal Endangered Species Act (ESA), the California Endangered Species Act (CESA), and the Natural Community Conservation Planning Act (NCCPA) and will provide information for the U.S. Army Corps of Engineers (USACE) and the Regional Water Quality Control Board (RWQCB) in Clean Water Act (CWA) Section 408, 404, and 401 applications, as well as information necessary for USACE to issue a Rivers and Harbors Act Section 10 permit.

ES.1.4 Federal, State, Regional, and Local Requirements

In addition to DWR and Reclamation, several federal, State, regional, and local agencies, as well as decision-making bodies, have jurisdiction over resources that could be affected by the proposed Project, or have other permitting or regulatory authority over certain aspects of the proposed Project. These agencies and decision makers will review and consider the information contained in the final EIR/EIS, and will consider it in their decision-making process. Refer to Table 1-1 in Chapter 1 Introduction for key consultation requirements for the NODOS Project.

All federal, State, regional, and local legislation and policies that were considered during impact evaluations for each of the resource chapters, or that will be used for decision making for the proposed Project, are detailed in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

ES.1.5 Notice of Preparation and Notice of Intent

DWR filed a Notice of Preparation (NOP) with the State Clearinghouse on November 5, 2001, and Reclamation published a Notice of Intent (NOI) in the *Federal Register* on November 9, 2001 to announce the intent to prepare a joint EIR/EIS for the proposed Project. The NOP/NOI notified the public of the Project proposal, announced the dates and locations of public meetings, and solicited public comments to help guide development of the EIR/EIS, pursuant to CEQA and NEPA, respectively. Copies of the NOP and NOI are included in Appendix 36A.

ES.1.6 Proposed Project

The proposed Project would consist of a new offstream surface storage reservoir with two main dams, up to nine saddle dams, and up to five recreation areas. The reservoir would have an associated inlet/outlet structure and would be connected to the Sacramento River by two existing canals and a new pipeline. Water conveyance between the reservoir and the canals and pipeline would be facilitated by two new regulating reservoirs and their associated pumping/generating plants. A new transmission line would connect the pumping/generating plants and their associated electrical switchyards to an existing transmission line in the proposed Project area. New roads and a bridge would be constructed to provide access to the proposed Project facilities and over the proposed reservoir, and some existing roads would be relocated or improved. The proposed Project would require modifications to an existing canal and pumping plant. A more complete description of the proposed Project can be found in Chapter 3 Description of Proposed Project/Proposed Action and Alternatives.

ES.1.6.1 Study Areas

The proposed Project has the potential to influence SWP and CVP system operations and water deliveries over a large geographic area. To effectively evaluate the proposed Project's three action alternatives' effects on environmental resources in different geographic regions, DWR and Reclamation identified three study areas to be evaluated in this EIR/EIS: the Extended, Secondary, and Primary study areas. These three study areas are summarized below.

Extended Study Area

The Extended Study Area includes the entire service areas of the SWP and CVP and is the largest and most diverse of the three study areas, in terms of size, geography, land use, and habitat conditions. As such, it has been described and evaluated at the lowest level of detail. These two service areas are located within all or portions of the following 39 counties: Alameda, Butte, Calaveras, Colusa, Contra Costa, El Dorado, Fresno, Glenn, Imperial, Kern, Kings, Los Angeles, Madera, Merced, Monterey, Napa, Nevada, Orange, Placer, Plumas, Riverside, Sacramento, San Benito, San Bernardino, San Diego, San Joaquin, San Luis Obispo, Santa Barbara, Santa Clara, Santa Cruz, Shasta, Solano, Stanislaus, Sutter, Tehama, Tulare, Tuolumne, Ventura, and Yolo. The proposed Project's purpose of improved water supply reliability has the potential for long-term direct and indirect effects within those two service areas. The SWP and CVP service areas included in the Extended Study Area are shown on Figure 1-6 in Chapter 1 Introduction. The Extended Study Area would also include wildlife refuges that could receive Level 4 water supply from the proposed Project. Those wildlife refuges, which are located within seven counties in the Extended Study Area, are shown on Figure 1-7 in Chapter 1 Introduction.

Secondary Study Area

The Secondary Study Area is smaller than the Extended Study Area and has been described and evaluated in more detail than for the Extended Study Area. The Secondary Study Area is defined as the area of potential operational effects, including SWP and CVP facilities that could experience reservoir water surface elevation fluctuations and stream flow changes downstream from their facilities. Those facilities are located within the following 22 counties: Alameda, Butte, Colusa, Contra Costa, Del Norte, El

Dorado, Glenn, Humboldt, Marin, Placer, Sacramento, San Francisco, San Mateo, Santa Clara, Shasta, Solano, Sonoma, Sutter, Tehama, Trinity, Yolo, and Yuba. Operational changes could occur as a result of the coordinated and integrated operation of the proposed Project's facilities with those State and federal projects located on the American River, Trinity River, Sacramento River, Clear Creek, Spring Creek, Feather River, and the Delta. The Secondary Study Area is shown on Figure 1-8 in Chapter 1 Introduction.

Primary Study Area

The Primary Study Area is the focus of the resource evaluations in this EIR/EIS. The Primary Study Area includes the areas within Glenn and Colusa counties where short-term and long-term direct effects from constructing, operating, and/or maintaining proposed Project facilities may occur. This study area includes the footprints of the proposed Sites Reservoir inundation area and other proposed facilities (e.g., dams, intakes/discharge facilities, pipelines, transmission line, pumping/generating plants, recreation areas, road relocation areas, borrow areas and associated facilities). It also includes the construction disturbance areas, i.e., the footprint of each proposed facility plus the area around each facility that would be disturbed over the short-term by Project-related construction activities, vehicles, and equipment. The Primary Study Area also includes the land parcels that surround those Project facilities; these parcels would be purchased but not developed for the proposed Project and are referred to as the "Project Buffer."

There are differences in the facilities associated with the proposed Project alternatives; therefore, the Primary Study Areas for the three alternatives also differ. The Primary Study Areas associated with Alternatives A, B, and C are shown on Figure 1-9A, Figure 1-9B, and Figure 1-9C, respectively, in Chapter 1 Introduction.

ES.1.7 Areas of Controversy/Issues to be Resolved

The following areas of controversy and issues to be resolved have been identified to date through stakeholder meetings or during the preparation of this EIR/EIS.

- Golden eagles have been identified as foraging within the proposed Sites Reservoir Inundation Area and nesting within the proposed recreation areas. USFWS has expressed concern about the potential loss of nesting and foraging habitat for golden eagles, which are protected by the Bald and Golden Eagle Protection Act.
- Project development would require the demolition of existing structures, acquisition of private property, and relocation of displaced parties. These actions concern property owners within the Primary Study Area.

ES.2 Approach to Alternatives Analysis

ES.2.1 Overview of the Alternatives Analysis

The NODOS Project alternatives analysis was completed in phases. The study of the NODOS Project was originally derived from the CALFED Program's identification of a range of activities that, if implemented, could concurrently improve the quality and reliability of California's water supplies as well as ecosystem conditions and levee integrity in the Sacramento-San Joaquin Delta. Among many recommended activities, the CALFED Program identified the need for an additional 3.0-MAF of storage north of the Delta to meet environmental and water supply needs. The CALFED Program also expressed a preference for offstream over onstream storage to avoid redirected impacts to fisheries and other aquatic species. The CALFED Program initially identified 52 potential surface storage locations[1] but retained only 12 reservoir locations statewide for further study (CALFED, 2000). For a summary of the CALFED Program Inventory of Potential Surface Water Storage Sites, refer to Appendix 2A. Red Bank, Newville, Colusa, and Sites are four (of the 12) reservoir locations that are offstream and located north of the Delta. Consistent with these recommendations, DWR initiated studies of the four north-of-the-Delta offstream storage alternatives in 1997.

The consideration and evaluation of the four alternatives is described below. DWR and Reclamation eliminated the Red Bank and Colusa alternatives from further consideration based upon a comparison of environmental effects and feasibility considerations, which are documented in the 2000 NODOS Investigation Progress Report and in the 2006 NODOS Initial Alternatives Information Report. This allowed DWR and Reclamation to compare and evaluate the No Project/No Action Alternative, the Newville Reservoir Alternative, and the Sites Reservoir Alternative in greater detail, consistent with NEPA and CEQA requirements. Based on the detailed evaluation of these alternatives, Sites Reservoir was selected as the preferred proposed Project alternative.

DWR and Reclamation have also completed a more detailed evaluation of effects, consistent with CEQA and NEPA requirements, of three configurations of Sites Reservoir, hereafter called Alternative A, Alternative B, and Alternative C. The results and conclusions of these evaluations are found in Chapters 6 through 35. For purposes of CEQA, these alternatives should be considered as three variations of the Sites Reservoir Alternative (i.e. the preferred Project alternative). For NEPA purposes, the evaluation of Alternative A, Alternative B, Alternative C, and the No Project/No Action Alternative were evaluated in detail in accordance with the Council on Environmental Quality regulation 1502.14b.

ES.2.2 Alternatives Considered But Rejected from Further Consideration

Following an evaluation of the NODOS Investigation Progress Report (July 2000), the Red Bank and Colusa alternatives were eliminated from further consideration. The reasons for eliminating these two reservoir locations are described in further detail in Chapter 2 Alternatives Analysis. The Red Bank Alternative was eliminated because it was determined early in the evaluation process that a reservoir at Red Bank would have more numerous and more significant impacts to the physical environment than other alternatives. Relative to other alternatives, Red Bank would have a larger on-stream component, would impact lands with greater habitat diversity, would substantially reduce sediment contributions from Cottonwood Creek to the Sacramento River, and would result in significant impacts to spring-run Chinook salmon and steelhead on South Fork Cottonwood Creek. Furthermore, the level of overall benefits (water supply, water quality, ecosystem enhancement, hydropower) realized by the Red Bank Alternative would be less than that of other locations considered due to the smaller storage capacity of the reservoir. The Colusa Reservoir Alternative was not recommended for further consideration because its larger facilities would have an overall greater impact on environmental and cultural resources than the other smaller reservoir alternatives, its high total capital cost for storage capacity made it the least cost effective alternative, and the estimated average annual cost per yield would be comparatively excessive.

[1] The results of this inventory are presented in the March 7, 1997 draft report, *CALFED Bay-Delta Program Storage and Conveyance Component Inventories*. The inventory includes 51 potential surface water storage sites. Subsequently, the August 2000 *CALFED Initial Surface Water Storage Screening Report* added the San Luis Enlargement to the list of potential sites.

ES.2.3 Alternatives Selected for Analysis

DWR and Reclamation selected the Sites Reservoir and Newville Reservoir alternatives, along with the No Project/No Action alternative, for further analysis in the NODOS Project EIR/EIS. DWR's NOP and Reclamation's NOI also identified other potential alternatives, including conjunctive use or Shasta Reservoir enlargement, either as stand-alone projects or in conjunction with other NODOS Project alternatives to meet NODOS Project objectives. Subsequent evaluations by other programs determined that the potential for conjunctive use is limited because Sacramento Valley groundwater basins recharge annually, leaving no space for operable storage. Conjunctive use was, therefore, not retained as a feasible alternative.

Reclamation is investigating Shasta Lake enlargement as part of its Shasta Lake Water Resources Investigation. However, State agency involvement in this project is effectively barred by Public Resources Code section 5093.542. Shasta Lake enlargement was, therefore, not retained as a feasible alternative to meet NODOS Project objectives. The alternatives retained for further analysis are briefly described below and described in further detail in Chapter 2 Alternatives Analysis.

ES.2.3.1 Existing Conditions and the No Project/No Action Alternative

The CEQA Baseline for assessing significance of impacts of the proposed Project is normally the environmental setting, or Existing Conditions, at the time a NOP is issued. The NOP for the proposed Project was published on November 5, 2001. However, because the preparation of this environmental document has occurred over many years, it was deemed necessary to update the baseline condition date to June 2009 to include programs, projects, or policies that have been implemented during the document's preparation. Changes in the regulatory environment since November 2001 have fundamentally changed water management in California and necessitate updating the baseline conditions for environmental analyses in this EIR/EIS. These changes include the issuance of new biological opinions (BO) by the U. S. Fish and Wildlife Service (USFWS) in December 2008 and the National Marine Fisheries Service (NMFS) in June 2009 on the operations of the State Water Project and Central Valley Project. Consequently, June 2009 (following the release of NMFS' BO) was selected as the proposed Project's Existing Conditions date.

CEQA requires an analysis of an alternative in which the proposed Project is not implemented, referred to as the No Project Alternative. No Project conditions include reasonably foreseeable changes in Existing Conditions and changes that would be reasonably expected to occur in the foreseeable future if the project were not implemented, based on current plans and consistent with available infrastructure and community services. NEPA also requires an analysis of an alternative in which the proposed Project is not implemented, referred to as the No Action Alternative. The No Action Alternative represents a projection of current conditions to reasonably foreseeable future conditions that could occur if the proposed Project or alternatives are not implemented.

The No Action Alternative assumptions are consistent with the requirements and limitations prescribed by CEQA; therefore, in this EIR/EIS, the No Action Alternative also represents the No Project Alternative. The No Project/No Action Alternative assumptions include the assumptions related to the State Water Project (SWP) and Central Valley Project (CVP), ongoing programs and policies by governmental and nonprofit entities, and assumptions related to annual actions that vary every year. The No Project/No Action Alternative includes projects and programs with clearly defined management and/or operational plans, including facilities being constructed as of June 2009[2]. The No Project/No Action Alternative also includes projects and programs that received approvals and permits in 2009 to remain consistent with existing management direction. Those actions are consistent with the continuation of existing management direction or level of management for plans, policies, and operations by the lead agencies and other agencies. Refer to Chapter 2 Alternatives Analysis for the key assumptions associated with the No Project/No Action Alternative, as well as summaries of the following:

- SWP and CVP operations included in the No Project/No Action Alternative (Table 2-11 in Chapter 2 Alternatives Analysis)
- Projects and programs included in the No Project/No Action Alternative (Table 2-12 in Chapter 2 Alternatives Analysis)
- Ongoing programs included in the No Project/No Action Alternative (Table 2-13 in Chapter 2 Alternatives Analysis)

ES.2.3.2 Sites Reservoir Alternative

The Sites Reservoir Alternative, which would be located in Antelope Valley, approximately 10 miles west of the town of Maxwell in Glenn and Colusa counties, would be formed by constructing two major dams on Stone Corral Creek and Funks Creek. Initial evaluation of the Sites Reservoir Alternative focused on a 1.81-MAF reservoir that would also require the construction of nine saddle dams along the southern edge of the Hunters Creek watershed. Diversions from the Colusa Basin Drain (CBD), the Sacramento River, and local tributaries could provide potential sources of water supply for Sites Reservoir. Multiple conveyance options would be possible, with 13 optional conveyance systems (using existing and new conveyance infrastructure) from the Sacramento River, two from CBD, and two from Stony Creek. The description for the Sites Reservoir Alternative was further developed to include details for the appurtenant facilities shown in Figures 2-2 and 2-3 in Chapter 2 Alternatives Analysis.

Non-irrigation season flows in the CBD, the Sacramento River, and local tributaries remained potential sources of water supply for the offstream Sites Reservoir Alternative. Potential conveyance systems from these sources to the reservoir included existing and/or enlarged Tehama-Colusa (T-C) and Glenn-Colusa Irrigation District (GCID) canals, or a new conveyance facility from the Sacramento River near Moulton Weir and/or from the CBD to the existing Funks Reservoir on the T-C Canal. Conveyance from Stony Creek was also considered. All conveyance alternatives required enlargement of the existing Funks Reservoir to provide adequate storage capacity for pumping of water into the reservoir and hydropower generation. Major project facilities would be situated near the Funks Creek damsite, including outlet works, power plant, intake structure, and maintenance facilities. Additionally, up to five potential recreation facility locations were identified to meet the secondary objective of developing additional recreation opportunities in the study area.

ES.2.3.3 Newville Reservoir Alternative

The Newville Reservoir Alternative would be located upstream from Black Butte Reservoir, approximately 18 miles west of the City of Orland and 23 miles west-southwest of the City of Corning in Glenn and Tehama counties. Alternative reservoir sizes of 1.9-MAF and 3.0-MAF were considered. The 1.9-MAF reservoir would be formed by a dam on North Fork Stony Creek and a saddle dam at Burrows

[2] The lead agencies have established June 2009 as the Existing Conditions date; it is characterized in Chapters 6 through 31 as the Environmental Setting/Affected Environment discussion.

Gap. The 3.0-MAF reservoir would require up to five additional saddle dams and a dike. A small diversion dam and diversion from Thomes Creek would transfer water to the reservoir. Other source options include Stony Creek and the Sacramento River. Multiple conveyance options would be possible using existing infrastructure (e.g., canals), new infrastructure (e.g., canals, tunnels, and/or pipelines), or a combination of new and existing facilities. The description for the Newville Reservoir Alternative was refined further to include details for the appurtenant facilities shown in Figures 2-4, 2-5, 2-6, and 2-7 in Chapter 2 Alternatives Analysis. Continued evaluation of the Newville Reservoir Alternative focused on the 1.9-MAF reservoir size. The Sacramento River and Black Butte Reservoir were considered, in addition to Thomes Creek, as potential sources of water supply for the Newville Reservoir Alternative. Potential conveyance systems from these sources to the reservoir included the existing or enlarged T-C Canal with a new conveyance between the GCID and T-C canals, a new conveyance from the T-C Canal to the existing Black Butte Reservoir, and a new conveyance from Black Butte Reservoir to Newville Reservoir. A new conveyance from a proposed Thomes Creek diversion at a location north and west of the Newville Reservoir Alternative was also considered. Additionally, five potential recreation areas were identified to meet the secondary objective of developing additional recreation opportunities in the study area.

ES.2.4 Preferred Proposed Project Alternative

Comparisons of the biological and cultural resources for the Sites Reservoir and Newville Reservoir alternatives indicated a greater impact potential for the Newville Reservoir Alternative. Because of the consistently higher potential for biological and cultural resources impacts associated with the Newville Reservoir Alternative, and because the Newville Reservoir Alternative would not avoid or reduce any of the significant adverse effects associated with the Sites Reservoir Alternative, DWR and Reclamation selected the Sites Reservoir Alternative as the preferred proposed Project alternative to be retained for further study and more detailed evaluation.

ES.2.4.1 Sites Reservoir Storage Alternatives

DWR and Reclamation considered various storage sizes of Sites Reservoir, including 800 TAF, 1.27 MAF, 1.81 MAF, and 2.1 MAF. These four storage sizes were selected to reflect a range of storage values that would allow for a useful comparison of the costs and benefits estimates. These four storage sizes also represent points on the cost curve where the proposed Project's costs would change significantly due to the need for new Project features, such as dams or embankments.

DWR and Reclamation determined early in the investigation that a 2.1-MAF reservoir may present significant design challenges based on a review of the reservoir rim topography, site geology, and a cursory evaluation of the relationship between embankment volume and reservoir storage. Therefore, a maximum reservoir elevation of 540 feet, corresponding to a reservoir size of 2.1 MAF, was eliminated from further consideration. Reservoir sizes of 800 TAF, 1.27 MAF, and 1.81 MAF were, therefore, carried forward for further consideration.

ES.2.4.2 Sites Reservoir Conveyance Alternatives

Preliminary operations simulations indicated that 3,000 to 6,000 cfs of total inflow capacity would be needed to reliably fill Sites Reservoir. Because Sites Reservoir would be located offstream, water would need to be delivered both to and from the reservoir. As a result, conveyance facilities would be needed to transport water to Sites Reservoir, and to deliver water from Sites Reservoir to service areas, the Sacramento River, and other locations to meet various water resources needs and uses. DWR and

Reclamation determined that, to maximize operational flexibility, the conveyance facilities would need to be able to:

- Deliver water directly from Sites Reservoir to meet local needs in the vicinity of the existing GCID and T-C canals
- Deliver water in an integrated manner with existing CVP and SWP operations to facilitate meeting additional needs throughout the Bay-Delta system.
- Release water directly to the Sacramento River to meet additional needs throughout the Bay-Delta system and provide downstream benefits for Delta water quality and water supply reliability for CVP, SWP, and Level 4 wildlife refuge water supply. Additionally, the ability to release water directly to the Sacramento River would allow Sites Reservoir to respond to Delta emergencies.

Conveyance facilities alternatives that would divert water from the Sacramento River included the existing GCID and T-C canals, and a new pipeline, known as the Delevan Pipeline. Tributary source conveyance facilities alternatives included new pipelines from the CBD and Stony Creek. Conveyance facilities alternatives that were evaluated initially had a range of capacity sizes. Each of the options for the conveyance alternatives were evaluated based on cost, the importance of providing direct release to the Sacramento River, and preliminary assessments of potential environmental and cultural resources impacts.

The conveyance options retained were:

- T-C Canal at its existing capacity of 2,100 cfs
- GCID Canal at its existing capacity of 1,800 cfs
- A new Delevan Pipeline at capacities of 1,500 cfs, 2,000 cfs, and 3,000 cfs

The T-C and GCID canals at their existing capacities would be the most cost-effective conveyance alternatives and were retained. The three smallest Delevan Pipeline alternatives were also retained as they could be combined with the T-C and GCID canals to provide conveyance packages with up to 6,900 cfs total capacity for use in initial alternative development and allowed for an evaluation of benefits associated with the proposed Delevan Pipeline's ability to return water directly to the Sacramento River.

ES.2.4.3 Sites Reservoir Operational Alternatives

Eight initial Sites Reservoir operational alternatives, each with a range of conveyance packages and operational emphases, were considered and evaluated with the CalSim-II operations model in the NODOS Plan Formulation Report (DWR and Reclamation, 2008). The operational alternatives assumed a Sites Reservoir storage size of 1.8 MAF. All of the initial Project operational alternatives evaluated met the proposed Project's primary objectives, but to varying degrees. The proposed Project operational alternative that emphasized a balanced mix of benefits to water supply reliability, water quality, and ecosystem enhancement generated the greatest net annual economic benefit and minimized environmental impacts, and therefore was selected as the operational scenario for detailed evaluation in this environmental document. This operational alternative was the only one evaluated that resulted in economic benefits that exceeded costs (i.e. benefit-cost ratio greater than 1.0). The other operational alternatives that prioritized one benefit category (i.e. water supply reliability, water quality, or ecosystem enhancement) were eliminated from further consideration.

ES.2.4.4 Sites Reservoir Storage, Conveyance, and Operations Formulation

Based on the initial evaluation of storage, conveyance and operational alternatives, the following proposed Project features were retained for further evaluation:

- Sites Reservoir Storage: 800 TAF, 1.27 MAF, and 1.81 MAF
- Sites Reservoir Conveyance: Existing T-C Canal (2,100-cfs capacity), existing GCID Canal (1,800-cfs capacity), and new Delevan Pipeline (1,500-cfs, 2,000-cfs, and 3,000-cfs capacity)
- Operational scenario that emphasized a balanced mix of benefits to water supply reliability, water quality, and ecosystem enhancement

To further evaluate and optimize reservoir storage and conveyance options, preliminary costs were estimated and operations modeling was performed. Based on preliminary operations simulations, a 3,000-cfs Delevan Pipeline was eliminated from consideration. Modeling results of the above-listed conveyance options indicated that a 2,000-cfs conveyance was adequate to meet the proposed Project objectives. A preliminary estimate was made of the net annual benefit associated with each reservoir storage and conveyance options combination that was retained. Based on the analysis, three reservoir size and conveyance options were combined with new hydropower facilities to develop three configurations of Sites Reservoir, hereafter referred to as Alternative A, Alternative B, and Alternative C in this EIR/EIS. Following is a brief description of the No Project/No Action Alternative and Alternatives A, B, and C that are evaluated in this EIR/EIS:

- **No Project/No Action Alternative.** The No Project/No Action Alternative assumes that no actions would be taken to provide storage north of the Delta to improve water supply reliability, to enhance the survivability of anadromous fish or drinking water quality in the Delta, or to improve flexible hydropower generation.
- **Alternative A – 1.27-MAF Sites Reservoir with Delevan Pipeline.** Alternative A includes a 1.27-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals and a new Delevan Pipeline (2,000-cfs diversion/1,500-cfs release). This alternative also includes new hydropower facilities.
- **Alternative B – 1.81-MAF Sites Reservoir with Release-only Delevan Pipeline.** Alternative B includes a 1.81-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals, and a new release-only Delevan Pipeline (1,500-cfs release). This alternative also includes new hydropower facilities.
- **Alternative C – 1.81-MAF Sites Reservoir with Delevan Pipeline.** Alternative C includes a 1.81-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals and a new Delevan Pipeline (2,000-cfs diversion/1,500-cfs release). This alternative also includes new hydropower facilities.

ES.2.5 Proposed Project Action Alternatives

Table ES-2 provides a summary list of proposed Project facilities for each action alternative.

Table ES-2
Proposed Project Features by Action Alternative

Project Feature	Component of Alternative A	Component of Alternative B	Component of Alternative C
1.27-MAF Sites Reservoir (requires 9 dams total)	Yes	No	No
1.81-MAF Sites Reservoir (requires 11 dams total)	No	Yes	Yes
Golden Gate and Sites Dams	Yes	Yes	Yes
9 Saddle Dams	No	Yes	Yes
7 Saddle Dams	Yes	No	No
Up to 5 Recreation Areas	Yes	Yes	Yes
Road Relocations and South Bridge	Yes	Yes	Yes
Sites Pumping/Generating Plant	Yes; 5,900-cfs pumping capacity; 5,100 cfs generating capacity	Yes; 3,900-cfs pumping capacity; 5,100 cfs generating capacity	Yes; 5,900-cfs pumping capacity; 5,100 cfs generating capacity
Electrical Switchyards	Yes	Yes	Yes
Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure	Yes	Yes	Yes
Sites Reservoir Inlet/Outlet Structure	Yes	Yes	Yes
Field Office Maintenance Yard	Yes	Yes	Yes
Holthouse Reservoir Complex (includes Holthouse Reservoir and Dam, breached Funks Dam, existing Funks Reservoir Dredging, Holthouse Spillway and Stilling Basin, Holthouse Pumping Plant, T-C Canal Discharge Dissipater, T-C Canal Bypass Pipeline, and Holthouse to T-C Canal Pipeline)	Yes	Yes	Yes
Pump Installation at the Red Bluff Pumping Plant	Yes	Yes	Yes
GCID Canal Facilities Modifications	Yes	Yes	Yes
GCID Canal Connection to the Terminal Regulating Reservoir (TRR)	Yes	Yes	Yes
TRR (includes the TRR to Funks Creek Pipeline and Outlet)	Yes	Yes	Yes
TRR Pumping/Generating Plant	Yes	Yes	Yes

Table ES-2
Proposed Project Features by Action Alternative

Project Feature	Component of		
	Alternative A	**Alternative B**	**Alternative C**
TRR Pipeline (3.5-mile-long pipeline to convey water from the TRR to Holthouse Reservoir) and TRR Pipeline Road	Yes	Yes	Yes
Delevan Transmission Line	Yes; Sites Pumping/Generating Plant to WAPA/PG&E[3] Line plus WAPA/PG&E Line to Sacramento River	Yes; Sites Pumping/Generating Plant to WAPA/PG&E Line	Yes; Sites Pumping/Generating Plant to WAPA/PG&E Line plus WAPA/PG&E Line to Sacramento River
Delevan Pipeline (2,000 cfs with 2 pipelines)	Yes	Yes	Yes
Delevan Pipeline Intake Facilities (includes fish screen and pumping/generating facilities)	Yes; 2,000 cfs diversion capacity; 1,500 cfs release capacity	No	Yes; 2,000 cfs diversion capacity; 1,500 cfs release capacity
Delevan Pipeline Discharge Facility	No	Yes; 1,500 cfs release capacity	No
Project Buffer	Yes	Yes	Yes
Potential Acreage of Temporary Land Use Impacts	17,680	19,637	19,636
Potential Acreage of Permanent Land Use Impacts	26,425	26,424	26,425

The following are Project-related ecosystem enhancement actions common to all action alternatives:

- Ecosystem Enhancement Storage Account—Operational Actions
- Ecosystem Enhancement Fund—Nonoperational Actions

Ecosystem enhancement actions have been designed to support the NODOS Project objective of increased fish survival. Based upon recommendations from federal and State fish agencies, the proposed Project would provide operational and nonoperational ecosystem enhancement actions. Conceptually, the operational and non-operational actions would be most effective if implemented concurrently. These proposed Project facilities, operational and non-operational actions, and proposed seasonal schedule for Project operations are discussed in further detail in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives.

ES.3 Summary of Potential Environmental Effects and Mitigation Commitments

Project operations were developed by DWR and Reclamation in coordination with State and federal resource agencies and local water interests to maximize a broad array of Project benefits (objectives) and minimize or avoid Project-related adverse effects. The operations evaluated in this environmental document represent an operational scenario designed to concurrently maximize achievement of the

[3] The proposed Project would connect with either the existing PG&E Transmission Line or the existing WAPA Transmission Line.

Project objectives of improving water supply reliability, increasing the survival of anadromous fish, improving Delta water quality, and providing flexible hydropower generation. The impact analyses included in the resource chapters assess Sites Reservoir and the potential response of CVP and SWP facilities under each alternative using this single operational scenario.

The proposed Project action alternatives would affect environmental resources in all three study areas. Some of the impacts would be temporary, construction-related effects that would be less than significant or would be reduced to less-than-significant levels through mitigation. Other impacts would be permanent, some of which would remain significant and unavoidable despite proposed mitigation measures. In addition, some effects of the proposed Project would be beneficial.

Table ES-3 (provided at the end of this chapter) summarizes the impacts by environmental resource for each proposed Project alternative, the level of significance of the impact prior to mitigation, the proposed mitigation measure, and the level of significance of the impact after mitigation.

ES.3.1 Identified Significant and Unavoidable Impacts

As shown in Table ES-3, the proposed Project action alternatives would likely result in the following potentially significant and unavoidable direct and indirect impacts.

ES.3.1.1 Botanical Resources

Two plant species with suitable habitat around the proposed Sites Reservoir footprint edges were likely not adequately included in the reservoir footprint surveys of 1998-99, and therefore, may occur within the footprint: *Amsinckia lunaris* (CNPS List 1B) and *Sidalcea keckii* (CNPS List 1B and federally endangered). Construction of the proposed Sites Reservoir and Dams could therefore result in the loss of these species, as well as the loss of some CNPS List 4 species, for which mitigation measures may not be adequate to reduce impacts to less than significant levels.

ES.3.1.2 Terrestrial Biological Resources

Construction and filling of the proposed Sites Reservoir Inundation Area, as well as construction of the proposed Recreation Areas, would result in the permanent loss of foraging and nesting habitat for the golden eagle. Pursuant to the Bald and Golden Eagle Protection Act, implementation of mitigation measures would not reduce this impact to less than significant levels.

ES.3.1.3 Cultural Resources

Increased water level fluctuations at San Luis Reservoir and other service area reservoirs associated with proposed Project operations could impact significant archaeological sites, traditional cultural properties, or human remains. Because complete assessment of the effects of water level fluctuations on cultural resources has never been conducted, it is possible that mitigation measures would not reduce this impact to less than significant levels. Construction of the proposed Project facilities would affect built environment resources. If these resources are determined to be eligible for listing in the California Register of Historical Resources or National Register of Historic Places, mitigation measures would not reduce the impact to less than significant levels.

ES.3.1.4 Land Use

Construction and filling of the proposed Sites Reservoir Inundation Area would result in the physical division of the community of Sites, resulting in a significant and unavoidable impact. Construction of the proposed Project facilities would result in conflicts or incompatibilities with existing and designated land uses and existing zoning for agricultural and forest land use, as well as the conversion of lands that have Williamson Act contracts. Implementation of mitigation measures may not reduce these impacts to less than significant levels.

ES.3.1.5 Air Quality

Construction activities associated with all proposed Primary Study Area Project facilities, as well as activities (such as use of roads, recreation, electricity generation and consumption, and sediment dredging) associated with the long-term operation and maintenance of the proposed Project, would result in significant and unavoidable emissions of PM_{10}, ROG, and NO_x.

ES.3.1.6 Climate Change and Greenhouse Gas Emissions

Increased electricity use associated with Project-related changes in CVP operations would be served by energy generated at CVP hydroelectric facilities that emit no GHGs and consequently would result in a corresponding reduction in supply of GHG-emissions-free electricity available to sell to California's electricity users. Substitute electricity supplies for this reduction may result in GHG emissions that would have a cumulatively considerable effect. Monitoring to measure the indirect change in emissions would not be feasible; mitigation would also therefore not be feasible.

ES.3.1.7 Visual Resources

The proposed South Bridge, Terminal Regulating Reservoir (TRR), and associated TRR facilities would be visually dominant and in high contrast to the surrounding landscape, resulting in a significant and unavoidable impact on a scenic vista. In addition, the proposed Sites Reservoir would have a significant impact on a scenic vista when water levels are drawn down during Dry to Critical water years and during some late summer months. The proposed Sites Reservoir and the proposed Road Relocations would impact large contiguous areas of grazing land and the proposed TRR and associated facilities would be visually intrusive due to their scale and designed height, causing substantial degradation of the existing visual character of the site. The large water surface of the proposed Sites Reservoir would also introduce a substantial new potential source of daytime and nighttime glare in the area.

ES.3.2 Short-Term Uses vs. Long-Term Productivity

NEPA requires consideration of the relationship between short-term uses of the environment and the maintenance and enhancement of long-term productivity of the affected resources for a Proposed Action.

Implementation of any of the proposed Project action alternatives would require the construction of new facilities, improvements to existing facilities, the demolition of existing structures, removal of existing roads, and the inundation of lands. These activities would result in short-term and long-term impacts on the resources evaluated in this EIR/EIS.

Potential benefits of proposed Project implementation include improved water supply reliability for agricultural, urban, and environmental uses, and for Delta emergency response; increased survival of anadromous and endemic fish populations; improved drinking and environmental water quality in the Delta; increased flexible hydropower generation to support integration of renewable energy sources; improved local flood damage reduction; and increased recreational opportunities. Environmental uses and habitat for a variety of aquatic and terrestrial species along the Sacramento River and waterways within the study areas would also be maintained, and potentially enhanced, through the proposed ecosystem enhancement storage account, and the proposed ecosystem enhancement fund. All of the action alternatives would also result in indirect and induced employment, as discussed in the Growth Inducing Impacts section. In addition, sales and profits for businesses that support the construction industry in the Primary Study Area would result in increased profits for the duration of the construction period.

In summary, the long-term benefits of the improved operational flexibility of the State's water system would outweigh the short-term and long-term adverse effects on the individual resources areas evaluated in this DEIS/EIR.

ES.3.3 Irreversible or Irretrievable Commitments

CEQA requires a discussion of the significant irreversible environmental changes that would be caused by the proposed Project should it be implemented. In addition, an EIS prepared under NEPA must analyze irreversible and irretrievable commitments of resources (NEPA Section 102(2)(c)(v) and 40 CFR 1502.16). Reclamation and other federal agencies have interpreted irreversible and irretrievable commitments to mean the use of nonrenewable resources and the effects this use would have for future generations. Irreversible commitment of resources occurs as a result of the use or destruction of a specific resource (e.g., minerals extraction, destruction of cultural resources) which cannot be replaced or, at a minimum, restored over a long period of time. Irretrievable commitment of resources refers to actions resulting in the loss of production, harvest, or use of natural resources. It represents opportunities foregone for the period of time that a resource cannot be used (e.g., land conversion to new uses; construction of levees preventing the natural flooding of flood plains). In other words, the production lost is irretrievable, but the action is not irreversible. If the use changes, it is possible to resume production. Irretrievable commitments of resources are evaluated to assure that proposed consumption is justified.

The commitment of resources would generally be similar for all of the proposed Project's action alternatives. The proposed Project would result in the irreversible and irretrievable commitment of the following resources during Project construction, operation, and maintenance:

- Construction materials, including wood, rock, soil and metal
- Energy expended in the form of electricity, gasoline, diesel fuel, oil, and lubricants for equipment and transportation vehicles that would be needed for Project construction, operation, and maintenance
- Construction labor
- Permanent changes in land use, including the conversion of prime agricultural land to other uses and the relocation of graves, at proposed Project facility locations due to land that would be committed to new and modified Project facilities and land areas inundated with water
- Changes in the visual resources and landscape character of lands where proposed Project facilities would be located, including large structures and new sources of light
- Effects on biological and cultural resources located at proposed Project facility locations, including vegetation removal, the disturbance of traditional cultural practices, and the disturbance of cultural resources potentially eligible for listing on the California Register of Historical Resources and the National Register of Historic Places

Some of these resources that would be used for the proposed Project are nonrenewable resources and are considered irretrievably and irreversibly committed because reuse is not possible or is highly unlikely.

However, nonrenewable resources are expected to account for a minimal portion of the region's resources and the proposed Project's use of nonrenewable resources would not affect the availability of these resources for other needs within the region.

CEQA Guidelines Section 15126.2 (c) also states that irreversible environmental damage can result from environmental accidents associated with a project. Construction of the proposed Project would result in the use, transport, storage, and disposal of hazardous wastes. DWR and Reclamation would require all construction, operation, and maintenance activities to comply with applicable federal, State, and local laws related to hazardous materials, which would significantly reduce the likelihood and severity of accidents that could cause irreversible environmental damage as a result of proposed Project construction, operation, and maintenance. In addition, the proposed Sites Reservoir dams would be designed and constructed pursuant to conservative guidelines and criteria designed to prevent failure.

ES.3.4 Growth-Inducing Impacts

Implementation of the proposed Project would improve water supply reliability for agricultural, urban, and environmental uses; improve water quality; provide more options for water management; increase recreational opportunities; and increase temporary and permanent employment opportunities. These Project-related changes would not be expected to result in growth-inducing effects for the following reasons.

ES.3.4.1 Improved Water Supply Reliability and Water Quality for Agricultural, Urban, and Environmental Uses

The expected increase in water yield associated with Project implementation would be within the range of projected increases of water supplies by major urban water users in their recent Urban Water Management Plans (UWMPs) to provide adequate water supplies for planned growth. Because the UWMPs have identified adequate water supplies to meet future water demands in 2030 for the Long-Term average and Dry and Critical Dry year conditions, it does not appear that lack of water supplies is an obstacle to growth in these major urban communities. Project-related increased water supply reliability is therefore not expected to be growth inducing.

The expected increased water deliveries to agricultural water users in the Extended Study Area, which would range from zero to five percent, are not expected to be growth inducing, and could reduce the potential to change adopted land use plans that would allow conversion of agricultural lands to urban uses.

ES.3.4.2 Increased Recreational Opportunities

Expected Project-related increased recreation expenditures would represent less than 0.2 percent of total industrial expenditures in the Primary Study Area and are therefore not anticipated to increase growth within the entire Primary Study Area. However, increased recreation use could adversely affect public services due to increased traffic. The expected increase in traffic would result in a less-than-significant impact with implementation of mitigation measures.

ES.3.4.3 Increased Employment Opportunities

The expected magnitude of Project-related increased employment opportunities in the agricultural sector would be less than one percent, when compared to the regional economy of the Extended Study Area, and is therefore not anticipated to result in growth-inducing impacts. Although the expected increased water supply deliveries could result in increased employment and other economic benefits, the effects on housing and population are expected to be minor in the Extended Study Area, when compared to the total housing and population.

Project construction and operation would be expected to result in a minor increase in jobs and population in the Primary Study Area, which could be accommodated within available housing units. An adequate housing supply exists to accommodate the change in population, and as such, this expected increase associated with Project implementation is not anticipated to be growth inducing.

ES.3.5 Cumulative Impacts

The California Code of Regulations' Guidelines for the Implementation of the California Environmental Quality Act (CEQA Guidelines) and federal National Environmental Policy Act (NEPA) regulations require that the cumulative impacts of a proposed project be addressed in an Environmental Impact Report/Environmental Impact Statement (EIR/EIS). Cumulative impacts are impacts on the environment that result from the incremental impacts of a proposed action when added to other past, present, and reasonably foreseeable future actions.

The cumulative impact assessment for the proposed Project considered projects and programs identified under Existing Conditions (which includes the current effects of past projects) and reasonably foreseeable and probable future projects. The criterion for considering whether a project was reasonably foreseeable and probable in this EIR/EIS was whether the project had been defined in adequate detail, either through the completion of publicly available preliminary evaluations, feasibility studies, or draft environmental and engineering documents, to estimate potential impacts.

Projects considered in the cumulative impacts analysis included 11 multi-region projects and actions; two local agency projects and actions in the vicinity of the proposed NODOS Project facilities; 24 water supply, water quality, and hydropower projects and actions in the vicinity of the proposed NODOS Project facilities and/or potentially affected by SWP and CVP operations; and 21 ecosystem improvement projects and actions in the vicinity of the proposed NODOS Project facilities and/or potentially affected by SWP and CVP operations (refer to Chapter 35 Cumulative Impacts for the names descriptions of each of project considered).

Implementation of the proposed Project would result in the cumulatively considerable incremental contribution to an overall substantial cumulative adverse effect for the following resources.

ES.3.5.1 Botanical Resources

Adverse effects due to loss of vegetation within the inundation area of the proposed Sites Reservoir and within and adjacent to the inundation area of the proposed Holthouse Reservoir would potentially remain substantial and unavoidable following implementation of mitigation measures; in addition, the loss of botanical resources associated with some future projects in the Extended and Secondary study areas would be substantial and unavoidable

ES.3.5.2 Terrestrial Biological Resources

Adverse effects due to the loss of golden eagle nesting and foraging habitat within the inundation area of the proposed Sites Reservoir and some of the proposed Recreation Areas would remain substantial and unavoidable following implementation of mitigation measures; in addition, the loss of wildlife habitat associated with some future projects in the Extended and Secondary study areas would be substantial and unavoidable

ES.3.5.3 Cultural Resources

Project-related water level fluctuations in the Extended Study Area could result in substantial effects to cultural resources because complete assessment of the effects of water level fluctuations on cultural resources has never been conducted; construction of the proposed Project facilities would result in potentially substantial and unavoidable effects to historic resources and traditional cultural properties; in addition, effects to cultural and historical resources due to disturbance or inundation from future projects within the Extended and Secondary study areas would be substantial and unavoidable

ES.3.5.4 Land Use

Construction of the proposed Project facilities would result in conflicts or incompatibilities with existing and designated land uses and existing zoning for agricultural and forest land use, as well as the conversion of lands that have Williamson Act contracts, which could remain substantial and unavoidable; the physical division of the community of Sites caused by inundation of the lands within the proposed Sites Reservoir would result in a substantial and unavoidable effect; in addition, future projects within the Extended and Secondary study areas would result in substantial and unavoidable changes in land uses and loss of agricultural lands

ES.3.5.5 Recreation Resources

Potential Project-related operational changes could result in reduced water surface elevations at San Luis Reservoir; in addition, future projects within the Extended and Secondary study areas could contribute to further reductions in summer water storage elevations and flows in rivers downstream of the CVP and SWP reservoirs

ES.3.5.6 Air Quality

Construction of the proposed Project facilities would result in substantial and unavoidable effects to air quality; in addition, future projects within the Extended and Secondary study areas would result in substantial and unavoidable effects to air quality

ES.3.5.7 Climate Change and Greenhouse Gas Emissions

Proposed Project operation would require a small increase in electricity usage to operate the CVP and would consequently reduce supply of GHG-emissions-free electricity available to sell to California electricity users - because it is unknown which type of power source would be used to substitute for the lost power, the proposed Project could result in potentially substantial and unavoidable effects to GHG emissions; in addition, operation of future projects within the Extended and Secondary study areas would result in potentially substantial and unavoidable effects to GHG emissions because it is unknown which type of power source would be used to provide the additional electricity needed for those projects

ES.3.5.8 Visual Resources

Substantial and unavoidable Project-related effects to visual resources would occur due to glare from the water surface of the proposed Sites Reservoir, changes in the visual characteristic of the area from rural and undeveloped to an area with more infrastructure such as the proposed South Bridge and connecting roadways, and change in views across the valley floor due to the six-foot high embankments of the proposed Terminal Regulating Reservoir; in addition, future projects within the Extended and Secondary study areas would result in substantial and unavoidable effects to visual resources

ES.3.6 Responsibilities for Mitigation Monitoring Plan and Implementation

As part of proposed Project planning and environmental assessment, DWR, Reclamation and/or other partners would incorporate certain environmental commitments and best management practices into the action alternatives to avoid or minimize potential impacts. Reclamation would also coordinate planning, engineering, design and construction, operation, and maintenance phases of the proposed Project with applicable resource agencies. The following environmental commitments would be incorporated into any action alternative for any Project-related construction activities:

- Conduct DWR Environmental Site Assessment
- Develop and Implement Construction Management Plan
- Comply with Permit Terms and Conditions
- Develop and Implement Erosion and Sediment Control Plan
- Develop and Implement Stormwater Pollution Prevention Plan
- Develop and Implement Feasible Spill Prevention and Control Plan
- Implement Fisheries Conservation Measures
- Implement Water Quality Protection Measures
- Prepare and Implement Revegetation Plan
- Asphalt Removal

A detailed Mitigation Monitoring Plan is provided in Appendix 1A.

ES.4 Coordination with Concerned Agencies and Stakeholders

In accordance with NEPA and CEQA, DWR and Reclamation have conducted the following public scoping and agency coordination and consultation activities. Further information is provided in Chapter 36 Consultation and Coordination.

ES.4.1 Public Scoping

DWR and Reclamation notified interested parties of the scoping period and upcoming public scoping meetings through electronic and postal mailings and through publication of the NOP and NOI. Public notifications were also made through direct mailings to local landowners in and near the Sites and Newville reservoir alternative sites, and by advertisements in four local newspapers prior to the public meetings. In addition, a news release was placed on the DWR and Reclamation website homepages.

DWR and Reclamation conducted three scoping meetings (one meeting each in Sacramento, Maxwell, and Fresno, CA) to seek public input and comments prior to the preparation of the EIR/EIS. In addition, DWR and Reclamation held a scoping meeting with the Native American tribes in Williams, CA. At the scoping meetings and during the scoping comment period, the public was invited to submit written comments regarding the scope, content, and format of the environmental document by mail, fax, or email to representatives at DWR and Reclamation. A Scoping Report, which was prepared at the end of the scoping meetings and comment period, is included in Appendix 36A.

ES.4.2 Consultation

Since late 2001, DWR and Reclamation have met with the following stakeholders, interested parties, and State and federal regulatory agencies, including:

- Environmental Interests, County Boards of Supervisors, and Water Contractors
- Sacramento River Flow Regime Technical Advisory Group (TAG)
- California Bay-Delta Public Advisory Committee, Water Supply Subcommittee Briefings
- Common Assumptions Stakeholder Technical Workgroup
- Area Landowners
- Study Area Tours

ES.4.3 Coordination

Coordination efforts with local water interests, counties, and other State and federal agencies throughout the environmental documentation process included the following:

- Sites Memorandum of Understanding Partners
- Sites Project Joint Powers Authority
- Cooperating Agencies (Bureau of Indian Affairs, Western Area Power Administration, USACE, Colusa Indian Community Council, Cortina Indian Rancheria, and Sites Project JPA)
- Responsible Agencies (CDFW, State Water Resources Control Board, Central Valley Regional Water Quality Control Board - Central Valley Region 1, Tehama-Colusa Canal Authority, Glenn-Colusa Irrigation District, and Sites Project JPA)
- Trustee Agencies (CDFW, California State Lands Commission, California Department of Parks and Recreation, and University of California)
- Native American Representatives (Colusa Indian Community Council, Cortina Indian Rancheria, Grindstone Indian Rancheria, and Paskenta Band of Nomlaki Indians)
- Environmental Coordination Advisory Team (DWR, Reclamation, CDFW, USFWS, NMFS/NOAA Fisheries, CVRWQCB, USEPA, and USACE)

ES.5 Preliminary Administrative Draft EIR

The Preliminary Administrative Draft EIR has not been reviewed or approved for adequacy in meeting CEQA and NEPA requirements. The California Department of Water Resources (DWR) is releasing this document to provide decision-makers, stakeholders, and the public with up-to-date and detailed information on the investigation.

Release of this material does not constitute the initiation of formal public review of the Draft EIR as provided by CEQA Guidelines Section 15087. Although comments are welcome and may be considered in preparation of the Draft EIR, DWR will not respond to comments received on this document.

Please note the following reading guidance for this preliminary administrative draft. Refer to the summary Table of Contents for a list of chapters and appendixes. At this time, a detailed Table of Content, List of Abbreviations and Acronyms, Index, and Chapter 37, References, are not included. Abbreviations and acronyms are defined at first use in each chapter, and references are included in a

References section at the end of each chapter and appendixes when necessary. Some chapters/appendixes include figures and tables at the end of the chapters/appendixes.

In the future, a Public Draft EIR/EIS will be circulated for public and agency review and comment. The public review process and Proposed Project/Proposed Action approval process is discussed in Chapter 36 Consultation and Coordination.

Delevan Pipeline Discharge Facility	N/A	N/A	Significant	N/A	Land-4a	Less than Significant
21. Recreation Resources						
Impact Rec-1: Increase the Use of Existing Neighborhood and Regional Parks or Other Recreational Facilities such that Substantial Physical Deterioration of the Facility would Occur or be Accelerated						
Extended Study Area						
Wildlife Refuge Water Use, San Luis Reservoir, Other Reservoirs	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Secondary Study Area						
Trinity Lake, Trinity River, Klamath River downstream of the Trinity River, Shasta Lake, Sacramento River, Pump Installation at the Red Bluff Pumping Plant, Clear Creek, Lake Oroville, Feather River, Folsom Lake, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, Other Reservoirs	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Sutter Bypass, Yolo Bypass	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A

Table ES-3
Summary of Environmental Effects by Resource

Impact	Level of Significance by Alternative				Recommended Mitigation	
	No Project/ No Action Alternative	**A**	**B**	**C**	**Mitigation Measure**	**Level of Significance With Mitigation**
Primary Study Area	No Substantial Adverse Effect				None	N/A
All Primary Study Area Project Facilities with the exception of the Delevan Pipeline Intake/Discharge Facilities	N/A	No Impact	No Impact	No Impact	None	N/A
Delevan Pipeline Intake Facilities	N/A	Less than Significant	N/A	Less than Significant	None	N/A
Delevan Pipeline Discharge Facility	N/A	N/A	Less than Significant	N/A	None	N/A
Impact Rec-2: Require the Construction or Expansion of Existing Recreational Facilities, which may have an Adverse Effect on the Environment						
Extended Study Area	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Secondary Study Area	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
All Primary Study Area Project Facilities	N/A	No Impact	No Impact	No Impact	None	N/A
Impact Rec-3: Reduce Recreation Use Levels at Existing Nearby Recreation Facilities by Providing an Alternative New Site for Recreation Visitors						
Extended Study Area	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Secondary Study Area						
Trinity Lake, Trinity River, Klamath River downstream of the Trinity River, Shasta Lake, Sacramento River, Pump Installation at the Red Bluff Pumping Plant, Clear Creek, Feather River, American River, Sutter Bypass, Yolo Bypass, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, Other Reservoirs	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Lake Oroville, Folsom Lake	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
All Primary Study Area Project Facilities	N/A	No Impact	No Impact	No Impact	None	N/A
Impact Rec-4: Affect Recreation Use Levels and/or Recreation Benefits at Existing Reservoirs or Rivers due to Changes in Operating Criteria						
Extended Study Area						
San Luis Reservoir	Beneficial Effect/No Substantial Adverse Effect	Beneficial Effect/ Potentially Significant	No Impact/ Beneficial Effect/ Potentially Significant	Less than Significant/Beneficial Effect/ Potentially Significant	Rec-4a: Extend the Existing Dinosaur Point Boat Ramp at San Luis Reservoir (Alternative C only)	Less than Significant
					Rec-4b: Extend the Basalt Campground Water Intake at San Luis Reservoir	Less than Significant
Other Reservoirs	Potentially Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Secondary Study Area						
Trinity Lake	Beneficial Effect/ No Substantial Adverse Effect	Beneficial Effect	Beneficial Effect	Beneficial Effect	None	N/A
Klamath River downstream of the Trinity River, Clear Creek, Sacramento-San Joaquin Delta; Suisun Bay, San Pablo Bay, San Francisco Bay, Other Reservoirs	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Trinity River; Feather River; Sacramento River, Sutter Bypass, Yolo Bypass	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A

Table ES-3
Summary of Environmental Effects by Resource

Impact	Level of Significance by Alternative				Recommended Mitigation	
	No Project/ No Action Alternative	**A**	**B**	**C**	**Mitigation Measure**	**Level of Significance With Mitigation**
Shasta Lake	No Substantial Adverse Effect/Potentially Substantial Adverse Effect/Beneficial Effect	Beneficial Effect	Beneficial Effect	Beneficial Effect	None	N/A
Lake Oroville	Potentially Substantial Adverse Effect/ Beneficial Effect	No Impact/ Beneficial Effect	No Impact/ Beneficial Effect	No Impact/ Beneficial Effect	None required	N/A
Folsom Lake	Potentially Substantial Adverse Effect	Beneficial Effect/ Potentially Beneficial Effect	Beneficial Effect	Beneficial Effect	None	N/A
American River	Potentially Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None required	N/A
Pump Installation at the Red Bluff Pumping Plant	N/A	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	No Substantial Adverse Effect	N/A	N/A	N/A	None	N/A
Impact Rec-5: Reduce Recreation Use Levels at Existing Recreation Facilities During the Period of Construction						
Extended Study Area	N/A	N/A	N/A	N/A	None	N/A
Secondary Study Area						
Pump Installation at the Red Bluff Pumping Plant	N/A	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	N/A				None	N/A
Sites Reservoir Inundation Areas, Sites Reservoir Dams; Recreation Areas, Road Relocations and South Bridge; Sites Pumping/Generating Plant; Sites Electrical Switchyard; Tunnel; Sites Reservoir Inlet/Outlet Structure; Field Office Maintenance Yard; Holthouse Reservoir Complex; Holthouse Reservoir Electrical Switchyard, GCID Canal Facilities Modifications; GCID Canal Connection to the TRR; TRR; TRR Pumping/Generating Plant; TRR Electrical Switchyard, TRR Pipeline; TRR Pipeline Road, Delevan Pipeline Electrical Switchyard, Project Buffer	N/A	No Impact	No Impact	No Impact	None	N/A
Delevan Pipeline	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A

Delevan Pipeline Intake Facilities	N/A	Less than Significant	N/A	Less than Significant	None	N/A
Delevan Pipeline Discharge Facility	N/A	N/A	Less than Significant	N/A	None	N/A
22. Socioeconomics						
Impact Socio-1: Effects on Regional Economics						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Impact Socio-2: Effects on Population and Housing						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Impact Socio-3: Effects on Local Government Fiscal Conditions						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A

Table ES-3
Summary of Environmental Effects by Resource

Impact	Level of Significance by Alternative				Recommended Mitigation	
	No Project/ No Action Alternative	**A**	**B**	**C**	**Mitigation Measure**	**Level of Significance With Mitigation**
Impact Socio-4: Effects on Recreation Economics						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Impact Socio-5: Effects on Agricultural Economics						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Impact Socio-6: Effects on M&I Water Use Economics						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
23. Environmental Justice						
Impact Env Jus-1: A Disproportionate Share of an Adverse Impact (such as Traffic, Noise, Dust, Hazards, and/or Socioeconomic Effects) on a Minority or Low-Income Population, Including the Potential for Minority or Low-Income Populations to be Disproportionately Affected by Multiple Adverse Exposures Impacts						
Extended Study Area	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Secondary Study Area	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Primary Study Area						
Minority, Low-Income, and Hispanic Populations	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Job and Recreational Opportunities	No Substantial Adverse Effect	Potentially Beneficial Effect	Potentially Beneficial Effect	Potentially Beneficial Effect	None	N/A
24. Air Quality						
Impact Air Qual-1: Conflict with an Applicable Air Quality Plan, Contribute Substantially to an Air Quality Violation, and/or Result in a Cumulatively Considerable Net Increase of Nonattainment Pollutants						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
Construction Impacts	N/A	Significant	Significant	Significant	Air Qual-1a: Develop a Fugitive Dust Control Plan.	Significant and Unavoidable for Emissions of PM_{10}
					Air Qual-1b: Implement Measures to Reduce Equipment and Vehicle Exhaust Emissions.	Significant and Unavoidable for Emissions of NO_x, PM_{10}, and ROG
						Less than Significant for Emissions of SO_x, CO, and $PM_{2.5}$
Operation and Maintenance Impacts	N/A	Significant	Significant	Significant	Air Qual-1a	Less than Significant
					Air Qual-1b	Less than Significant
Impact Air Qual-2: Expose Sensitive Receptors to Substantial Pollutant Concentrations						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A

Table ES-3
Summary of Environmental Effects by Resource

Impact	Level of Significance by Alternative				Recommended Mitigation	
	No Project/ No Action Alternative	**A**	**B**	**C**	**Mitigation Measure**	**Level of Significance With Mitigation**
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Impact Air Qual-3: Create Objectionable Odors Affecting a Substantial Number of People						
Extended and Secondary Study Areas	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
25. Climate Change and Greenhouse Gas Emissions						
Impact GHG-1: Generation of Cumulative GHG Emissions						
Extended, Secondary, and Primary Study Areas						
Construction, Operation, and Maintenance of the Proposed Project	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
Operation of Existing SWP Facilities	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
CVP Operational Emissions	No Substantial Adverse Effect	Potentially Significant	Potentially Significant	Potentially Significant	No Feasible Mitigation	Potentially Significant and Unavoidable
Open Water Surfaces and Tailraces	No Substantial Adverse Effect	Less than Significant	Less than Significant	Less than Significant	None	N/A
26. Navigation, Transportation, and Traffic						
Navigation						
Impact Nav-1: Conflict with Navigation Along any of the Navigable Waterways within the Primary, Secondary, or Extended Study Areas						
Extended and Secondary Study Areas	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
Construction of Delevan Pipeline Intake/ Discharge Facilities	N/A	Less than Significant	Less than Significant	Less than Significant	None required	N/A
Transportation and Traffic						
Impact Trans-1: Conflict with an Applicable Plan, Ordinance, or Policy Establishing Measures of Effectiveness for the Performance of the Circulation System, Considering all Modes of Transportation						
Extended and Secondary Study Areas	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	No Substantial Adverse Effect	Less than Significant/ Significant	Less than Significant/ Significant	Less than Significant/ Significant	Trans-1: Prepare and Implement a Project Operation Traffic Control Plan	Less than Significant
Impact Trans-2: Conflict with an Applicable Congestion Management Program, Including, but not Limited to, Level of Service Standards and Travel Demand Measures, or Other Standards Established by the County Congestion Management Agency for Designated Roads or Highways						
Extended, Secondary and Primary Study Areas	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Impact Trans-3: Substantially Increase Hazards Due to a Design Feature or Incompatible Uses						
Extended and Secondary Study Areas	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
Construction	N/A	Potentially Significant	Potentially Significant	Potentially Significant	Trans-3: Prepare and Implement a Project Construction Traffic Control Plan	Less than Significant
Operation and Maintenance	N/A	No Impact	No Impact	No Impact	None	N/A
Impact Trans-4: Result in Inadequate Emergency Access						
Extended and Secondary Study Areas	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A

Table ES-3
Summary of Environmental Effects by Resource

Impact	Level of Significance by Alternative				Recommended Mitigation	
	No Project/ No Action Alternative	**A**	**B**	**C**	**Mitigation Measure**	**Level of Significance With Mitigation**
Primary Study Area	No Substantial Adverse Effect				None	N/A
Construction	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
Operation and Maintenance	N/A	No Impact	No Impact	No Impact	None	N/A
Impact Trans-5: Conflict with Adopted Policies, Plans, or Programs Regarding Public Transit, Bicycle, or Pedestrian Facilities, or Otherwise Decrease the Performance or Safety of Such Facilities						
Extended and Secondary Study Areas	No Substantial Adverse Effect	No Impact	No Impact	No Impact	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
Construction and Operation	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
Maintenance	N/A	No Impact	No Impact	No Impact	None	N/A
27. Noise						
Impact Noise-1: Expose persons to or generation of noise levels in excess of established standards						
Extended Study Area	No Substantial Adverse Effect	No Impact	Same as Alt. A	Same as Alt. A	None	N/A
Secondary Study Area						
Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex; Feather River; Sutter Bypass; Yolo Bypass; Folsom Lake; Lake Natoma; American River; Sacramento-San Joaquin Delta; Suisun Bay; San Pablo Bay; San Francisco Bay	No Substantial Adverse Effect	No Impact	Same as Alt. A	Same as Alt. A	None	N/A
Pump Installation at the Red Bluff Pumping Plant	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
Primary Study Area	No Substantial Adverse Effect				None	N/A
Sites Reservoir Inundation Area, Sites Reservoir Dams, Recreation Areas, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Holthouse Reservoir Complex, Holthouse Reservoir Electrical Switchyard, Delevan Pipeline Electrical Switchyard	N/A	No Impact	No Impact	No Impact	None	N/A
Road Relocations and South Bridge	N/A				None	N/A
Construction	N/A	Significant Impact	Significant Impact	Significant Impact	Noise-1a: DWR and Reclamation Shall Include in the Construction and Maintenance Contracts Specifications to Reduce Noise Levels	Less than Significant
Operation and Maintenance	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
GCID Canal Facilities Modifications	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
TRR, GCID Canal Connection to the TRR, TRR Pumping/Generating Plant, TRR Electrical Switchyard, TRR Pipeline, TRR Pipeline Road	N/A				None	N/A
Construction	N/A	Significant Impact	Significant Impact	Significant Impact	Noise-1a	Less than Significant
Operation	N/A	Potentially Significant	Potentially Significant	Potentially Significant	Noise-1b: Design Facilities to Incorporate Noise Mitigation	Less than Significant
Maintenance	N/A	Less than Significant	Less than Significant	Less than Significant	None	N/A
Delevan Pipeline, Delevan Transmission Line	N/A				None	N/A

1. Introduction

1.1 Proposal and Lead Agencies

This Draft Environmental Impact Report/Environmental Impact Statement (DEIR/EIS) has been prepared by the California Department of Water Resources (DWR) and the U.S Department of the Interior (DOI), Bureau of Reclamation, Mid-Pacific Region (Reclamation) to address the potential effects of alternative plans for the North-of-the-Delta Offstream Storage (NODOS) Project. The NODOS Project described in this document has been developed as part of the NODOS Investigation.

This chapter contains background information regarding DWR and Reclamation; describes the purpose of and need for the proposed Project, including discussion of Project objectives; describes the authorizations for DWR and Reclamation to study NODOS; summarizes the California Environmental Quality Act (CEQA) and National Environmental Policy Act (NEPA) requirements for this DEIR/EIS; and provides a general overview of the environmental process for this DEIR/EIS.

DWR is serving as the State lead agency for compliance with CEQA. DWR was created in 1956 to manage the water resources of California in cooperation with other agencies, to benefit the State's people, and to protect, restore, and enhance the natural and human environments. One of DWR's primary responsibilities is to operate and maintain the State Water Project (SWP), which delivers water to agricultural, municipal, and industrial contractors in the Central Valley, the San Francisco Bay Area, upper Feather River areas, central coast, and southern California. Of the contracted water supply, approximately 75 percent goes to municipal and industrial users and 25 percent to agricultural users. One of DWR's goals is to protect and improve the water resources and dependent ecosystems of statewide significance, including the Sacramento-San Joaquin Bay-Delta Estuary. DWR's responsibilities and goals have informed this investigation. The DWR contact person for the proposed Project is:

Mr. Sean Sou
California Department of Water Resources
901 P Street
Sacramento, CA. 95814
sean.sou@water.ca.gov
Fax: (916) 651-9292

Reclamation is serving as the federal lead agency for compliance with NEPA. Reclamation was established in 1902 to assist in meeting the increasing water demands of the West. The mission of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public. Reclamation is the largest water provider in the country and the second largest producer of hydroelectric power in the western United States. Reclamation's Mid-Pacific Region is responsible for managing the Central Valley Project (CVP), which stores and delivers approximately 20 percent of the state's developed water – up to seven million acre-feet (MAF) annually – to more than 250 water contractors throughout California. Of the contracted water supply, approximately 70 percent goes to agricultural users, 20 percent is dedicated to fish and wildlife habitat, and 10 percent goes to municipal and industrial users. The Reclamation contact person for the proposed Project is:

Ms. Sharon McHale
U.S. Bureau of Reclamation
2800 Cottage Way, MP-700
Sacramento CA. 95825
smchale@usbr.gov
Fax: (916) 978-5094

The NODOS Project has been investigated by DWR and Reclamation in coordination with cooperating and responsible agencies, other resource agencies, stakeholders, and the public. The study is consistent with the 1983 U.S. Water Resources Council *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* (P&Gs) (WRC, 1983), NEPA, CEQA, and other pertinent federal, State, and local laws and policies. The NODOS Project includes both this DEIR/EIS and the accompanying feasibility report and appendices. While the DEIR/EIS describes the potential effects of NODOS Project alternatives, the draft feasibility report highlights the potential costs and benefits of the alternatives.

1.2 Purpose and Need and Project Objectives

Purpose and need and project objectives are important elements of an EIR and an EIS, as they document the reasons for a project. CEQA requires a statement of project objectives. NEPA requires a statement of the purpose and need for the action. This section describes the purpose and objectives of the proposed Project and need for the action.

1.2.1 Purpose Statement and Project Objectives

The purpose of the proposed Project is to build offstream surface storage located north of the Delta. The proposed Project's primary objectives are to:

- Improve water supply reliability for agricultural, urban, and environmental uses
- Increase survival of anadromous and endemic fish populations
- Improve environmental and drinking water quality in the Delta
- Provide flexible hydropower generation to support integration of renewable energy sources

The secondary objectives for the proposed Project, based on opportunities that were identified during formulation of alternatives that met the primary objectives, are to:

- Develop additional recreation opportunities
- Provide incremental flood damage reduction opportunities

An initial step in the planning process is to identify and then define problems, needs, and opportunities. Consistent with the requirements of CEQA, NODOS Project objectives were derived from this needs assessment. Needs and objectives were considered and developed in an iterative manner so that a more thorough understanding of each need and objective could be developed. DWR and Reclamation have relied upon several sources of information during the NODOS Project's needs and objectives development process. The CALFED Bay-Delta Program (CALFED Program), for example, provided a comprehensive overview of California's water resources needs. In addition to their water management responsibilities, DWR and Reclamation have also developed water resources planning information related to water resources needs. CALFED and the lead agencies also provided opportunities for input related to needs from State and federal resources agencies, local and regional water interests, and the public. The need for the proposed Project is described below, including background provided by the CALFED Program.

1.2.1.1 CALFED Bay-Delta Program and North-of-the-Delta Offstream Storage

The NODOS Project is derived from and relies upon information developed by and for the CALFED Program. However, the NODOS Project DEIR/EIS is not programmatically tiered from the CALFED Program.

The CALFED Program was established to "develop and implement a long-term comprehensive plan that will restore ecological health and improve water management for beneficial uses of the Bay-Delta system" (CALFED, 2000). The CALFED Program identified the need for up to six million acre-feet of additional storage, including an additional three million acre-feet of storage north of the Delta. The CALFED Program sought to build a framework for managing California's water resources, stating that "expanding water storage capacity is critical to the successful implementation of all aspects of the CALFED Program. Not only is additional storage needed to meet the needs of a growing population, but, if strategically located, it will provide much needed flexibility in the system to improve water quality and support fish restoration efforts. Water supply reliability depends upon capturing water during peak flows and during wet years, as well as more efficient water use through conservation and recycling" (CALFED, 2000). The CALFED Program began in May 1995 to address the complex issues that surround the Bay-Delta with a cooperative interagency effort of 18 State and federal agencies with management or regulatory responsibilities for the Bay-Delta. In addition, the CALFED Program was a collaborative effort including representatives of agricultural, urban, environmental, fishery, and business interests, Indian tribes and rural counties who have contributed to the process.

The CALFED Program objectives were fourfold: 1) to restore the ecological health of a fragile and depleted Bay-Delta estuary; 2) to improve the water supply reliability for the State's farms and growing cities that draw water from the Delta and its tributaries, including seven million acres of the world's most productive farmland; 3) to protect the drinking water quality of the 27 million Californians who rely on the Delta for their supplies; and 4) to protect the Delta levees that ensure its integrity as a conveyance and ecosystem. Surface storage is part of an overall water management strategy that incorporates other CALFED Program actions, such as conservation, water use efficiency, conveyance, transfers, groundwater storage and conjunctive use, and habitat restoration to meet these Program objectives.

In 1997, DWR initiated the North-of-the-Delta Offstream Storage Investigation, which Reclamation joined later. Consistent with CALFED's surface storage screening (described in Chapter 2 Alternatives Analysis), the Investigation considered four potential reservoir locations north-of-the-Delta. Evaluations and determinations for each reservoir location are included in this DEIR/EIS. Refer to Chapter 2 Alternatives Analysis for a more detailed history of the CALFED Program, its relationship to the NODOS Project, and the evaluation of the four reservoir locations. The NODOS Project would help provide the needed additional north-of-the-Delta surface storage identified by the CALFED Program. The CALFED Record of Decision (ROD) (CALFED, 2000) suggested several objectives for consideration by the NODOS Project, including water supply reliability, fish survival, and water quality, and identified a need for additional operational flexibility that is described below.

1.2.1.2 Needs and Project Objectives

As noted above, the NODOS Project identified six needs and opportunities that are the basis of the primary and secondary objectives. The NODOS Project also identified one additional need: operational flexibility. Following is a description of the needs and opportunities identified by the NODOS Project.

1.2.1.3 Water Supply Reliability for Agricultural, Urban, and Environmental Uses

The California Water Plan Update identifies two supporting elements to achieve the State's vision for water resources: sustainable water uses and reliable water supplies. Water managers and users are concerned with both the quantity and frequency of their supplies, which are direct measures of water supply reliability. For surface water systems such as the CVP and SWP, the reliability for a particular user is determined by both runoff and system-specific needs and capabilities. In drier years, there is less water available for delivery than in wetter years. System needs include the total water user demand on the system and requirements such as water quality standards, instream flows for habitat or species, and flood operations. The following provides examples of reliability challenges in California.

Water supply reliability requires the delivery of specified amounts of water at predictable locations and times. A review of DWR's SWP Delivery Reliability Reports since 2002 (2002, 2005, 2007, 2009, and 2011) indicates declining SWP reliability. Average SWP delivery reliability has been reduced by almost 500,000 acre-feet. However, limitations on water exports during wet conditions have resulted in greater reservoir storage during drought conditions, and that in turn has slightly increased drought delivery reliability. Despite marginal reliability improvements in drier conditions, additional reliability is still needed. The CVP has experienced similar reductions in delivery reliability.

During prolonged droughts (such as 1987 to 1992 and 2007 to 2009) or multiple dry years, water in storage is reduced and water supplies are less reliable, which increases competition among water users. This competition is exacerbated by increased environmental requirements and reduced natural rainfall for agriculture. A new surface storage reservoir would provide a means of improving water supply reliability, especially during drier periods.

From a planning perspective, emergency response has been incorporated into the water supply reliability objective. By improving water in storage at any given time, operators would have additional water available in storage to respond to specific types of emergencies, including emergency water supply for maintenance of Delta salinity following a levee failure.

In addition, California's mountain snowpack is melting earlier in spring and is projected to decrease over time, and sea level rise along the coast is beginning to threaten Delta water supplies and estuarine habitat as seawater intrudes into the Delta. Runoff is concentrated during shorter periods, and additional water is required to maintain Delta water quality. In addition to impacting water in storage, all of these effects tend to diminish water supply reliability. The additional storage provided by the proposed Project would help mitigate and adapt to these reliability trends.

1.2.1.4 Survival of Anadromous and Endemic Fish Populations

Populations of anadromous and endemic fish species within the Sacramento Valley river system and Bay-Delta are declining. The primary causes of the anadromous fish species decline have been identified as barriers to historic habitat, habitat degradation, predation from introduced species, reduced instream flows, and increased water temperatures (NMFS, 2009). Several potential causes of fish species declines in the Bay-Delta have been identified, including a combination of reduced habitat suitability (such as changing salinity), reduced food sources, entrainment, invasive species, predation, and toxins (Baxter et al., 2010). Onstream dams block many of the native anadromous species from their historic spawning areas. This impact of onstream dams is partially mitigated with cold water releases that keep the water downstream of the dams cold enough to provide limited spawning and rearing habitat. Similar to deliveries, water temperature has a reliability that is based upon operations and hydrology. The reliability of cold water in these streams can be increased and temperatures for anadromous fish can be improved by both maintaining additional water in storage year to year and releasing additional water at specific times to improve temperatures. Additional water in storage can also be released to improve Delta outflow. These actions must be balanced and coordinated with water deliveries to achieve desirable conditions. Additional storage from the proposed Project would provide a source of additional water within the SWP and CVP systems that could be used to facilitate several ecosystem restoration and enhancement actions to improve conditions in the Delta and Sacramento River watershed.

1.2.1.5 Water Quality

Water quality concerns associated with the Delta include salinity and toxins (e.g., pesticides, dissolved ammonia, and methyl mercury) from up-river sources. The CVP and SWP systems currently meet water quality requirements by releasing additional water from upstream reservoirs. Additional water in storage from new proposed Project storage could improve Delta water quality by providing higher-quality supplemental flows dedicated to Delta outflow during periods when Delta water quality is impaired. Water quality improvements would benefit drinking water quality for urban customers, irrigation, and the Bay-Delta ecosystem.

1.2.1.6 Flexible Hydropower Generation

California's renewable energy goal is to increase the portion of energy produced by renewable sources in the State to 33 percent by 2020. By law, a hydroelectric generation facility that exceeds 30 megawatts is ineligible to be considered a renewable electrical generation facility, so none of the electricity generated by the proposed Project could be counted towards that goal (Pub. Util. Code, § 399.12). Nevertheless, the design and operation of the proposed Project would take advantage of other intermittent renewable energy sources such as wind and solar, which are less reliable than other non-renewable sources of energy. There is a need to match renewable energy sources with reliable and flexible generation energy sources to cover short-term gaps in generation, such as when winds diminish in wind generation-intensive areas. The proposed Project would be built with pumping/generating plants capable of producing hydropower. Electricity would be generated when water is released from the proposed Sites Reservoir into the proposed Holthouse Reservoir, and from the proposed Holthouse Reservoir to the proposed Terminal Regulating Reservoir and into the Sacramento River. The proposed Project would also be capable of daily pump-back operations. In pump-back operations mode, water would be released from the proposed Sites Reservoir into the proposed Holthouse Reservoir during on-peak hours to generate electricity, and water would be pumped back into the proposed Sites Reservoir during the off-peak hours to complete the pump-back operations cycle. Additional storage provided by the proposed Project could facilitate flexible hydropower generation, which could be quickly ramped up or down to complement wind or solar generation to meet power demands and support reliable operation of the power grid. Hydropower provided by the proposed Project could be brought online relatively quickly, and would be well suited to provide flexible generation. The effect would be to operate the reservoir like a battery, charging it with renewable energy such as wind when that energy was available but underutilized, and then producing energy during times of peak demand. Hydropower, when paired with solar and wind energy, could reduce greenhouse gas emissions associated with the use of non-renewable sources of energy.

1.2.1.7 Additional Recreation Opportunities

Generally, large metropolitan areas, such as Sacramento, have high demands for water-oriented recreational opportunities. Some of these demands are served by reservoirs on the western slope of the Sierra Nevada. However, as population increases in the Sacramento Valley, demands for flat water, river, and land-based recreation are expected to increase. The planning of any reservoir north of the Delta provides an opportunity to develop new recreational facilities and provide additional opportunities for recreation activities such as fishing, swimming, camping, boating, and hiking. The proposed Project would provide up to five new recreation areas.

1.2.1.8 Incremental Flood Damage Reduction

Offstream storage can provide incremental flood damage reduction improvements to areas located immediately downstream of the reservoir that are prone to flooding. The proposed Project would not dam a major stream, but would dam two ephemeral creeks that are known to cause local flood damage. The proposed Project would therefore provide local flood damage reduction.

1.2.1.9 Operational Flexibility

Operational flexibility was identified as a need by both the CALFED Program and the NODOS Project. Operational flexibility can be defined as the ability of water systems to adapt and respond to changing or uncertain conditions. Water in storage is a metric of operational flexibility; increased water in storage provides increased operational flexibility for a system by allowing system operators and water managers to do more. Water managers employ the flexibility of the systems they manage to accomplish a variety of water management objectives. As noted above in the discussion of Project objectives, additional water in storage can be used to deliver more water to users, improve ecosystem conditions within the system, or improve water quality. In this sense, operational flexibility has a direct relationship with water management generally, and with meeting water management objectives specifically.

California’s water management challenges include growing drought impacts, declining ecosystems, diminishing water quality, increasing climate change impacts to the State’s hydrology, increasing flood risk, and aging infrastructure (DWR, 2009). The California Water Plan Update (DWR, 2009) notes that, “the entire system—water and flood management, watersheds, and ecosystems – has lost its resilience and is changing in undesirable ways.” This loss of resiliency is the result of decreased operational flexibility.

An example of the loss of operational flexibility in the State’s water systems is the declining trend of end-of-water-year storage. Shasta Lake is California’s largest reservoir and the largest storage facility of the CVP. The water stored in Shasta Lake represents approximately 41 percent of the total storage capacity of the CVP (Reclamation, 2013). Lake Oroville is the State’s second largest reservoir and keystone of the SWP. Figure 1-1 shows the trend in Shasta Lake end-of-water-year storage (i.e. water in storage) from 1953 to 2012. Figure 1-2 shows the trend in Lake Oroville end-of-water-year storage from 1968 to 2012. The trend of end-of-water-year storage is diminishing, from over 3 million acre-feet to under 2.5 million acre-feet at Shasta Lake, and from 2.4 million acre-feet to approximately 1.8 million acre-feet at Lake Oroville. Generally, there is less water in storage at the beginning of each water year (i.e. end of September) than has been available over the history of either reservoir. There are likely many reasons for these trends[1]. However, consideration of the operational changes over time associated with the State’s

[1] Fundamentally, water in storage is directly related to two factors: inflow (i.e. hydrology) and releases (i.e. operations). The trend of inflow to the Shasta Lake is essentially flat (i.e. has not varied over time), with a slight upward trend. The Lake Oroville inflow trend is diminishing, but at a slower rate than storage. Therefore, it is likely that the diminishing trend in end of water year storage is due primarily to changes in operations over time. Some highlights of these changes are generally described in the text.

two largest water systems is helpful to understand these trends. When the CVP and SWP were first constructed, the systems had operational flexibility. Deliveries and regulatory requirements were less; both have increased over time. The flexibility that the systems originally possessed has been used to meet the greater delivery amounts and increasing regulatory requirements needed to protect habitats and species.

Today, the CVP and SWP systems do more than ever, including increased deliveries to agricultural, urban, and environmental (refuge supply) users, as shown in Figure 1-3. The reservoirs are serving more purposes than they have historically. Due to changing regulatory requirements, the quantities of water needed to meet Delta water quality standards have increased. The quantities of water dedicated to habitat and ecosystem functions are greater as well, including new commitments associated with the CVP Improvement Act in 1992 (CVPIA) and years following, as well as the 2008 and 2009 Biological Opinions for the protection of both Delta and upstream fish species. Consequently, the CVP and SWP water systems have lost flexibility in timing, location, and capacity to meet these multiple objectives, resulting in increased competition and conflicting demands for limited water in storage. All of these increasing commitments are affecting the system reservoirs generally, and Shasta Lake and Lake Oroville specifically, which can be seen in the decreasing end-of-water-year storage trends.

Requested contract delivery amounts and actual deliveries have also increased over time for both the CVP and SWP. For example, historical deliveries from the Delta are shown in Figure 1-3. These Delta deliveries are both the largest and most variable portion of CVP and SWP deliveries. Chronologically, deliveries reached a peak around 1990 and then varied with runoff and operational limits over the next two decades. Without significant improvements to north of Delta storage, a continuing trend of diminishing end-of-September storage into the future is likely. While the effect of the 1992 CVPIA should be fully reflected in the historic trend, now twenty years after implementation, the effects on the trend of the 2008 and 2009 Biological Opinions are not.

In addition, it is anticipated that the system will be more constrained in the future, with increasing challenges due to the effects of increasing temperatures, sea-level rise, and variability and uncertainty from changing snow and rainfall patterns. For example, climate scientists expect that California's natural water storage in the form of snow, which water managers and operators rely on for more effective reservoir storage operations, will diminish. Sea-level rise will require additional water to be dedicated to salinity repulsion in the Delta, including additional releases from upstream reservoirs. These changes will further diminish reservoir storage and the operational flexibility of the systems that depend on them. These and other effects associated with climate change are described in greater detail in Chapter 25 Climate Change and Greenhouse Gas Emissions.

Additional water in new storage, such as additional water in a new offstream storage reservoir located north of the Delta, would contribute to increased system flexibility. From a system perspective, operational flexibility can be assessed by evaluating the additional water in storage that can be used to meet existing and future water demands. To achieve this kind of flexibility, additional storage would be most effective when operationally integrated with existing SWP and CVP facilities. Supplemental north of Delta storage would provide the ability to increase the water in storage in existing system reservoirs such as Shasta Lake, Lake Oroville, Trinity Lake, and Folsom Lake. The additional water in new offstream storage and increasing water levels in existing reservoirs can meet a larger set of system objectives. For example, water users and ecosystem needs immediately downstream of existing reservoirs need additional water in those reservoirs to meet those needs; additional water in new offstream storage alone would not improve the system's ability to meet needs below existing reservoirs without integration.

The total improvement in flexibility would be both additional water in existing reservoirs and additional water in new offstream storage.

This type of effective additional storage would be able to provide a wide range of water resources benefits throughout the State, including increased water supply reliability for agricultural, environmental, municipal, and industrial uses; water quality maintenance and improvement; increased flexible hydropower generation; and maintenance and improvement of aquatic ecosystems. Most of these existing system objectives have operating or allocation rules based upon the amount of water in storage. These rules or operations guidance explicitly acknowledge the relationship between water in storage (i.e. system operational flexibility) and meeting system needs or objectives.

1.3 North-of-the-Delta Offstream Storage Study Authorizations

The CALFED ROD (CALFED, 2000) directed DWR and Reclamation to: 1) complete environmental and planning documentation for the NODOS Project and 2) develop a joint planning program through a Memorandum of Understanding (MOU) with local water interests, counties, and State and federal agencies to carry out the NODOS Project. This DEIR/EIS and the companion draft Feasibility Report constitute the completion of environmental and planning documentation. Following the signing of the CALFED ROD, DWR and Reclamation formed a MOU partnership with local water interests and other State and federal agencies to investigate offstream storage north of the Delta. Local, regional, and other State and federal agency participation has continued during the investigation. DWR received authorization to study the NODOS Project beginning in 1996. Reclamation received feasibility study authority to investigate the NODOS Project in 2003.

State of California authorities for the NODOS Investigation are summarized below:

- **Proposition 204. The Safe, Clean, Reliable Water Supply Act of 1996:** Notwithstanding Section 13340 of the Government Code, the money in the subaccount is hereby continuously appropriated, without regard to fiscal year, to the department, for the administration of this article and for feasibility and environmental investigations for any of the following projects: (a) Off-stream storage upstream of the Delta that will provide storage and flood control benefits in an environmentally sensitive and cost-effective manner.

- **Budget Act, 1997 to 1998:** This act authorized DWR to continue feasibility and environmental studies pertaining to the Sites Reservoir and alternatives. As a result, DWR expanded the 1997 reconnaissance study to a broader investigation.

- **Proposition 50. Water Security, Clean Drinking Water, Coastal and Beach Protection Act of 2002:** The sum of $825 million shall be available for appropriation by the Legislature from the fund for the balanced implementation of CALFED expenditures and grants pursuant to this chapter shall be limited to…$50 million for surface water storage planning and feasibility studies.

- **Proposition 84. 2006 Safe Drinking Water Bond Act:** The sum of $65 million shall be available to DWR for planning and feasibility studies related to the existing and potential future needs for California's water supply, conveyance, and flood control systems. The studies shall be designed to promote integrated, multi-benefit approaches that maximize public benefits of the overall system including protection of the public from floods, water supply reliability, water quality, and fish, wildlife, and habitat protection and restoration.

Federal authorities for the NODOS Investigation are summarized below:

- **Public Law 108-7. Consolidated Appropriations Resolution, Sec. 215, 2003:** The Secretary of the Interior, in performing CALFED-related activities, may undertake feasibility studies for Sites Reservoir, Los Vaqueros Reservoir Enlargement, and Upper San Joaquin Storage projects. These storage studies should be pursued along with ongoing environmental and other projects in a balanced manner.
- **Public Law 108-137. Energy and Water Development Appropriations Act, Sec. 211, 2003:** The Secretary of the Interior, in performing CALFED-related activities, may undertake feasibility studies for Sites Reservoir, Los Vaqueros Reservoir Enlargement, and Upper San Joaquin Storage projects, hereafter. These storage studies should be pursued along with ongoing environmental and other projects in a balanced manner.
- **Public Law 108-361. CALFED Bay-Delta Authorization Act (2004):** (1) Record of Decision (ROD) as general framework. The ROD is approved as a general framework for addressing CALFED, including its components related to water storage, ecosystem restoration, water supply reliability (including new firm yield), conveyance, water-use efficiency, water quality, water transfers, watersheds, the Environmental Water Account, levee stability, governance, and science. (2) Secretary of the Interior. The Secretary of the Interior is authorized to carry out the activities…to the extent authorized under the reclamation laws, the Central Valley Project Improvement Act (title XXXIV of Public Law 102-575; 106 Stat. 4706), the Fish and Wildlife Coordination Act (16 U.S.C. 661 et seq.), the Endangered Species Act (ESA) of 1973 (16 U.S.C. 1531 et seq.), and other applicable law…Description of Activities Under Applicable Law (1) Water storage (i) planning and feasibility studies for (I) the Sites Reservoir in Colusa County.

1.4 CEQA and NEPA Requirements

Both CEQA and NEPA require governmental agencies to evaluate the environmental impacts of their proposed decisions before making formal commitments to carry them out, and that such evaluation be done in detail, and with public involvement. CEQA is a California law and applies to State and local agencies, whereas NEPA is a federal law and applies to federal agencies. For the proposed Project, CEQA requires preparation of an EIR, and NEPA requires preparation of an EIS.

Despite the similarities between the two laws, important differences exist. CEQA requires that State and local government agencies consider the environmental consequences of projects over which they have discretionary authority before taking action on those projects. As described in the *CEQA Guidelines* Section 15121(a), an EIR is a public informational document that assesses the potential environmental effects of the proposed project, as well as identifies mitigation measures and alternatives to the proposed project that could reduce or avoid adverse environmental impacts. CEQA requires that the lead agency (DWR) prepare an EIR if any “potentially significant impacts” are identified that could not be mitigated to a less-than-significant level.

The *CEQA Guidelines* identify several types of EIRs, each applicable to different project circumstances. This EIR was prepared as a Project EIR pursuant to *CEQA Guidelines* Section 15161. This type of EIR focuses primarily on the changes in the environment that would occur as a result of Project implementation, and examines all phases of a particular project (i.e., planning, construction, maintenance, and operation).This DEIR/EIS discloses the Project-level direct, indirect, and cumulative impacts of the alternatives, including a

No Project/No Action Alternative. The CEQA requirement to determine a "significance threshold" for expected impacts presents an important or critical feature of the document. Thresholds of significance are developed using applicable regulations where they exist, or best professional judgment. CEQA requires agencies to implement feasible mitigation measures or feasible alternatives as a means of reducing the severity of significant environmental effects identified in EIRs, and CEQA requires lead agencies to adopt a Mitigation Monitoring and Reporting Plan for changes to the Project that it has adopted to mitigate or avoid significant effects on the environment (*CEQA Guidelines* Section 15097).

Pursuant to NEPA and the Council on Environmental Quality's (CEQ's) NEPA regulations, federal agencies are required to evaluate the environmental effects of an action, including feasible alternatives, and identify mitigation measures to minimize adverse effects when they propose to carry out, approve, or fund a project that may have a significant effect on the environment. Reasonable alternatives must be rigorously and objectively evaluated pursuant to NEPA (as opposed to CEQA's requirement that they be discussed in "meaningful detail"). Pursuant to NEPA, the evaluation of potential impacts must include socioeconomic impacts, whereas CEQA does not require such analysis. Although mitigation is identified in NEPA documents, it is not required to be implemented.

DWR and Reclamation have determined that this combined DEIS/EIR is the most appropriate and accessible means to comply with both CEQA and NEPA because of the complex nature of the proposed Project, need for coordination among federal and State agencies, the need to complete environmental review as expeditiously as possible, and to reduce unnecessary duplication of effort. This document satisfies the requirements of CEQA and NEPA for disclosing environmental impacts and identifying feasible alternatives, mitigation measures, and modifications to the Project that would reduce those impacts.

The alternatives discussed in this DEIR/EIS have been evaluated on an equal non-preferential basis and at an equal level of detail, according to NEPA standards. The Proposed Project/Preferred Alternative will be identified in the Final EIR/EIS (FEIR/FEIS), with that selection to be informed through the CEQA and NEPA processes. Although a final Mitigation Monitoring Plan is not required to be included in an EIR, a draft Mitigation Monitoring Plan has been prepared and included in this DEIR/EIS as Appendix 1A, and is circulated for public and agency review.

1.4.1 Purpose and Intended Use of this DEIR/EIS

CEQA Guidelines Section 15124(d) requires that an EIR contain a statement briefly describing the intended uses of the EIR. The *CEQA Guidelines* indicate that the EIR should identify the ways in which the Lead Agency and any responsible agencies would use this document in their approval or permitting processes. The purpose of this DEIR/EIS is to present the process and overall findings of the NODOS Investigation. This investigation was performed to evaluate the feasibility and impacts of constructing a new water storage facility north-of-the-Delta to improve the flexibility of the SWP and CVP systems to ensure these systems can continue to meet the water supply, water quality, environmental, and energy needs of California.

This DEIR/EIS serves as a companion document to the Draft Feasibility Report, published separately. This DEIR/EIS, and the associated Draft Feasibility Report, is intended to be used by DWR and Reclamation when considering approval of the proposed Project. It provides the needed information for DWR, Reclamation, National Marine Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), and the California Department of Fish and Wildlife (CDFW) to support compliance with the federal Endangered Species Act (ESA), the California Endangered Species Act (CESA), the Natural Community Conservation Planning Act (NCCPA), and the federal Fish and Wildlife Coordination Act. It also provides needed information for the U.S. Army Corps of Engineers (USACE) and the Regional Water Quality Control Board (RWQCB) in Clean Water Act (CWA) Section 408, 404, and 401 applications, as well as information necessary for USACE to issue a Rivers and Harbors Act Section 10 permit.

1.5 Federal, State, Regional, and Local Requirements

In addition to DWR and Reclamation, several federal, tribal, State, regional, and local agencies, as well as decision-making bodies, have jurisdiction over resources that could be affected by the proposed Project, or have other permitting or regulatory authority over certain aspects of the proposed Project. These agencies and decision makers will review and consider the information contained in the FEIR/EIS for issuance of permits. Table 1-1 describes key consultation requirements for the NODOS Project:

Table 1-1
Anticipated Permits, Approvals and Authorizations for the NODOS Project

Jurisdiction	Responsibility
Federal Agency Permits, Approvals, and Authorizations	
Federal Energy Regulating Commission (FERC)	• Operational changes to existing hydroelectric facilities may necessitate a license amendment from FERC.
National Marine Fisheries Services (NMFS/ NOAA Fisheries)	• Endangered Species Act Section 7 consultation and incidental take authorization • Fish and Wildlife Coordination Act compliance • Magnuson-Stevens Fishery Conservation and Management Act compliance
Natural Resources Conservation Service (NRCS)	• Farmland Protection Policy Act compliance
United States Army Corps of Engineers (USACE)	• Rivers and Harbors Act Section 9 (construction of dikes) and Section 10 (alteration of navigable waters) permitting • Clean Water Act Section 404 (discharge of dredge or fill material) permitting and associated Section 401 water quality certification; Section 408 (levee modification) permitting • Executive Order 11990 (protection of wetlands) compliance
United States Department of the Interior, Bureau of Reclamation (Reclamation)	• NEPA lead agency • Executive Order 12898 (environmental justice) compliance • Executive Order 11988 (floodplain management) compliance
United States Department of the Interior Secretary	• Responsible for publishing the Record of Decision.
United States Department of Justice, Civil Rights Division	• Americans with Disabilities Act compliance
United States Environmental Protection Agency (EPA) California Environmental Protection Agency (Cal-EPA)	• Spill prevention control and countermeasure plan (SPCCP) developed in accordance with United States Code of Federal Regulations (CFR), Title 40, Part 112 (40 CFR 112) • Clean Air Act and State Implementation Plan compliance • Safe Drinking Water Act compliance

Table 1-1
Anticipated Permits, Approvals and Authorizations for the NODOS Project

Jurisdiction	Responsibility
United States Fish and Wildlife Service (USFWS)	• Endangered Species Act Section 7 consultation and incidental take authorization • Fish and Wildlife Coordination Act compliance • Bald and Golden Eagle Protection Act compliance • Migratory Bird Treaty Act compliance • Wild and Scenic Rivers Act compliance
State Agency Permits, Approvals, and Authorizations	
California Air Resources Board	• Criteria pollutant standards compliance
California Department of Boating and Waterways	• California Harbors and Navigation Code compliance
California Department of Conservation	• Designating Important Farmland in the State
California Department of Fish and Wildlife (CDFW)	• Lake and Streambed Alteration Agreement permitting (pursuant to Section 1602 of the California Fish and Game Code) • California Endangered Species Act consultation and incidental take authorization (Section 2081) • Compliance with Fish and Game Code Sections related to fully protected species, birds of prey, native plant protection, invasive species, sufficient fisheries flows below dams, fish screening, and asphalt removal
California Department of Toxic Substances Control	• Compliance with generation, transportation, treatment, storage, and disposal of hazardous waste regulations
California Department of Transportation (Caltrans)	• Issuance of an encroachment and transportation permits • Approval of a transportation management plan
California Department of Water Resources (DWR)	• CEQA lead agency • Conduct environmental site assessment
California Energy Commission	• Compliance with State energy policies
California Office of Historic Preservation	• National Historic Preservation Act Section 106 consultation
California State Lands Commission (CSLC)	• Potential lease from CSLC for work in areas under CSLC jurisdiction (e.g. along Sacramento River)
California Water Commission	• Quantification of public benefits of water storage projects
Central Valley Flood Protection Board	• Levee and floodway encroachment permitting
Delta Stewardship Council	• Delta Plan consistency
Native American Heritage Commission	• Identification of sacred sites and Most Likely Descendants for Native American burials and provision of Native American contact information
Regional and Local Agency Permits, Approvals, and Authorizations	
Colusa and Glenn Counties	• Surface Mining and Reclamation Act (SMARA) permitting or exemption if borrow is required from borrow site(s) not previously permitted under SMARA.
Planning Department	• Issuance of Conditional Use Permit (CUP) • Rezoning of parcels in both counties • Conformance with CEQA environmental review requirements

Table 1-1
Anticipated Permits, Approvals and Authorizations for the NODOS Project

Jurisdiction	Responsibility
Engineering and Surveying Services Department	• Plan approval for any County road or bridge crossings at creeks or grading for structures within 50 feet from the top of creek banks; grading and drainage plan; and grading permit • Erosion control plan development and permitting • Building and electrical permitting • Development of blasting Plan for foundation and roadway installation
Environmental Health Services Department	• Septic and water system permitting
Roads Department	• Encroachment permitting • Construction traffic control plan development for County roads • Assessment of fees for increases in peak-hour trips, if required • Heavy haul permitting • Roadway damage and repair bonds
Fire Department	• Annual permitting for the use and storage of hazardous and flammable materials/wastes • Hazardous materials business plan development • Fire protection plan development
Colusa County Air Pollution Control District (CCAPCD) Glen County APCD	• Emission permitting
State Water Resources Control Board (SWRCB) and Central Valley Regional Water Quality Control Board	• Clean Water Act Section 401 certification Clean Water Act Section 402 National Pollutant Discharge Elimination System (NPDES) permitting (requirements include preparation of a construction stormwater pollution prevention plan [SWPPP] intended to comply with Glenn and Colusa County requirements) • Water rights regulation

All federal, State, regional, and local legislation and policies that were considered during impact evaluations for each of the resource chapters, or that will be used for decision making for the proposed Project, are detailed in Chapter 4 Environmental Compliance and Permit Summary of this DEIR/EIS.

Local and regional coordination has been an important part of the NODOS Project. Subsequent to the passage of the 2009 Comprehensive Water Package, local water interests and counties formed the Sites Project Joint Powers Authority (Sites JPA), which includes water districts and county governments. The Sites Project JPA became a cost-share partner of the NODOS Project when it requested and received State funding in 2011 to help support development of the DEIR/EIS. The Sites JPA is also a cooperating and responsible agency.

1.6 Notice of Preparation and Notice of Intent

DWR filed a Notice of Preparation (NOP) with the State Clearinghouse on November 5, 2001, and Reclamation published a Notice of Intent (NOI) in the *Federal Register* on November 9, 2001 to announce the intent to prepare a joint EIR/EIS for the proposed Project. The NOP/NOI notified the public of the Project proposal, announced the dates and locations of public meetings, and solicited public comments to help guide development of the EIR/EIS, pursuant to CEQA and NEPA, respectively. The NOP/NOI identified the No Project, No Action, Sites Reservoir, and Newville Reservoir alternatives for analysis. The NOP/NOI also identified other potential alternatives, including conjunctive use or Shasta Reservoir enlargement, either as stand-alone projects or in conjunction with other NODOS Project alternatives to meet the NODOS Project objectives.

1.7 Proposed Project/Proposed Action Concept

The proposed Project would consist of a new offstream storage reservoir with two main dams, up to nine saddle dams, and up to five recreation areas. The reservoir would have an associated inlet/outlet structure and would be connected to the Sacramento River by two existing screened canals and a new screened pipeline. Water conveyance between the reservoir and the canals and pipeline would be facilitated by two new regulating reservoirs and their associated pumping/generating plants. A new transmission line would connect the pumping/generating plants and their associated electrical switchyards to an existing transmission line in the proposed Project area. New roads and a bridge would be constructed to provide access to the proposed Project facilities and over the proposed reservoir, and some existing roads would be relocated or improved. The proposed Project would require modifications to an existing canal and pumping plant. A more complete description of the proposed Project can be found in Chapter 3 Description of Proposed Project/Proposed Action and Alternatives. The proposed Project would be operated generally in the following manner (Figure 1-4) to achieve Project objectives and the Project purpose:

- Runoff from tributaries entering the Sacramento River downstream of Keswick Dam, and Shasta Lake releases for flood management operations, would be diverted to the existing Red Bluff Pumping Plant (and then to the T-C Canal), to the existing GCID Pumping Plant (and then to the GCID Canal), and/or to the proposed Delevan Pipeline Intake.
- Water from the screened T-C Canal would be diverted/stored in the proposed Holthouse Reservoir Complex and conveyed to the proposed Sites Reservoir, whenever possible, until Sites Reservoir is filled.
- Water from the screened GCID Canal would be diverted/stored/pumped in the proposed Terminal Regulating Reservoir and conveyed to the proposed Sites Reservoir, whenever possible, until Sites Reservoir is filled.
- Water from the proposed screened Delevan Pipeline Intake would be diverted/stored/pumped in the pumping plant and forebay, and would be conveyed to the proposed Holthouse Reservoir, and to the proposed Sites Reservoir, whenever possible, until Sites Reservoir is filled.
- Water would be released from the proposed Sites and Holthouse reservoirs via the proposed Delevan Pipeline and its associated intake/discharge facilities to the Sacramento River, and electricity would be generated for action alternatives that have a pumping/generating plant at the proposed Delevan Pipeline Intake Facilities.
- Water would be released from the proposed Sites and Holthouse reservoirs to the T-C Canal for diversion to water users, and electricity would be generated.
- Water would be released from the proposed Sites and Holthouse reservoirs to the proposed Terminal Regulating Reservoir and the GCID Canal for diversion to downstream water users, and electricity would be generated.

- Because water would be diverted from the Sacramento River through fish screens to the proposed Sites Reservoir, and releases would be made from the proposed Sites Reservoir back to the Sacramento River and to T-C Canal and GCID Canal water users, operations of existing SWP and CVP facilities throughout the state could be modified to improve flow and water quality conditions for the benefit of anadromous and endemic fish populations; municipal, industrial, and agricultural water users; and wildlife refuges.

DWR and Reclamation developed three action alternatives to meet the primary objectives of the proposed Project. The process that was used to develop the alternatives is described in Chapter 2 Alternatives Analysis. Maps and detailed descriptions of the three action alternatives are provided in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives.

1.8 Proposed Project/Proposed Action Location

The proposed Sites Reservoir would be located in Antelope Valley, approximately 10 miles west of the town of Maxwell, in both Glenn and Colusa counties. Other proposed Project facilities would be located in Tehama, Glenn, or Colusa counties (Figure 1-5).

1.9 Study Areas

The proposed Project has the potential to influence SWP and CVP system operations and water deliveries over a large geographic area. To effectively evaluate the effects of the proposed Project's three action alternatives on environmental resources in different geographic regions, DWR and Reclamation identified three study areas to be evaluated in this DEIR/EIS: the Extended, Secondary, and Primary study areas.

The Extended Study Area, consisting of the SWP and CVP service areas, is the largest and most diverse of the three study areas in terms of size, geography, land use, and habitat conditions. As such, it has been described and evaluated in the resource chapters of this document (Chapters 6 through 31) at the lowest level of detail. The Secondary Study Area is smaller than the Extended Study Area and consists of the SWP and CVP facilities that could be affected by proposed Project operations; this study area has been described and evaluated in the resource chapters in more detail than for the Extended Study Area. The Primary Study Area includes the proposed Project facilities and the land immediately surrounding them that would be included in the proposed Project boundary (referred to in this document as the Project Buffer); as such, this study area is the focus of the resource evaluations in this DEIR/EIS. These three study areas are described in more detail below and are shown in Figure 1-6.

1.9.1 Extended Study Area

The Extended Study Area includes the entire service areas of the SWP and CVP. These two service areas are located within all or portions of the following 39 counties: Alameda, Butte, Calaveras, Colusa, Contra Costa, El Dorado, Fresno, Glenn, Imperial, Kern, Kings, Los Angeles, Madera, Merced, Monterey, Napa, Nevada, Orange, Placer, Plumas, Riverside, Sacramento, San Benito, San Bernardino, San Diego, San Joaquin, San Luis Obispo, Santa Barbara, Santa Clara, Santa Cruz, Shasta, Solano, Stanislaus, Sutter, Tehama, Tulare, Tuolumne, Ventura, and Yolo. The proposed Project's purpose of improved water supply reliability has the potential for long-term direct and indirect effects within these two service areas. The Extended Study Area would also include wildlife refuges that could receive Level 4 water supply from the proposed Project. Those wildlife refuges, which are located within seven counties in the Extended Study Area, are shown on Figure 1-7.

1.9.2 Secondary Study Area

The Secondary Study Area is defined as the area of potential operational effects, including SWP and CVP facilities that could experience water surface elevation fluctuations or stream flow changes. Those facilities are located within the following 22 counties: Alameda, Butte, Colusa, Contra Costa, Del Norte, El Dorado, Glenn, Humboldt, Marin, Placer, Sacramento, San Francisco, San Mateo, Santa Clara, Shasta, Solano, Sonoma, Sutter, Tehama, Trinity, Yolo, and Yuba.

Operational changes could occur as a result of the coordinated and integrated operation of the proposed Project's facilities with those State and federal projects located on the American River, Trinity River, Sacramento River, Clear Creek, Spring Creek, Feather River, and the Delta. The Secondary Study Area is shown on Figure 1-8.

1.9.3 Primary Study Area

The Primary Study Area is defined as the areas within Glenn and Colusa counties where short-term and long-term direct effects from constructing, operating, and/or maintaining proposed Project facilities may occur. This study area includes the footprints of the proposed Sites Reservoir Inundation Area and other proposed facilities (e.g., dams, intakes/discharge facilities, fish screens, pipelines, transmission line, pumping/generating plants, recreation areas, road relocation areas, borrow areas, and associated facilities). It also includes the construction disturbance areas, i.e., the footprint of each proposed facility plus the area around each facility that would be disturbed over the short-term by Project-related construction activities, vehicles, and equipment. The Primary Study Area also includes the land parcels that surround those Project facilities; these parcels would be purchased but not developed for the proposed Project and are referred to as the "Project Buffer".

DWR and Reclamation have developed three action alternatives (Alternatives A, B, and C which are described in Chapter 2 Alternatives Analysis) to meet the purpose, need, and objectives of the proposed Project. There are differences in the facilities associated with the three alternatives; therefore, the Primary Study Areas for the three alternatives also differ. The Primary Study Areas associated with Alternatives A, B, and C are shown on Figure 1-9A, Figure 1-9B, and Figure 1-9C, respectively. Detailed descriptions of each proposed Project facility are provided in Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives.

1.10 Areas of Controversy/Issues to be Resolved

The following areas of controversy and issues to be resolved have been identified to date through stakeholder meetings or during the preparation of this DEIR/EIS:

- **Impacts on Terrestrial Biological Resources:** Golden eagles have been identified as foraging within the proposed Sites Reservoir Inundation Area and nesting within the proposed recreation areas. USFWS has expressed concern about the potential loss of nesting and foraging habitat for golden eagles, which are protected by the Bald and Golden Eagle Protection Act.
- **Impacts on Project Area Property Owners:** Project development would require the demolition of existing structures, acquisition of private property, and relocation of displaced parties. These actions concern property owners within the Primary Study Area.

1.11 Public Review of the Draft EIR/EIS

This DEIR/EIS is being circulated to local, State, and federal agencies**,** as well as to interested organizations and individuals who may wish to review and comment on it. The DEIR/EIS and a Notice of Completion (NOC) has been filed with the Office of Planning and Research, State Clearinghouse; has been publicly noticed in the *Federal Register* and XX newspapers; and is currently being circulated for a review period of 90 days. During this review period, written comments may be submitted to the DWR and Reclamation representatives listed in Section 1.1 of this chapter.

Comments received in response to the DEIR/EIS will be addressed in a Response to Comments addendum document which, together with the revised DEIR/EIS text, will constitute the FEIR/EIS. DWR will provide a written proposed response to a public agency on comments made by that agency at least 10 days prior to certifying the EIR (Reclamation will provide such comments at least 30 days prior to certifying the EIS as required by NEPA). DWR will then review the proposed Project, the EIR, and the public testimony, and decide whether to certify the EIR and adopt any findings and statements of overriding significance before deciding whether to approve or deny the proposed Project. If the proposed Project is approved, DWR will file a Notice of Determination (NOD) with the Governor's Office of Planning and Research, State Clearinghouse within five days of Project approval. This filing will trigger a 30-day period in which a legal challenge to the document may be filed.

Concurrent with this CEQA process, Reclamation will consider the EIS and Proposed Action, and may issue a ROD for the proposed Project and publish it in the Federal Register.

1.12 Organization of the DEIR/EIS

This DEIR/EIS includes the following chapters:

- **Executive Summary:** This chapter provides a summary of the Project description, a description of issues to be resolved and areas of controversy, the significant environmental impacts that would result from implementation of the alternatives, and mitigation proposed to reduce or eliminate those impacts.
- **Chapter 1 Introduction:** This chapter describes the purpose, need, objectives, authorization, location of the alternatives being evaluated, and the three study areas; provides an overview of the environmental review process and background for the proposed Project; summarizes the intended use of the EIR/EIS, and lists the areas of controversy and issues to be resolved.
- **Chapter 2 Alternatives Analysis:** This chapter describes the approach used to develop the action alternatives that are evaluated in this DEIR/EIS, including a discussion of the evaluation of alternative reservoir locations, reservoir sizes, and conveyance alternatives. It also describes Existing Conditions and the No Project/No Action Alternative.
- **Chapter 3 Description of Proposed Project/Proposed Action and Alternatives:** This chapter describes in detail the proposed Project facilities included in the action alternatives (Alternatives A, B, and C), and describes Project operation for each of the action alternatives.
- **Chapter 4 Environmental Compliance and Permit Summary:** This chapter presents the regulatory framework for the resources chapters (Chapters 6 through 31).

- **Chapter 5 Guide to Resources Analysis:** This chapter describes the process used to develop the environmental setting (i.e., affected environment) and evaluate the environmental impacts (i.e., environmental consequences) of implementing the alternatives, defines types of impacts and levels of significance, describes mitigation measure development and eliminated topics, and summarizes the modeling tools and analytical methods that were used for each resource analysis.
- **Chapters 6 through 31 Resource Chapter Evaluations:** These chapters include descriptions of the environmental setting (i.e., affected environment), contain assessments of the potential impacts of each of three alternatives within each of three study areas, and list mitigation measures for identified significant and potentially significant impacts, where appropriate, for the following resources:
  - Surface Water Resources
  - Surface Water Quality
  - Fluvial Geomorphology and Riparian Habitat
  - Flood Control and Management
  - Groundwater Resources
  - Groundwater Quality
  - Aquatic Biological Resources
  - Botanical Resources
  - Terrestrial Biological Resources
  - Wetlands and Other Waters of the U.S.
  - Geology, Minerals, Soils, and Paleontology
  - Faults and Seismicity
  - Cultural Resources
  - Indian Trust Assets
  - Land Use
  - Recreation Resources
  - Socioeconomics
  - Environmental Justice
  - Air Quality
  - Climate Change and Greenhouse Gas Emissions
  - Navigation, Transportation, and Traffic
  - Noise
  - Public Health and Environmental Hazards
  - Public Services and Utilities
  - Visual Resources
  - Power Production and Energy
- **Chapter 32 Short-term Uses vs. Long-term Productivity:** This chapter describes the short-term uses vs. long-term productivity of the proposed Project.
- **Chapter 33 Irreversible or Irretrievable Commitments of Resources**: This chapter describes the irreversible or irretrievable commitments of resources associated with the proposed Project.
- **Chapter 34 Growth-Inducing Impacts**: This chapter describes the growth-inducing impacts associated with the proposed Project.
- **Chapter 35 Cumulative Impacts**: This chapter describes the cumulative impacts of the proposed Project.

- **Chapter 36 Consultation and Coordination:** This chapter describes the public scoping process and the agencies and organizations that have been consulted throughout the process of the NODOS Investigation.
- **Chapter 37 References:** This chapter lists the sources of information used to prepare the DEIR/EIS. All references are listed by the chapter in which they were cited.
- **Chapter 38 List of Preparers and Contributors:** This chapter lists the individuals who participated in the preparation of this DEIR/EIS, and provides the qualifications for those individuals, in order of organization and agency.
- **Chapter 39 EIR/EIS Distribution List:** This chapter lists the elected officials; governmental departments; federal, tribal, State, and local agencies; special interest groups; and individuals who received notice of availability of this DEIR/EIS.
- **Appendixes:** The appendixes are located at the back of this DEIR/EIS and are listed in the Table of Contents

1.13 Preparers of the DEIR/EIS

This DEIR/EIS has been prepared by a multi-disciplinary team at the direction of the two lead agencies: DWR and Reclamation. Additionally, the lead agencies have actively solicited input and review from cooperating and responsible agencies, notably USFWS, NMFS, CDFW, SWRCB, Central Valley Regional Water Quality Control Board, Sites JPA, Colusa Indian Community Council, Western Area Power Administration (WAPA), USACE, Bureau of Indian Affairs (BIA), and Cortina Indian Rancheria, described in Chapter 36 Consultation and Coordination. Throughout the DEIR/EIS preparation process, input has been solicited and considered from affected parties and agencies, including local governments, interest groups, and individuals. Chapter 38 List of Preparers and Contributors provides a comprehensive list of the individuals involved in the preparation of the DEIR/EIS, and Chapter 39 EIR/EIS Distribution List provides a list of parties that requested to be involved in the proposed Project in some manner.

2. Alternatives Analysis

2.1 Introduction

CEQA Guidelines Section 15126.6 requires that an EIR describe and evaluate a reasonable range of alternatives that would feasibly meet most of the basic project objectives but would avoid or substantially lessen significant Project impacts. CEQA also requires that an EIR evaluate the “No Project” alternative along with its impacts. An EIR need only examine in detail alternatives that the lead agency determines could feasibly attain most of the objectives of the project and would avoid or substantially lessen at least one of the significant environmental effects of the project.

The National Environmental Policy Act’s (NEPA’s) implementing regulations are administered by the Council on Environmental Quality (CEQ) (40 CFR 1500 et seq.). Section 1502.14 of the CEQ Regulations for Implementing NEPA requires that an EIS rigorously explore and objectively evaluate all reasonable alternatives to the project, including a No Action Alternative and reasonable alternatives not within the jurisdiction of the lead agency. Additionally, NEPA requires that an EIS devote substantial treatment to each alternative considered in detail, including the proposed action, so that reviewers may evaluate their comparative merits.

This chapter summarizes the alternatives development process and alternatives analysis for the NODOS Project. A more detailed description of this comprehensive and iterative process is included in the NODOS Project Feasibility Report.

The proposed Project is defined as north-of-the-Delta offstream storage that should achieve, as much as possible, the following objectives: 1) Improve water supply reliability for agricultural, urban, and environmental uses, 2) Increase survival of anadromous and endemic fish populations, 3) Improve environmental and drinking water quality in the Delta, 4) Provide flexible hydropower generation to support integration of renewable energy sources, 5) Develop additional recreation opportunities, and 6) Provide incremental flood damage reduction opportunities.

2.2 Approach to Alternatives Analysis

2.2.1 Overview of the Alternatives Analysis

The NODOS Project alternatives analysis was completed in phases. The study of the NODOS Project was originally derived from the CALFED Bay-Delta Program’s (CALFED Program) identification of a range of activities that, if implemented, could concurrently improve the quality and reliability of California’s water supplies as well as ecosystem conditions and levee integrity in the Sacramento-San Joaquin Delta. Among many recommended activities, the CALFED Program identified the need for an additional 3.0-MAF of storage north of the Delta to meet environmental and water supply needs. The CALFED Program also expressed a preference for offstream over onstream storage to avoid redirected impacts to fisheries and other aquatic species. The CALFED Program initially identified 52 potential surface storage locations[1] but retained only 12 reservoir locations statewide for further study (CALFED, 2000). For a

[1]The results of this inventory are presented in the March 7, 1997 draft report, *CALFED Bay-Delta Program Storage and Conveyance Component Inventories* (CALFED, 1997). The inventory includes 51 potential surface water storage sites. Subsequently, the August 2000 *CALFED Initial Surface Water Storage Screening Report* added the San Luis Enlargement to the list of potential sites.

summary of the CALFED Program Inventory of Potential Surface Water Storage Sites, refer to Appendix 2A. Red Bank, Newville, Colusa, and Sites are four (of the 12) reservoir locations that are offstream and located north of the Delta. Consistent with these recommendations, DWR initiated studies of the four north-of-the-Delta offstream storage alternatives in 1997.

The consideration and evaluation of these four alternatives is described below. DWR and Reclamation eliminated the Red Bank and Colusa alternatives based upon a comparison of environmental effects and feasibility considerations, which are documented in the 2000 NODOS Investigation Progress Report and in the 2006 NODOS Initial Alternatives Information Report. This allowed DWR and Reclamation to compare and evaluate the No Project/No Action Alternative, the Newville Reservoir Alternative, and the Sites Reservoir Alternative in greater detail, consistent with NEPA and CEQA requirements. Based on the detailed evaluation of these alternatives, the Sites Reservoir Alternative was selected as the preferred proposed project alternative.

DWR and Reclamation have also completed a more detailed evaluation of effects, consistent with CEQA and NEPA requirements, of three configurations of Sites Reservoir, hereafter called Alternative A, Alternative B, and Alternative C. The results and conclusions of these evaluations are found in Chapters 6 through 35. For purposes of CEQA, these alternatives should be considered as three variations of the Sites Reservoir Alternative (i.e. the preferred Project alternative). For NEPA purposes, Alternative A, Alternative B, Alternative C, and the No Project/No Action Alternative were evaluated in detail in accordance with the Council on Environmental Quality regulation 1502.14b.

2.2.2 Alternatives Considered

The four north-of-the-Delta offstream storage reservoir alternatives are described below and are shown on Figure 2-1:

- **Red Bank Alternative:** The Red Bank Alternative would be located approximately 17 miles west of the City of Red Bluff in Tehama County. This project would be comprised of a 104-TAF Dippingvat Reservoir on South Fork Cottonwood Creek, and a 250-TAF Schoenfield Reservoir on Red Bank Creek. The primary source of water would be from South Fork Cottonwood Creek, with water diverted from Dippingvat Reservoir to Schoenfield Reservoir. Two small dams and reservoirs, Lanyan and Bluedoor, would be located on small tributaries of Red Bank Creek and would be part of the conveyance from Dippingvat to Schoenfield. Dippingvat Reservoir would be an onstream storage facility used for short-term storage and diversion; Schoenfield is considered to be an offstream storage facility. This alternative location was designed to allow water stored in Schoenfield Reservoir to be released down Red Bank Creek directly into the Tehama-Colusa Canal intake. The Red Bank Alternative was conceived to provide an alternative water supply to the Tehama-Colusa Canal which would not require operation of the Red Bluff Diversion Dam (RBDD) during critical fish passage periods (estimated to be approximately two months per year).
- **Newville Reservoir Alternative:** The Newville Reservoir Alternative would be located upstream from Black Butte Reservoir, approximately 18 miles west of the City of Orland and 23 miles west-southwest of the City of Corning in Glenn and Tehama counties. Alternative reservoir sizes of 1.9-MAF and 3.0-MAF were considered. The 1.9-MAF reservoir would be formed by a dam on North Fork Stony Creek and a saddle dam at Burrows Gap. The 3.0-MAF reservoir would require up to five additional saddle dams and a dike. A small diversion dam and diversion from Thomes Creek would transfer water to the reservoir. Other water source options include Stony Creek and the Sacramento

River. Multiple conveyance options would be possible using existing infrastructure (e.g., canals), new infrastructure (e.g., canals, tunnels, and/or pipelines), or a combination of new and existing facilities.

- **Sites Reservoir Alternative:** The Sites Reservoir Alternative, which would be located in Antelope Valley, approximately 10 miles west of the town of Maxwell in Glenn and Colusa counties, would be formed by constructing two major dams on Stone Corral Creek and Funks Creek. Evaluation of the Sites Reservoir Alternative focused on a 1.8-MAF reservoir that would also require the construction of nine saddle dams along the southern edge of the Hunters Creek watershed. Diversions from the Colusa Basin Drain (CBD), the Sacramento River, and local tributaries could provide potential sources of water supply for Sites Reservoir. Multiple conveyance options would be possible, with 13 optional conveyance systems (using existing and new conveyance infrastructure) from the Sacramento River, two from CBD, and two from Stony Creek.

- **Colusa Reservoir Alternative:** The Colusa Reservoir Alternative would be located in north-central Colusa County and south-central Glenn County, approximately 12 miles southwest of the community of Willows and 10 miles west of Maxwell. The Colusa Reservoir Alternative, a 3.0-MAF storage project, would include the area inundated by the 1.8-MAF Sites Reservoir (described above) plus the adjacent Logan Creek and Hunters Creek watersheds to the north (known as the Colusa Cell). The Colusa Cell would require four major dams along Logan Ridge in addition to those described for Sites Reservoir: one for Logan Creek and three for Hunters Creek and its tributaries. The Colusa Cell would add up to 67 percent greater storage capacity to Sites Reservoir. Water source and conveyance options for diversion and delivery to offstream storage would be similar to those for Sites Reservoir. Diversions from the Colusa Basin Drain (CBD), the Sacramento River, and local tributaries would provide potential sources of water supply for the Colusa Reservoir Alternative. Multiple conveyance options would be possible using existing infrastructure (e.g., canals), new infrastructure (e.g., canals, tunnels, and/or pipelines), or a combination of new and existing infrastructure.

Previous studies, going back as far as the 1940s, were conducted at each of the four reservoir alternative locations. Data gathered during the NODOS Investigation was used to supplement those studies to allow for comparative evaluation of the alternatives. During the NODOS Investigation, geology, geotechnical, and engineering studies were conducted. Wetland delineations and cultural resources surveys were also conducted, as well as studies of the following environmental resources: vernal pool species, rare plants, plant communities, valley elderberry longhorn beetles, mammals, birds, fish, amphibians, and reptiles. Studies were conducted at similar levels of effort for each reservoir alternative and focused primarily on the reservoir footprints. The results of these studies were summarized in the July 2000 *North of the Delta Offstream Storage Investigation Progress Report* (DWR 2000). Environmental resources data collected for the four reservoir alternatives for the 2000 Progress Report are summarized in Tables 2-1 through 2-9.

2.2.3 Alternatives Considered but Rejected from Further Consideration

Following an evaluation of the results of the NODOS Investigation Progress Report (DWR, 2000), the Red Bank and Colusa alternatives were eliminated from further consideration. The reasons for eliminating these two alternatives are provided below.

2.2.3.1 Red Bank Alternative

The following issues contributed to the decision to eliminate the Red Bank Alternative from further consideration:

- Because the primary storage for the Red Bank Alternative (Schoenfield Reservoir) would be offstream, the Red Bank Alternative was initially retained. However, the supply source (Dippingvat Reservoir) would be onstream, which would result in greater environmental impacts and implementation challenges. If Dippingvat Reservoir was removed from the alternative, another water supply source would be needed to fill Schoenfield Reservoir, and the storage volume of the Red Bank Alternative would be reduced to 0.25-MAF. This reduced storage volume would reduce the alternative's ability to provide broad benefits (when compared to the other location alternatives considered). In addition to the small storage capacity, initial geotechnical investigations indicated the potential for excessive reservoir leakage.

- The Red Bank Alternative location has greater habitat diversity than the other locations considered. More than 60 percent of the Red Bank Alternative location consists of blue oak-foothill pine habitat and approximately 20 percent consists of blue oak woodland habitat. In comparison, approximately 99, 85, and 89 percent of the Colusa, Newville, and Sites reservoir alternative locations, respectively, are dominated by annual grassland habitat. Consequently, the Red Bank Alternative site is able to support numerous wildlife species, and supports a relatively high winter deer use compared to the other locations.
- Cottonwood Creek is the largest undammed tributary in the upper Sacramento River Basin and is the most important source of sediments to the Sacramento River. These sediments are necessary for river meander, riparian recruitment, and spawning habitat. The Red Bank Alternative would substantially reduce sediment contributions to the Sacramento River.
- The South Fork of Cottonwood Creek also provides spawning habitat for fall-run and late-fall-run Chinook salmon, and supports spring-run Chinook salmon in some years. In addition to these potential fishery impacts, the California red-legged frog, federally listed as threatened, was observed during field surveys. As evaluated, this alternative would result in significant and unavoidable adverse effects to spring-run Chinook salmon and steelhead on the South Fork Cottonwood Creek.

Because of the potential for greater environmental impacts, the Red Bank Alternative was not recommended for further consideration. In addition, the conceptual purpose of the Red Bank Alternative was to supply the Corning and T-C canals early in the irrigation season, which would allow the RBDD gates to be raised an additional month or more. Subsequent to the elimination of the Red Bank Alternative from further consideration, NMFS released a Biological Opinion (2000) that requires phasing out the use of the RBDD gates. Construction of the Red Bluff Diversion Dam Fish Passage Improvement Project, which allows the RBDD gates to remain open permanently, was completed in September 2012. This new infrastructure and required operational change makes the proposed Red Bank Alternative obsolete.

2.2.3.2 Colusa Reservoir Alternative

The following issues contributed to the decision to eliminate the Colusa Reservoir Alternative from further consideration:

- The Colusa Reservoir Alternative surface area (28,000 acres) would be two times larger than the surface area of the Sites Reservoir Alternative (14,000 acres). Colusa's larger reservoir footprint (1.9 times the 1.9-MAF (14,500 acres) and 1.6 times the 3.0-MAF (7,000 acres) Newville Reservoir options), and its larger facilities would have an overall greater environmental impact than the other smaller reservoir alternatives.
- The potential reservoir size of the Colusa, Newville, and Sites alternatives were compared with respect to their capital construction cost for reservoir storage, yield, and unit cost of storage per deliverable Project yield. This comparison helped identify, on an annualized basis, the relative cost-effectiveness of each measure. The total capital storage cost (in 2004 dollars) for Sites Reservoir (1.8-MAF) was estimated at $320,250,000; Colusa Reservoir (3.0-MAF) at $1,411,520,000; and Newville Reservoir (1.9-MAF) at $235,134,000. Colusa Reservoir's high total capital storage cost (4.4 to 6.0 times the cost of the Newville and Sites reservoir alternatives respectively) made the Colusa Reservoir Alternative the least cost effective alternative.
- A preliminary economic assessment was conducted to compare the average annual cost of storage per yield for the three reservoirs. The estimated average annual cost per yield would be similar in

magnitude for the Sites Reservoir Alternative ($64 per acre-feet) and the Newville Reservoir Alternative ($47 per acre-feet), but would be comparatively excessive for the Colusa Reservoir Alternative ($235 per acre-feet). The Sites Reservoir Alternative's average annual cost for storage per unit yield would be approximately 36 percent greater than the Newville Reservoir Alternative. The Colusa Reservoir Alternative's average annual cost for storage per unit yield would be approximately 367 percent greater than the Sites Reservoir Alternative and approximately 500 percent greater than Newville Reservoir Alternative, while the increase in yield between the Colusa Reservoir Alternative and the Sites and Newville reservoir alternatives would only be approximately 19 percent.

All of the environmental and cultural resources effects of the Colusa Reservoir Alternative would be additive to those of the Sites Reservoir Alternative, as the Colusa Reservoir Alternative includes the entire reservoir footprint of the Sites Reservoir Alternative. These potential environmental effects would include substantial additional loss of wildlife habitat (13,664 acres) and impacts to wetlands and waters of the U.S., including an additional loss of 444 acres of waters of the U.S. above those identified for the 1.8 MAF Sites Reservoir Alternative. All other environmental effects would be additive to those of the 1.8 MAF Sites Reservoir Alternative. The Colusa Reservoir Alternative was determined to be infeasible due to cost, and undesirable based on substantially greater environmental effects as compared to either the Sites or Newville reservoir alternatives. Additionally, comparatively the Colusa Reservoir Alternative would fail to substantially lessen any significant effects. Because of this comparative lack of efficiency and greater environmental impact, the Colusa Reservoir Alternative was not recommended for further consideration.

2.3 Alternatives Selected for Analysis

The Sites and Newville reservoir alternatives were retained for further consideration. In addition, a No Project Alternative and No Action Alternative were added for consideration.

2.3.1 Background

DWR and Reclamation retained both the Sites and Newville reservoir alternatives for further analysis, as both alternatives were considered technically feasible and not enough data had been gathered to provide a meaningful comparison between the two alternatives. The NODOS Investigation continued engineering, geologic, environmental, and cultural resource data collection on the reservoir footprints. Additionally, these evaluations were expanded to include other major project facilities including diversions, conveyance routes, road relocations, recreation areas, and regulating reservoirs for both the Sites and Newville reservoir alternatives. These data allowed a more complete and robust comparison of the environmental effects of the two alternatives. DWR's November 5, 2001 Notice of Preparation (NOP) and Reclamation's November 9, 2001 Notice of Intent (NOI) indicated that the No Project, No Action, Sites Reservoir, and Newville Reservoir alternatives would be analyzed in the NODOS Project EIR/EIS. Reclamation's NOI also allowed for the evaluation of other alternatives to meet NODOS Project objectives, including conjunctive use or Shasta Reservoir enlargement, either as stand-alone projects or in conjunction with other NODOS Project alternatives.

Subsequent evaluations by other programs determined that the potential for conjunctive use is limited because Sacramento Valley groundwater basins recharge annually, leaving no space for operable storage (NHI and GCID 2011; URS 2007). Conjunctive use was, therefore, not retained as a feasible alternative.

Reclamation is investigating Shasta Lake enlargement as part of its Shasta Lake Water Resources Investigation. State involvement in this project is effectively barred by Public Resources Code section 5093.542, which authorizes DWR to participate in studies involving the technical and economic feasibility of enlargement of Shasta Dam but otherwise prohibits DWR or any State department or agency to assist or cooperate with any other entity on a project "…that could have an adverse effect on the free-flowing condition of the McCloud River, or on its wild trout fishery." As a result, Shasta Lake enlargement was not retained as a feasible alternative to meet NODOS Project objectives. Along with the No Project/No Action alternative, the Sites and Newville reservoir alternatives were retained for further analysis.

The alternatives were evaluated based on their ability to meet the following NODOS Project primary and secondary objectives (Table 2-10).

Table 2-10
North-of-the-Delta Offstream Storage Project Primary and Secondary Planning Objectives*

Primary Objectives	Secondary Objectives
Improve water supply reliability for agricultural, urban, and environmental uses.	Develop additional recreation opportunities in the study area
Improve environmental and drinking water quality in the Delta.	Provide incremental flood damage reduction opportunities
Increase survival of anadromous fish populations, as well as the health and survivability of other aquatic species	
Provide flexible hydropower generation to support integration of renewable energy sources	

*Primary planning objectives are the first priority that Project alternatives must address; Secondary planning objectives are opportunities that should be considered, to the extent possible, while meeting the Primary objectives.

Source: DWR and Reclamation, 2008.

The alternatives retained for further analysis are described below.

2.3.2 No Project/No Action Alternative

Existing Conditions, the No Project Alternative, and the No Action Alternative are described below to explain how the No Project/No Action Alternative was developed. The nature of the CEQA No Project Alternative and NEPA No Action Alternative are discussed briefly and separately below, but because the alternatives are, in this case, the same, all subsequent references will be to the No Project/No Action Alternative.

2.3.2.1 Existing Conditions

The CEQA Baseline for assessing significance of impacts of the proposed Project is the environmental setting, or Existing Conditions, at the time a NOP is issued, as provided for in CEQA Guidelines section 15125. However, the CEQA lead agency has the discretion, where appropriate, to fully or partially update baseline conditions beyond the time of the issuance of the NOP. The CEQA Baseline is developed to assess the significance of impacts of the proposed Project in relation to the actual environment upon which the proposed Project will operate. Generally, this environment is represented by conditions that exist at the time the NOP is issued. However, if the preparation of the EIR occurs over many years, it may be more relevant to expand the definition to include programs, projects, or policies that have been implemented during the preparation of the EIR.

The NOP for the proposed Project was published on November 5, 2001. However, because the preparation of this environmental document has occurred over many years, it was deemed necessary to update the baseline condition to June 2009 to include programs, projects, or policies that have been implemented during the document's preparation. Changes in the regulatory environment since November

2001 have fundamentally changed water management in California and necessitate updating the baseline conditions for environmental analyses in this DEIR/EIS. These changes include the issuance of new biological opinions (BO) by the U. S. Fish and Wildlife Service (USFWS) in December 2008 and the National Marine Fisheries Service (NMFS) in June 2009 on the operations of the State Water Project and Central Valley Project. Consequently, June 2009 (following the release of NMFS' BO) was selected as the proposed Project's Existing Conditions date.

2.3.2.2 No Project Alternative

CEQA requires an analysis of an alternative in which the proposed Project is not implemented. CEQA calls this scenario the No Project Alternative. The No Project Alternative allows decision-makers to use the EIR to compare the impacts of approving the proposed Project with the future conditions of not approving the proposed Project. Under CEQA, the No Project Alternative is the baseline for assessing the significance of impacts of the proposed Project (CEQA Guidelines section 15126.6 subsection (c) (1)). Analysis of the No Project Alternative proceeds along different lines depending upon the nature of the project. Where, as here, the project is a development project on identifiable property, the "no project" alternative is the circumstance under which the project does not proceed (CEQA Guidelines section 15126.6 subsection (e) (3)(B)). The No Project Alternative compares the environmental effects of the property remaining in its existing state against environmental effects which would occur if the project is approved.

CEQA Guidelines section 15126.6, subdivision (e)(2), indicates that No Project conditions include reasonably foreseeable changes in Existing Conditions and changes that would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services.

Many of the reasonably foreseeable programs and projects included within the No Project Alternative will affect water supply, water quality, or anadromous fisheries. To clearly identify and separate the environmental effects of these reasonably foreseeable projects and programs included under the No Project Alternative, this DEIR/EIS includes analyses of both the Existing Conditions and the No Project Alternative compared to the proposed Project.

2.3.2.3 No Action Alternative

Similar to CEQA, NEPA also requires an analysis of an alternative in which the proposed Project is not implemented. The NEPA Baseline for assessing environmental effects, including cumulative effects, of the proposed Project and alternatives is defined as the No Action Alternative. The No Action Alternative also demonstrates the future consequences of not meeting the need of the proposed Project. The No Action Alternative generally focuses on programs, projects, or policies that would affect or be affected by the proposed Project or the alternatives. The No Action Alternative represents a projection of current conditions to reasonably foreseeable future conditions that could occur if the proposed Project or alternatives are not implemented. The No Action Alternative includes Existing Conditions and future actions that are authorized; approved through completion of NEPA, CEQA, and Endangered Species Act compliance processes; funded; and permitted.

The No Action Alternative assumptions are consistent with the requirements and limitations prescribed by CEQA; therefore, analysis of the No Action Alternative is the same as for the No Project Alternative, and the two are treated as one alternative in this document. The No Project/No Action Alternative assumptions include the assumptions related to the State Water Project (SWP) and Central Valley Project (CVP), ongoing programs and policies by governmental and nonprofit entities, and assumptions related to annual actions that vary every year. The No Project/No Action Alternative includes projects and programs with clearly defined management and/or operational plans, including facilities being constructed as of June 2009[2]. The No Project/No Action Alternative also includes projects and programs that received approvals and permits in 2009 to remain consistent with existing management direction. Those actions are consistent with the continuation of existing management direction or level of management for plans, policies, and operations by the lead agencies and other agencies. Table 2-11 provides a summary of SWP and CVP operations included in the No Project/No Action Alternative.

Table 2-11
Summary of SWP and CVP Operations Included in the No Project/No Action Alternative

Non-SWP and CVP Project: Water Rights: Pursuant to water rights and SWRCB Decision for Existing Facilities
Federal and State Refuges with Level 2 Water Supplies: Firm Level 2 water needs
Level 4 Refuge Supplies: Met through water acquisition by Reclamation
American River Demands: Water Rights: Full water rights CVP Contracts: Full contracts, including Freeport Regional Water Project
Operations of SWP Facilities: Existing Facilities with NMFS BO and USFWS BO conditions FERC License Renewal for Oroville Project South Bay Aqueduct Improvement and Enlargement Project
Operations of CVP Facilities: Existing Facilities with NMFS BO and USFWS BO conditions New Red Bluff Diversion Dam Fish Passage Improvement Facilities Interim implementation for San Joaquin River Restoration Plan Freeport Regional Water Project Delta Mendota Canal-California Aqueduct Intertie
Operations of non-CVP Facilities: City of Stockton Delta Water Supply Project Contra Costa Water District's Middle River Intake and Pump Station (previously known as the Alternative Intake Project) Contra Costa Fish Screen Project (Rock Slough) Los Vaqueros Reservoir Expansion to 160 TAF of total storage capacity (60 TAF increase in storage capacity over existing capacity of 100 TAF) Full implementation of Grasslands Bypass Project

Notes:
NMFS = National Marine Fisheries Service
TAF = thousand acre-feet
USFWS = U.S. Fish and Wildlife Service

The projects and programs that are included in the No Project/No Action Alternative are summarized in Table 2-12. For a more detailed description of each project or program included in the No Project/No Action Alternative, refer to Appendix 2B.

The No Project/No Action Alternative includes continued implementation of operations, maintenance, enforcement, and protection programs by federal, State, and local agencies and non-profit groups, as summarized in Table 2-13, and described in detail in Appendix 2C.

[2] The lead agencies have established June 2009 as the Existing Conditions date; it is characterized in Chapters 6 through 31 as the Environmental Setting/Affected Environment discussion.

Table 2-12
Projects and Programs Included in the No Project/No Action Alternative

Agency	Project/Program	Comments
California Department of Water Resources	Mayberry Farms Subsidence Reversal and Carbon Sequestration Project	Completed in 2010.
Contra Costa Water District	Contra Costa Canal Fish Screen Project	Completed in late 2011.
Contra Costa Water District, Bureau of Reclamation, and California Department of Water Resources	Middle River Intake and Pump Station (previously known as the Alternative Intake Project)	Completed in July 2010.
California Department of Water Resources	Federal Energy Regulatory Commission License Renewal for Oroville Project	Final EIR in 2008. FERC license will be issued and operations will be in accordance with NMFS BO.
Freeport Regional Water Authority and U.S. Bureau of Reclamation	Freeport Regional Water Project	Completed in 2011.
Reclamation District 2093	Liberty Island Conservation Bank	Being implemented. Permits and approvals acquired in 2009.
City of Stockton	Delta Water Supply Project - Phase I	Completed in 2012.
U.S. Bureau of Reclamation and State Water Resources Control Board	Battle Creek Salmon and Steelhead Restoration Project	Construction started in 2009. Estimated completion in 2014.
Tehama Colusa Canal Authority and U.S. Bureau of Reclamation	Red Bluff Diversion Dam Fish Passage Improvement Project	Completed in September 2012.
U.S. Bureau of Reclamation, California Department of Fish and Wildlife, and Natomas Central Mutual Water Company	American Basin Fish Screen and Habitat Improvement Project	Estimated completion in 2014.
U.S. Bureau of Reclamation	Delta-Mendota Canal/California Aqueduct Intertie	Completed in April 2012.
U.S. Bureau of Reclamation, U.S. Army Corps of Engineers, Sacramento Area Flood Control Agency, and Central Valley Flood Protection Board	Folsom Dam Safety and Flood Damage Reduction Project	Being constructed. Estimated completion in 2015.
Yolo County	General Plan Update	Adopted in November 2009.
Zone 7 Water Agency and California Department of Water Resources	South Bay Aqueduct Improvement and Enlargement Project	Completed in 2012.

Note:
BO = Biological Opinion
NMFS = National Marine Fisheries Service

Many ongoing programs include development of future projects that would require separate environmental documentation as well as continued operations, maintenance, and/or enforcement activities. The No Project/No Action Alternative does not include future projects that have not been specifically defined or do not have completed environmental documentation. It is recognized that it is the intent of the SWP and CVP to comply with the NMFS Operations BO and USFWS Operations BO, although the specific actions for new facilities have not been identified or evaluated at this time.

Table 2-13
Ongoing Programs Included in the No Project/No Action Alternative

Agency	Program
California Department of Boating and Waterways	Egeria Densa Control Programs
California Department of Boating and Waterways	Water Hyacinth Control Programs
California Department of Fish and Wildlife	Invasive Species Program
California Department of Fish and Wildlife	California Aquatic Invasive Species Management Plan
California Department of Fish and Wildlife	Zebra Mussel Rapid Watch Program and Response Plan for California
California Department of Fish and Wildlife	Fish Screen Passage Program
California Department of Fish and Wildlife	Delta-Bay Enhanced Enforcement Program
California Department of Fish and Wildlife	Ecosystem Restoration Program Conservation Strategy
California Department of Fish and Wildlife	Lower Sherman Island Wildlife Area Land Management Plan
California Department of Fish and Wildlife	Yolo Bypass Wildlife Area Land Management Plan
California Department of Fish and Wildlife and U.S. Fish and Wildlife Service	Hatchery and Stocking Program
California Department of Fish and Wildlife, California Department of Food and Agriculture, and California State Parks	Watercraft Inspection Programs
California Department of Water Resources	Delta Levees Flood Protection Program
California Department of Water Resources	Levee Repair-Levee Evaluation Program
California Department of Water Resources	Interagency Ecological Program
California Department of Water Resources	South Delta Temporary Barriers Program
California Department of Water Resources	Stockton Deep Water Ship Channel Demonstration Dissolved Oxygen Project
California Department of Water Resources	Zebra Mussel Watch Program
California Department of Water Resources and California Department of Fish and Wildlife	Delta Fish Agreement (Four Pumps Project)
California Department of Water Resources and Yuba County Water Agency	Lower Yuba River Accord
California State Lands Commission	Marine Invasive Species Program
Central Valley Regional Water Quality Control Board	Cache Creek, Bear Creek, Sulfur Creek, Harley Gulch Mercury TMDL
Central Valley Regional Water Quality Control Board	Irrigated Lands Regulatory Program
California Partners in Flight	Riparian Habitat Joint Venture
Central Valley Joint Venture Program	Central Valley Joint Venture
Contra Costa County and East Contra Costa County Habitat Conservancy	East Contra Costa County Habitat Conservation Plan and Natural Community Conservation Plan
Delta Protection Commission	Delta Protection Commission Land Use and Resource Management Plan Update
East Bay Municipal Utility District	Lower Mokelumne River Spawning Habitat Improvement Project
National Marine Fisheries Service, Bureau of Reclamation, and California Department of Water Resources	BO on the Long-Term Operations of the CVP and SWP (Sacramento River Winter-run Chinook Salmon, Central Valley Spring-run Chinook Salmon, Central Valley Steelhead, Southern Distinct Population Segment of North American Green Sturgeon, and Southern Resident Killer Whales)
Sacramento County	Sacramento International Airport Master Plan

Table 2-13
Ongoing Programs Included in the No Project/No Action Alternative

Agency	Program
Sacramento Area Flood Control Agency, Central Valley Flood Protection Board, and U.S. Army Corps of Engineers	Flood Management Program
Sacramento County, Sacramento, Citrus Heights, Elk Grove, Folsom, Galt, and Rancho Cordova	Sacramento Stormwater Quality Partnership
San Francisco Bay Regional Water Quality Control Board	San Francisco Bay Mercury TMDL
San Joaquin Council of Governments	San Joaquin County Multi-Species Habitat Conservation and Open Space Plan
San Joaquin County, Stockton, Tracy, and State Water Resources Control Board	San Joaquin County, Stockton, and Tracy Stormwater Management Programs
Bay Area Stormwater Management Association Agencies	Bay Area Stormwater Management Programs
U.S. Army Corps of Engineers	Delta Dredged Sediment Long-Term Management Strategy
U.S. Army Corps of Engineers	Suisun Bay Channel Operations and Maintenance
U.S. Army Corps of Engineers	Suisun Channel (Slough) Operation and Maintenance
U.S. Bureau of Reclamation and California Department of Water Resources	Water Year 2010 Interim Flows Project (San Joaquin River)
U.S. Bureau of Reclamation and U.S. Fish and Wildlife Service	Anadromous Fish Screen Program
U.S. Bureau of Reclamation, U.S. Fish and Wildlife Service, National Marine Fisheries Service, California Department of Water Resources, and Department of Fish and Wildlife	San Joaquin River Restoration Program
U.S. Coast Guard	Ballast Water Management Program
U.S. Fish and Wildlife Service	Stone Lakes National Wildlife Refuge Comprehensive Conservation Plan
U.S. Fish and Wildlife Service	North American Waterfowl Management Plan
U.S. Fish and Wildlife Service, U.S. Bureau of Reclamation, and California Department of Water Resources	BO on the Long-Term Operations of the CVP and SWP (Delta Smelt)
U.S. Fish and Wildlife Service, U.S. Bureau of Reclamation, and California Department of Fish and Wildlife	San Joaquin Basin Action Plan
University of California, Davis and California Department of Water Resources	Smelt Hatchery Program
Yolo County	Yolo County Stormwater Management Program

Note:
BO = Biological Opinion

The following are other key assumptions for the No Project/No Action Alternative:

- The California Endangered Species Act (CESA) and the Federal Endangered Species Act (ESA) would continue to be implemented on a case-by-case basis for future programs and projects that have a potential to take listed species pursuant to each act.
- The No Project/No Action Alternative assumes settlement water rights holders in the Sacramento and San Joaquin river watersheds will use their full contract amounts by 2025 based on their contracts with Reclamation.
- The No Project/No Action Alternative assumes continued operations of flood management facilities by the federal, State, and local agencies. In addition, the No Project/No Action Alternative assumes that, without future engineering and environmental analyses, levee failures due to flooding, erosion,

subsidence, wave action, seismic events, burrowing animals, physical encroachment (such as barge collisions), or other causes would be repaired as part of ongoing programs. The No Project/No Action Alternative assumes that these repairs also would occur on privately owned levees that are integral to the main waterways in the Delta, such as repairs that occurred to privately owned levees following the 1996 and 1997 floods.

- The No Project/No Action Alternative also includes existing facilities for SWP, CVP, and Contra Costa Water District, and the Tehama-Colusa Canal and Glenn-Colusa Irrigation District Canal. Summary descriptions of these facilities are provided in Appendix 2D.
- Operations of the SWP and CVP by DWR and Reclamation, respectively, are described in the August 2008 Biological Assessment for the Long-term OCAP for the CVP and SWP prepared by Reclamation and modified by the 2009 NMFS BO and 2008 USFWS BO.
- SWP and CVP operational assumptions also include continued operations under the Coordinated Operations Agreement; SWRCB Decision 1641 (D-1641); use of Joint Points of Diversion (which allows DWR and Reclamation to use both the SWP and CVP diversion capacity capabilities in accordance with D-1641); SWRCB Water Quality Control Plan adopted in 2006; and implementation of the *Central Valley Project Improvement Act including environmental water actions in accordance with Section 3406(b)(2)*.
- The No Project/No Action Alternative assumes completion of the RBDD Fish Passage Improvement Project, and year-round gates out operations.
- The No Project/No Action Alternative does not assume new Delta conveyance facilities to be in place, rather Delta exports would continue to be pumped through the Banks and Jones pumping plants.
- The No Project/No Action Alternative does not include assumptions of future changes in facilities operations, land use, or policies to accommodate or mitigate the adverse impacts associated with climate change.
- The No Project/No Action Alternative does not include assumptions for climate change related to sea level rise and changes in precipitation patterns, including changes in ratios between snow and rainfall. A sensitivity analysis to account for climate change effects on the proposed Project was performed and is presented in Chapter 25 Climate Change and Greenhouse Gas Emissions.
- Population growth is expected to continue to occur in California throughout the period of project analysis (i.e., 100 years).

2.3.3 Sites Reservoir Alternative

The description of the Sites Reservoir Alternative was developed to include details for the appurtenant facilities shown in Figures 2-2 and 2-3. Evaluation of the alternative continued to focus on a 1.8-MAF reservoir size, although a range of reservoir sizes were also considered.

During this phase of the investigation, non-irrigation season flows in the CBD, the Sacramento River, and local tributaries remained potential sources of water supply for the offstream Sites Reservoir Alternative. Potential conveyance systems from these sources to the reservoir included existing and/or enlarged Tehama-Colusa (T-C) and Glenn-Colusa Irrigation District (GCID) canals, or a new conveyance facility from the Sacramento River near Moulton Weir and/or from the CBD to the existing Funks Reservoir on the T-C Canal. Conveyance from Stony Creek was also considered. All conveyance alternatives required enlargement of the existing Funks Reservoir to provide adequate storage capacity for pumping of water into the reservoir and hydropower generation. Major project facilities would be situated near the Funks Creek damsite, including outlet works, power plant, intake structure, and maintenance facilities. Additionally, up to five potential recreation facility locations were identified to meet the secondary objective of developing additional recreation opportunities in the study area.

Construction of Sites Reservoir would require relocation of two county roads (Sites Lodoga and Huffmaster roads) and the community of Sites.

2.3.4 Newville Reservoir Alternative

The description for the Newville Reservoir Alternative was also developed and refined to include details for the appurtenant facilities shown in Figures 2-4, 2-5, 2-6, and 2-7. Evaluation of the alternative focused on the 1.9-MAF reservoir size. A 3.0-MAF reservoir size was also considered and evaluated. However, all of the environmental and cultural resources effects, as well as the cost, of the 3.0- MAF reservoir would be additive to those of the 1.9-MAF reservoir. The 3.0-MAF Newville Reservoir was therefore not evaluated further.

The Sacramento River and existing Black Butte Reservoir were considered, in addition to Thomes Creek, as potential sources of water supply for the Newville Reservoir Alternative. Potential conveyance systems from these sources to the reservoir included the existing or enlarged T-C Canal with a new conveyance between the GCID and T-C canals, a new conveyance from the T-C Canal to the existing Black Butte Reservoir, and a new conveyance from Black Butte Reservoir to the Newville Reservoir Alternative. A new conveyance from a proposed Thomes Creek diversion at a location north and west of the Newville Reservoir Alternative was also considered. Additionally, five potential recreation areas were identified to meet the secondary objective of developing additional recreation opportunities in the study area.

Construction of the Newville Reservoir Alternative would require relocation of portions of three county roads, including Round Valley Road, Garland Road, and County Road 306.

2.4 Resource Impact Comparison for Selected Alternatives

A review of potential impacts to biological and cultural resources for the Sites Reservoir and Newville Reservoir alternatives indicated a greater impact potential for the Newville Reservoir Alternative. Potential impacts for both reservoir alternatives, as well as the No Project/No Action Alternative, are described below.

2.4.1 Cultural Resources

Table 2-14 presents a comparison of the cultural resources survey results for the Sites Reservoir (1.8-MAF) and Newville Reservoir (1.9-MAF) alternatives. Newville Reservoir Alternative data represent totals for the reservoir footprint only, while Sites Reservoir Alternative data include data associated with all major proposed Project facilities, including conveyance routes, road relocations, recreation areas, hydropower facilities, and a terminal regulating reservoir. Despite the smaller survey area, the Newville Reservoir Alternative location contains substantially more cultural resources than the Sites Reservoir Alternative location, including more middens. Middens are indicative of long periods of site occupation and are an important cultural resource, as they can be expected to yield substantial cultural information and human remains. Under the No Project/No Action Alternative, no impacts to cultural resources or cemeteries are expected.

Table 2-14
Comparison of Potential Cultural Resource Impacts associated with the Sites Reservoir and Newville Reservoir Alternatives

Cultural Resource	Number of Cultural Resources Identified	
	Sites Reservoir Alternative	Newville Reservoir Alternative*
Historic and prehistoric sites*	147	250
Cemeteries	2	2
Middens	57	80

*Newville Reservoir Alternative survey data for reservoir footprint only

2.4.2 Terrestrial Biological Resources

2.4.2.1 Wildlife Habitat

The Newville Reservoir Alternative could result in the permanent direct habitat loss of up to 24,866 acres, compared to 18,308 acres at the Sites Reservoir Alternative. The Newville Reservoir Alternative location also contains greater habitat and structural diversity, with the potential affected acreage of every habitat type greater for the Newville Reservoir Alternative than the Sites Reservoir Alternative(Table 2-15). Under the No Project/No Action Alternative, no permanent loss of most habitat types is expected to occur. Blue oak woodlands would likely continue to be lost due to ongoing fuelwood harvest at both reservoir alternative locations.

Table 2-15
Potential Permanent Habitat Loss Comparison between the Sites Reservoir and Newville Reservoir Alternatives

Habitat Type	Potential Permanent Habitat Loss (acres)*	
	Sites Reservoir Alternative	Newville Reservoir Alternative
Annual grassland	16,311	17,556
Blue oak woodland	924	2,532
Wetlands	249	525
Riparian	75	476
Chaparral	1	422
Agricultural	250	1,744
Valley oak woodland	4	104
Juniper woodland	0	36
Shale barren	0	268
Blue oak/foothill pine	494	1,203
Total acreage	18,308	24,886

*Acreage values include all project features including reservoirs, dams, road relocations, and conveyance routes where habitat would be permanently modified.

2.4.2.2 Wildlife Species

Several invertebrate species protected under the federal Endangered Species Act have the potential to occur at or near both the Sites Reservoir and Newville Reservoir alternatives locations, including valley elderberry longhorn beetle, vernal pool fairy shrimp, Conservancy fairy shrimp, and vernal pool tadpole shrimp.

Protocol-level surveys conducted at the Sites Reservoir Alternative location indicate that none of the federally-listed vernal pool invertebrates are present. Vernal pools at the Newville Reservoir Alternative location were not surveyed.

Protocol-level surveys indicate that nearly twice as many elderberry stems would be affected, and that the presence of the valley elderberry longhorn beetle is much higher (based on surveyed emergence holes), at the Newville Reservoir Alternative location than at the Sites Reservoir Alternative location (Table 2-16). Under the No Project/No Action Alternative, no significant loss of vernal pool habitat is expected. Continued long-term degradation related to disking for dryland grain production will likely continue at the Sites Reservoir Alternative location. No significant additional loss of elderberry shrubs at either reservoir alternative is expected under the No Project/No Action Alternative.

Table 2-16
Valley Elderberry Longhorn Beetle Survey Results Comparison between the Newville Reservoir and Sites Reservoir Alternatives

VELB* Survey Criteria	Number Observed per Location	
	Sites Reservoir Alternative	Newville Reservoir Alternative
Total elderberry stems	672	1201
Elderberry stems with emergence holes	18	264

*VELB = valley elderberry longhorn beetle

Comparison of Sites and Newville reservoir alternatives indicate that both locations have the potential for short-term construction-related impacts to the giant garter snake, which is State and federally listed as threatened. Under the No Project/No Action Alternative, no short-term or long-term impacts to giant garter snake are expected.

The California red-legged frog, federally listed as threatened, was found during field surveys in the vicinity of the Newville Reservoir Alternative location. This species was not found during field surveys at the Sites Reservoir Alternative location. No adverse effects to California red-legged frog are expected under the No Project/No Action Alternative.

Comparison of the Sites and Newville reservoir alternatives indicate comparable occurrence of, and potential impacts to, State and federally listed birds and mammals. Both reservoir alternative locations would result in take under the Bald and Golden Eagle Protection Act. No substantial take of State or federally listed birds or mammals are expected under the No Project/No Action Alternative. Some minor degradation of golden eagle nesting and foraging habitat will likely continue under the No Project/No Action Alternative due to ongoing fuelwood harvest and ground squirrel control activities at both reservoir alternative locations.

The Newville Reservoir Alternative would impact a portion of the Thomes Creek deer herd's winter range. The Sites Reservoir Alternative location does not include deer winter range. Under the No Project/No Action Alternative, degradation of deer wintering habitat at the Newville Reservoir Alternative location will likely continue due to fuelwood harvest of oaks.

2.4.3 Aquatic Biological Resources

The Newville Reservoir Alternative includes a diversion on Thomes Creek. This diversion is included as a project component (even though it is onstream) because it can provide approximately 200-TAF per year of additional water to storage by gravity (without requiring pumping). Subsequent engineering evaluation indicated substantial design difficulties in providing a suitable diversion which can pass both fish and sediment at this location. This diversion would result in substantial adverse effects to spring-run Chinook salmon, steelhead, and sediment passage. Without feasible fish passage measures, adverse effects to anadromous fisheries would occur. These adverse effects would not be consistent with the NODOS Project primary planning objective of increased survival of anadromous fish populations, or CALFED's direction to avoid significant redirected impacts including those associated with new onstream reservoirs. By comparison, the tributary streams that would be affected by the Sites Reservoir Alternative, which include Stone Corral and Funks creeks, are ephemeral and do not support anadromous fisheries.

Under the No Project/No Action Alternative, no changes to anadramous fish habitat or populations are expected at either reservoir alternative location. However, many programs and projects included under the No Project/No Action Alternative are designed specifically to improve fish habitat and increase fish populations in the Sacramento Valley and Delta, including the Red Bluff Diversion Dam Fish Passage Improvement Project, Battle Creek Salmon and Steelhead Restoration Project, Contra Costa Canal Fish Screen Project, American Basin Fish Screen and Habitat Improvement Project, the CDFW Fish Screen and Passage Program, Delta Fish Agreement, OCAP Biological Opinions, and the Lower Yuba River Accord.

2.4.4 Botanical Resources

Field studies indicate that the Newville Reservoir Alternative contains greater numbers of rare plant species, higher priority plant species, and greater numbers of rare plant populations than the Sites Reservoir Alternative (Table 2-17). No substantial impacts to rare plant populations are expected at either reservoir alternative location under the No Project/No Action Alternative. Continued minor degradation of some rare plant populations will likely occur due to land use practices such as dryland farming, year-round grazing, and herbicide use.

Table 2-17
Comparison of Rare Plant Species and Populations at the Sites and Newville Reservoir Alternatives

Listing Status	Number of Rare Plants Observed (species/populations)	
	Sites Reservoir Alternative	Newville Reservoir Alternative
State or federal threatened or endangered	0	0
State or federal species of concern	0	3/57
CNPS 1A	0	0
CNPS 1B	0	5/122
CNPS 2	0	0
CNPS 3	0	0
CNPS 4	4/37	7/183

Note:
CNPS=California Native Plant Society List

2.4.5 Wetlands and Waters of the U.S.

Comparison of the Newville and Sites reservoir alternatives indicates that the Newville Reservoir Alternative would impact significantly greater amounts of wetlands and waters of the U.S. (Table 2-18), including jurisdictional wetlands, than the Sites Reservoir Alternative. No substantial loss of wetlands or waters of the U.S. are expected at either reservoir alternative location under the No Project/No Action Alternative. Minor continued degradation of vernal pool habitats will likely continue due to disking for dryland grain farming.

Table 2-18
Comparison of Potential Impacts to Wetlands and Waters of the U.S. between the Sites and Newville Reservoir Alternatives.

Resource	Wetlands and Waters of the U.S. Potentially Impacted (acres)	
	Sites Reservoir Alternative	Newville Reservoir Alternative
Wetlands	196	390
Waters of the U.S.	175	231
Total wetlands and waters*	**371**	**621**

*Reservoir footprint data comparisons

2.4.6 Energy and Greenhouse Gas Emissions

The Newville Reservoir Alternative would require more energy for pumping than the Sites Reservoir Alternative because minimum conveyance distances would be greater (18 to 23 miles for Newville Reservoir, compared to one to 13 miles for Sites Reservoir), more pumping plants would be required, and higher pumping elevations (approximately 400 feet higher pumping elevation for Newville Reservoir) would be required for conveyance for Newville Reservoir Alternative. Higher conveyance-related energy requirements associated with the Newville Reservoir Alternative would result in relatively greater operational greenhouse gas emissions than for the Sites Reservoir Alternative. In addition, due to its greater embankment volume (35 million cubic yards for the Newville Reservoir Alternative vs. 22 million cubic yards for the Sites Reservoir Alternative), the Newville Reservoir Alternative would result in greater construction equipment hours and, therefore, greater GHG emissions during construction. Under the No Project/No Action Alternative, little change in the current levels of GHG emissions is expected because agricultural cultivation is the largest contributor of GHG emissions within the reservoir alternative locations, and the amount of land under cultivation at those locations is not expected to change.

2.4.7 Surface Water Resources

The Sites Reservoir Alternative would increase water supply reliability for agricultural, municipal, industrial, and environmental water users. The Newville Reservoir Alternative would increase water supply reliability for agricultural water users in the Sacramento Valley directly, and then potentially for other users by exchange. Elimination of the Thomes Creek Diversion for the Newville Reservoir Alternative due to its infeasibility would significantly increase the alternative’s construction costs, as other water sources 1) require much longer and more expensive conveyances, and 2) would have long-term greater operational costs, as they require pumpage instead of gravity to fill or refill the reservoir. Water supply reliability would be improved under the No Project/No Action Alternative with implementation of the many projects and programs included in the No Project/No Action Alternative, including South Bay Aqueduct Improvement and Enlargement Project, Freeport Regional Water Project, Delta Mendota Canal-California Aqueduct Intertie, City of Stockton Delta Water Supply Project, Contra Costa Water District’s Middle River Intake and Pump Station Project, and Los Vaqueros Reservoir Expansion. Water supply reliability is increasingly linked to conservation measures issued under the federal Endangered Species Act. Some fish restoration actions identified under the No Project/No Action

Alternative may serve to expedite species recovery and ultimately result in improved water supply reliability. Examples include the Red Bluff Diversion Dam Fish Passage Improvement Project, Battle Creek Salmon and Steelhead Restoration Project, Contra Costa Canal Fish Screen Project, American Basin Fish Screen and Habitat Improvement Project, the CDFW Fish Screen and Passage Program, Delta Fish Agreement, OCAP Biological Opinions, and the Lower Yuba River Accord.

2.4.8 Flood Management

The Sites Reservoir Alternative could provide some local flood management benefits to lands that are currently prone to flooding during high flow events on Funks and Stone Corral creeks; the Newville Reservoir Alternative would have little flood management potential since the reservoir would be located upstream of Black Butte Reservoir, an existing flood management facility. Diversion facilities on Thomes Creek would have little or no ability to store water or provide downstream flood protection. Under the No Project/No Action Alternative, the Folsom Dam Safety and Flood Damage Reduction Project would improve flood protection for the Lower American River and the City of Sacramento.

2.4.9 Cost and Engineering Feasibility

Comparison of cost and engineering feasibility of the Sites and Newville reservoir alternatives indicate that both alternatives are technically feasible. However, construction and operational costs would be greater for the Newville Alternative due to greater embankment requirements, and greater conveyance length and lift. Costs and engineering feasibility associated with the No Project/No Action Alternative are not applicable.

2.4.10 Sites-Newville Impact Comparison Conclusion

Surveys indicated that the Sites Reservoir and Newville Reservoir Alternatives would have similar potential impacts to giant garter snakes, State- and federally-listed birds and mammals, and that both would result in take under the Bald and Golden Eagle Protection Act. However, surveys also indicated that the Newville Reservoir Alternative would have a much higher potential for adverse impacts to cultural resources, wildlife habitat and diversity, elderberry plants and the valley elderberry longhorn beetle, the red-legged frog, deer winter range, rare plants and plant populations, and anadromous fish.

In addition, the Newville Reservoir Alternative would be more expensive to construct and operate than the Sites Reservoir Alternative, and would result in relatively greater construction and operation-related greenhouse gas emissions.

2.5 Preferred Proposed Project Alternative

DWR and Reclamation selected the Sites Reservoir Alternative as the preferred proposed Project alternative to be retained for further study and more detailed evaluation because of the consistently higher potential for biological and cultural resources impacts associated with the Newville Reservoir Alternative, and because the Newville Reservoir Alternative would not avoid or reduce any of the significant adverse effects associated with the Sites Reservoir Alternative.

Once the Sites Reservoir Alternative was identified as the preferred proposed Project alternative (hereafter proposed Project), all other necessary proposed Project features were conceptually developed and refined, including analyses of reservoir storage size, conveyance, and operational alternatives to maximize achievement of the NODOS Project objectives.

2.5.1 Sites Reservoir Storage Size Alternatives

DWR and Reclamation considered various storage sizes of Sites Reservoir, including 800 TAF, 1.27 MAF, 1.81 MAF, and 2.1 MAF. These four storage sizes were selected to reflect a range of storage values that would allow for a useful comparison of the costs and benefits estimates. These four storage sizes also represent points on the cost curve where the proposed Project's costs would change significantly due to the need for new Project features, such as dams or embankments.

Table 2-19 presents a summary of each Sites Reservoir storage size that was initially considered, including the total number of dams that would be required to impound Sites Reservoir and the total embankment volume that would be required for each of the four storage sizes.

Table 2-19
Summary of Dams and Embankment Volume of Potential Sites Reservoir Storage Sizes

Reservoir Storage (MAF)	Maximum Water Surface Elevation (feet)	Reservoir Surface Area (acres)	Total Number of Dams[a] (main + saddle)	Total Embankment Volume (CY)
0.80	440	10,200	2 + 3	6,900,000
1.27	480	12,400	2 + 7	11,018,400
1.81	520	14,200	2 + 9	22,009,000
2.10	540	15,100	2 + 7[b]	33,800,000

[a]Total number of dams includes the Sites and Golden Gate dams and the saddle dams.
[b]Saddle dams 7, 8, and 9 become one continuous embankment for the 2.1-MAF reservoir.

Notes:
MAF = million acre-feet
CY = cubic yards

Source: DWR, 2004

Based on a review of the reservoir rim topography, site geology, and a cursory evaluation of the relationship between embankment volume and reservoir storage, DWR and Reclamation determined early in the investigation that a 2.1-MAF reservoir may present significant design challenges. Reservoir elevations at or above 540 feet elevation would likely require grouting of the lower saddle areas along the relatively steep ridges of the eastern rim to ensure the proposed Project would perform satisfactorily. This treatment, combined with the increasing relationship between embankment material volume and reservoir surface elevations, would result in larger unit costs (reservoir cost per acre-foot of storage) for reservoir elevations above 540 feet elevation. Therefore, the Sites Reservoir storage capacities below 540 feet elevation were considered to be more economical on a unit cost basis. Limiting the maximum reservoir elevation to 520 feet elevation would provide assurance that unknown conditions (such as leakage) on the relatively steeper slopes of the eastern reservoir rim would not result in large increases in proposed Project costs during the later stages of design. Therefore, a maximum reservoir elevation of 540 feet, corresponding to a reservoir size of 2.1 MAF, was eliminated from further consideration. Reservoir storage capacities of 800 TAF, 1.27 MAF, and 1.81 MAF were, therefore, carried forward for further consideration, including initial alternative development and evaluation.

2.5.2 Sites Reservoir Conveyance Alternatives

Preliminary operations simulations indicated that 3,000 to 6,000 cfs of total inflow capacity would be needed to reliably fill Sites Reservoir. Because Sites Reservoir would be located offstream, water would need to be diverted to and released from the reservoir. As a result, diversion and conveyance facilities would be needed to transport water to Sites Reservoir, and to deliver water from Sites Reservoir to service areas, the Sacramento River, and other locations to meet various water resources needs and uses.

It was determined that, to maximize operational flexibility, the diversion and conveyance facilities would need to be able to:

- Release water directly from Sites Reservoir to meet local needs in the vicinity of the existing GCID and T-C canals
- Release water in an integrated manner with existing CVP and SWP operations to facilitate meeting additional needs throughout the Bay-Delta system
- Release water directly to the Sacramento River to meet additional needs throughout the Bay-Delta system and provide downstream benefits for Delta water quality and water supply reliability (through additional supplies or alternative source) for CVP, SWP, and Level 4 wildlife refuge water supply. Additionally, the ability to release water directly to the Sacramento River would allow Sites Reservoir to respond to Delta emergencies, including releasing flows to repel saltwater intrusion following a Delta levee failure.

Conveyance facilities alternatives that would divert water from the Sacramento River included the existing GCID and T-C canals, and a new pipeline, known as the Delevan Pipeline. Tributary source conveyance facilities alternatives included new pipelines from the CBD and Stony Creek. Conveyance facilities alternatives that were evaluated initially had a range of capacity sizes, known as options (Table 2-20), and are illustrated schematically in Figure 2-8.

Table 2-20
Conveyance Facilities Alternatives Considered for Sites Reservoir

Conveyance Facility Alternative	Source	Option Capacity Description
GCID Canal[a]	Sacramento River at Hamilton City	Existing 1,800-cfs capacity Expand to 3,000-cfs capacity Expand to 4,000-cfs capacity Expand to 5,000-cfs capacity
T-C Canal[a]	Sacramento River at Red Bluff	Existing 2,100-cfs capacity Modify to 2,700-cfs capacity Expand to 4,000-cfs capacity Expand to 5,000-cfs capacity
Delevan Pipeline[b]	Sacramento River opposite Moulton Weir	1,500-cfs capacity 2,000-cfs capacity 3,000-cfs capacity 4,000-cfs capacity 5,000-cfs capacity
Colusa Basin Pipeline[b]	Colusa Basin Drain	1,000-cfs capacity 3,000-cfs capacity
Stony Creek Pipeline[b]	Stony Creek at Black Butte Afterbay	1,000-cfs capacity 2,100-cfs capacity

[a]Existing conveyance facility.
[b]Proposed new conveyance facility.
Notes:
cfs = cubic feet per second
GCID = Glenn-Colusa Irrigation District
T-C = Tehama-Colusa
Source: DWR and Reclamation, 2008.

Each of the options for the conveyance alternatives were evaluated based on cost, the importance of providing direct release to the Sacramento River, and preliminary assessments of potential environmental and cultural resources impacts. Table 2-21 summarizes preliminary cost estimates for the conveyance alternative options and indicates the ability of the option to provide direct releases to the Sacramento River.

Table 2-21
Preliminary Cost and Sacramento River Direct Release Potential for the Sites Reservoir Conveyance Options

Conveyance Facility Alternative	Option Capacity Description	Cost Estimate[a] (millions)	Ability to Provide Direct Release to Sacramento River?
GCID Canal[b]	Existing 1,800-cfs capacity Expand to 3,000-cfs capacity Expand to 4,000-cfs capacity Expand to 5,000-cfs capacity	$178.5[d] $302.3 $463.8 $552.3	No No No No
T-C Canal[b]	Existing 2,100-cfs capacity Modify to 2,700-cfs capacity Expand to 4,000-cfs capacity Expand to 5,000-cfs capacity	$0 $110.9 $398.2 $556.5	No No No No
Delevan Pipeline[c]	1,500-cfs capacity 2,000-cfs capacity 3,000-cfs capacity 4,000-cfs capacity 5,000-cfs capacity	$364.9 $421.4 $574.3 $747.2 $917.2	Yes Yes Yes Yes Yes
Colusa Basin Pipeline[c]	1,000-cfs pipeline capacity 3,000-cfs pipeline capacity	$145.9 $362.9	No No
Stony Creek Pipeline[c]	1,000-cfs capacity 2,100-cfs capacity	$87.9 $168.3	No No

[a]Costs are 2007 preliminary construction costs and do not include mitigation, engineering, or administrative costs.

[b]Existing conveyance facility.

[c]Proposed new conveyance facility.

[d]Costs are not $0 due to the cost of restoring the design capacity of the GCID Canal for 14 miles. This cost was later removed because GCID would restore the 14 miles of Canal to design capacity as part of its required annual maintenance.

Notes:

cfs = cubic feet per second
GCID = Glenn-Colusa Irrigation District
T-C = Tehama-Colusa

Source: DWR and Reclamation, 2008.

Based on DWR's and Reclamation's conveyance evaluation, the following options were eliminated from further consideration:

- **GCID Canal Expansions:** Expansion of the GCID Canal would require the acquisition of temporary and permanent rights-of-way. For example, the larger GCID Canal expansion options would require approximately 1,890 acres of land during construction. Permanent land area acquired for the canal expansion would be 940 acres, of which 727 acres are classified as prime agricultural land (preliminary estimates based on field survey). California's desire to preserve agricultural land is reflected in the California Land Conservation Act, also known as the Williamson Act. Other environmental considerations in the canal expansion footprint would include the loss of 286 elderberry stems greater than 1-inch in diameter, adverse effects to salmon and steelhead related to siphon enlargements, loss of giant garter snake habitat, disturbance of nesting habitat for the

Swainson's hawk, and extensive loss of jurisdictional wetlands, including vernal pools. The potential impacts to prime agricultural land and environmental resources associated with these facilities support the recommendation not to further evaluate GCID Canal expansions.

- **T-C Canal Modification and Expansions:** There were 2,468 acres of agricultural land determined to be within 100 feet of the T-C Canal modification and expansion area footprint; of these, 1,244 acres are classified as prime agricultural land (preliminary estimates based on field survey). Environmental considerations in the expansion area footprint would include the loss of vernal pool plants and invertebrates, loss of California tiger salamander habitat, loss of 170 elderberry stems greater than 1-inch in diameter, adverse effects to salmon and steelhead related to siphon enlargements, potential giant garter snake habitat loss, disturbance of nesting habitat for the Swainson's hawk, and loss of jurisdictional wetlands, including vernal pools. These potential impacts to prime agricultural land and environmental resources support the recommendation not to further evaluate T-C Canal modifications or expansion.
- **4,000 and 5,000 cfs Delevan Pipeline:** These options were determined to be inefficient and infeasible due to cost, which would be $747 million and $917 million, respectively. These preliminary construction cost estimates are presented in 2007 dollars and do not include mitigation, engineering, or administrative costs. Additionally, the smaller pipeline sizes were determined to be able to reliably fill and drain Sites Reservoir when combined with other conveyance options.
- **Colusa Basin Pipeline:** The water from the CBD is considered to be of relatively poor water quality when compared to Sacramento River water and is, therefore, less desirable. The CBD is the single largest source of agricultural return flows to the Sacramento River; as a result, it has elevated values for alkalinity, electrical conductivity, and total dissolved solids. Nitrogen and phosphorus concentrations also are generally higher in the CBD. Water taken from the CBD into Sites Reservoir and then released back through the conveyance system could cause water quality impacts to local agricultural users and create a new point source of relatively lower quality water if discharged into the Sacramento River. Therefore, neither Colusa Basin Pipeline conveyance option was recommended for further consideration.
- **Stony Creek Pipeline:** The Stony Creek Pipeline conveyance options would rely on increased capacity of the T-C Canal downstream of Orland. The T-C Canal modification and expansion conveyances were eliminated from further consideration (as indicated above); therefore, the Stony Creek Pipeline conveyance options were also eliminated from further consideration.

The conveyance options retained were:

- T-C Canal at its existing capacity of 2,100 cfs
- GCID Canal at its existing capacity of 1,800 cfs
- A new Delevan Pipeline at capacities of 1,500 cfs, 2,000 cfs, and 3,000 cfs

The T-C and GCID canals at their existing capacities would be the most cost-effective conveyance options. These conveyance options were retained because they could be combined to provide conveyance packages with up to 6,900 cfs total capacity for use in initial alternative development. In addition, these conveyance options allowed for an evaluation of benefits associated with the proposed Delevan Pipeline's ability to return water directly to the Sacramento River.

2.5.3 Sites Reservoir Operational Alternatives

Eight initial Sites Reservoir operational alternatives, each with a range of conveyance packages and operational emphases, were considered and evaluated with the CalSim-II operations model in the NODOS Plan Formulation Report (DWR and Reclamation, 2008). The operational alternatives assumed a Sites Reservoir storage size of 1.8 MAF. All of the initial Project operational alternatives evaluated met the proposed Project's primary objectives, but to varying degrees. The proposed Project operational alternative that emphasized a balanced mix of benefits to water supply reliability, water quality, and ecosystem enhancement generated the greatest net annual economic benefit and minimized environmental impacts, and therefore was selected as the operational scenario for detailed evaluation in this environmental document. This operational alternative was the only one evaluated that resulted in economic benefits that exceeded costs (i.e. benefit-cost ratio greater than 1.0). The other operational alternatives that prioritized one benefit category (i.e. water supply reliability, water quality, or ecosystem enhancement) were eliminated from further consideration.

2.5.4 Sites Reservoir Storage, Conveyance, and Operations Formulation

Based on the initial evaluation of storage, conveyance and operational alternatives, the following proposed Project features were retained for further evaluation:

- Sites Reservoir Storage: 800 TAF, 1.27 MAF, and 1.81 MAF
- Sites Reservoir Conveyance: existing T-C Canal (2,100-cfs capacity), existing GCID Canal (1,800-cfs capacity), and new Delevan Pipeline (1,500-cfs, 2,000-cfs, and 3,000-cfs capacity)
- Operational scenario that emphasized a balanced mix of benefits to water supply reliability, water quality, and ecosystem enhancement

To further evaluate and optimize reservoir storage and conveyance options, preliminary costs were estimated and operations modeling was performed. Table 2-22 identifies the reservoir storage and conveyance facility options that were evaluated and their associated total capital costs.

The purpose of the operations modeling was to reduce the number of possible Project combinations and to help formulate Sites Reservoir alternatives with the most efficient conveyance options and reservoir storage sizes. The operations simulations modeling was performed using an assumed operational scenario that provided a balanced mix of water supply reliability, water quality, and ecosystem enhancement. This operational scenario was similar to the operational scenario described above that generated the greatest net economic benefits. The water supply yield of the conveyance options and Sites Reservoir storage combinations was analyzed for long-term average and driest period's average hydrologic conditions. Preliminary economic evaluation was performed to value the water supply yield benefits for each combination. Net annual economic benefits were estimated and used as the primary economic metric to rank and compare the combinations as shown in Table 2-23.

Based on the preliminary operations simulations described above, a 3,000-cfs Delevan Pipeline was eliminated from consideration. Preliminary modeling results of the above-listed conveyance options indicated that a 2,000-cfs conveyance was adequate to meet the proposed Project objectives. Constructing a larger Delevan Pipeline would require a larger intake/discharge structure that would result in greater environmental impacts due to its presence in an area that has sensitive habitat. Constructing a larger pipeline would also significantly increase the construction cost and operational expense. Therefore, a 3,000-cfs Delevan Pipeline was not considered further.

Table 2-22
Sites Reservoir Storage and Conveyance Options Combinations

Reservoir Storage (TAF)	Conveyance				Capital Cost ($Billion, 2007)*
	T-C+GCID Capacity (cfs)	Delevan Pipeline: Diversion Capacity (cfs)	Delevan Pipeline: Release Capacity (cfs)	Total Diversion Capacity (cfs)	
800	3,900	0	0	3,900	$1.96
800	3,900	1,500	1,125	5,400	$2.92
800	3,900	2,000	1,500	5,900	$3.13
800	3,900	3,000	2,250	6,900	$3.56
1,270	3,900	0	0	3,900	$2.22
1,270	3,900	1,500	1,125	5,400	$3.15
1,270	3,900	0	1,500	3,900	$3.09
1,270	3,900	2,000	1,500	5,900	$3.36
1,270	3,900	3,000	2,250	6,900	$3.79
1,810	3,900	0	0	3,900	$2.64
1,810	3,900	1,500	1,125	5,400	$3.56
1,810	3,900	0	1,500	3,900	$3.50
1,810	3,900	2,000	1,500	5,900	$3.77
1,810	3,900	0	2,250	3,900	$3.82
1,810	3,900	3,000	2,250	6,900	$4.19

Table 2-23 presents a preliminary estimate of the net annual economic benefit that is associated with each reservoir storage and conveyance options combination that was retained, ranked in order of highest to lowest potential net annual economic benefit.

As shown in Table 2-23, the first three reservoir storage and conveyance options combinations are estimated to perform much better than the remainder of the reservoir storage and conveyance options combinations that were considered. These three reservoir size and conveyance options combinations were combined with new hydropower facilities to develop three configurations of Sites Reservoir denoted as Alternative A, Alternative B, and Alternative C in this DEIR/S. These action alternatives and the No Project/No Action Alternative provided a range of alternatives for further refinement and detailed analysis in the Feasibility Report and DEIR/EIS. The Red Bank, Colusa, Newville, and Sites reservoir alternatives considered and described previously and these refined action alternatives together provide a reasonable range and serve to meet the requirements of CEQA; NEPA; other pertinent federal, State, and local laws, regulations, and policies; and the Principles and Guidelines (P&Gs) presented in the U.S. Water Resources Council's *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* (USWRC,1983). Following is a brief description of the No Project/No Action Alternative and Alternatives A, B, and C that are evaluated in this DEIR/EIS:

- **No Project/No Action Alternative:** The No Project/No Action Alternative assumes that no actions would be taken to provide storage north of the Delta to improve water supply reliability, to enhance the survivability of anadromous fish or drinking water quality in the Delta, or to improve flexible hydropower generation.

- **Alternative A – 1.27-MAF Sites Reservoir with Delevan Pipeline:** Alternative A includes a 1.27-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals and a new Delevan Pipeline (2,000-cfs diversion/1,500-cfs release). This alternative also includes new hydropower facilities.
- **Alternative B – 1.81-MAF Sites Reservoir with Release-only Delevan Pipeline:** Alternative B includes a 1.81-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals, and a new release-only Delevan Pipeline (1,500-cfs release). This alternative also includes new hydropower facilities.
- **Alternative C – 1.81-MAF Sites Reservoir with Delevan Pipeline:** Alternative C includes a 1.81-MAF Sites Reservoir with conveyance to and from the reservoir provided by the existing T-C and GCID canals and a new Delevan Pipeline (2,000-cfs diversion/1,500-cfs release). This alternative also includes new hydropower facilities.

Table 2-23
Preliminary Net Economic Benefit Estimates for Sites Reservoir Storage and Conveyance Options Combinations

Reservoir Storage (TAF)	Conveyance				Net Annual Benefit ($Million, 2007)
	TC+GCID Capacity (cfs)	Delevan Pipeline: Diversion Capacity (cfs)	Delevan Pipeline: Release Capacity (cfs)	Total Diversion Capacity (cfs)	
1,810	3,900	0	1,500	3,900	$16.3
1,270	3,900	2,000	1,500	5,900	$16.2
1,810	3,900	2,000	1,500	5,900	$14.1
1,270	3,900	1,500	1,125	5,400	$7.6
1,810	3,900	1,500	1,125	5,400	$7.9
1,810	3,900	0	2,250	3,900	$4.1
1,270	3,900	0	1,500	3,900	-$0.7
800	3,900	1,500	1,125	5,400	-$14.1
800	3,900	2,000	1,500	5,900	-$17.4
1,270	3,900	0	0	3,900	-$18.1
800	3,900	0	0	3,900	-$23.0
1,810	3,900	0	0	3,900	-$33.7

3. Description of the Proposed Project/Proposed Action and Alternatives

This chapter describes the three proposed Project action alternatives that are evaluated in this DEIR/EIS. For descriptions of Existing Conditions and the No Project/No Action Alternative, refer to Chapter 2 Alternatives Analysis. For a depiction of the proposed Project facilities included for each of the action alternatives, refer to Figures 1-9A, 1-9B, and 1-9C in Chapter 1 Introduction for Alternatives A, B, and C, respectively.

3.1 Proposed Project Features and Facilities

Provided below are descriptions of the common and unique proposed Project facilities that are components of the three action alternatives. Table 3-1 provides a summary list of proposed Project features for each alternative.

Table 3-1
Proposed Project Features by Action Alternatives

Project Feature	Component of		
	Alternative A	Alternative B	Alternative C
1.27-MAF Sites Reservoir (requires 9 dams total)	Yes	No	No
1.81- MAF Sites Reservoir (requires 11 dams total)	No	Yes	Yes
Golden Gate and Sites Dams	Yes	Yes	Yes
9 Saddle Dams	No	Yes	Yes
7 Saddle Dams	Yes	No	No
Up to 5 Recreation Areas	Yes	Yes	Yes
Road Relocations and South Bridge	Yes	Yes	Yes
Sites Pumping/Generating Plant	Yes; 5,900-cfs pumping capacity; 5,100 cfs generating capacity	Yes; 3,900-cfs pumping capacity; 5,100 cfs generating capacity	Yes; 5,900-cfs pumping capacity; 5,100 cfs generating capacity
Electrical Switchyards	Yes	Yes	Yes
Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure	Yes	Yes	Yes
Sites Reservoir Inlet/Outlet Structure	Yes	Yes	Yes
Field Office Maintenance Yard	Yes	Yes	Yes
Holthouse Reservoir Complex (includes Holthouse Reservoir and Dam, breached Funks Dam, existing Funks Reservoir Dredging, Holthouse Spillway and Stilling Basin, Holthouse Pumping Plant, T-C Canal Discharge Dissipater, T-C Canal Bypass Pipeline, and Holthouse to T-C Canal Pipeline)	Yes	Yes	Yes
Pump Installation at the Red Bluff Pumping Plant	Yes	Yes	Yes
GCID Canal Facilities Modifications	Yes	Yes	Yes

Table 3-1
Proposed Project Features by Action Alternatives

Project Feature	Component of		
	Alternative A	**Alternative B**	**Alternative C**
GCID Canal Connection to the Terminal Regulating Reservoir (TRR)	Yes	Yes	Yes
TRR (includes the TRR to Funks Creek Pipeline and Outlet)	Yes	Yes	Yes
TRR Pumping/Generating Plant	Yes	Yes	Yes
TRR Pipeline (3.5-mile-long pipeline to convey water from the TRR to Holthouse Reservoir) and TRR Pipeline Road	Yes	Yes	Yes
Delevan Transmission Line	Yes; Sites Pumping/Generating Plant to WAPA/PG&E[1] Line plus WAPA/PG&E Line to Sacramento River	Yes; Sites Pumping/Generating Plant to WAPA/PG&E Line	Yes; Sites Pumping/Generating Plant to WAPA/PG&E Line plus WAPA/PG&E Line to Sacramento River
Delevan Pipeline (2,000 cfs with 2 pipelines)	Yes	Yes	Yes
Delevan Pipeline Intake Facilities (includes fish screen and pumping/generating facilities)	Yes; 2,000 cfs diversion capacity; 1,500 cfs release capacity	No	Yes; 2,000 cfs diversion capacity; 1,500 cfs release capacity
Delevan Pipeline Discharge Facility	No	Yes; 1,500 cfs release capacity	No
Project Buffer	Yes	Yes	Yes
Potential Acreage of Temporary Land Use Impacts	17,680	19,637	19,636
Potential Acreage of Permanent Land Use Impacts	26,425	26,424	26,425

Note:
MAF = million acre-feet

3.1.1 Proposed Project Facilities Common to all Action Alternatives

Many proposed Project facilities are common to the three action alternatives (Alternatives A, B, and C) evaluated in this draft EIR/EIS.

These proposed Project facilities, all of which are considered integral to the performance of the proposed Project, are identified on Figure 3-1 and include the following features that are common to all action alternatives:

- Sites Reservoir Inundation Area (Section 3.1.1.1)
- Recreation Areas (Section 3.1.1.2)
- Road Relocations and South Bridge (Section 3.1.1.3)
- Sites Pumping/Generating Plant (Section 3.1.1.4)

[1] The proposed Project would connect with either the existing PG&E Transmission Line or the existing WAPA Transmission Line.

- Electrical Switchyards (Section 3.1.1.5)
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure (Section 3.1.1.6)
- Sites Reservoir Inlet/Outlet Structure (Section 3.1.1.7)
- Field Office Maintenance Yard (Section 3.1.1.8)
- Holthouse Reservoir Complex (Section 3.1.1.9)
- Pump Installation at the Red Bluff Pumping Plant (Section 3.1.1.10)
- GCID Canal Facilities Modifications (Section 3.1.1.11)
- GCID Canal Connection to Terminal Regulating Reservoir (TRR) (Section 3.1.1.12)
- Terminal Regulating Reservoir (Section 3.1.1.13)
- TRR Pumping/Generating Plant (Section 3.1.1.14)
- TRR Pipeline and TRR Pipeline Road (Section 3.1.1.15)
- Delevan Pipeline (Section 3.1.1.16)
- Project Buffer (Section 3.1.1.17)

The following are Project-related ecosystem enhancement actions common to all action alternatives:

- Ecosystem Enhancement Storage Account—Operational Actions (Section 3.1.2.1)
- Ecosystem Enhancement Fund—Nonoperational Actions (Section 3.1.2.2)

These proposed Project facilities and operational and non-operational ecosystem enhancement actions are discussed in detail in the following sections.

3.1.1.1 Sites Reservoir Inundation Area

The proposed Sites Reservoir would be located in Antelope Valley, approximately 10 miles west of the town of Maxwell (Figure 3-1). The smallest reservoir configuration considered for the action alternatives is 1.27 million acre-feet (MAF), which is discussed in Section 3.1.4.1 and the largest reservoir configuration considered for the action alternatives is 1.81 MAF, which is discussed in Section 3.1.5.1. The inundation area of Sites Reservoir would be created by filling Antelope Valley after the construction of up to 11 dams, depending on the reservoir size. The proposed dams include Golden Gate Dam on Funks Creek, Sites Dam on Stone Corral Creek, and various saddle dams on the northern end of the reservoir, between the Funks Creek and Hunters Creek watersheds (dams are discussed further in Sections 3.1.4.2 and 3.1.5.2).

Construction. Construction information is provided in Section 3.1.4.2 for the 1.27-MAF reservoir and Section 3.1.5.2 for the 1.81-MAF reservoir.

Operations. Operations information is provided in Section 3.1.4.2 for the 1.27-MAF reservoir and Section 3.1.5.2 for the 1.81-MAF reservoir.

Maintenance. Maintenance information is provided in Section 3.1.4.2 for the 1.27-MAF reservoir and Section 3.1.5.2 for the 1.81-MAF reservoir.

3.1.1.2 Recreation Areas

The development of up to five Recreation Areas at the proposed Sites Reservoir could meet public demand for recreation opportunities. Potential Recreation Areas at Sites Reservoir were screened based on the site topography and the effect of potentially large fluctuations in the water surface levels due to normal reservoir operations. Five locations were determined to be potentially feasible recreation areas:

- **Stone Corral Recreation Area –** The Stone Corral Recreation Area (Figure 3-2A) would be located on the eastern shore of the proposed Sites Reservoir, north of the existing Maxwell Sites Road and proposed Sites Dam. Access would be provided by either the proposed South Bridge or Eastside roads. The maximum proposed size of the Stone Corral Recreation Area is 235 acres.
- **Saddle Dam Recreation Area –** The Saddle Dam Recreation Area (Figure 3-2B) would be located on the northeast side of the proposed Sites Reservoir, along the edges of the proposed Saddle Dams 3, 4, and 5. Access would be provided from the proposed Saddle Dam Road via the proposed North Road. The maximum proposed size of the Saddle Dam Recreation Area is 329 acres.
- **Peninsula Hills Recreation Area –** The Peninsula Hills Recreation Area (Figure 3-2C) would be located on the northwest shore of the proposed Sites Reservoir, to the north of the existing Sites Lodoga Road and across the reservoir from the proposed Saddle Dam Recreation Area. Access would be provided from the proposed Peninsula Road via the existing Sites Lodoga Road. The maximum proposed size of the Peninsula Hills Recreation Area is 373 acres.
- **Antelope Island Recreation Area –** The Antelope Island Recreation Area (Figure 3-2D) would be located in the southwestern portion of the proposed Sites Reservoir. Antelope Island would offer boat-in access only; however, during construction, a temporary road would provide access to the island. The maximum proposed size of the Antelope Island Recreation Area is 49 acres.
- **Lurline Headwaters Recreation Area –** The Lurline Headwaters Recreation Area (Figure 3-2E) would be located near the southeast tip of the proposed Sites Reservoir. Access would occur from the proposed Lurline Road. The maximum proposed size of the Lurline Headwaters Recreation Area is 219 acres.

The proposed Sites Reservoir has the potential to support an average of approximately 410,000 recreation days annually. Collectively, recreation opportunities at the proposed Recreation Areas could provide: boating, camping, picnicking, fishing, swimming, and hiking. Depending on the recreation area, proposed facilities may include boat launch sites, trails, designated swimming and fishing access, picnic tables, shaded canopies, campfire rings/barbeques, vault toilets, and dumpsters. In addition, gravel parking areas would be provided for camp sites, day-use areas, and boat launch facilities. An initial phase of recreation development would be implemented, consistent with a Recreation Plan that would be developed. Some subset of these recreational facilities may be constructed initially based on the environmental analysis included in this DEIR/EIS and Homeland Security guidelines, but all five Recreation Areas could potentially be constructed in the future.

The approximate number of proposed facilities at each proposed recreation area is listed in Table 3-2.

Table 3-2
Approximate Number of Proposed Facilities at the Proposed Recreation Areas

Recreation Areas	Features
Stone Corral Recreation Area	50 campsites (car and recreational vehicle) 10 picnic sites (with parking at each site) 6-lane[a] boat launch site Hiking trails Electricity Potable Water[b] 1 kiosk 10 vault toilets

Table 3-2
Approximate Number of Proposed Facilities at the Proposed Recreation Areas

Recreation Areas	Features
Saddle Dam Recreation Area	10 picnic sites (with parking at each site) Swim area (50 parking stalls) Fishing access parking (20 stalls) Hiking trails 1 kiosk 5 vault toilets
Peninsula Hills Recreation Area	200 campsites (car and recreational vehicle) 1 group camp area[c] 10 picnic sites (with parking at each site) Hiking trails Electricity Potable Water[b] 1 kiosk 19 vault toilets
Antelope Island Recreation Area	12 campsites (boat-in) Hiking trails 1 vault toilet
Lurline Headwaters Recreation Area	50 campsites (car and recreational vehicle) 3 group camp areas 10 picnic sites (with parking at each site) Fishing access parking (10 stalls) Hiking trails Electricity 1 kiosk 8 vault toilets

[a]Reducing the number of boat lanes with increasing water depth.
[b]Treated water from the reservoir will be the source of potable water.
[c]Each group camp area has been sized to accommodate 24 people.

Construction. It is anticipated that all construction activities associated with the five Recreation Areas would occur within the proposed footprints of the recreation areas and the temporary and permanent access road areas. The total construction disturbance area of the five Recreation Areas would be approximately 1,205 acres. However, construction disturbance may be much less because recreational facilities would be designed and constructed to minimize vegetative disturbance, including tree removal.

Anticipated ground-disturbing activities at potential Recreation Areas during construction include:

- Surveying
- Clearing and grubbing
- Excavation
- Backfilling
- Road and parking lot construction
- Utility connections
- Installation of amenities
- Boat ramp construction
- Site revegetation

Operations. It is anticipated that the proposed Recreation Areas would not have onsite staff. A fee collection box and camping information would likely be available at the kiosk near each recreation area's entrance. It is expected that the majority of use at the proposed facilities would occur between Memorial Day (end of May) and Labor Day (beginning of September) of each year, but that activities such as hiking and fishing may occur year-round.

Maintenance. Maintenance activities would include collection of overnight and day-use fees at the fee collection boxes, road grading, water system maintenance, trash removal at picnic sites and overnight campsites, vegetation maintenance, restroom/vault toilet cleaning and restocking of paper goods, boat ramp debris removal, lake debris control, lake hazard marking, lake boom and barrier maintenance, signage, fence maintenance, fuels management, and law enforcement. During peak recreation use periods, these activities would likely occur on a daily basis, except for road grading, which is expected to occur once per year prior to the start of the recreation season. During the non-peak seasons, the activities other than road grading would likely occur on a weekly basis.

3.1.1.3 Road Relocations and South Bridge

The proposed Sites Reservoir would inundate several roads within Colusa County's jurisdiction. Travel between the towns of Maxwell and Lodoga along the existing Maxwell Sites Road and Sites Lodoga Road would be blocked by the new reservoir. Approximately six miles of the existing Huffmaster Road, a gravel county road, would also be inundated. Huffmaster Road provides access to private properties primarily within the proposed Sites Reservoir footprint and the community of Leesville, southwest of the proposed reservoir. Peterson Road, also a gravel county road that provides access to private property, is located entirely within the proposed reservoir footprint. Existing roads would be rerouted, as necessary, to provide alternate access routes.

Approximately 46 miles of new roads would provide construction and maintenance access to the proposed Project facilities, as well as provide public access to the proposed Recreation Areas. The locations of proposed roads, the proposed South Bridge, and existing roads near the proposed Sites Reservoir that would be affected by Project construction and/or operation are shown in Figures 3-3A and 3-3B.

Five road alternatives were evaluated to determine the best method of connecting the towns of Maxwell and Lodoga. To determine the best road alternative available, weighted criteria were independently assessed for shortest travel time, least total cost, least annual operations and maintenance cost, shortest emergency response time, least impact to wildlife habitat, least impact to wetlands and riparian areas, and least impact to public safety. Of the road alternatives, the South Bridge Alternative had the highest ranking. The portions of Maxwell Sites and Sites Lodoga roads that would be inundated by the proposed reservoir would be replaced by a new bridge (South Bridge Alternative). The road would start approximately one mile east of the proposed Sites Dam on Maxwell Sites Road. The new route would consist of the proposed Eastside Road, Stone Corral Road, the South Bridge, and an approach road west to Sites Lodoga Road. This route would also provide access to the proposed Stone Corral Recreation Area.

The proposed South Bridge would be a two-lane concrete bridge 35.5 feet wide and approximately 1.6 miles long. The top deck elevation would be 45 feet above the proposed Sites Reservoir's maximum normal water surface elevation. For the roads leading up to and away from the bridge, the proposed road right-of-way would be 60 feet wide with a four percent grade. Culverts and minor bridges would be constructed to provide passage for streams and drainage of surrounding areas, including the construction of a culvert where the proposed Eastside Road would cross Funks Creek. Guardrails, signs, striping and lighting would be installed after the roads are completed pursuant to Caltrans/AASHTO design specifications. Permanent fencing would be installed along both edges of the right-of-way (60 foot width).

The proposed North Road and Saddle Dam Road (both new gravel roads) would provide access to northern portions of the proposed Sites Reservoir, saddle dams, and Saddle Dam Recreation Area. A new road, Eastside Road, would be gravel from the existing County Road 69 to near the proposed Sites Pumping/Generating Plant, and paved south of the plant. The proposed Eastside Road would connect the proposed Stone Corral Road to County Road 69, providing access to the northern portions of the proposed Sites Reservoir, Holthouse Reservoir Complex, Golden Gate Dam and appurtenant structures, and to properties northeast of the proposed Sites Reservoir. Along the west side of the proposed Sites Reservoir, the proposed Peninsula Road would provide access from Sites Lodoga Road to the proposed Peninsula Hills Recreation Area. The proposed Sulphur Gap Road would provide access to southern portions of the proposed Sites Reservoir, the Lurline Headwaters Recreation Area, private property adjacent to the proposed Com Road, and would connect to Huffmaster Road.

The proposed road alignment around the proposed saddle dams on the northern rim would not change for the three alternatives. However, Alternatives B and C would require approximately 1.2 miles of additional roads to access Saddle Dams 1 and 2. Saddle Dams 1 and 2 would not be needed for Alternative A (Alternative A includes a small saddle dam north of Golden Gate Dam, also called Saddle Dam No. 1. This small Saddle Dam No. 1 is different from the Saddle Dam No. 1 included in Alternatives B and C). The access road to Golden Gate Dam would be longer in Alternative A because the dam would be set farther back (approximately 0.25 mile long in Alternatives B and C versus 0.55 mile in Alternative A). Alternatives B and C would require approximately 0.4 mile of additional spur roads to access the saddle dams that would be set back further than Alternative A.

Permanent facility access roads constructed from gravel and asphalt would facilitate operation and maintenance activities. These proposed access roads would require new construction or the relocation of existing public county roads and bridges; these activities would follow Caltrans and AASHTO design standards. During construction, gravel roads would be constructed on the following detour and construction roads: the proposed Sulphur Gap and Lurline roads, and an existing dirt road west of the proposed Lurline Headwaters Recreation Area to Huffmaster Road.

Characteristics of the proposed roadways, South Bridge, and the minor structures, respectively, are listed in Tables 3-3, 3-4, and 3-5.

Table 3-3
Characteristics of Proposed Roadways and South Bridge Approaches

Road or Segment Name	Gravel Road (miles)	Paved Road (miles)	Paved Bridge (miles)	Total (miles)

Notes:
Mi = miles
T-C Canal = Tehama-Colusa Canal

Table 3-4
Proposed South Bridge Characteristics

Item	Dimension
Bridge Length	Approximately 8,500 feet (1.6 miles)
Bridge Width	35.5 feet
Bridge Height[a]	Approximately 45 feet
Bridge Depth[b]	20 foot maximum, 8 foot minimum
Spans	400 feet maximum, 260 feet minimum, 22 spans total
Columns – 1.81 MAF Dimensions	18 feet by 14 feet square, hollow, maximum height approximately 300 feet, 21 columns total
Columns – 1.27 MAF Dimensions	18 feet by 14 feet square, hollow, maximum height approximately 260 feet, 21 columns total
Foundations	3-foot-diameter cast-in-place drilled shafts, 8 per footing, 168 total

[a]The bridge height is the distance from the top of the bridge deck to the maximum water surface elevation.
[b]The bridge depth is the distance from the top of the bridge deck to the bottom of the bridge structure that sits atop the columns.

Table 3-5
Characteristics of Proposed Minor Structures*

Item	Typical Dimensions
Culverts (over unnamed streams), 17 total	6 foot diameter by 100 foot length
Minor Bridge (over named streams), 1 total	40 foot width by 80 foot length

*Minor structures would be built using steel pipe or pre-cast pieces.

Construction. The total construction disturbance area would consist of approximately 1,330 acres. It would include the footprint of the proposed roads and stream crossings, the materials and equipment staging areas, the area needed to construct the facilities, and construction access roads. The total construction disturbance area would also include the footprint of the proposed South Bridge structure, the materials and equipment staging areas, the area needed to construct the facilities, and access roads.

Traffic that is not construction-related would be diverted around Project construction disturbance areas.

If necessary, an asphalt batch plant would be built on-site and outside of the proposed Sites Reservoir footprint. An asphalt batch plant footprint would occupy approximately 15 acres and would be located adjacent to the footprint of the proposed Field Office Maintenance Yard. This location would be centrally located to the proposed Project's paving needs, is relatively flat, and has shallow soils and impervious subsoil that should allow for easy spill containment and site cleanup. Alternatively, the construction contractor may obtain asphalt from regional commercial sources. Concrete bridge construction would include excavation for foundations and abutments; installing cast-in-place concrete formwork; placing reinforcing steel; installing bridge deck expansion joints; pouring and curing concrete; removing concrete forms; installing bridge barriers, bridge railings, bridge lighting, approach roadway guardrails, fences, signs, and reflectors; and painting approach and bridge deck striping.

Anticipated ground-disturbing activities during construction include:

- Surveying and marking
- Clearing and grading the construction workspace
- Preparing the construction materials laydown and equipment staging areas
- Transportation of materials and equipment to the project site
- Building concrete and/or asphalt batch plant
- Road cuts and fills
- Bridge foundation construction
- Bridge column construction
- Bridge span construction
- Installing culverts and minor bridges
- Laying aggregate road base and asphalt
- Installing fences, guardrails, and signs
- Installing roadway striping and reflectors
- Erosion and stormwater management
- BMP implementation
- Site restoration and clean-up

Operations. Not applicable.

Maintenance. Typical road maintenance would consist of chip sealing; patching; grading; crack filling; asphalt overlays; repairing damaged guardrails, fencing, and signage; embankment erosion repair; and vegetation control. Typical culvert and minor bridge maintenance would consist of debris removal, cleaning, and repairing steel pipe corrosion and pre-cast concrete cracks.

Typical bridge maintenance would consist of clearing debris from bridge deck and deck drainage outlets; barrier, railing and light repairs; concrete deck and expansion joint repairs; approach slab and guardrail repairs; and abutment erosion maintenance and repair. In addition, annual safety and maintenance inspections would be conducted pursuant to Caltrans/AASHTO requirements to maintain a bridge condition monitoring record.

3.1.1.4 Sites Pumping/Generating Plant

The purpose of the proposed Sites Pumping/Generating Plant would be to pump water from the proposed Holthouse Reservoir to the proposed Sites Reservoir to fill it and to generate electricity during the release of water from Sites Reservoir to Holthouse Reservoir. The Sites Pumping/Generating Plant would be located approximately 3,300 feet southeast of the proposed Golden Gate Dam (Figure 3-4).

The Sites Pumping/Generating Plant would lift water from Holthouse Reservoir into Sites Reservoir and would be connected to Holthouse Reservoir by a long excavated approach channel. The existing Funks Reservoir operates in coordination with the T-C Canal between elevations of 203 and 205 feet. However, with the proposed Holthouse Reservoir design which incorporates the existing Funks Reservoir, the Sites Pumping/Generating Plant would operate with tailwater elevations down to elevation 192 feet during pumping to take advantage of the full 6,500 acre-feet active capacity of Holthouse Reservoir. A 30-foot-diameter tunnel would be located on the inlet side of the Sites Pumping/Generating Plant connection to Sites Reservoir.

Water from Holthouse Reservoir would be drawn into the Sites Pumping/Generating Plant by the various pumping and pumping-generating units. The number of units operating would be selected to provide the approximate pumping capacity needed to deliver all water stored in the reservoir on a daily basis during the off-peak pumping period. The Sites Pumping/Generating Plant would be a conventional, indoor-type pumping-generating plant with an in-line arrangement of vertical pumping units. The Sites Pumping/Generating Plant for Alternatives A and C would have a total pumping capacity of approximately 5,900 cfs and a release capacity of 5,100 cfs. The Sites Pumping/Generating Plant for Alternative B would have a total pumping capacity of approximately 3,900 cfs and a release capacity of 5,100 cfs.

A Four Breaker Ring Bus would be required at the Sites Pumping/Generating Plant. The ring bus would be approximately 500 feet by 300 feet. The ring bus breaker would allow the electrical current flowing to each individual pump station to be isolated and interrupted, if required, for maintenance or safety without interrupting the current to the other pump stations.

Construction. Construction information is provided in Section 3.1.4.5 for the 5,900-cfs Sites Pumping/Generating Plant and Section 3.1.5.5 for the 3,900-cfs Sites Pumping/Generating Plant.

Operations. Operations information is provided in Section 3.1.4.5 for the 5,900-cfs Sites Pumping/Generating Plant and Section 3.1.5.5 for the 3,900-cfs Sites Pumping/Generating Plant.

Maintenance. Maintenance information is provided in Section 3.1.4.5 for the 5,900-cfs Sites Pumping/Generating Plant and Section 3.1.5.5 for the 3,900-cfs Sites Pumping/Generating Plant.

3.1.1.5 Electrical Switchyards

Electrical switchyards would be needed to step down the electrical voltage from high voltage lines (used to transmit electricity over long distances) to a lower voltage that can be used by the pumps and other machinery in the proposed pumping/generating plants. An electrical switchyard would be constructed near where the proposed Delevan Transmission Line would cross an existing transmission line (either PG&E 230-kV, WAPA 500-kV, or WAPA 230-kV transmission lines that are aligned north-south); at the proposed Sites Pumping/Generating Plant; and at the proposed TRR Pumping/Generating Plant. The switchyard sites would be graded flat and would have multiple pieces of electrical equipment on concrete pads. The proposed Sites Electrical Switchyard associated with the Sites Pumping/Generating Plant would be approximately 3.5 acres in size. The proposed TRR Electrical Switchyard associated with the TRR Pumping/Generating Plant would be approximately 100 feet long by 50 feet wide. The proposed Holthouse Reservoir Electrical Switchyard or the Delevan Pipeline Electrical Switchyard associated with a transmission line tie-in to the existing WAPA Transmission Line or PG&E Transmission Line, respectively, would be approximately four acres in size. At each switchyard, one transmission tower (approximately 50 feet tall) would receive the electrical line entering the site. A four breaker ring bus would be required at each switchyard[2]. The ring bus would have multiple metallic poles with heights varying between 15 feet tall and 60 feet tall. The switchyards would be surrounded by a six- to eight-foot-high chain link fence with barb or serpentine wire along the top.

The switchyards and transmission lines connecting the pumping/generating plants to the grid would provide all of the electricity needed by the pumping plants. The switchyards and transmission lines would allow the pumping/generating plants to feed electricity back into the electrical grid during generation activities.

The proposed Sites Electrical Switchyard would be located north of and immediately adjacent to the proposed Sites Pumping/Generating Plant (Figure 3-4). The proposed Holthouse Reservoir Electrical Switchyard connecting to the existing WAPA or PG&E transmission lines would be located within the footprint of the existing Funks Reservoir facilities or within a portion of the surveyed footprint of Holthouse Reservoir (facility not shown in figure). The proposed TRR Electrical Switchyard would be located within the footprint of the TRR Pumping/Generating Plant (Figure 3-5). The proposed Delevan Pipeline Electrical Switchyard connecting to the existing PG&E transmission line would be located within the Delevan Pipeline right-of-way at the location where the source transmission lines cross the pipeline (Figure 3-5). No additional construction disturbance area would be required for this switchyard beyond what would be required for the Delevan Pipeline (discussed in Section 3.1.1.16).

Construction. The total construction disturbance area for the switchyards would include the footprint of each of the proposed switchyards, the materials and equipment staging area, electrical transformer area, and temporary access roads. The construction disturbance areas for the TRR-associated switchyard and the PG&E tie-in switchyard would be located within the Delevan Pipeline construction disturbance area. For the WAPA tie-in switchyard, the construction disturbance area would be located within Holthouse Reservoir Complex disturbance area. The construction disturbance area for the Sites Electrical Switchyard would be located within the Sites Reservoir Inlet/Outlet Structure disturbance area.

Anticipated major construction activities include clearing and grading the construction workspace; placing necessary construction materials at staging areas; and preparing the switchyard pad.

Operations. Operation of the proposed switchyards would be done remotely.

Maintenance. The proposed switchyards and transmission lines would require maintenance once or twice a year. Maintenance activities may include annual washing and cleaning of insulating equipment, preventative maintenance, scans of the switchyard under full load and routinely scheduled testing to meet Western Electricity Coordinating Council (WECC) requirements. Regular maintenance activities would include inspections for damage done by animals and maintaining landscaping.

---

[2] The ring bus breaker would allow the electrical current flowing to each individual pump station to be isolated and interrupted, if required, for maintenance or safety without interrupting the electrical current to the other pump stations.

3.1.1.6 Tunnel from Sites Pumping/Generating Plant to Sites Inlet/Outlet Structure

The purpose of the proposed tunnel is to transport water between the proposed Sites Pumping/Generating Plant and the proposed Sites Reservoir Inlet/Outlet Structure. The tunnel alignment would be located west of the existing Funks Reservoir and south of the proposed Golden Gate Dam on Funks Creek. The tunnel alignment would fall between the proposed Sites Pumping/Generating Plant location and the proposed Sites Reservoir Inlet/Outlet Structure location, and would be approximately 4,030 feet long (Figure 3-4).

The proposed 30-foot-diameter tunnel size is designed to meet DWR's Division of Safety of Dams' (DSOD) emergency drawdown release criteria. The tunnel would have a maximum discharge capacity of 23,000 cfs with a corresponding tunnel velocity of 32.5 feet per second (fps). Pumping velocities through the tunnel would be approximately 8.35 fps for the 5,900-cfs pumping plant included as part of Alternative A and Alternative C, and 5.51 fps for the 3,900-cfs plant included as part of Alternative B.

The tunnel from the upstream portal would be concrete-lined to prevent rock fallout and to ensure a smooth interior surface, thus reducing head loss and minimizing seepage into the surrounding rock. The tunnel would extend from the inlet to a vertical gate shaft with a fixed wheel gate. Downstream of the gate shaft, the tunnel would continue until the depth of rock cover dictates use of a steel liner. The tunnel would be concrete lined with an additional steel liner in the first 1,000 feet adjacent to the pumping plant.

Construction. The total construction disturbance area would be approximately 3.4 acres. It would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, and access roads. There would be no permanent aboveground disturbance area for this facility.

Anticipated ground-disturbing activities during construction include surveying and marking, clearing and grading, building access roads, installing temporary power to site, developing staging and material laydown areas, transporting construction materials and equipment to site, cofferdam and diversion construction at Golden Gate Dam, tunnel excavation, dewatering, concrete and steel liner installation, and site restoration and cleanup.

Operations. The typical operation scenario for the proposed tunnel would be 24 hours per day, seven days per week. Tunnel operation would be conducted remotely. The tunnel would transport flows between the proposed multi-level Sites Reservoir Inlet/Outlet Structure upstream and the Sites Pumping/Generating Plant downstream. During emergency release operations, the tunnel could discharge a maximum flow rate of approximately 23,000 cfs.

Maintenance. Maintenance would likely occur on an annual basis in coordination with maintenance and inspection of the proposed Sites Reservoir Inlet/Outlet Structure and multi-level intake tower upstream, and the proposed Sites Pumping/Generating Plant downstream.

To allow for tunnel inspection maintenance, low-level gate stop logs would be used to shut off flow from the low-level inlet structure to the downstream tunnel section. The stop logs would be lowered from a barge above and dropped into the low-level inlet structure. In addition, the multi-level tower wheel gates would be closed off to completely isolate the tunnel from reservoir flows for inspection and maintenance.

Typical tunnel inspection and maintenance may consist of checking for concrete cracks and leaks and missing or defective steel lining connections (bolts, rivets) at joints between lining sections and around connections with the Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure tower gates, and low-level intake structure.

3.1.1.7 Sites Reservoir Inlet/Outlet Structure

The purpose of the proposed Sites Reservoir Inlet/Outlet Structure would be to regulate proposed Sites Reservoir releases through the proposed tunnel to the proposed Sites Pumping/Generating Plant. The structure would be located on the west end of the tunnel and southwest of the proposed Golden Gate Dam (Figure 3-4). The structure would consist of a low level inlet/outlet structure for emergency drawdown releases, a multi-level inlet/outlet tower with two fixed wheel gates, and a tower access bridge.

The low level inlet/outlet structure would be approximately 120 feet from bottom of foundation to the top of trashracks. The rectangular structure dimensions would be approximately 100 feet by 120 feet. The three 30-foot by 30-foot intake openings would be covered by trashracks.

The multi-level inlet/outlet tower would have multiple inlet ports with the capability of drawing water at different levels in the reservoir, and trashracks with port valves (butterfly valves) embedded in the inlet tower tiers with four valves around each tier. The tower would also contain movable fish screens around two tiers for varied operational purposes (6,000 cfs for two tiers). Each port valve could be operated independently or all valves could be operated together in each tier. The tiers would be spaced approximately 20 feet apart down the tower beginning approximately 30 feet below the maximum reservoir water level. The high inlet tower/shaft would also contain two 9-foot by 35-foot fixed wheel gates at the base of the tower to isolate the tower from the main tunnel for inspection and maintenance. The main tower shaft would have an inner diameter of 30 feet and an outer diameter of 39 feet. Cranes would be used to hoist the fish screens, port valves, and gates for necessary inspection and maintenance.

The tower details would be similar for both the proposed 1.27 and 1.81 MAF Sites Reservoir sizes, but the tower elevations and number of inlet ports would be different. Table 3-6 provides a comparison of tower details for the two reservoir sizes under consideration.

Table 3-6
Proposed Sites Reservoir Inlet/Outlet Structure Tower Consideration

	1.81-MAF Reservoir Alternative B and Alternative C	1.27-MAF Reservoir Alternative A
Top Elevation	580.0 Feet	540.0 Feet
Bottom Elevation (Top of Bench)	320.0 Feet	320.0 Feet
Inside Diameter	30 Feet	30 Feet
Outside Diameter	39 Feet	39 Feet
Number of Ports	36 (4 Each at 9 Levels)	28 (4 Each at 7 Levels)
Functional Reservoir Release Elevations	520 Feet to 340 Feet	480 Feet to 340 Feet

A bridge would provide access to the multi-level tower from the nearby access road. The bridge length would be approximately 440 feet for the 1.27-MAF Sites Reservoir (Alternative A) and 540 feet for the 1.81-MAF Sites Reservoir (Alternatives B and C). The bridge deck elevation would be approximately equal to the dam crest heights (approximately 500 feet for the 1.27-MAF reservoir and 540 feet for the 1.81-MAF reservoir). The bridge is expected to be a simple welded-plate girder system with a lightweight concrete deck. The girders would be supported by the multi-level inlet/outlet tower, cast-in-place reinforced concrete piers, and a reinforced concrete abutment.

To meet DWR's DSOD's requirements, an emergency release outlet would be constructed to allow water levels behind the dam to be lowered quickly if the integrity of the dam is at risk. The 30-foot diameter tunnel with a maximum release capacity of 23,000 cfs is designed to meet DSOD's emergency drawdown release criteria. The emergency release would bypass the pump/generator units by passing water through an alternate outlet manifold (called the Emergency Release Bypass Outlet). The Emergency Release Bypass Outlet would be a 26-foot-diameter pipe that splits off from the tunnel/main inlet-outlet manifold. The 26-foot-diameter pipe would split into two 18-foot-diameter pipes, then into four 13-foot-diameter pipes, then into eight 9-foot-diameter pipes that would terminate at fixed cone valves. An Emergency Notification Plan would be developed, and would include a protocol for notifying downstream entities if an emergency release were to occur.

Construction. The total construction disturbance area would be approximately 110 acres. It would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, and access roads.

Anticipated ground-disturbing activities during construction include surveying and marking, clearing and grading, building access roads, installing temporary power to the site, preparing materials laydown and equipment staging areas, transporting construction materials and equipment to the site, tower shaft excavation (separate from tunnel), dewatering, building the multi-level tower base and deck, building the access bridge to the multi-level tower, installing cranes on the tower deck, building the low-level intake structure, and finished grading and site clearing.

Operations. The proposed multi-level inlet/outlet tower and low-level intake structure would be operated remotely. The multi-level tower port valves could be operated independently or by tier. Port valve operations could be adjusted locally or remotely via a supervisory control and data acquisition (SCADA) system. Port valve operations would be changed by adjusting the hydraulic operators.

Maintenance. The stop gates could be raised and lowered between tiers to stop flow by tier if a port valve needed to be cut off from flow for inspection or maintenance. The gates could be raised or lowered by crane on-site or remotely via a SCADA system. Typical maintenance of the proposed inlet/outlet structure is expected to occur annually, and would consist of servicing the hydraulic equipment (hoist cranes, control motors) and fish screen pumps. Hydraulic equipment maintenance service would primarily involve lube and filter replacements.

The emergency stop gate maintenance would be performed annually. Maintenance would involve moving them through a full stroke (open and closed) position. Annual inspections for corrosion and wear would also be performed.

As part of emergency preparedness checks, the gate operation electrical control panel would be tested every six months.

The port valve hydraulic operators are very high maintenance items requiring quarterly inspection and maintenance. Typical port valve maintenance would involve lube and filter replacements along with checking for hydraulic line damage.

The concrete low-level intake structure is considered to be low-maintenance given it has no mechanical component and would be underwater. Annual maintenance typically would occur along with annual tunnel and tower inspections and maintenance. With the stop logs in place (normal operation), typical maintenance would include inspections for excessive leaking and cracks around the connection with the tunnel portal.

3.1.1.8 Field Office Maintenance Yard

Due to the size of the proposed Project area and the number of proposed facilities, a staffed operation and maintenance complex (Field Office Maintenance Yard) would be built on-site (Figure 3-4) to service all proposed Project facilities. An administration building and parking area would be constructed to meet Project needs.

Construction. The total construction disturbance area would be approximately 18 acres, with approximately 12 acres of permanent space for the proposed footprints of the administrative and maintenance buildings. Buildings may include an Administration Building, Plant Maintenance Warehouse, Service and Supply Warehouse, Utility Craft Office, Mechanical Equipment Shop, Heavy Equipment Shop, Project Surveillance Building, and General Maintenance Headquarters.

Construction of the proposed Field Office Maintenance Yard would include the following:

- Transportation of materials to the project site
- Clearing and grading the site for construction
- Placing construction materials at staging areas
- Constructing Administrative and Maintenance buildings
- Constructing ancillary facilities (e.g., leach-field, water treatment, incinerator, lighting, concrete pad for refueling island, aboveground fuel tanks, perimeter fencing)
- Site restoration after construction is complete

Operations. The typical operations scenario for the proposed Field Office Maintenance Yard would be 24 hours per day, seven days per week. The facility would be fully staffed during normal business hours, when scheduled maintenance of Project facilities would occur. Minimum personnel staffing would occur during off-peak hours to respond to emergency situations. Spare parts for mechanical and electrical equipment would be stored in the warehouse along with lubricants, oils, and greases to maintain equipment. Daily operations could include personnel traveling from the Field Office Maintenance Yard to Project facilities and performing scheduled repairs, inspection, and maintenance of Project equipment, observing Project facilities and operations, and as-needed emergency repairs. Equipment repair and overhaul (e.g., pumps, turbines) may take place at the facility. The SCADA system would be operated and monitored remotely from the Administration Building.

Daily operations may include fueling and washing vehicles and equipment, gathering technical data on water quality and project facilities conditions, and maintaining and repairing mechanical equipment.

Maintenance. Periodic maintenance would likely be performed on an as-needed basis including road, building, vegetation, and fence maintenance, as well as debris removal.

3.1.1.9 Holthouse Reservoir Complex

The existing 40-foot-high Funks Dam forms the 2,250 acre-foot Funks Reservoir one mile downstream of the proposed Golden Gate Dam site. This reservoir was constructed by Reclamation and is part of the T-C Canal system. Funks Reservoir serves as a re-regulating reservoir to stabilize flows in the canal downstream of Funks Reservoir as diverters come on line and off line. The existing Funks Reservoir would be expanded to form the proposed Holthouse Reservoir (Figure 3-4) by constructing a new dam

(Holthouse Dam) and reservoir to the east of Funks Reservoir, and breaching the existing Funks Dam so that the new and existing reservoirs would act as one unit with an enlarged active storage capacity of approximately 6,500 acre-feet and a surface area of approximately 450 acres. The proposed Holthouse Reservoir is required to facilitate balancing and regulating the proposed Sites Reservoir inflows and outflows through the proposed Sites Pumping/Generating Plant, and to provide sufficient supplemental storage to allow simultaneous pump back power generation.

The 6,500 acre-foot Holthouse Reservoir would allow the Sites Pumping/Generating Plant to perform a pumped-storage function for up to six hours per day while simultaneously collecting and storing inflows from the Sacramento River through the T-C and GCID canals (all three alternatives), and through the proposed Delevan Pipeline (Alternatives A and C). All water would be pumped into Sites Reservoir from Holthouse Reservoir during off-peak power periods on a daily basis.

The proposed Holthouse Dam would include two sections: a combination concrete and roller compacted concrete (RCC) dam section near the center that would accommodate the inlet/outlet facilities for the proposed Delevan and TRR pipelines, and earth embankments on either side of the concrete dam to close off the valley and form Holthouse Reservoir. The total length of the dam would be approximately 7,800 feet. The RCC dam section would be approximately 400 feet long. Maximum dam heights would be approximately 45 feet. The crest elevation of the dam would be at elevation 214 feet to match the crest of the existing Funks Reservoir Dam and the surrounding topography. A grout curtain would be installed under both dam sections to control underseepage.

Operating levels within Holthouse Reservoir would vary between elevation 206.0 feet and 192.0 feet, which would provide the required active storage capacity of approximately 6,500 acre-feet. Elevation 206.0 feet corresponds to the 2011 normal operating level in existing Funks Reservoir. There would be approximately 1,000 acre-feet of dead storage in Holthouse Reservoir due to topographic elevations near the new Holthouse Dam. This space could be allocated to sediment accumulation, disposal of excess excavated material from the proposed Project, or for disposal of existing sediment.

Pump-back operations would involve the daily procurement of relatively inexpensive power sources (i.e. renewable energy) to pump water from the proposed Holthouse Reservoir up to the proposed Sites Reservoir during off-peak hours of power usage, and release that pumped water from Sites Reservoir to Holthouse Reservoir during peak hours of power usage. Pump-back power production provides flexible generation and would be used to compensate for rapid changes in electric power demand, such as from increased air conditioning use on very hot days, as well as to compensate for changes in power production from variable renewable power sources, such as wind and solar power projects. Although water delivery and power production are given equal weight in the planning goals for the Project, pump-back power operations would likely be secondary to water delivery operations because of the various restrictions on water operations from contracts and from environmental restrictions, but would be optimized within those restrictions to produce the greatest value to users. Pump-back operations from the afterbay to the forebay of each of the two or three (depending upon the chosen alternative) proposed Project pumping/generating facilities would be possible, but only the Sites Pumping/Generating Plant would be used for daily pump-back operations because of the operational limitations placed on the smaller forebays and afterbays of the other Project pumping/generating facilities.

Besides the dam and reservoir, the Holthouse Reservoir Complex would also include the following features:

- **Holthouse Pumping Plant –** The reservoir operating levels could drop down below elevation 198.0 feet, which is the minimum level that could supply water to the downstream T-C Canal by gravity. To supply water to the canal when reservoir elevations are below 198.0 feet, a low head pumping plant would be installed with a capacity of 800 cfs. The pumps would draw water from the inlet/outlet piping. The water would be pumped up to the canal in a buried pipeline (the Holthouse to T-C Canal Pipeline) outside of the downstream toe of the dam. The pipeline would be a single 10-foot-diameter pipe or two 7-foot-diameter pipes. An energy dissipating structure would be provided at the discharge point to the canal.
- **Holthouse Spillway and Stilling Basin and Spillway Bridge –** An emergency spillway with a capacity of 23,000 cfs would be required in the Dam to pass the emergency Sites Reservoir drawdown flows required by DWR's DSOD. The stair-step RCC spillway with confining walls on both sides would be constructed near the center of the RCC dam. The spillway crest length would be approximately 375 feet and the crest would be set at an elevation of 206 feet, which corresponds to the current normal maximum operating level in Funks Reservoir. When passing the maximum design flow, the water depth over the spillway would be approximately seven feet. A stilling basin would be built below the spillway to dissipate the energy of the flowing water from the spillway to prevent erosion downstream of the dam. A 375-foot-long bridge would be built over the spillway to provide access across the dam.
- **Western Area Power Administration Transmission Line Relocation –** Eight Western Area Power Administration (WAPA) transmission line towers are located within the footprint of the proposed Holthouse Reservoir. Based upon preliminary contacts with WAPA, the preferred relocation alternative is one that would move a segment of the line to the west so that it would cross at a narrow spot in the existing Funks Reservoir. The relocated span would be approximately 1,000 feet.
- **Sites Pumping/Generating Plant Approach Channel –** The Sites Pumping/Generating Plant would be connected to Holthouse Reservoir by an earthern approach channel approximately 8,300 feet long. The Channel is expected to have relatively flat slope toward the Sites Pumping/Generating Plant and would be constructed at an elevation below the operating range of the reservoir. The Channel would have a trapezoidal geometry with a bottom width of approximately 200 feet and a top width of 400 to 700 feet. When Holthouse Reservoir is full, the channel would be nearly entirely submerged. This channel would allow water from Holthouse Reservoir to flow by gravity to or from the pumping/generating plant, and would allow upstream Funks Creek flows to enter Holthouse Reservoir via an approach channel spillway.
- **Existing T-C Canal Connections –** The T-C Canal would be modified to enter the Holthouse Reservoir at a point behind the Holthouse Dam. A new baffle block energy dissipating spillway structure (T-C Canal Discharge Dissipater) would be constructed near Holthouse Dam to convey water down into the reservoir regardless of reservoir level. Approximately 0.5 mile of the existing canal beyond the new tie-in point up to the current connection point to Funks Reservoir would be abandoned. A portion of the downstream canal within the Holthouse Reservoir limits would also be abandoned. Because it would be possible to supply water to the downstream canal by gravity at times when the Holthouse Reservoir is high, a new gate-controlled outlet would be provided from the reservoir near the abutment of the Holthouse Dam.

- **T-C Canal Construction Bypass Pipeline –** Installation of a bypass would be required to divert T-C Canal flow before starting modifications to existing Funks Reservoir. The bypass would be maintained as a permanent feature following modification of Funks Reservoir and construction of Holthouse Reservoir, as requested by TCCA. The proposed bypass would consist of a 12-foot-diameter pipeline starting approximately 2,600 feet upstream of the T-C Canal inlet into Funks Reservoir. The bypass would route the required flows around Funks Reservoir during reservoir modification construction. The bypass construction would require installation of two cofferdams on the upstream portions of the T-C Canal to isolate the area of embankment cut and pipe installation. The Funks Reservoir would be dewatered and the existing check structure would be dismantled and reconstructed approximately 3,000 feet upstream. The check structure would consist of two 18-foot by 15.5-foot gates, electrical control, hoists, and concrete supports and reinforcement. The facility would be relocated slightly downstream of the bypass. The bypass would need to be gated or valve controlled to regulate releases downstream, as required by the TCCA.

Construction. The total construction disturbance area would consist of approximately 640 acres. It would include the proposed footprints of Holthouse Reservoir, Holthouse Dam, Holthouse Spillway and Stilling Basin, Holthouse Pumping Plant, T-C Canal Discharge Dissipater, T-C Canal Construction Bypass Pipeline, the Holthouse to T-C Canal Pipeline, and buffer lands adequate for construction staging.

Construction materials for the earth dam would come from required excavations for the proposed Sites Pumping/Generating Plant and the channel connecting the enlarged reservoir with the Sites Pumping/Generating Plant. The material in the existing Funks Dam could also be reused to construct the new dam. Approximately 680,000 cubic yards of core material and 2,200,000 cubic yards of earth and rockfill would be required to construct the dam.

Construction materials for the proposed Holthouse Dam would include imported sands and gravel. Processed rock from Project excavations could also be used if the material is found to be suitable for such use. On-site material sources would be explored in future investigations for the Project. Approximately 150,000 cubic yards of RCC material would be required.

Because the existing Funks Reservoir is an on-stream reservoir, a significant portion of the reservoir active storage has been displaced due to sediment accumulation from Funks Creek. Although topographic data are available for the reservoir from the original construction drawings, there is no current bathymetric data to support an estimate of the amount of sedimentation that has actually accumulated. However, it is believed that the current active capacity could be as low as 1,500 acre-feet. This would mean that approximately 750 acre-feet, or 1.2 million loose cubic yards of sediment has accumulated. A bathymetric survey of the existing reservoir would be performed as part of future design phases of the proposed Project to establish the volume and physical characteristics of the sediment so the material can be properly managed during design and construction.

A large portion of the accumulated sediment would be removed and relocated to construct the new Holthouse Reservoir, in particular the low level flow channel connecting the reservoir with the Sites Reservoir Pumping/Generating Plant. Once a diversion system is installed to route Funks Creek flows around the Holthouse Reservoir work site, the sediment can be dewatered over a period of time by ditching and sumping. Once dry enough to be excavated and moved, the material can be disposed of in the lower elevations of the new Holthouse Reservoir in a dead storage area or in backwater areas around the perimeter of the existing reservoir. The construction schedule for the proposed Project should allow adequate time to dewater and remove the material without affecting the new dam construction (which is outside the limits of sediment accumulation).

Typical summer releases from Funks Reservoir range from 500 cfs to 800 cfs. Total flows of 50 cfs to 200 cfs for off-peak limited agricultural releases would be needed between November and February, possibly stretching to March, depending on the weather. The proposed bypass consists of a 12-foot-diameter pipeline starting approximately 2,600 feet upstream of the T-C Canal inlet into Funks Reservoir. The bypass would route the required flows around Funks Reservoir during reservoir modification construction.

Operations. Funks Reservoir is operated by TCCA pursuant to a contract with Reclamation. Operation of the proposed Holthouse Reservoir would be coordinated with TCCA, but operated by the designated operator of the proposed Sites Reservoir. During fall and winter months, inflows from the conveyance system and water for power generation would be stored during on-peak power periods. The stored water plus ongoing off-peak inflows from the conveyance systems would then be pumped to Sites Reservoir during the partial-peak/off-peak power period on a daily basis. During the spring and summer months when releases are being made from Sites Reservoir, released water would go through the Sites Pumping/Generating Plant to generate power. Holthouse Dam would maintain releases to Funks Creek of up to 10 cfs year-round based on a recommendation from CDFW staff. This flow is intended to replace the existing seepage flow on Funks Creek below Funks Dam.

Maintenance. Current periodic maintenance required for Funks Reservoir includes road, vegetation, and fence maintenance, as well as debris removal, on an as-needed basis. The reservoir is also drained annually. These maintenance activities are expected to be the same for the proposed Holthouse Reservoir. Periodic maintenance and inspection of Holthouse Reservoir would be coordinated with T-C Canal operators or could be conducted at a centralized maintenance and operation office for the proposed Sites Reservoir.

3.1.1.10 Pump Installation at the Red Bluff Pumping Plant

The TCCA Fish Passage Improvement Project was constructed at the RBDD and completed in 2012. The Fish Passage Improvement Project (Figure 3-6) included a fish screen, a pumping plant at the Mill Site (known as the Red Bluff Pumping Plant), canal, siphon, a forebay, switchyard, and a bridge across Red Bank Creek. The fish screen structure was designed to meet National Oceanic and Atmospheric Administration-National Marine Fisheries Service (NOAA Fisheries) and California Department of Fish and Wildlife (CDFW) criteria for diversion flows of 80 cfs to 2,500 cfs. The 2,500-cfs Red Bluff Pumping Plant includes 11 vertical axial-flow pumps. Nine of the 11 vertical axial-flow pumps (seven 250-cfs and two 125-cfs) were installed in the pumping plant, having a combined total rated capacity of 2,000 cfs. The pumping plant includes two additional pump bays designed for the future installation of two 250-cfs vertical axial-flow pumps.

The proposed Project would require pumping capacity that exceeds the existing total rated capacity of the Red Bluff Pumping Plant. Therefore, the installation of one additional 250-cfs vertical axial-flow pump into an existing concrete pump bay at the pumping plant would be required (Figure 3-6). The proposed Project also includes the operation and maintenance of the proposed additional pump. The proposed additional pump at the pumping plant would allow for a total diversion up to 2,160 cfs for each proposed Project alternative in winter and spring months, including up to 2,100 cfs for diversion to the proposed Sites Reservoir, and an additional 50 to 60 cfs for maintaining existing winter and spring flow operations of the T-C Canal.

Construction. Installation of the 250-cfs vertical axial flow pump unit would require the following major construction activities[3]:

- The pump unit bay includes an existing 84-inch diameter steel pipe embedded in the pumping plant back wall. The existing steel pipe includes a blind flange on the afterbay side of the pumping plant back wall to prevent water from draining back into the forebay. The blind flange would be removed and replaced with an 84-inch butterfly valve. A new 84-inch diameter flanged steel pipe spool (approximately three feet long) would be connected to the butterfly valve and terminate with a new 84-inch flap gate. Permanent supports would be required beneath the butterfly valve and flap gate.
- Dewatering of the afterbay would likely be required. Therefore, installation of the pump should be performed during the non-irrigation season to minimize interruptions to the irrigation delivery system. A mobile crane would be required to install the piping and appurtenances.
- Pumping plant unit bay stoplogs would be installed, using a mobile crane, to accommodate dewatering the pump bay.
- The pump bay would be inspected and all sediment would be removed. Access to the bottom floor of the pumping plant is provided at each bay via 4.5-foot by 7-foot access hatches and ladders.
- Roof hatches over the pump unit bay would be removed using a mobile crane.
- The pump would be installed in accordance with the pump manufacturer’s written installation instructions, including constructing the pump pedestal and connecting the pump discharge nozzle to the discharge pipe via a new flexible coupling.
- Electrical conductors and a SCADA system would be installed.

Operations. The Red Bluff Pumping Plant includes a control system to provide remote manual and remote auto control of pumps and associated appurtenances. The pumping plant and associated gravity conveyance system are designed to deliver water to the existing 17-acre settling basin located to the west of the RBDD. Once in the settling basin, water would flow to Check No. 1 on the T-C Canal and the Corning Pumping Plant.

Maintenance. It is anticipated that the following basic preventative measures would be undertaken on a regular basis to maintain the vertical axial-flow pump and its appurtenances that would be installed as part of the proposed Project. These activities would occur as part of the regular maintenance activities for the Red Bluff Pumping Plant:

- Wash down or pressure wash, as necessary
- Check for rust/corrosion, annually; maintain all coatings
- Visually inspect for damage or wear, monthly
- Assess fluids and lubrication; address as necessary
- Inspect pumping plant trashracks daily and remove debris as necessary
- Visually inspect butterfly valves and flap gates, monthly

The proposed additional Project pump would not increase the frequency of maintenance activities required at the pumping plant, nor would it require additional personnel to perform pump maintenance. However, the volume and timing of non-TCCA water diversions, through any of the pumps, could impact

[3] A formal work plan that describes all construction activities would be required prior to the start of construction.

the sediment load distributed to the TCCA system (i.e., the pumping plant forebay and settling basin). Increased sedimentation associated with non-TCCA water diversions may require more frequent dredging within the pumping plant forebay than prior to the Project pump's installation and operation.

3.1.1.11 GCID Canal Facilities Modifications

The GCID Canal is an existing irrigation canal that delivers water from the Sacramento River to water users along its route from its diversion point northwest of Hamilton City to southeast of the City of Williams. The canal is an unlined earthen channel, with capacity varying from 3,000 cfs at the upstream end to 300 cfs at the southern terminus.

The existing canal facilities divert water from the Sacramento River into a forebay where the water is pumped by the Main Pump Station into the GCID Canal. The existing canal facilities include the intake and bypass channels, fish screens, main pump station and forebay, headgates, gradient facility, and the GCID Canal. These facilities are located approximately five miles northwest of Hamilton City. Proposed Project improvements in this area include a new headgate structure and canal lining. A railroad siphon replacement is also proposed near the City of Willows.

For the proposed Project, the existing headgate structure would be left in place to continue to serve as a bridge between County Road 203 and County Road 205. The existing headgate structure would continue to operate during construction of the new headgate structure, and diversion activities would continue throughout construction. The existing headgate would not be adequate for proposed winter season Project operation during high-river flows due to the large head-drop across the structure during high river level conditions. A new headgate structure would be constructed upstream of the existing structure. The new headgate structure would include three automated gates (two vertical roller gates and one radial gate). The new headgate structure would provide the following three main operations:

- Isolate the Main Canal, as needed, for repairs or other purposes, such as the canal reach between the Main Pump Station and Stony Creek, to prevent local flooding during high river levels.
- Control flow when the headworks are under gravity inflow conditions and the pumping plant is shut down, which occur during high river levels.
- Control water elevations downstream of the existing headworks, as necessary, to extend their operating range under higher river levels.

Design consideration for the new headgate includes:

- The structure's invert and crest would be based on matching the existing canal invert and top of bank elevations, respectively.
- The relatively deep channel section in this reach of the canal would result in a structure that is over 30 feet high.
- The design condition for this structure, for sliding and over-turning stability, would occur with maximum water levels on the upstream side (during high river levels), and a drained canal on the downstream side (for emergency shutdown).

The water level and flow control functions would involve operating conditions that would result in water surface drops across the headgate of between three and 15 feet, which would require a set of energy dissipater blocks immediately below the gates to slow down and stabilize the water discharging under each gate.

The canal reach immediately downstream of the new headgate structure would be lined with concrete for approximately 200 feet to prevent erosion due to the turbulent flow conditions.

The Union Pacific Railroad Siphon at Mile 26.6 does not meet design and operation criteria for the proposed Project and would need to be replaced. The existing Railroad Siphon structure was built in the early 1900s and includes two 6-foot-diameter barrels and five 7.25-foot by 6-foot barrels. At maximum existing flows of approximately 2,000 cfs, the head loss across the Railroad Siphon, due to high flow velocity and poor entrance and exit transitions, reduces upstream canal freeboard to very marginal conditions. Based on the structure’s age, hydraulic capacity restrictions, and use as a major transportation link, it should be replaced. The new structure would consist of three prefabricated box culverts. Typical future maximum velocity and head losses would be approximately four fps and 0.2 foot, respectively.

The proposed replacement of the Railroad Siphon would require coordination and planning with railroad operators. Construction restrictions may exist regarding minimizing interference with regular railroad operations. To the extent possible, replacement of the Railroad Siphon would take place during periods of lowest train traffic and railroad shutdown time would be minimized.

Construction. The total construction disturbance area would consist of approximately five acres. It would consist of the existing canal prism, existing operation and maintenance roads, and an additional 50 feet on both sides. The total construction disturbance area would include the footprint of the proposed facilities (new headgate structure, canal lining, and replacement of Railroad Siphon), the materials and equipment staging area, the area needed to construct the facilities, and access roads. All of the construction activities for the new facilities would occur within the existing GCID right-of-way.

Water delivery to the GCID service area would be maintained during the primary irrigation season (early April through mid-October). The GCID Canal is typically out of service each year between January 7th and February 20th for maintenance. Construction activities would be scheduled during this maintenance period whenever possible. If construction activities are required outside of the maintenance period, a temporary bypass channel would be built around the construction site to allow diversion water to flow past and maintain regular canal operation. The temporary bypass channel would be constructed within the existing GCID right-of-way using a combination of excavation, earth embankment, and sheetpile walls to isolate the construction site from the canal. After completion of construction, the temporary bypass would be filled in, earth embankments and sheetpile walls would be removed, and the area would be restored to pre-construction conditions.

Operations. The intake and fish screen facility would operate year-round and would be very similar to existing operations.

GCID is currently adding the SCADA system to the existing GCID Canal system. The new proposed GCID Canal facilities for the proposed Project may need to be incorporated into GCID’s SCADA system. The design of new systems would be coordinated with GCID to ensure proper integration.

Use of the canal for conveyance to the proposed Sites Reservoir would require increased automation between the GCID facilities and other proposed Project conveyance systems. The available capacity for winter season operation (October through March) of Project conveyance would range from a minimum of approximately 1,270 cfs during an average November to a maximum of approximately 1,750 cfs during an average March. There is currently little to no available capacity from April through September. To accommodate the proposed Project flow, flows need to be monitored and controlled consistently. SCADA operations and monitoring could be done remotely and would not require the presence of daily on-site personnel. Instead, daily operation and monitoring would be managed from a central location and would not require additional staff beyond existing personnel.

Maintenance. Required maintenance activities would be very similar to current maintenance. Periodic inspection and maintenance of mechanical systems, such as the screen cleaning system, would be required. Water level monitoring would continue to be done automatically. Additional sediment and debris removal activities may also be required due to increased diversions during high river water levels.

Debris that enters the intake channel, such as large floating trees, can block flows in the channel, get entangled at the face of the fish screen, block the water control structure, or cause other disruptions to proper operating conditions. Typically, the debris builds up during winter season flood flows and is removed at the beginning of the irrigation season in late March to early April. Because of wintertime diversions, a larger debris load is expected at the intake channel, screen structure, and bypass channel. It is expected that debris removal would be required during the winter season to maintain proper operating conditions. It may be necessary to retrofit the mouth of the intake channel with a floating log boom to deflect larger debris and provide increased protection to the fish screens.

The upper one-third of the intake channel is typically dredged once every three years and the entire channel is dredged once every 10 years. The volume of the dredged materials varies from approximately 30,000 to 130,000 cubic yards. The future volume of sediment in the intake channel is expected to increase with increased Project-related wintertime operation and the following assumptions were made regarding future dredging operations:

- A larger dredge with increased capacity and working depth than is currently used would be required. Supporting equipment, such as a high-capacity crane equipped with a grappling hook and clamshell, would be required to assist in debris removal.
- Dredging operation would occur year-round.
- Because dredging would occur year-round, a new U.S. Army Corps of Engineers 404 permit would be needed to allow dredging during the winter season.

Dredged materials would continue to be placed on the 11-acre off-site disposal location to the southwest of the pump station, at sites on Montgomery Island, and along the canal banks.

The new headgate structure would require annual inspection and maintenance including painting and motor control unit inspections, similar to typical check structures along the canal.

Expected periodic maintenance activities for the canal that would require on-site personnel would include:

- Maintaining canal banks to repair sloughing and erosion damage
- Filling in animal burrow holes
- Removing vegetation
- Removing debris from upstream of the check structures
- Maintaining gate operators
- Repairing and repainting gates.

A dedicated maintenance period is required for the canal from January 7th through February 20th every year. During this maintenance period, the canal will be shut down.

3.1.1.12 GCID Canal Connection to the Terminal Regulating Reservoir

The purpose of the proposed connection from the GCID Canal to the TRR would be to reduce the velocity of flows from the GCID Canal to approximately 1 fps to form a stable pool. The stable pool would occur just before the turnout to the connecting channel to the proposed TRR.

The connection from the GCID Canal to the TRR would be located north of the proposed TRR Pipeline between the GCID Canal and the TRR, (Figure 3-5). It would have two features: (1) the GCID Canal energy dissipation bay with check structure, and (2) the TRR inlet channel and inlet control structure. The bay would be located along a reach of the GCID Canal approximately 500 feet long, with a 220-foot bottom width, 20-foot depth and embankment slopes of 1.5 to 1. On the east end of the bay, the reservoir inlet channel would divert flow to the TRR. On the south end of the bay, a new radial-gate check structure would serve two purposes: (1) maintain a water surface elevation in the canal transition section to provide available head for conveyance into the TRR and (2) control flow to the remaining downstream reach of the GCID Canal.

The inlet channel would connect the Main Canal to the TRR. The channel would be a lined trapezoidal cross-section, having a 70-foot bottom width and a length of 400 feet, with embankment slopes of 1.5 to 1. The inflow control structure would be very similar to a standard GCID Canal check structure, with three large radial gates to control flow into the TRR. The structure’s top deck width would accommodate vehicle traffic to allow access along the Canal. A transition apron (a large concrete pad) into the reservoir would be located immediately downstream of the control gates. The apron would be 160 feet wide and 100 feet long. The function of the concrete apron would be to provide an erosion-resistant area for energy dissipation as the water enters the TRR.

The earthen embankment for the inlet channel would be approximately 20 feet high. When the radial gates at the check structure open, the gates would be approximately 15 feet above the embankment.

Construction. The total construction disturbance area would consist of approximately seven acres. It would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, and access roads. This construction disturbance area would be within the larger construction disturbance area for the proposed TRR.

Anticipated ground-disturbing activities during construction include:

- Transportation of materials to the proposed Project site
- Clearing and grading the construction workspace
- Placing construction materials at staging areas
- Dewatering and building a temporary bypass channel
- Excavation of canal energy dissipation bay
- Reservoir inlet excavation and embankment construction
- Construction of check structure

It is anticipated that the proposed reservoir inlet from the GCID Canal to the proposed TRR would be constructed by first building a temporary bypass channel to the west of the existing canal alignment. The temporary bypass channel would be approximately 1,000 feet long, and would connect into the GCID Canal upstream and downstream of the construction zone to supply water to the remaining reach of the

Canal downstream of the TRR area. The temporary bypass channel would be constructed using a combination of excavation, earth embankment, and sheetpile walls to isolate the construction site from the diversion canal. Following completion of the new check structure, the temporary bypass would be filled in, earth embankments and sheetpile walls would be removed, and the area would be restored to pre-construction conditions.

Operations. Gate operation of the new GCID Canal Check Structure would normally be controlled automatically, with an option for local or remote manual control. Gate operation would be established either using upstream or downstream water-level controls, depending on the overall operating regime for the future canal system.

Flow into the reservoir would be controlled by the proposed TRR inlet control gates. An integrated SCADA and communication system would be required to coordinate operations between the GCID Pump Station, GCID Canal, and the proposed TRR, TRR Pumping/Generating Plant, and Holthouse Reservoir. SCADA operation and monitoring would be done remotely and would not require the presence of daily on-site personnel. Instead daily operation and monitoring would be managed from a central location.

Maintenance. Maintenance activities would include (1) removing debris that could collect upstream of check structures, (2) maintaining gate operators to provide adequate control of gates, (3) periodically repairing and re-painting the connection, and (4) dredging the dissipation bay and inlet channel for sediment concurrently with the proposed TRR dredging.

3.1.1.13 Terminal Regulating Reservoir

Water conveyed down the GCID Canal would be directed into the proposed TRR (Figure 3-5). A new pump station (the proposed TRR Pumping/Generating Plant) would then convey the water from the TRR via the proposed TRR Pipeline to the proposed Holthouse Reservoir. The TRR would be required to provide operational storage for the TRR Pumping/Generating Plant to balance normal and emergency flow variations between the upstream GCID Canal Pump Station, the 40 miles of connecting canal, and the TRR Pumping/Generating Plant.

The TRR would be constructed on the valley floor adjacent to the GCID Canal by a combination of excavation and embankment. The TRR would be located approximately three miles northeast of Holthouse Reservoir. The TRR would be composed of an earth embankment dam, concrete emergency overflow weir, an outfall standpipe, and an approximately 4,000-foot-long underground 60-inch-diameter outlet pipe to Funks Creek (the TRR to Funks Creek Pipeline). The outlet pipe would be used, as necessary, to drain the reservoir for operation and maintenance and emergency purposes. A15-foot-wide gravel road (the proposed TRR Pipeline Road) would be constructed on top of the embankment to provide access to the facility for operation and maintenance.

The embankment materials would be impervious earthen material compacted to DWR’s DSOD standards. The 200-acre TRR would be approximately 15 feet deep with a maximum water depth of 12 feet, leaving three feet of freeboard. The maximum excavation depth of the TRR would be approximately nine feet, and the maximum embankment height would be approximately six feet above existing grade. The total storage volume in the TRR would be divided into three operational components: (1) two feet of dead storage beneath the lower operating limit of the pump station; (2) five feet of normal operational storage; and (3) five feet of emergency storage. The maximum water surface elevation in the TRR could not exceed the water surface elevation in the GCID Canal because it is a gravity flow system. The bottom dimensions of the TRR would be approximately 2,900 feet by 2,900 feet, and the reservoir would have a maximum storage capacity of 2,000 acre-feet. The TRR capacity is designed to provide normal operating and emergency storage as well as a forebay for the proposed TRR Pumping/Generating Plant.

Major appurtenance features would include a GCID Canal transition bay, a connecting channel from the GCID Canal to the TRR, and a flow control inlet structure.

Construction. The total construction disturbance area would consist of approximately 300 acres. The proposed TRR site is currently in agricultural production (including rice crops, annual row crops, and orchards). The total construction disturbance area would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, and access roads. This staging area could be the same as, or nearby, the GCID Canal Connection staging area because the construction sites are located adjacent to each other. In addition, the portion of the proposed Delevan Pipeline construction disturbance area that would abut the TRR could also be used for the TRR staging area.

Anticipated major construction activities include transportation of materials to the proposed work site, clearing and grading the construction work space, staging of construction materials, dewatering, constructing fencing around the perimeter, constructing lighting, and excavation and embankment construction.

Operation. In coordination with GCID Canal operation, water would be diverted to the proposed TRR by gravity. Flow into the TRR would be controlled by the TRR inlet control gates. An integrated SCADA and communication system would coordinate operation between the Main Pump Station, GCID Canal, and the proposed TRR, TRR Pumping/Generating Plant, and Holthouse Reservoir. Flow to Holthouse Reservoir and the water surface in the TRR would be regulated by the TRR Pumping/Generating Plant. TRR pump operators would require continuous communication with GCID Main Pump Station and canal operators to coordinate water allocation for both irrigation demands and proposed Sites Reservoir delivery. This coordination would be simpler in the mid-winter season when there is low irrigation demand and most of the flow in the GCID Canal would be conveyed to the TRR. Coordinating water allocation may be more complex during the early to late spring in years when water would be diverted to Sites Reservoir because of high river flows, and irrigation demands increase. TRR operation would likely be controlled remotely and would not require the presence of daily on-site personnel. The reservoir would be designed to allow emergency releases during operation first to the GCID Canal via the GCID Canal Connection to the TRR (when hydrologically feasible), and then to Funks Creek via the proposed TRR to Funks Creek Pipeline. Release flows would be controlled by an energy dissipater and small concrete structure at the terminal end of the pipeline.

Maintenance. Typical maintenance of the proposed TRR would include dredging to remove sediment when it is drained, clearing vegetation from the slopes of the embankments, and maintaining the gravel service road atop the embankment. Draining the TRR for maintenance would be accomplished by a standpipe and drain structure at the invert of the reservoir. Drained water would be conveyed to Funks Creek via the proposed TRR to Funks Creek Pipeline. Draining/dredging of the TRR is likely to be required every seven to 10 years depending on variable sediment transport conditions in the Sacramento River and the surrounding areas. Sediment removed during the dredging activities would be placed on the surrounding levees' embankments.

3.1.1.14 TRR Pumping/Generating Plant

The purpose of the proposed TRR Pumping/Generating Plant would be to pump water from the proposed TRR to the proposed TRR Pipeline, which would convey water to the proposed Holthouse Reservoir. Return flows from the proposed Holthouse Reservoir to the proposed TRR would flow through the TRR Pumping/Generating Plant to generate power.

The TRR Pumping/Generating Plant would pump 1,800 cfs of water from the TRR to Holthouse Reservoir. The TRR Pumping/Generating Plant would generate power from flows released through it with a maximum return flow of 1,500 cfs. The minimum water elevation in Holthouse Reservoir for operation of the TRR Pumping/Generating Plant would be 112 feet, and its maximum water elevation for operation would be 121.5 feet.

The TRR Pumping/Generating Plant would be located adjacent to the TRR on the north side (Figure 3-5), and would be approximately three miles northeast of Holthouse Reservoir. On the north side of the TRR, the TRR Pumping/Generating Plant would connect to the TRR Pipeline. The TRR Pumping/Generating Plant would consist of two 620 cfs and two 325 cfs Francis Vane pumps for pumping and two 750 cfs Kaplan turbines for generating during release flows.

Structures associated with the TRR Pumping/Generating Plant would include the following:

- Mechanical Features
  - 84-inch online Spherical Valve on each discharge line.
  - Air Chambers and Butterfly Valves with Hydraulic Power Units.
  - Compressors
  - Generators
  - Gantry Crane – 100 tons
  - Service air and water system
  - Acoustical flowmeter on each discharge line
- Electrical Features
  - Switchyard Transformers
  - Control system
  - Switchgears
  - Grounding grids
  - Control cabinets
- Refilling Pump Units

The discharge lines may periodically need to be dewatered for inspection and maintenance. These lines would need to be filled at a slow rate to allow the release of air through air and vacuum valves. To accomplish this, one or two 100 cfs pump units would be installed.

Construction. The total construction disturbance area would consist of approximately one acre, and would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, and access roads. The construction disturbance area would fall within the construction disturbance area of the proposed TRR Pipeline (discussed in Section 3.1.1.15).

Excavation would be conducted using temporary slopes of 1.5:1 for the 25 feet deep trench along the pipelines, and a temporary slope of 2:1 for the 40 feet deep foundation of the pump stations. The pump station foundations would be excavated in in-situ materials and no major improvements to the foundations would be required. During construction, the topsoil material would be excavated, stockpiled separately, and replaced to ensure native grasses and plants would grow.

Anticipated ground-disturbing activities during construction include:

- Transportation of materials to the proposed Project site
- Clearing and grading the construction workspace
- Placing construction materials at staging areas
- Dewatering
- Excavating the forebay (approach channel) and pumping plant
- Construction of the forebay, pump house, and pump bay
- Site restoration after construction is complete

Operations. An integrated SCADA and communication system would be used for the proposed TRR Pumping/Generating Plant. Flow to the proposed Holthouse Reservoir and the water surface in the proposed TRR would be regulated by the TRR Pumping/Generating Plant. TRR pump operators would require continuous communication with GCID Main Pump Station and canal operators to coordinate water allocation for both irrigation delivery and for proposed Sites Reservoir filling. This coordination would be simpler in the mid-winter season when most flows are conveyed only to the TRR for filling Sites Reservoir. Coordinating water allocation may be more complex during the early to late spring in years when water would be diverted to fill Sites Reservoir and delivered to meet irrigation demands.

Maintenance. Routine maintenance and monitoring would likely be required on a daily basis. Regular maintenance and inspection would have to be done for each pump unit and the related equipment, such as gates, valves, and electrical equipment, with possible additional inspections and maintenance needed after earthquakes or storm or flood events.

3.1.1.15 TRR Pipeline

The 3.5-mile-long proposed TRR Pipeline would convey water from the proposed TRR to the proposed Holthouse Reservoir (Figure 3-5). The TRR Pipeline would be bi-directional, allowing water to be pumped from the TRR to Holthouse Reservoir for storage, and allowing water to flow by gravity from Holthouse Reservoir for release to the TRR/GCID Canal. As water released from Holthouse Reservoir flows through the proposed TRR Pumping/Generating Plant at the end of the TRR Pipeline, it would pass through turbines to generate electricity.

The proposed TRR Pipeline would have a capacity of 1,800 cfs to convey water that is pumped from the TRR to Holthouse Reservoir. The capacity of the TRR Pipeline to convey water by gravity flow from Holthouse Reservoir to the TRR would be 1,500 cfs. The TRR Pipeline would consist of two 12-foot-diameter reinforced concrete pipes. It would be buried a minimum of 10 feet (to top of pipe) below the ground surface. Proposed facilities associated with the TRR Pipeline include blow-off structures and air valve structures.

The proposed alignment of the TRR Pipeline would cross the existing GCID Canal and a main Pacific Gas and Electric (PG&E) natural gas distribution line. At these locations, the bore and jack construction method would be used. Bore and jack construction would entail excavating a large pit on each side of the existing infrastructure (highway, railroad, or canal in this case) and then tunneling horizontally under the structure without disturbing it. Due to the high water table in the area, this construction method may require dewatering the area. All additional work required for bore and jack construction would be conducted within the construction disturbance area and would not require the disturbance of additional land.

The TRR Pipeline would also cross the easement of the existing PG&E 230-kV line. No permanent aboveground structures associated with the pipeline, other than a 16-foot wide, 2.1 mile-long gravel maintenance road (the proposed TRR Pipeline Road) from the GCID Canal to the proposed Holthouse Reservoir Spillway and Stilling Basin, would be constructed.

Other existing infrastructure that the TRR Pipeline could potentially cross include: gas lines, water lines, sewer lines, and communications lines. The bore and jack construction method would be used at these utility crossings. Disruptions to these utilities would be minimized to the extent possible, and the ground surface would be restored to pre-construction conditions after installation of the TRR Pipeline. Construction activities for the proposed TRR Pipeline would occur within the identified construction disturbance area and would require only slightly more excavation than is required for the pipeline.

Construction. The construction disturbance area for the proposed TRR Pipeline would be approximately 335 feet wide from the TRR to the proposed Holthouse Reservoir (3.5 miles). The total construction disturbance area, which would also include a temporary concrete batch plant, would fall within the construction disturbance area for the proposed Delevan Pipeline discussed in Section 3.1.1.16.

Anticipated major construction activities include:

- Clearing and grading the construction workspace
- Stockpiling topsoil
- Placing necessary construction materials at staging areas
- Transportation of materials to the Project site
- Trenching/excavation of pipeline route
- De-watering
- Bedding preparation
- On-site fabrication of pipe
- Installation of pipe and valves
- Crossings of roads and utilities
- Backfill and compaction of trench
- Replacement of topsoil
- Revegetation and restoration of pipeline route
- Construction of a gravel maintenance road

Operations. Operation of the proposed TRR Pipeline would not require daily workers at the site.

Maintenance. Periodic inspection and maintenance of the proposed TRR Pipeline would likely occur once per year, with possible additional inspections and maintenance needed after storm or flood events. Permanent rights-of-way for the land overlying the pipeline would be maintained to provide future access. The proposed gravel maintenance road would be graded, as needed.

3.1.1.16 Delevan Pipeline

The approximately 13.5-mile-long proposed Delevan Pipeline would convey water from the Sacramento River to the proposed Holthouse Reservoir to fill the proposed Sites Reservoir, and/or convey water from Holthouse Reservoir to the Sacramento River for releases (Figure 3-1). The Delevan Pipeline would parallel the proposed TRR Pipeline at its western end and would share a common trench and outlet structure into Holthouse Reservoir (Figure 3-5).

The Delevan Pipeline would have a 2,000 cfs capacity to convey water from the proposed Delevan Pipeline Intake Facilities (on the Sacramento River) to Holthouse Reservoir. The capacity of the Delevan Pipeline to convey water from Holthouse Reservoir to the Sacramento River would be 1,500 cfs. Because of the available head, releases through the Delevan Pipeline could be made to the river by gravity without the need for pumping. The Delevan Pipeline would consist of two 12-foot-diameter reinforced concrete pipes.

From the Sacramento River, the Delevan Pipeline would be aligned due west until reaching the GCID Canal. At the GCID Canal, the Delevan Pipeline would turn southwesterly and would parallel the TRR Pipeline in a shared trench until it reaches the Holthouse Reservoir Complex.

Proposed facilities associated with the Delevan Pipeline include blow-off structures, air valve structures, and outlet and energy dissipater structure.

Alternatives A and C would include a bi-directional Delevan Pipeline; further details are provided in Section 3.1.4.4. Alternative B would include a release-only Delevan Pipeline; further details are provided in Section 3.1.5.3.

Construction. Construction information is provided in Section 3.1.4.4 for the proposed bi-directional Delevan Pipeline and Section 3.1.5.3 for the proposed release-only Delevan Pipeline.

Operations. Operations information is provided in Section 3.1.4.4 for the proposed bi-directional Delevan Pipeline and Section 3.1.5.3 for the proposed release-only Delevan Pipeline.

Maintenance. Maintenance information is provided in Section 3.1.4.4 for the proposed bi-directional Delevan Pipeline and Section 3.1.5.3 for the proposed release-only Delevan Pipeline.

3.1.1.17 Project Buffer

The proposed Project Buffer (Figure 3-1) would consist of the total amount of land that would be acquired for the proposed Project beyond the facility footprints, out to the nearest existing parcel boundaries. The proposed Project Buffer would surround the proposed Sites Reservoir, Holthouse Reservoir Complex, and all proposed facilities located between these two facilities; the proposed TRR and associated facilities; and the proposed Delevan Pipeline Intake/Discharge facilities[4]. Because the intent of the Project Buffer is to create a “buffer” around proposed Project facilities, while following existing parcel boundaries, the width of the buffer around proposed Project facilities would vary. The Project Buffer would serve several purposes:

- It would avoid splitting parcels and rendering parcel remnants unusable by existing landowners.
- It would provide a buffer between proposed Project facilities and adjacent existing land uses to avoid potential conflicts in land uses.
- It would prevent shoreline development around the proposed Sites Reservoir.

[4] The proposed Delevan Transmission Line, Delevan Pipeline, TRR Pipeline, and TRR Pipeline Road would not have an associated buffer. These proposed Project facilities would not require additional lands for long-term operation and maintenance. The Delevan and TRR pipelines would be underground features that would have periodic aboveground structures that include blow-off structures, air valve structures, and an outlet and energy dissipater structure. The TRR Pipeline Road would be located above the TRR Pipeline. The Delevan Transmission Line would result in aboveground development only at each transmission tower.

- It would prevent livestock access to the reservoirs, and prevent livestock wastes from entering the proposed reservoirs.

Construction. The lands within the proposed Project Buffer would remain undeveloped; the existing vegetation would be maintained as wildlife habitat and protected from fuelwood harvest, grazing, and other forms of environmental degradation. Existing structures would be demolished and the remaining land would be managed as wildlife habitat. Existing agricultural lands would not be maintained as agriculture but converted and managed as wildlife habitat.

The Project Buffer boundary would be fenced using standard three-strand barbed wire fences with posts, in areas where the parcels are not already fenced, so that the entire Project Buffer boundary would be fenced. A fuelbreak would be constructed around the perimeter of the Project Buffer.

Operations. Not applicable.

Maintenance. Maintenance activities that are proposed to be undertaken within the Project Buffer boundary include fence maintenance and periodic boundary fuelbreak maintenance.

3.1.2 Ecosystem Enhancement Actions

Ecosystem enhancement actions could be undertaken to support the increase fish survival NODOS Project objective. Based upon recommendations from federal and State fish agencies with regulatory authority over the project, Reclamation and DWR propose to provide two types of ecosystem enhancement actions: operational and nonoperational. Conceptually, the operational and non-operational actions might be most effective if implemented concurrently. The operational and nonoperational ecosystem enhancement actions are described in the following sections.

3.1.2.1 Ecosystem Enhancement Storage Account—Operational Actions

The proposed Project would provide a unique opportunity to create the first firm asset ecosystem enhancement storage account (EESA) in California managed by the State and/or the federal government and dedicated to restoration actions beyond regulatory requirements. As part of the CALFED Bay-Delta Program, the Ecosystem Restoration Program (ERP) developed an integrated systems approach based on reversing the fundamental causes of decline in fish and wildlife populations by recognizing the natural processes that created historic habitats and using these processes to help regenerate habitats. The ERP was not designed as mitigation for CALFED projects; instead, it was intended to fulfill the objectives of environmental stewardship and improving ecological processes and increasing the amount and quality of habitat, equal with other program goals related to water supply reliability, water quality, and levee system integrity.

The ERP identified over 600 programmatic actions to improve ecological health. The ERP advocated an adaptive management implementation strategy that supports the flexible use of environmental water. This adaptive approach has been accommodated in Project planning by dedicating proposed Project storage allocation to ERP objectives (an ERP pool or account), and then giving resource managers the ability to adjust priorities based on the monitoring of implemented actions, as well as potential new priorities. The NODOS Project planning team identified ERP objectives that could be supported by implementing a NODOS Project and prioritized actions with input from the Sacramento River Flow Regime Technical Advisory Group. This Technical Advisory Group included environmental advocacy groups, academics, and representatives from federal and California water resource and wildlife agencies (the Technical

Advisory Group is described in more detail in Chapter 36 Consultation and Coordination). The Technical Advisory Group met with the NODOS Project management team from 2002 through 2004. Ultimately, Reclamation and DWR adopted a list of objectives, including both tributary actions and Delta actions, which were incorporated into the proposed operations strategy for the NODOS Project action alternative plans:

- Improve the reliability of coldwater pool storage in Shasta Lake to increase Reclamation's operational flexibility to provide suitable water temperatures in the Sacramento River. This action would operationally translate into the increase of Shasta Lake storage levels in May, and increased coldwater pool in storage, with particular emphasis on Below Normal, Dry, and Critical water year types.
- Provide releases from Shasta Dam of appropriate water temperatures, and subsequently from Keswick Dam, to maintain mean daily water temperatures year-round at levels suitable for all species and lifestages of anadromous salmonids in the Sacramento River between Keswick Dam and RBDD, with particular emphasis on the months of highest potential water temperature-related impacts (i.e., July through November) during Below Normal, Dry, and Critical water year types.
- Increase the availability of coldwater pool storage in Folsom Reservoir, by increasing May storage and coldwater pool storage, to allow Reclamation additional operational flexibility to provide suitable water temperatures in the lower American River. This action would utilize additional coldwater pool storage by providing releases from Folsom Dam (and subsequently from Nimbus Dam) to maintain mean daily water temperatures at levels suitable for juvenile steelhead over-summer rearing and fall-run Chinook salmon spawning in the lower American River from May through November during all water year types.
- Stabilize flows in the lower American River to minimize dewatering of fall-run Chinook salmon redds (i.e., October through March) and steelhead redds (i.e., January through May), and reduce isolation events (specifically, flow increases to greater than or equal to 4,000 cfs with subsequent reduction to less than 4,000 cfs) of juvenile anadromous salmonids, particularly from October through June. Reduce the reliance upon Folsom Reservoir as a "real-time, first response facility" to meet Delta objectives and demands, particularly from January through August, to reduce flow fluctuation and water temperature-related impacts to fall-run Chinook salmon and steelhead in the lower American River.
- Provide supplemental Delta outflow during summer and fall months (i.e., May through December) to move X2 location westward, downstream of Collinsville (81 kilometers). X2 is the location of the 2 parts per thousand salinity contour (isohaline), one meter off the bottom of the estuary, as measured from the Golden Gate Bridge. The abundance of several estuarine species, such as delta smelt, longfin smelt, Sacramento splittail, and starry flounder has been correlated with X2 location. There is general consensus among the fisheries agencies that there is larger and higher quality habitat for delta smelt and other species when X2 location is west of the confluence of the Sacramento and San Joaquin rivers.
- Improve the reliability of coldwater pool storage in Lake Oroville to improve water temperature suitability for juvenile steelhead and spring-run Chinook salmon over-summer rearing and fall-run Chinook salmon spawning in the lower Feather River from May through November during all water year types. Provide releases from Oroville Dam to maintain mean daily water temperatures at levels suitable for juvenile steelhead and spring-run Chinook salmon over-summer rearing, and fall-run

Chinook salmon spawning in the lower Feather River. Stabilize flows in the lower Feather River to minimize redd dewatering, juvenile stranding, and isolation of anadromous salmonids.

- Stabilize flows in the Sacramento River between Keswick Dam and the RBDD to minimize dewatering of fall-run Chinook salmon redds (for the spawning and embryo incubation lifestage periods extending from October through March), particularly during fall months.
- Provide increased flows from spring through fall in the lower Sacramento River by reducing diversions at RBDD (into the T-C Canal) and at Hamilton City (into the GCID Canal), and by providing supplemental flows (at the proposed Delevan Pipeline). This action would provide multiple benefits to riverine and estuarine habitats, and to anadromous fishes and estuarine-dependent species (e.g., delta smelt, splittail, longfin smelt, Sacramento splittail, starry flounder, and *Crangon franciscorum*) by reducing entrainment, providing or augmenting transport flows, increasing habitat availability, increasing productivity, and improving nutrient transport and food availability.

Conceptually, the EESA would use Project assets, including storage and conveyance, to support modified operations that facilitate habitat enhancement actions. Use of these assets would be limited to supporting ecosystem enhancement actions and could not be used for other Project benefits or non-Project benefits. The EESA is conceptually intended to allow some ability to adaptively manage the list of operational actions supported by the proposed Project. The priority of actions included in the proposed Project action alternatives may change over time. New priorities may arise. Project planners recommend that any changes to the proposed EESA operational actions be subject to a relatively high degree of consensus of a governance board that would be formed to manage the ecosystem enhancement actions. Planning studies, including environmental documentation and permitting, may be required and could be funded by the Ecosystem Enhancement Fund (discussed below) if a modification is supported by the governance board.

3.1.2.2 Ecosystem Enhancement Fund—Nonoperational Actions

The proposed Ecosystem Enhancement Fund (EEF) would be established as an endowment to provide long-term funding for aquatic habitat restoration actions on the Sacramento River and its tributaries that do not necessarily require additional water. Projects funded through the EEF would be in addition to any proposed Project mitigation or CVPIA or OCAP requirements. Projects eligible for EEF funding would include those that would directly benefit anadromous fish, with an emphasis on actions in the Sacramento River (e.g., spawning gravel augmentation; side channel, riparian, or floodplain restoration; and instream aquatic habitat construction downstream from Keswick Dam). Similar to the proposed EESA, the EEF has been included in each proposed Project action alternative. The monetary size of the EEF would be the same in each alternative.

Seed money in the amount of $30 million would be invested into an interest bearing account. Each year, 90 percent of the accrued interest would be allocated by fund managers for fisheries habitat enhancement projects, with an emphasis on projects for the Sacramento River. The remaining 10 percent of the accrued interest would be rolled back into the account to ensure the long-term viability of the funding source. The growth of the fund is intended to allow fund managers to make ongoing contributions to facilitate non-operational actions, as the cost to implement those actions increases over time.

A governance board may be formed to manage the fund, prioritize potential projects, and collaboratively determine funded actions, based upon habitat needs. The fund would support planning and implementation of priority non-operational actions. Planning includes environmental documentation and permitting, as necessary. Projects funded by the EEF would be subject to environmental documentation and permitting separate from the proposed NODOS Project.

The EEF is currently in the conceptual stage, and is not an activity that may cause either a direct physical change in the environment, or a reasonably foreseeable indirect physical change in the environment, for which environmental review is yet required.

3.1.3 Reservoir Operations Common to all Action Alternatives

The operations evaluated in this environmental document represent an operational scenario designed to concurrently maximize achievement of the Project objectives of improving water supply reliability, increasing the survival of anadromous fish, improving Delta water quality, and providing flexible hydropower generation and minimize environmental impacts. One of the key components of the proposed operational scenario is the integration of new Project storage operations with operations of the existing CVP and SWP system and facilities. The integrated storage approach would facilitate a wider range of benefits. The foundational idea behind this approach is that operations of the existing system could be improved. Many of the needs associated with the existing operations strategy are directly related to storage. System storage is a primary driver for many operations decisions of the existing system, including delivery allocations, instream flows, and water quality requirements in the Delta. In addition, maintenance of the cold water pool in existing reservoirs is a storage target that has a certain reliability. The reliability of meeting these storage targets could be improved with new storage that is integrated; the reliability of existing reservoir storage targets could not be improved with new independent storage. Fundamentally, the system is more reliable when there is more water available in storage at any given time. More specifically, reliability could be improved for meeting ecosystem and water quality objectives, as well as for deliveries of agricultural, municipal and industrial, and environmental users. Through integrated operations of new Project storage, all three proposed Project action alternatives would be able to achieve the purpose of the Project and improve the ability to meet Project objectives.

The proposed operational scenario is reflected in the operations simulation modeling that is the primary planning tool to determine many of the proposed Project benefits and impacts. The ability of each proposed Project action alternative to implement the strategy effectively is subject to the proposed Project conveyance options included, the storage capacity of the proposed Sites Reservoir, and the coordinated operation of Sites Reservoir with other existing facilities.

The proposed operational scenario has three components: (1) operating criteria for diversion of flows from the Sacramento River to fill the proposed Sites Reservoir; (2) operating criteria to achieve benefits associated with the proposed Project primary objectives in specific year types (such as drought or driest periods) and other hydrologic conditions; and (3) integrating the operations[5] of Sites Reservoir with the SWP and CVP reservoirs, including Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake.

Each proposed Project action alternative would be operated to divert Sacramento River flows to maximize the filling of the proposed Sites Reservoir as long as those flows were not needed to meet (1) existing CVP and SWP and other water rights diversions, (2) existing regulatory requirements including SWRCB D-1641 (SWRCB, 1999), CVPIA 3406(b)(2), the 2008 USFWS BO (USFWS, 2008), and the 2009 NMFS BO (NMFS, 2009) and other instream flow requirements, and (3) flow conditions to minimize the

[5] For purposes of this discussion, integrated operations means that water from Sites Reservoir can be used, in some cases, as a substitute for water from these other reservoirs. The needs and uses of the CVP and SWP systems could be met from an additional source, Sites Reservoir, by integrating Sites Reservoir operations with those of the other reservoirs.

impact of diversion operations on achieving the primary objectives for anadromous fish survival and Delta water quality. A schedule of flow criteria for Sacramento River flows at Red Bluff, Hamilton City, Wilkins Slough, and Freeport were used to limit the impact of proposed Project diversion operations. An additional set of criteria was used to identify and restrict diversions during potential pulse flow conditions to protect out-migrating anadromous fish.

Each proposed Project action alternative would be operated to achieve benefits associated with the Project's primary objectives in specific year types, including drought (i.e. driest periods) and other hydrologic conditions. For purposes of proposed Sites Reservoir operations, drought conditions are defined as the sequence of years in which the Sacramento Valley water year type[6] in two consecutive years is Critical following Critical, Dry, or Above Normal; Dry following Critical or Dry; or Above Normal following Critical year types. In drought conditions, the priority operations were: (1) cold water pool conservation in Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake; (2) regulation of Sacramento River summer flows for best use of cold water for control of temperature conditions adverse to anadromous fish; and (3) increasing Delta export and SWP allocations to improve water supply reliability to South-of-the-Delta municipal and industrial water users. During these drought conditions, the proposed Sites Reservoir stored water would be released into the system as rapidly as possible to meet these needs and achieve these three objectives.

In other hydrologic conditions (non-drought), approximately one third of the proposed Sites Reservoir stored water would be used to (1) manage and improve Delta water quality in the summer and fall at municipal and industrial intakes, (2) improve flows for Delta fisheries habitat based on the X2 location, and (3) stabilize Sacramento River fall flows for improving spawning and rearing success of anadromous fish. Water quality for municipal and industrial users would be improved both by improving Delta water quality at municipal and industrial intakes in non-drought conditions, as well as increasing Delta exports in drought conditions (TDS levels in exports from the Delta are often lower than other supplies, such as from the Colorado River, so there is a blending improvement by increasing deliveries from the Delta).

Each proposed Project action alternative would be operated to integrate and coordinate the proposed releases from Sites Reservoir with releases from Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. Often, and especially in drought (driest periods) hydrologic conditions, proposed releases from Sites Reservoir would allow releases from other reservoirs to be reduced while still meeting requirements for minimum instream flow objectives and Delta salinity control objectives. Through this reduction in releases, storage could be conserved in Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake for other uses. This improvement in storage conditions throughout the system of reservoirs would add significantly to the operational flexibility and meet the Project's primary objectives of improving fish survival, Delta water quality, water supply reliability, and supporting renewable integration needs with hydropower in the most effective way possible.

With the increase in operational flexibility described above, recreation opportunities would also be increased. The secondary objectives would be met by accomplishing the Project's purpose and primary objectives.

---

[6] Sacramento Valley Water Year Type Classification (40-30-30 Index), defined by the State Water Resources Control Board in Water Right Decision 1641 (SWRCB, 1999), classifies Sacramento Valley water year types in five categories: Wet, Above Normal, Below Normal, Dry, and Critical. The classification is determined based on the sum of the unimpaired runoff of four rivers: Sacramento River upstream of Bend Bridge, near Red Bluff; Feather River inflow to Oroville Reservoir; Yuba River at Smartville; and American River inflow to Folsom Reservoir.

For actions associated with hydropower generation, the performance of the proposed Project action alternative would depend on seasonal decisions and the type of hydropower operation. There are three types of hydropower operations that could be supported by proposed Project facilities:

- Seasonal hydropower is determined by the normal water operations of the proposed Project. As the Project pumps or releases water for its normal operation, power would be consumed or generated by the hydropower facilities.
- Daily pump-back hydropower operation is determined by the leftover capacity in the proposed Sites Pumping/Generating Plant and Holthouse Reservoir. When those facilities have extra capacity, the proposed Sites Reservoir would release water through the Sites Pumping/Generating Plant into Holthouse Reservoir during on-peak electrical times to generate high revenue power. During off-peak times, the water would be pumped back into Sites Reservoir.
- Renewable integration hydropower is determined by the need to firm up other renewable power sources, such as wind and solar. The proposed Project could release water through the Sites Pumping/Generating Plant to generate power to firm up those power sources when those types of power sources produce less power. Similarly, power could be consumed by pumping water into Sites Reservoir from Holthouse Reservoir when renewable sources peak and the grid has a surplus of power that can be "saved" for later generation when the renewable peak has diminished.

Offstream hydropower is well suited to provide flexible hydropower generation. Flexible hydropower generation, provided by the proposed Project's offstream reservoirs, could be ramped up or down quickly to complement wind or solar generation to meet electrical demands and support reliable operation of the power grid. Hydropower could also reduce greenhouse gas emissions when paired with solar and wind energy. To ensure that the greenhouse gas emissions from construction activities are mitigated within the first 15 years of operation, the proposed Project would: (1) obtain at least 20 percent of the power used for pumping water from the Sacramento River and the proposed Holthouse Reservoir into the proposed Sites Reservoir from wind and/or solar energy, and (2) use at least 20 percent of the project's generated power and/or served pump load to provide integration services needed to firm up highly variable wind and/or solar generation. The 20 percent integration with wind and/or solar energy goal will be achieved with variable speed pumping-generating units installed at the proposed Project's pumping/generating plants.

A schedule of proposed operations is provided in Table 3-7. Table 3-7 shows which type of beneficiary operation relates to the drought (driest periods) and other hydrologic conditions, and what priority is assumed for each operation within each class of hydrologic conditions. The season in which the operation would occur is also described.

3.1.4 Alternative A—Proposed Facilities Unique to Alternative A

Alternative A would focus on meeting the proposed Project's primary objectives by constructing a 1.27-MAF Sites Reservoir and relying on the existing T-C Canal (2,100-cfs diversion) and GCID Canal (1,800-cfs diversion), and the proposed Delevan Pipeline (2,000-cfs diversion/1,500-cfs release), to convey water to and from the reservoir. Alternative A would use the common features described in Section 3.1.1, in addition to the features described below.

3.1.4.1 1.27-MAF Sites Reservoir Inundation Area

The smallest reservoir configuration considered for the action alternatives is 1.27 MAF (Figure 3-1). The proposed 1.27-MAF Sites Reservoir would have a maximum water surface elevation of 480 feet above mean sea level (msl) (the minimum operating water surface would be at elevation 340 feet), and an inundation area of approximately 12,400 acres. The inundation area of the 1.27-MAF Sites Reservoir would be created by filling Antelope Valley after the construction of nine dams. The proposed dams include Golden Gate Dam on Funks Creek, Sites Dam on Stone Corral Creek, one saddle dam near Golden Gate dam, one saddle dam north of Golden Gate Dam, and five saddle dams on the northern end of the reservoir, between the Funks Creek and Hunters Creek watersheds (all dams are discussed further in Section 3.1.4.2).

Many areas within the proposed Sites Reservoir Inundation Area would be used for staging of materials and equipment prior to and during construction of the Sites Reservoir dams.

Construction. The total construction disturbance area would be approximately 13,440 acres, consisting of the proposed inundation area footprint and temporary construction-related disturbance area. Anticipated ground-disturbing activities during construction include:

- **Clearing and Grubbing.** Approximately 94 percent of the reservoir inundation area footprint is composed of annual grasslands; as a result, clearing and grubbing would not be needed in this area. The remaining six percent consists of blue oak woodland, agricultural crops, and other vegetation, which would be cleared.
- **Demolition of Existing Structures.** Twenty-two houses and four detached garages, one mobile home, 26 barns, and 37 other structures (combination of sheds, silos, and a pump house) within the Sites Reservoir Inundation Area would be demolished. Existing septic tanks and other storage tanks would also be removed. In addition, many miles of fencing and asphalt would be removed, erosion protection may be needed for prehistoric midden locations, and elderberry shrubs may need to be removed from their existing location and relocated.
- **Cemetery Relocation**. There are two private cemeteries that will need to be relocated.

Operations. The proposed Sites Reservoir is considered an offstream storage facility because the reservoir would receive very little natural runoff from its own 83-square mile watershed. Average annual natural inflow into the reservoir would be 15,000 acre-feet, which is near one percent of the 1.27-MAF reservoir storage capacity. The reservoir would be filled predominantly by diversions directly or indirectly from the Sacramento River using existing or new conveyances. Specific reservoir operations are discussed in Section 3.1.3.

Maintenance. Maintenance activities for the proposed Sites Reservoir Inundation Area may include law enforcement, garbage removal, and maintenance of signs, culverts, and buoys.

Table 3-7
Description of Proposed Seasonal Schedule for Project Operations

Objective	Detail of Operation	Priority of Operation[a]	Year Type Most Suitable for Operation[b]	Months Most Suitable for Operation[c]											
				Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
General Operation															
Conveyance	Diversions at Red Bluff (T-C Canal), at Hamilton City (GCID Canal) and at the proposed Delevan Pipeline (if included) could occur in any month. Diversions of excess Delta flows would only be allowed once SWRCB D-1641, CVPIA 3406(b)(2), 2008 USFWS BO and 2009 NMFS BO requirements were met and SWP Article 21 demands were satisfied, and other excess Delta flow diversions (e.g., Freeport Regional Water Project, Los Vaqueros Reservoir, cities of Fairfield, Vacaville, and Benicia) were satisfied. Diversions would be restricted by Sacramento River bypass criteria at Red Bluff, Hamilton City, Wilkins Slough, and Freeport, and restrictions associated with protecting fish outmigration related pulse flows (7 to 10 days once a month when flow conditions provide). Shading highlights the period in which diversion operations would occur, with the November through March season shaded the heaviest.	n/a	n/a												
Seasonal Storage Operation	Fill Sites Reservoir during excess flow events throughout the winter and spring and drain during peak release periods throughout the summer and fall. The months in which the high and low storage points would occur in the typical seasonal cycle are indicated.	n/a	n/a		Fill Cycle High Point					Drain Cycle Low Point				Fill Cycle	
Water Supply Operations															
SWP Contractors	Increase water supply reliability up to Table A contract amount in years when SWP delivery allocation is below 85 percent. Shading highlights period in which Delta exports would be increased. Table A represents the maximum annual contract amount of water delivery that SWP contractors can receive.	DP-1	BN, D, C												
Level 4 Water Supply for Wildlife Refuges	Determine Level 4 wildlife refuge water supply by replacement of purchases of north-of-the-Delta (3.35 TAF per year maximum) and south-of-the-Delta (101.09 TAF per year maximum) water to supplement refuges supplies up to Level 4 criteria (CVPIA). Shading highlights period in which transfer operations would occur.	AVG-3	AN,BN,D												
CVP Contractors	Determine CVP water supply reliability by reliability increase in any year when water supply availability limits allocations. There would be little effect if Delta export capacity is limiting allocations. Reliability increase would mostly affect agricultural service contractors. Shading highlights the typical agricultural diversion pattern.	AVG-4	AN,BN,D												
Water Quality Operation															
Delta Water Quality	Determine ability to improve water quality conditions at urban/municipal and industrial intakes by ability to augment Delta outflow. Operations would include Delta outflow augmented above base D1641 operations for up to six months with monthly rate varying within 750-cfs, 1,000-cfs and 1,500-cfs tiers; maximum of 450 TAF per period. Shading highlights period in which Delta outflow would be augmented.	AVG-1	AN,BN,D												
Hydropower Operation															
Flexible Hydropower Generation	Include dedicated pump/generation facilities with a dedicated afterbay/forebay of 6,500 acre-feet allowing more than 30 hours per week of uninterrupted operation and generation potential increases with increased head conditions and revenue increases with increased difference in prices between diurnal pumping and generation cycles.	n/a	ALL												
Ecosystem Enhancement Storage Account (EESA) Actions/Operation															
EESA-1: Shasta Coldwater Pool	Improve the reliability of coldwater pool storage in Shasta Lake to increase Reclamation's operational flexibility to provide suitable water temperatures in the Sacramento River. This action would operationally translate into the increase of Shasta Lake May storage levels, and increased coldwater pool in storage, with particular emphasis on Below Normal, Dry, and Critical water year types.	DP-1	BN, D, C												
EESA-2: Sacramento River Flows for Temperature Control	Provide releases from Shasta Dam of appropriate water temperatures, and subsequently from Keswick Dam, to maintain mean daily water temperatures year-round at levels suitable for all species and lifestages of anadromous salmonids in the Sacramento River between Keswick Dam and Red Bluff Diversion Dam, with particular emphasis on the months of highest potential water temperature-related impacts (i.e., July through November) during Below Normal, Dry, and Critical water year types.	DP-2	BN, D, C												
EESA-3: Folsom Lake Cold Water Pool	Increase the availability of coldwater pool storage in Folsom Lake, by increasing May storage and coldwater pool storage, to allow Reclamation additional operational flexibility to provide suitable water temperatures in the lower American River. This action would use additional coldwater pool storage by providing releases from Folsom Dam (and subsequently from Nimbus Dam) to maintain mean daily water temperatures at levels suitable for juvenile steelhead over-summer rearing and fall-run Chinook salmon spawning in the lower American River from May through November during all water year types.	DP-2	D, C												

Table 3-7
Description of Proposed Seasonal Schedule for Project Operations

Objective	Detail of Operation	Priority of Operation[a]	Year Type Most Suitable for Operation[b]	Months Most Suitable for Operation[c]
EESA-4: Stabilize American River Flows	Stabilize flows in the lower American River to minimize dewatering of fall-run Chinook salmon redds (i.e., October through March) and steelhead redds (i.e., January through May), and reduce juvenile anadromous salmonids isolation events (specifically, flow increases to 4,000 cfs with subsequent reduction to < 4,000 cfs), particularly from October through June. Reduce the reliance upon Folsom Lake as a "real-time first response facility" to meet Delta objectives and demands, particularly from January through August, to reduce flow fluctuation and water temperature-related impacts to fall-run Chinook salmon and steelhead in the lower American River.	DP-2	ALL	
EESA-5: Delta Outflow for Delta Smelt Habitat Improvement (Summer/Fall)	Provide supplemental Delta outflow during summer and fall months (i.e., May through December) to improve X2 (if possible, west of Collinsville 81 km) and increase estuarine habitat, reduce entrainment, and improve food availability for anadromous fishes and other estuarine-dependent species (e.g., delta smelt, longfin smelt, Sacramento splittail, starry flounder, and *Crangon franciscorum*). Shading highlights period in which Delta outflow would be augmented (operation coordinated with Delta Water Quality action).	AVG-2	ALL	
EESA-6: Lake Oroville Coldwater Pool	Improve the reliability of coldwater pool storage in Lake Oroville to improve water temperature suitability for juvenile steelhead and spring-run Chinook salmon over-summer rearing and fall-run Chinook salmon spawning in the lower Feather River from May through November during all water year types. Provide releases from Oroville Dam to maintain mean daily water temperatures at levels suitable for juvenile steelhead and spring-run Chinook salmon over-summer rearing and fall-run Chinook salmon spawning in the lower Feather River. Stabilize flows in the lower Feather River to minimize redd dewatering, juvenile stranding, and isolation of anadromous salmonids.	DP-2	BN, D, C	
EESA-7: Stabilize Sacramento River Fall Flows	Stabilize flows in the Sacramento River between Keswick Dam and the Red Bluff Diversion Dam to minimize dewatering of fall-run Chinook salmon redds (for the spawning and embryo incubation lifestage periods extending from October through March), particularly during fall months. Avoid abrupt changes. Operations would be limited to not adversely impact coldwater pool operations in dry and critical years. Shading highlights period of greatest effect on stabilization or flows on a daily basis.	AVG-1	AN,BN,D	
EESA-8: Sacramento River Diversion Reduction at Red Bluff and Hamilton City	Provide increased flows from spring through fall in the lower Sacramento River by reducing diversions at Red Bluff Diversion Dam (into the T-C Canal) and at Hamilton City (into the GCID Canal), and by providing supplemental flows at the proposed Delevan Pipeline Intake/Discharge Facilities. This action would provide multiple benefits to riverine and estuarine habitats, and to anadromous fishes and estuarine-dependent species (e.g., delta smelt, splittail, longfin smelt, Sacramento splittail, starry flounder, and *Crangon franciscorum*) by reducing entrainment, providing or augmenting transport flows, increasing habitat availability, increasing productivity, and improving nutrient transport and food availability.	n/a	ALL	

[a]Priority of operation "DP" indicates that the operational priority has a driest period's emphasis and "AVG" indicates an average-to-wet hydrologic emphasis. The number 1-4 indicates priority within the associated hydrologic emphasis. "n/a" indicates that operations are not or cannot be easily defined within the priority structure of the scenario.

[b]Year type most suitable for operation is the D1641 40-30-30 year types that are reflected in operations studies; operations in these year types occur when supplies would be available in Sites Reservoir to support the operation, when the operations criteria in the scenario allow for prioritization of the operations, and when conditions are suitable for developing the benefit associated with the operation.

[c]The heavier shaded parts of each bar highlight the months in which conditions would be most suitable to the operations; the lighter shaded parts of each bar highlight the months that would be less suitable to the operations; operations in these months would occur when supplies are available in Sites Reservoir to support the operation, when the operations criteria in the scenario allow for prioritization of the operations, and when conditions are suitable for developing the benefit associated with the operation.

Notes:

AN = Above Normal
AVG = Average
BN = Below Normal
C = Critical
D = Dry
DP = Driest periods
GCID = Glenn-Colusa Irrigation District
NMFS = National Marine Fisheries Service
TAF = thousand acre-feet
T-C Canal = Tehama-Colusa Canal
USFWS = U.S. Fish and Wildlife Service

3.1.4.2 Dams for the 1.27-MAF Sites Reservoir

Nine dams would be needed to create the proposed 1.27-MAF Sites Reservoir (Figure 3-1): Golden Gate Dam, Sites Dam, one saddle dam near Golden Gate dam, one saddle dam north of Golden Gate Dam, and five saddle dams along the northern perimeter of the reservoir between the Funks Creek and Hunters Creek watersheds, near the Glenn-Colusa County line. The proposed Golden Gate Dam would be constructed on Funks Creek, approximately one mile west of the existing Funks Reservoir. The proposed Sites Dam would be constructed on Stone Corral Creek, approximately 0.25 mile east of the town of Sites and ten miles west of the town of Maxwell.

The Golden Gate Dam location was selected to optimize material quantities and construction costs with respect to the site topography. For the 1.27-MAF Sites Reservoir, the Golden Gate Dam would be located on the western edge of the ridges that form the east reservoir rim. This damsite is only suitable for reservoir elevations less than approximately 480 feet due to steep and narrow abutment ridges. Construction of an additional small Golden Gate saddle dam would be required. Due to the small size of this proposed saddle dam relative to the main Golden Gate Dam, the saddle dam materials and cost estimates have been included in the estimates for the main Golden Gate Dam.

The seven proposed saddle dams would be constructed as earthfill embankment dams, and are designed to be constructed primarily of on-site materials. Site topography, geology, seismicity, and foundation features were considered when selecting the dam alignments, design, and sections. The dam designs would conform to modern economic construction practices and incorporate conservative design measures. Table 3-8 lists the proposed height and length of the main and saddle dams, as well as the total volume of materials needed to construct the dam embankments.

Table 3-8
Characteristics of Proposed 1.27-MAF Sites Reservoir Dams for Alternative A

Dam	Maximum Height Above Base* (feet)	Crest Length (feet)	Total Embankment Volume (cubic yards)
Golden Gate Dam	270	2,250	5,987,000
Sites Dam	250	850	2,853,000
Saddle Dam No. 1	10	490	1,400
Saddle Dam No. 3	90	3,810	1,365,000
Saddle Dam No. 5	60	2,290	398,000
Saddle Dam No. 6	10	530	9,000
Saddle Dam No. 8a	65	2,990	390,000
Saddle Dam No. 8b	5	340	15,000
Golden Gate Saddle Dam	Included within Golden Gate Dam	Included within Golden Gate Dam	Included within Golden Gate Dam
Total			**11,018,400 cubic yards**

*Base is defined as ground surface elevation.

The crest elevation of all nine dams would be 500 feet, providing 20 feet of freeboard. Sites and Golden Gate dams would have crest widths of 30 feet and embankment slopes of 2.25:1 upstream and 2:1 downstream. The saddle dams would have crest widths of 20 feet and embankment slopes of 3:1 upstream and 2.5:1 downstream.

The nine dams would be constructed of compacted excavated materials (soil and rock). The four zones of the embankment dams are:

- **Zone 1:** Impervious core material comprised of low to medium plasticity clays, with lesser amounts of high plasticity clays and clayey sands.
- **Zone 2:** Filter, drain, and transition materials consisting of fresh rock processed to various sizes to meet filter compatibility and hydraulic conductivity requirements.
- **Zone 3:** Shell material consisting of processed clean rockfill up to 30-inch maximum particle size.
- **Zone 4:** Random material comprised of materials unsuitable for use as clean rockfill.

Material requirements for the Sites Reservoir dams constitute a major component of the overall proposed Project. A preliminary construction materials investigation identified and evaluated material sources for construction of the proposed dams. The construction materials investigation program examined materials available in or near the proposed Sites Reservoir, including alluvial deposits (recent and older alluvium), Venado sandstone of the Cortina Formation (fresh and weathered), and mudstone of the Boxer Formation. These material sources were investigated, tested, and evaluated to examine their suitability for use as the following types of construction materials:

- **Impervious core (Zone 1) –** A large amount of potential impervious material exists within or near the proposed Sites Reservoir area. Previous studies by Reclamation identified four main areas of alluvial deposits in the reservoir area encompassing roughly 36 million cubic yards of material. Additional impervious materials are located within required excavation areas for the appurtenant structures and the proposed Holthouse Reservoir Complex. These required excavation areas would be used to the maximum extent practicable. Additional quantities of impervious materials are located within the reservoir inundation area. The locations of these potential borrow areas are illustrated in Figure 3-7. The impervious materials are suitable for use in the proposed embankment dams, and are generally classified as low to medium plasticity clays, with lesser amounts of high plasticity clays, and clayey sand. If borrow areas inside the reservoir footprint prove inadequate, commercial sources would be used.
- **Filter, drain, and transition materials (Zone 2) –** Filter, drain, and transition materials for the proposed embankment dams would be imported from the closest off-site sand and gravel deposit, identified as an old channel on Stony Creek (between Orland and Willows), if additional testing of the Venado sandstone deposit (located within one mile of Golden Gate and Sites dam sites) indicates that it is not suitable. The Stony Creek deposit is approximately 30 to 35 miles from the Project area, and has an estimated material availability of 160 million cubic yards, which would exceed the Project construction requirement.
- **Rockfill and riprap (Zone 3) –** The best available source of clean rockfill material within the Project area is fresh Venado sandstone. Sandstone quarry areas have been identified within the reservoir inundation area and are presented in Figure 3-7. Sufficient quantities of fresh sandstone for rockfill material could be obtained from these quarries to construct the proposed embankment dams. It is possible that one centrally located quarry would be developed for Golden Gate and Sites dams instead of developing a quarry for each dam.

  Figure 3-7 also shows a proposed sandstone quarry location for construction of the saddle dams. The haul distance from this proposed quarry is approximately three to four miles from the saddle damsites. A potential alternate source of rockfill and riprap material for construction of the saddle dams is a ridge of conglomerate located within the reservoir area near Saddle Dam 3 (Figure 3-7). This potential rockfill source offers a shorter haul distance to the saddle dams (one to two miles). Development of the Venado sandstone quarry would be required for construction of the saddle dams, unless further testing of the conglomerate determines that it is a suitable material.

- **Random fill (Zone 4) –** It is anticipated that two general types of random materials would be generated during construction, depending upon the source of the material. One type of random material would be comprised of predominately weathered sandstone from the Cortina Formation, and the other type would be predominately mudstone from the Boxer Formation. Mudstone from the Boxer Formation would tend to be “soil like” after excavation and compaction operations because it is a low strength rock and tends to break down when exposed to air and water. The weathered Cortina Formation tends to have more fine materials and have less well-graded rockfill.

  At the Sites and Golden Gate damsites, random embankment material would be comprised of materials unsuitable for use as clean[7] rockfill. It would consist of weathered sandstone, mudstone, and slopewash from excavations for the dam foundations, appurtenant structures, and rockfill quarries. Material from clearing and grubbing operations would not be used in any embankment structure. Random material generated during construction of these dams would have haul distances of less than one mile.

  Random material would be generated from the Boxer Formation during construction of the saddle dams and designated borrow areas. Random material borrow areas for construction of the saddle dams have not been identified, but would be located within the reservoir area with haul distances of less than one mile. Sufficient quantities are available for construction of the saddle dams. Although the Boxer Formation material would function more as an upstream and downstream shell zone in the saddle dams, the term *random* is used for this material zone to be consistent with the terminology used for the design of Sites and Golden Gate dams.

- **Concrete aggregate –** Crushed Venado sandstone and off-site sand and gravel deposits were examined as potential sources of concrete aggregate. Preliminary testing performed on crushed samples of Venado sandstone indicates that it marginally meets concrete aggregate suitability criteria. Verification of the suitability of the Venado sandstone for use as concrete aggregate would be the focus of future investigations. Potential commercial sources of concrete aggregate borrow areas located north of the Primary Study Area, between Willows and Orland, are identified on Figure 3-8. These borrow areas would be used unless the additional testing mentioned above indicates that the Venado sandstone is suitable for concrete aggregate.

For the 1.27-MAF Sites Reservoir, there would be a minimal dam at the Saddle Dam No. 6 site because the ground level of the saddle is approximately at elevation 500 feet, 20 feet above the reservoir maximum operating level. However, it is anticipated that a core trench backfilled with clay would be required across the saddle to control seepage when the water is at or above the maximum operating level. A proposed emergency spillway at the 1.27-MAF Sites Reservoir would be located at Saddle Dam No. 6. The purpose of the spillway would be to release excess water as the result of overpumping after a probable maximum flood[8] (PMF), and to prevent overtopping the dams. If the PMF were to occur when the reservoir was at the normal maximum pool elevation (elevation 480 feet), the water surface elevation

[7] Clean rockfill refers to rockfill that is free from foreign matter.

[8] The probable maximum flood is the flood that may be expected from the most severe combination of critical meteorological and hydrologic conditions that is reasonably possible in the drainage basin being studied.

would rise to 486.25 feet. The dam crest elevation is 500 feet. Therefore; the spillway would be required only in the event that water was still being pumped into the reservoir after the PMF had been stored (an unlikely occurrence). The spillway at this location would include an excavated entry channel, a pipe through the saddle (and core trench), and an energy dissipating structure at the downstream end of the pipeline. The spillway would consist of one seven-foot-diameter concrete pipe sized primarily to accommodate inspection and maintenance activities. The invert of the spillway inlet would be at elevation 486.25 feet, 6.25 feet above the normal maximum pool.

Construction. The total construction disturbance area for the nine proposed dams would be approximately 90 acres. The total construction disturbance area would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, borrow areas, and access roads. The construction disturbance area for the dams would be within the construction disturbance area for the proposed Sites Reservoir Inundation Area.

Anticipated ground-disturbing activities during construction include:

- Surveying
- Setting up staging areas within the Sites Reservoir footprint
- Constructing access roads
- Transporting equipment to the Project site and setting up offices and batch plants
- Clearing and grubbing
- Diverting streams
- Excavation and stockpiling activities
- Grouting of foundations
- Construction of dam embankments
- Installation of monitoring equipment
- Constructing roads and buildings for facility operation and maintenance
- Project area cleanup, removal of equipment, and area restoration

Some of these activities are discussed in greater detail below:

- **Funks Creek and Stone Corral Creek Diversion Construction.** Diversion of Funks and Stone Corral creeks during construction of the proposed Golden Gate and Sites dams, and for the proposed facilities downstream, is anticipated to be accomplished by passing storm flows through a buried corrugated metal pipe or concrete pipe around the two construction areas. A low coffer dam would provide a dead pool large enough to protect the damsites from seasonal stream flows. During construction of Golden Gate and Sites dams, small coffer dams upstream of each damsite would provide protection for an approximately 50-year probability storm. Diversion at the entrance to the inlet/outlet works tunnel would require a coffer dam to approximately elevation 310 feet. Coffer dam installation would involve driving interlocking corrugated sheet piles into the ground. Diversion pipe installation would involve excavation, if necessary, laying of the two pipelines, and backfilling and grading around the pipe, as necessary.

  The upstream random zone of Golden Gate and Sites dams functions as an upstream toe berm, provides a convenient place to put waste materials from foundation excavation work during the initial stages of construction, and would also be used to divert Funks and Stone Corral creeks from the dam footprint.

  Sites Dam and Golden Gate Dam would have low-level outlet works capable of releasing stream maintenance flows of up to 10 cfs from October through May into Stone Corral Creek and Funks Creek after construction is completed to mimic the ephemeral nature of these streams. These low level outlet works would be incorporated as permanent facilities in the creek diversion systems installed at both damsites to pass winter storm runoff through the construction sites.

- **Obtaining and Stockpiling Borrow Materials.** To expedite dam construction, rockfill, drain, filter materials, and concrete aggregate would be excavated, processed, and stockpiled one year prior to the start of construction. Materials would be stockpiled near rock-processing plants that would be constructed for the proposed Project. It is anticipated that at least one rock-processing plant would be located within the reservoir footprint to service the impervious material borrow areas and the sandstone quarries.

  The rock-processing operation would consist of rock crushers to produce required sizes, shakers and screens to sort material sizes, and conveyor belts to transport sorted material to stockpiles.

  Stockpiled materials would be loaded by bulldozers, loaders, and possibly conveyors into large dump trucks and transported to the dam construction sites.

  Material excavation, processing, and stockpiling are anticipated to occur throughout the dam construction period.

- **Foundation Excavation.** Recent and older alluvium and decomposed and intensely weathered bedrock would be excavated from the entire footprint of the damsites to obtain a moderately weathered bedrock surface. In addition, moderately weathered bedrock would be excavated from the impervious core footprint down to the top of slightly weathered and/or fresh bedrock surface. Additional shaping of the foundations would be done to meet requirements that: (1) no excavation slopes should be steeper than 1:1 and (2) the core foundation should be approximately level in sections transverse to the dam alignment. To meet the second shaping requirement, a maximum transverse slope of 6:1 was adopted for the core foundation. Excavation depths would average approximately 20 feet. Excavation would be performed by the use of heavy equipment, but may require some blasting in the harder sandstone.

- **Foundation Treatment Grouting.** The foundation grouting for the proposed Golden Gate and Sites dams would consist of a two-row grout curtain, with one row of consolidation holes upstream and one row downstream of the curtain holes. The rows would parallel the dam centerline and would be spaced 10 feet apart. In addition, a 40-foot-wide by three-foot-thick grout cap was included in the design to prevent grout surface leakage during grouting of the upper stage. Foundation grouting for the proposed saddle dams would consist of a two-row vertical grout curtain spaced 10 feet apart parallel to the dam centerline. The saddle dam foundation grouting would also include a 20-foot-wide by three-foot-thick grout cap to prevent surface leakage of grout during grouting of the upper stage. Each row of consolidation and curtain grout holes for all dams would consist of mandatory primary and secondary holes spaced at 10 foot centers. Figures 3-9, 3-10, 3-11, and 3-12 show typical grouting at the proposed Golden Gate Dam, Sites Dam, and the saddle dams.

  The grout curtains would be constructed by drilling vertical holes into the bedrock and filling the holes with grout pumped in under pressure.

- **Dam Embankment Construction.** All proposed dams comprising the proposed Sites Reservoir would be constructed as zoned earth rockfill embankment dams, and would be constructed of four types of fill materials. The impervious core materials (finer material known as Zone 1), Zone 3 materials (rockfill and riprap), and Zone 4 materials (random materials) would be hauled in large dump trucks from the borrow sites that would be located within the reservoir footprint, spread by graders or bulldozers, moisture-conditioned with water trucks, and compacted with sheepsfoot rollers or compactors. Zone 2 materials (filter, drain, and transition materials) would be hauled in large dump trucks from commercial sources along the Stony Creek fan.

- **Monitoring Equipment Installation.** Monitoring equipment would be permanently installed at each proposed damsite including strong motion detectors and water pressure monitors.

Operations. Once the proposed dams are constructed and Sites Reservoir is filled, there would be few dam operations required other than release of water from the reservoir during normal or emergency operations.

Maintenance. Typical ongoing dam maintenance would consist of equipment, foundation, and embankment inspections and repairs. Debris and vegetation removal from the embankments and along the roads would be required. In addition, ongoing movement and seepage monitoring would be necessary. Dam security and/or law enforcement staff would patrol the proposed dams and other proposed Project features. Additional security measures may include fences to prevent automobiles and pedestrians from accessing the dams and other Project features, booms to prevent boats from approaching the dams, security gates, 24-hour security patrols, and security cameras.

3.1.4.3 Delevan Pipeline Intake Facilities

The proposed Delevan Pipeline Intake Facilities are a system of structures designed to divert water from the Sacramento River to the proposed Holthouse Reservoir for storage in the proposed Sites Reservoir. The facilities would also minimize harm to fish, safely release water from Sites Reservoir to the Sacramento River, and generate electricity when water is released from Holthouse Reservoir through the proposed Delevan Pipeline to the Sacramento River.

The proposed Delevan Pipeline Intake Facilities would be located on the Sacramento River at River Mile 158.5 in Colusa County (Figure 3-13A). The river intake/outlet would be located immediately downstream of the existing Maxwell Irrigation District intake and across the river from Moulton Weir, approximately 10 miles northeast of the town of Maxwell (Figure 3-13B). The total footprint of the site would be approximately 19 acres including the pumping plant buildings, fish screen, forebay, and afterbay.

Water that passes through the fish screen would be pumped up approximately 150 feet vertically through two 12-foot-diameter concrete pipes to Holthouse Reservoir. Water would also be able to flow back from Holthouse Reservoir, by gravity, to the Sacramento River. Reverse flow water would flow through the turbines to generate electricity. The water would then flow through the forebay and fish screen at a velocity of one foot per second into the Sacramento River. The one fps exit velocity is based on NMFS criteria for adult salmon diffusers to allow the water to exit the screen without extending a false attraction flow to the salmon.

The proposed pumping capacity of the Delevan Pipeline Intake Facilities would be 2,000 cfs when diverting water from the Sacramento River, and 1,500 cfs when releasing water to the Sacramento River (and generating electricity). Total lift capacity of the facility would be approximately 150 feet.

The proposed facilities at this site would include:

- **Flat plate fish screen structure –** The purpose of the fish screen structure would be to exclude fish that are present in the Sacramento River from the water that is being diverted into the pump station. The fish screen would also function as an outlet structure, dissipating the energy of the water being released to the river.

  The fish screen structure would consist of 32 13-feet-tall by 15-feet-wide flat plate screens. The structure would be approximately 560 feet long (the distance created by the 32 screens bays, the additional two blowout bays, and room for the screen cleaning equipment). Panels would be positioned with minimum protrusion into the river channel parallel to river flow. This facility has been designed in compliance with NOAA Fisheries and CDFW fish screen criteria.

- **Forebay, levee tubes, and afterbay –** After water passes through the fish screen it would flow into a 1.3-acre forebay. The forebay would allow fine sediment that is carried in the water to settle out. Water then travels through the levee tubes to pass under the existing Sacramento River levee and into the afterbay. The afterbay is a 2.3-acre concrete lined bay that would store water before it is pumped out by the pumping/generating plant.

  The levee tubes are a means to transfer water from the river through the levee to the pumping/generating plant afterbay. As the water enters the tubes, it would pass through a trash rack and sluice gate. It then would travel through 10 nine-foot-diameter pipes and exit through a trash rack into the afterbay. The tubes would handle a maximum flow of 2,000 cfs and maintain a velocity no greater than three fps during operation. The velocity through the pipes would allow for sediment to pass through without settling, and it would also minimize turbulence. The levee tubes' design would maintain a maximum velocity of three fps at 2,000 cfs during pumping intake and 2.3 fps at 1,500 cfs during discharge.

  A Sediment Spoil Area would be provided on the northeastern end of the afterbay for sediment removal. To remove sediment, a long arm excavator would be required in combination with a suction dredge or a clamshell. The suction dredge or clamshell would be used to remove the additional sediment in the area where the excavator could not reach. The sediment would ultimately be placed on the adjacent levee.

- **Pumping/generating plant –** The Delevan Pipeline Intake Facilities would pump water from the afterbay to Holthouse Reservoir and would also function to release water from Holthouse Reservoir. The Delevan Pipeline Intake Facilities building would be approximately 250 feet long by 80 feet wide and would have multiple stories to accommodate mechanical and electrical equipment. The pumping/generating plant would consist of four 600-cfs pumping/generating units (plus one standby unit) to provide a total pumping capacity of 2,000 cfs. Water would be pumped by the pumping/generating plant 150 feet up over 13.5 miles through the Delevan Pipeline. When water is released from Sites Reservoir and through Holthouse Reservoir, the intake facilities would function in reverse, capturing the energy and generating electricity. Release flows of up to 1,500 cfs could be passed through the pumping/generating plant.

- **Switchyard –** An electrical switchyard would be required adjacent to the pumping/generating plant that would step down the electrical voltage from high voltage lines to a lower voltage that can be used by the pumps and other machinery in the plant. A four breaker ring bus would be required at the switchyard. The ring bus would have multiple metallic poles with heights varying between 15 feet tall and 60 feet tall. The switchyard would be surrounded by a six to eight-foot-high chain link fence with barb or serpentine wire along the top.

- **Maintenance and electrical buildings –** Mechanical control and electrical buildings would also be constructed on the site to house mechanical and electrical equipment needed for the operation of the pumping/generating plant. The mechanical and electrical buildings would be approximately 5,000 square feet each. Facilities would be sited and designed such that electrical equipment would be sealed or placed at an elevation above the 100-year flood stage plus two feet of freeboard (elevation 82 feet).
- **Access Road –** A new on/off ramp from/to State Route 45 (SR 45) would be constructed to provide access to the pumping/generating plant. The width of the access road would be approximately 40 feet. The road would lead to both the pumping/generating plant building and flood gates.
- **Other Mechanical & Electrical Features –** Other miscellaneous features that may be included:
  - Spherical Valves
  - Air Chambers and Butterfly Valves
  - Compressors, Generators, Cranes
  - Service Air and Water Systems
  - Acoustical Flowmeters
  - Governors
  - Transformers
  - Switchgears
  - Grounding Grids
  - Controls Cabinets

The proposed Delevan Pipeline Intake Facilities site would be protected from flood conditions by constructing all of the mechanical and electrical equipment above the 100-year flood elevation (82 feet above msl). Although the forebay and afterbay would be submerged during extreme flood events, they would be designed to withstand these conditions. The site naturally slopes upward away from the river, and a flood protection levee with a height of 90 feet msl exists along the river approximately 275 feet west of the river. A wide berm or ring levee would be constructed behind the flood protection levee to provide additional protection for the equipment and facilities. The berm would encircle the afterbay, and the Delevan Pipeline Intake Facilities would be constructed on top of the berm, as would the mechanical and electrical buildings.

Construction. The total construction disturbance area would be approximately 19 acres. An additional disturbance area around the construction site would be required for staging of materials, equipment, and construction offices. This area is within the construction disturbance area for the proposed Delevan Pipeline. The staging area is estimated to be 1,700 feet by 1,000 feet (a total of 40 acres) located to the north of and adjacent to the facility site.

To isolate the proposed construction area from the Sacramento River, a cellular sheet pile coffer dam would be installed in the river near the location of the fish screen. Approximately 1,200 feet of sheet piles would be required to build the cofferdam. From the river bank at the upstream and downstream ends of the fish screen structure, the cofferdam would extend approximately 40 feet into the water from the river bank. Installation of the coffer dam would involve driving interlocking metal sheet piles into the ground one section after another until the entire length of the intake structure is isolated from the river. The height of the coffer dam would match the height of the surrounding levees. The coffer dam is likely to remain in place throughout the duration of facility construction. The area behind the coffer dam would be dewatered prior to construction by pumping water out from behind the coffer dam. After construction of the pump station is complete, the coffer dam would be removed by pulling the sheet piles out of the river.

Anticipated major construction activities include:

- Transportation of materials to the construction site
- Clearing and grading the construction workspace
- Placing necessary construction materials at staging areas
- Construction of a coffer dam within the Sacramento River
- De-watering the work area within the river
- Excavation of the forebay and pumping plant site
- Construction of electrical switchyard
- Construction of the berm/ring levee
- Construction of the pump house and pump bays
- Construction of the forebay structure
- Construction of the fish screens
- Removal of the coffer dam
- Fill and re-grading where needed at site
- Restoration of disturbed areas following the completion of construction

Construction of the proposed Delevan Pipeline Intake Facilities would require relocation of sections of the Maxwell Irrigation District and Tuttle Ranch pipelines that are located within the construction disturbance area. To minimize impacts to the operations of the Maxwell Irrigation District facilities during construction, either a temporary bypass pipeline would be constructed to provide water to Maxwell Irrigation District users, or arrangements will be made for supplemental water to be conveyed into the Colusa Basin Drain (CBD) for the Maxwell Irrigation District to pick up for delivery to its users. A temporary bypass pipeline would be constructed to provide water to Tuttle Ranch to irrigate its orchards.

Operations. Proposed diversion operations would be such that a minimum of 4,000 cfs would remain in the river channel immediately downstream of the diversion point. The assumed associated minimum water surface elevation at this design condition is 51 feet. The invert of the screen structure is set at 38 feet, four feet above the invert of the river, to reduce sediment deposition in front of the screen panels.

- **Intake Mode**: The Intake Mode is when water would be pumped from the Sacramento River to the proposed Sites Reservoir when the largest flows and velocities occur. Flow of water would move through the fish screen into the forebay, through the levee tubes, into the afterbay, through the proposed Delevan Pipeline to the proposed Holthouse Reservoir, and then to Sites Reservoir. During this operation, the screen cleaning mechanism would be working continuously to prevent buildup on the screen panels, the sediment removal system would be operating, the pumps would be operating, and the SCADA system would be monitoring water levels and pressures across the screen.

- **Discharge Mode:** The Discharge Mode is when water from Sites Reservoir would flow back through the pumping plant and into Holthouse Reservoir to generate electricity, is released into Delevan Pipeline and discharged into the afterbay, through the levee tubes, and into the forebay, and then released through the fish screen into the Sacramento River. During this operation, the fish screen cleaning mechanism would not need to operate because it would be located on the river side of the fish screen, the sediment removal system would remain in operation, and the SCADA system would be monitoring water levels and pressures across the screen.

- **Emergency Mode:** When the diversion would operate in intake or discharge mode and a pressure differential greater than 1.5 feet across the fish screen occurs, Emergency Mode would be activated. The pumps would stop operating, and the sluice gates would close to allow the forebay to fill up to match the water surface of the Sacramento River. If the pressure differential grows to above three feet, then the two blowout panels would trigger and release to allow an inflow of river water to allow the water levels to equalize. Additionally, if the river is at a very high water level and the pumps need to turn off, the sluice gates should close at the same rate that the pumps power down to prevent flooding of the afterbay.

A SCADA system would control all of the different operational modes. The system would be located on-site, and would broadcast status information to a manned remote location. The SCADA system provides a means to control the diversion without staffing the on-site facility.

A sediment removal system would be installed within the fish screen bays, moving sediment back into the river channel or into the forebay. Sediment that has settled out into the forebay would be removed mechanically to maintain optimal operational hydraulics. This would likely be an annual operation.

Maintenance. The proposed Delevan Pipeline Intake Facilities would likely be staffed daily to maintain, operate, and monitor the facility. It is anticipated that employees would be on-site during diversion (predominantly in winter) and release (predominantly in summer) activities.

3.1.4.4 Delevan Pipeline – 2,000-cfs Diversion/1,500-cfs Release

The approximately 13.5-mile-long proposed Delevan Pipeline would convey water from the Sacramento River to the proposed Holthouse Reservoir to fill the proposed Sites Reservoir, and would also convey water from Holthouse Reservoir to the Sacramento River for releases (Figure 3-1). The portion of the Delevan Pipeline that would be located to the west of the proposed TRR would parallel the proposed TRR Pipeline from the TRR to Holthouse Reservoir, and would share a common trench and outlet structure into Holthouse Reservoir (Figure 3-6).

The Delevan Pipeline would be bi-directional, allowing water to be pumped from the Sacramento River to Holthouse Reservoir for storage, and allowing water to flow by gravity from Holthouse Reservoir for release to the Sacramento River. As water released from Holthouse Reservoir flows through the pump station at the eastern end of the pipeline, it would pass through turbines to generate electricity.

The Delevan Pipeline would have a 2,000 cfs capacity to convey water from the proposed Delevan Pipeline Intake Facilities to Holthouse Reservoir. The capacity of the Delevan Pipeline to convey water from Holthouse Reservoir to the Sacramento River would be 1,500 cfs. The Delevan Pipeline would consist of two 12-foot-diameter reinforced concrete pipes.

The Delevan Pipeline would begin at the Delevan Pipeline Intake Facilities near the Sacramento River. The Delevan Pipeline would be aligned due west until reaching the GCID Canal. At the GCID Canal, the Delevan Pipeline would be aligned southwesterly and would parallel the TRR Pipeline in a shared trench until it reaches the Holthouse Reservoir Complex.

Proposed facilities associated with the Delevan Pipeline include blow-off structures, air valve structures, and an outlet and energy dissipater structure. Blowoff structures would be provided to clean low points in the pipeline and allow dewatering. Blowoff valves would release water from the pipeline. These valves are located at major water conveyances so that water can be drained directly into the river or canal and carried downstream. Air and vacuum valves would be required to evacuate air within the pipeline during filling, and supply air during normal dewatering, as well as to release accumulated air. Manholes would be used to access the pipeline for future maintenance or inspections. Aboveground features associated with the Delevan Pipeline are listed in Table 3-9.

Table 3-9
Aboveground Features Associated with the Proposed Delevan Pipeline

Aboveground Feature	Height Above Ground	Color	Appearance	Feature Locations
Manhole and Air Valve	4 feet Maximum, 108 inches Diameter	Gray	Concrete Box	At high points and at a minimum of every 2,500 feet along the pipeline
Manhole and Blowoff Valve	1 foot Maximum, 108 inches Diameter	Gray	Concrete Box	At low points and at the Sacramento River and the GCID Canal Crossing

The proposed alignment of the Delevan Pipeline would require five major crossings (SR 45, SR 99, Interstate-5 (I-5), Union Pacific Railroad, and the GCID Canal). The proposed pipeline route would also cross the easements of the existing PG&E 230-kV electrical transmission line and a major PG&E natural gas pipeline. No permanent aboveground structures, other than a gravel maintenance road (TRR Pipeline Road), would be constructed where the electric utility easements and the pipeline easements would intersect. Other existing infrastructure that the pipeline could potentially cross include: gas lines, water lines, sewer lines, communications lines, and other infrastructure. These major crossings would be accomplished with jack and bore construction.

In addition, the Delevan Pipeline would cross the CBD. The crossing location would be at the northern end of the drain. Construction of this crossing would likely occur during late fall, after the irrigation season ends and before winter rains begin. Portions of the CBD would likely be dewatered so that the pipeline trench could be excavated and the pipeline could be installed. Construction would be staged at this crossing and would occur within one half of the channel while an installed coffer dam bypasses flows on the other half of the channel. After installation, the CBD would be returned to service and would be reconstructed to pre-Project conditions.

Construction. The construction disturbance area of the proposed Delevan Pipeline would be approximately 2,500 acres. The construction disturbance area would include a temporary concrete batch plant (the same plant as used for the proposed TRR Pipeline).

Construction of the Delevan Pipeline would likely be done in three independent and concurrent sections. Two of the sections would likely begin from the same point and move in opposite directions. As pipelines are installed and tested, the trench would be backfilled to minimize the amount of open trenching.

The construction disturbance area for the Delevan Pipeline would be a linear area 13.5 miles long and approximately 300 feet wide from the Sacramento River to the proposed TRR (10 miles) and approximately 335 feet wide from the TRR to the proposed Holthouse Reservoir (3.5 miles). The additional width of the construction disturbance area would be needed to accommodate the additional TRR Pipeline from the TRR to Holthouse Reservoir. An additional construction disturbance area of 20 acres would be required for a concrete batch plant. Construction disturbance area boundaries would be marked with tape, flagging, or fencing. The construction disturbance area would pass through multiple areas close to residences, and would intersect with several roads. The entire Delevan Pipeline construction disturbance area would not be fenced. In high visibility areas or where the construction site requires a higher degree of protection for security or safety, a six-foot-high chain link fence would be installed around the work site.

- **Trenching/Excavation of Pipeline Route –** Approximately 6.3 million cubic yards of material would be excavated for the Delevan Pipeline trench. Topsoil would be stockpiled separately from other excavated materials. Trench excavation would be approximately 23 feet deep. For the portion of the Delevan Pipeline that would be installed between the Sacramento River and the TRR, the trench would be approximately 120 feet wide. A total of two 12-foot-diameter pipelines would be installed from the Sacramento River to the TRR. Trench excavation for the 3.5 miles from the TRR to Holthouse Reservoir would be approximately 165 feet wide to accommodate both the Delevan and TRR pipelines. A total of four 12-foot-diameter pipes would be installed from the TRR to Holthouse Reservoir. Trench side slopes would be approximately 1:1.5. No shoring would be installed under normal excavation conditions. Special conditions at some locations (unknown at this time) may require additional depth or width, or steeper or flatter side slopes, or shoring to accommodate localized soil conditions.

  The Delevan Pipeline trench would be excavated using trenchers and tracked and/ or wheeled excavators and backhoes, or pushed up using bulldozers. The type of soils encountered would determine the type of equipment used for trenching. Harder soils, such as caliche, would require larger trenchers. In specific areas, vacuum excavation, “pot-holing” with a backhoe or hand digging may be necessary to locate buried utilities.

  Excavation activities similar to the Delevan Pipeline excavation would also be done for electrical transmission pole footings that would be installed within the pipeline right-of-way. These activities would occur simultaneously with the pipeline excavation.

- **Dewatering –** Dewatering of the trench would be necessary in many locations and could be permitted to discharge into local irrigation ditches and drainage canals and/or the CBD after settling of silts. Silts would be disposed of with excavated material. Dewatering would be in accordance with CVRWQCB requirements and California Storm Water Quality Association BMPs for dewatering.

- **Bedding Preparation –** One foot of bedding material would be installed in the trench before installation of the pipeline. Bedding material would likely be sand, consolidated backfill, or cemented controlled density fill. The bedding material would be poured into the trench by dump truck, and spread along the bottom of the trench by a small grader or similar type of equipment.

- **On-Site Fabrication of Pipes –** All pipes would be fabricated on-site at the concrete batch plant. A fabrication and curing area for the pipes would be located within the 20-acre batch plant footprint. Pipes would be fabricated on-site from straight lengths of reinforcing steel.

- **Installation of Pipe and Valves –** The finished sections of the pipes would be transported from the concrete batch plant to the installation location primarily along the pipeline route on flatbed trucks traveling along the construction access roadway (within the construction disturbance area). These trucks would cross public roadways. Pipe sections would be offloaded from flatbed trucks and placed in the excavated pipeline trench by a 50-ton capacity crane. Once in place, the metal joining plates cast into the end of each pipe would be welded together and the joint would be covered with a cement-based sealing compound. At valve locations, pre-fabricated valves would be delivered to the site on flatbed trucks and installed into previously constructed structures within the trench using the same crane.

- **Backfill of Trench –** Approximately five million cubic yards of material would be needed to backfill the trench after the pipes are installed. Excavated material would be re-used to backfill the trench or moved to other Project locations for use, to the extent possible, after placement of pipes. Excess spoils from the excavation (estimated 1.3 million cubic yards) would be spread on adjacent agricultural lands of willing landowners within the 800-yard-wide corridor along the pipeline, used as backfill at the proposed Delevan Pipeline Intake Facilities, or placed in the proposed Sites Reservoir footprint. Excess spoils may also be used to reinforce existing levees in the area as part of a separate program, which would be subject to a separate environmental analysis. Re-use of excavated material may be limited by water content of excavated material and soil compaction requirements.

Operations. Operation of the proposed Delevan Pipeline would not require daily workers at the site.

Maintenance. Periodic inspection and maintenance of the proposed Delevan Pipleine would likely occur once per year, typically in the months of April and May, with possible additional inspections and maintenance needed after earthquakes or storm or flood events. Permanent rights-of-way for the land overlying the pipeline would be maintained to guarantee future access. Disturbed lands would be returned to agricultural production after pipeline construction.

3.1.4.5 Sites Pumping/Generating Plant (5,900-cfs)

The purpose of the proposed Sites Pumping/Generating Plant would be to pump water from the proposed Holthouse Reservoir to the proposed Sites Reservoir to fill the reservoir and to generate electricity during the release of water from Sites Reservoir to the Holthouse Reservoir. The Sites Pumping/Generating Plant would be located approximately 3,300 feet southeast of the proposed Golden Gate Dam (Figure 3-4).

The Sites Pumping/Generating Plant would have a total pumping capacity of 5,926 cfs and a release capacity of 5,100 cfs. Table 3-10 summarizes the pump and pump/turbine configuration for the 5,900-cfs Plant.

Table 3-10
Proposed Sites Pumping-Generating Plant Configuration for Alternative A

Unit Type	Number of Units	Net Head (ft)	Pumping Capacity (cfs)	Generating Capacity (cfs)	Total Pumping Capacity (cfs)	Total Generating Capacity (cfs)
Pump - Francis Vane (Dual Speed)	2 (+1 standby)	290	870	-	5,926	5,100
		162	870	-		
Pump - Francis Vane (Dual Speed)	2	290	435	-		
		162	435	-		
Pump/Turbine - Reversible Francis (Dual Speed)	4 (+1 standby)	290/270	663	1020		
		162/142	663	1020		
Pump/Turbine - Reversible Francis (Dual Speed)	2	290/270	332	510		
		162/142	332	510		

The Sites Pumping/Generating Plant has been designed as a conventional indoor-type pumping plant. The design includes an in-line arrangement of vertical pumping units with a reinforced concrete substructure and a steel superstructure. The size of each unit bay was determined based on the minimum required spacing between each unit. Two service bays have been incorporated on either side of the Sites Pumping/Generating Plant and have been sized to allow for two units to be serviced simultaneously while the remainder of the Sites Pumping/Generating Plant continues operation.

The pumps would be connected to a complex intake/outflow manifold. When water is drawn out of Holthouse Reservoir and pumped up to Sites Reservoir, the pumped water would flow through successive pipe connections until all eleven pipes coming from the pump units combine into a single 26-foot-diameter pipe. This pipe would then join the 26-foot-diameter pipe coming from the emergency bypass outlet, and the two pipes would connect to the 30-foot-diameter tunnel.

Additional proposed on-site facilities related to the Sites Pumping/Generating Plant include:

- Approach channel
- Pressure tunnel
- Emergency release bypass outlet
- Electrical switchyard
- Maintenance buildings
- Electrical connection
- Access roads

The Sites Pumping/Generating Plant would be connected to Holthouse Reservoir by an approximately 8,300 foot-long earthen approach channel (discussed in Section 3.1.1.9). On the other side of the Sites Pumping/Generating Plant, connecting the channel to Sites Reservoir, would be a 4,031-foot long, 30-foot-diameter tunnel (the tunnel is discussed in Section 3.1.1.6).An electrical switchyard (Sites Electrical Switchyard) would be required adjacent to the Sites Pumping/Generating Plant that would step down the electrical voltage from high voltage lines to a lower voltage that could be used by the pumps and other machinery in the plant.

Construction. The total site footprint of the proposed Sites Pumping/Generating Plant and approach channel would be approximately 75 acres. An additional 20 acres of land adjacent to the plant would likely be disrupted during construction.

Anticipated ground-disturbing activities include:

- Transportation of materials to the construction site
- Clearing and grading the construction workspace
- Placing construction materials at staging areas
- Excavating the approach channel and pumping plant
- Dewatering
- Constructing the forebay, pump house, and pump bay
- Site restoration after construction is complete

Operations. A SCADA system would control all of the different proposed operational modes. The system would be located on-site and would broadcast status information to a manned remote location. Plant operators would require continuous communication with the TRR Pumping/Generating Plant, Delevan Pipeline Intake Facilities, and T-C Canal operators to coordinate flows into and out of the proposed Holthouse Reservoir and Sites Reservoir for filling and releasing.

Maintenance. Routine maintenance and monitoring of the proposed Sites Pumping/Generating Plant would likely be required on a daily basis. Regular maintenance and inspection would have to be done for each pump unit and the related equipment, such as gates, valves, and electrical equipment. The Sites Pumping/Generating Plant would be equipped with cranes to facilitate operation and maintenance. There would be a 100-ton capacity indoor bridge crane for assembly and maintenance of pumping/generating units and associated equipment. A 50-ton capacity outdoor traveling gantry crane would be installed for assembly and maintenance of butterfly valves. In addition, a 10-ton capacity outdoor traveling gantry crane would be installed to aid in the installation and removal of inlet gates and trashracks.

3.1.4.6 Delevan Transmission Line

The proposed Delevan Transmission Line would carry electricity from an existing power source (PG&E 230-kV, WAPA 500-kV, or WAPA 230-kV transmission lines) to the proposed pumping/generating plants. The proposed electrical switchyard and transmission line that would connect the pumping/generating plants to the grid would provide all of the electricity needed by the pumping plants. The switchyard and transmission line would allow the pumping/generating plants to feed electricity back into the electrical grid during generation activities.

Each of these new pumping/generating plants would be connected to the existing electrical grid by the proposed 230-kilovolt (kV) overhead Delevan Transmission Line. Each pumping/generating plant would have a dedicated switchyard to step the transmission down to usable motor voltage. The Delevan Transmission Line would parallel the proposed Delevan Pipeline route from the proposed Delevan Pipeline Intake facilities to the proposed TRR within a 150-foot-wide permanent transmission line easement 150 feet north of the permanent easement for the proposed Delevan and TRR pipelines[9] (Figure 3-1). From the TRR at about the GCID Canal crossing, the Delevan Transmission Line would travel in a southwesterly direction for a length of approximately 9,600 feet to the proposed T-C Canal Discharge Dissipater at the northeastern tip of the proposed Holthouse Reservoir. From Holthouse Reservoir, the Delevan Transmission Line would travel in a northwesterly direction for approximately 3,600 feet and then travel west for approximately 5,300 feet, at which point the transmission line would cross the proposed Eastside Road. From Eastside Road, the Delevan Transmission line would travel in a southwesterly direction for approximately 1,700 feet to connect to the proposed Sites Electrical Switchyard.

In addition, lower voltage overhead distribution lines would be connected to the proposed Golden Gate Dam, Sites Dam, South Bridge, and Stone Corral, Peninsula Hills, and Lurline Headwaters recreation areas. Electricity provided to Golden Gate Dam would likely come from the Sites Pumping/Generating Plant site through an easement along Funks Creek to the dam. Electricity to Sites Dam, South Bridge, and the three recreation areas would likely come from an existing overhead distribution line that parallels Sites Lodoga Road. The power line would be extended to Sites Dam along the canyon walls, through the Stone Corral Recreation Area (following roads when available), along the new Stone Corral Road to the South Bridge, and along Sites Lodoga Road to the proposed Peninsula Road to the Peninsula Hills Recreation Area. From Sites Dam, the power line would be extended approximately 3.1 miles in a southwesterly direction to the Lurline Headwaters recreation area.

Construction. The proposed Delevan Transmission Line construction disturbance area would be approximately 410 acres. The construction disturbance area for the transmission line would be completely

[9] The transmission line cannot be constructed within the same permanent easement as the pipeline because the footprint of the transmission tower footings would impede access to the pipeline during future maintenance activities.

contained within the permanent easement along the transmission line. The permanent easement would be approximately 150 feet wide along the entire alignment.

A portion of the existing agricultural fields within the transmission line alignment would be fallowed and not watered during construction of tower footings and placement of towers. A corridor approximately 150 feet wide would be needed for construction activities, staging areas, and stockpile areas. Anticipated major construction activities include clearing and grading the construction workspace; placing necessary construction materials at staging areas; excavating and constructing tower footings; erecting the transmission towers; and stringing the conductor.

The transmission line would cross an existing PG&E natural gas pipeline and transmission line. The pipeline crossing would be accomplished by siting the towers away from the pipeline. The crossing of high voltage lines requires special precautions during construction, and has specific design requirements to maintain minimum clearances from each other under conservative line operating conditions. At this crossing location, the proposed transmission line towers would be constructed approximately twelve feet higher than the typical transmission pole or tower height to ensure that minimum design and utility requirements are met.

The transmission line would be an above-ground feature, with the footings of the transmission towers resulting in a permanent change in land use and loss of wildlife habitat. Assuming a worst-case scenario of 70 transmission towers, each with a concrete pad for a base, over the entire length of the transmission line, the total permanent acreage that would change land use and result in habitat loss would be approximately 2.5 acres of a combination of rice and annual grassland habitat.

Operations. Operation of the proposed Delevan Transmission line and associated distribution lines would be an unmanned activity.

Maintenance. The proposed Delevan Transmission Line and associated distribution lines would require only periodic maintenance (once or twice a year), which would include equipment inspections and vegetation maintenance.

3.1.5 Alternative B—Proposed Facilities Unique to Alternative B

Alternative B would focus on meeting the proposed Project's primary objectives by constructing a proposed 1.81-MAF Sites Reservoir and relying on the existing T-C Canal (2,100-cfs diversion) and GCID Canal (1,800-cfs diversion) to convey water to the proposed Sites Reservoir, and a proposed release-only Delevan Pipeline (1,500-cfs release) to convey water from the reservoir. Alternative B would use the common features described in Section 3.1.1, in addition to the features described below.

3.1.5.1 1.81-MAF Sites Reservoir Inundation Area

Similar to the proposed 1.27-MAF Sites Reservoir discussed in Section 3.1.4.1, the proposed 1.81-MAF Sites Reservoir would be located approximately 10 miles west of the town of Maxwell (Figure 3-1). This reservoir configuration would have a storage capacity of 1.81 MAF, a maximum water surface elevation of 520 feet above msl (the minimum operating water surface would be at elevation 340 feet), and an inundation area of approximately 14,000 acres. The inundation area of the proposed 1.81-MAF Sites Reservoir would be created by filling Antelope Valley after the construction of 11 dams. The proposed dams include Golden Gate Dam on Funks Creek, Sites Dam on Stone Corral Creek, and nine saddle dams on the northern end of the reservoir, between the Funks Creek and Hunters Creek watersheds (all dams are discussed further in Section 3.1.5.2).

Many areas within Sites Reservoir Inundation Area would be used for staging of materials and equipment prior to and during construction of other proposed Project components (e.g., the Sites Reservoir dams).

Construction. The total construction disturbance area would be approximately 15,720 acres, consisting of the proposed inundation area footprint and a temporary construction disturbance area. Anticipated ground-disturbing activities during construction include clearing and grubbing, and demolition and removal of existing structures, such as residential dwellings, barns, and miscellaneous structures.

- **Clearing and Grubbing.** Ninety-two percent of the proposed reservoir inundation area footprint is composed of annual grasslands; as a result, clearing and grubbing would not be needed in this area. The remaining eight percent consists of blue oak woodland, agricultural crops, and other vegetation, which would be cleared.
- **Demolition of Existing Structures.** Twenty-two houses and four detached garages, one mobile home, 26 barns, and 37 other structures (combination of sheds, silos, and a pump house) within the proposed Sites Reservoir Inundation Area would be demolished. Existing septic tanks and other storage tanks would also be removed. In addition, many miles of fencing and asphalt would be removed, erosion protection may be needed for midden locations, and elderberry shrubs may need to be removed from their existing location and relocated. Demolition debris would likely be transported and disposed of at a landfill that is permitted to accept such waste.
- Two cemeteries would be relocated.

Operations. Operations of the proposed 1.81-MAF Sites Reservoir are the same as for the proposed 1.27-MAF reservoir (Section 3.1.4.1).

Maintenance. Maintenance of the proposed 1.81-MAF Sites Reservoir is the same as for the proposed 1.27-MAF reservoir (Section 3.1.4.1).

3.1.5.2 Dams for the 1.81-MAF Sites Reservoir

Eleven dams would be needed to create the proposed 1.81-MAF Sites Reservoir (Figure 3-1). The reservoir would be formed by the proposed Golden Gate Dam, Sites Dam, and nine saddle dams along the northern perimeter of the reservoir between the Funks Creek and Hunters Creek watersheds, near the Glenn-Colusa County line. Golden Gate Dam would be constructed on Funks Creek, approximately one mile west of Funks Reservoir. Sites Dam would be constructed on Stone Corral Creek, approximately 0.25 mile east of the town of Sites and ten miles west of the town of Maxwell. Saddle Dam Nos. 1, 2, 4, and 9 are generally characterized as small-sized dams, with heights ranging from approximately 40 to 50 feet. Saddle Dam Nos. 3, 5, 6, 7, and 8 are generally characterized as medium-sized dams, with heights ranging from approximately 70 to 130 feet. Saddle Dam Nos. 3, 5, and 8 are the tallest and largest of the nine proposed saddle dams, with embankment volumes of approximately 3.5, 1.5, and 1.9 million cubic yards, respectively.

The 11 dams would be constructed as zoned earth rockfill embankment dams, and are designed to be constructed primarily of on-site materials. Site topography, geology, seismicity, and foundation features were considered when selecting the dam alignments, design, and sections. The dam designs would conform to modern economic construction practices and incorporate conservative design measures.

Table 3-11 lists the proposed height and length of the 11 dams as well as the total volume of materials needed to construct the dam embankments.

Table 3-11
Characteristics of the Proposed Sites Reservoir Dams for Alternatives B and C

Dam	Maximum Height Above Base* (feet)	Crest Length (feet)	Total Embankment Volume (cubic yards)
Sites Dam	290	850	3,836,000
Golden Gate Dam	310	2,250	10,590,000
Saddle Dam No. 1	50	490	93,000
Saddle Dam No. 2	80	420	86,000
Saddle Dam No. 3	130	3,810	3,577,000
Saddle Dam No. 4	40	270	18,000
Saddle Dam No. 5	100	2,290	1,505,000
Saddle Dam No. 6	70	530	144,000
Saddle Dam No. 7	75	1,040	196,000
Saddle Dam No. 8	105	2,990	1,915,000
Saddle Dam No. 9	45	340	49,000
Total			**22,009,000 cubic yards**

*Base is defined as ground surface elevation.

The crest elevation of all 11 dams would be 540 feet, providing 20 feet of freeboard. Sites and Golden Gate dams would have crest widths of 30 feet and embankment slopes of 2.25:1 upstream and 2:1 downstream. The saddle dams would have crest widths of 20 feet and embankment slopes of 3:1 upstream and 2.5:1 downstream.

Saddle Dams 2, 3, and 5 would have fairly flat slopes on the left abutments[10] which require low dam heights (less than approximately 10 feet high). At these locations, the dam embankments would be strictly providing residual freeboard. Therefore, the typical saddle dam sections would be replaced at these locations with a small homogenous impervious embankment with a bentonite slurry wall for foundation seepage control. The crest elevation and width and slopes of the homogeneous embankment would match that of the saddle dams. Construction of the slurry wall configuration is a more economical option than construction of the typical embankment and excavation section. The slurry wall would be excavated to a depth corresponding to the moderately weathered bedrock surface, with average dimensions estimated at 20 feet deep by five feet wide. At the left abutment of Saddle Dam No. 2, the slurry wall section would also provide a defensive measure to control foundation seepage in the event that displacement occurs along the Salt Lake Fault. At this location, the slurry wall was extended to a depth of 40 feet to minimize the potential of foundation seepage along the fault zone.

The proposed emergency spillway at the proposed 1.81-MAF Sites Reservoir would be located at Saddle Dam No. 6. The purpose of the emergency spillway would be to release excess water as the result of overpumping after a probable maximum flood (PMF), and to prevent overtopping the dams. If the PMF were to occur when the reservoir was at maximum pool (elevation 520.0 feet), the water surface elevation

[10] Abutment direction refers to looking downstream. Therefore, the dam's left abutment would be the abutment on the left side of the dam when looking downstream.

would rise to 525.2 feet (with no reservoir releases). The dam crest elevation would be 540.0 feet. Therefore; the emergency spillway would be required only in the event that water was still being pumped into the reservoir after the PMF had been stored (an unlikely occurrence).

For the proposed 1.81-MAF Sites Reservoir, a proposed morning glory spillway[11] would be provided on a cut bench on the left abutment of the saddle dam. The outlet pipe would be installed under the dam on a cut bench on the dam abutment foundation. On the downstream side of the dam, the pipe would be installed downslope to the creek. An energy dissipating structure would be located at the end of the pipeline to control the discharge of water to the creek. The spillway would consist of one seven-foot-diameter concrete pipe sized primarily for inspection and maintenance activities. The spillway pipe inflow elevation would be set at 525.5 feet, 5.5 feet above normal maximum pool.

The 11 dams would be constructed of compacted excavated materials (soil and rock). The four zones of the embankment dams would be constructed as described for the proposed 1.27-MAF Sites Reservoir (Section 3.1.4.2).

Construction. The total construction disturbance area for the 11 proposed dams would consist of approximately 160 acres. It would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, borrow areas, and access roads. The construction disturbance area for the dams would be within the construction disturbance area for the proposed reservoir inundation area.

All other proposed construction activities would be the same as described for the proposed 1.27-MAF Sites Reservoir dams (Section 3.1.4.2).

Operations. All proposed operations activities are the same as described for the proposed 1.27-MAF Sites Reservoir dams (Section 3.1.4.2).

Maintenance. All proposed maintenance activities are the same as described for the proposed 1.27-MAF Sites Reservoir dams (Section 3.1.4.2).

3.1.5.3 Delevan Pipeline – 1,500-cfs Release Only

The approximately 13.5-mile-long release-only Delevan Pipeline would convey water from the proposed Holthouse Reservoir to the Sacramento River for releases. The portion of the proposed Delevan Pipeline that would be to the west of the proposed TRR would parallel the proposed TRR Pipeline from the TRR to Holthouse Reservoir, and would share a common trench and outlet structure into Holthouse Reservoir (Figure 3-1).

The capacity of the Delevan Pipeline to convey water from Holthouse Reservoir to the Sacramento River would be 1,500 cfs. The pipeline would consist of two 12-foot-diameter reinforced concrete pipes.

The Delevan Pipeline would begin at the proposed Delevan Pipeline Discharge Facility at the Sacramento River. The Delevan Pipeline would be aligned due west until reaching the GCID Canal. At the GCID Canal, the Delevan Pipeline would be aligned southwesterly and would parallel the TRR Pipeline in a shared trench until it reaches the Holthouse Reservoir Complex.

---

[11] A morning glory spillway is an uncontrolled spillway with a funnel-shaped outlet that allows water to spill into the funnel rather than spilling over the dam.

The proposed alignment of the Delevan Pipeline would require five major crossings (SR 45, SR 99, I-5, Union Pacific Railroad, and the GCID Canal). The proposed pipeline route would also cross the easement for the PG&E 230-kV electrical transmission line and a major PG&E natural gas pipeline. Other existing infrastructure that the Delevan Pipeline could potentially cross include: gas lines, water lines, sewer lines, communications lines, and other infrastructure. These major crossings would be accomplished with the jack and bore construction method.

In addition, the proposed Delevan Pipeline would cross the CBD. The crossing location would be at the northern end of the drain.

Construction. All construction activities would be the same as described for the proposed 2,000-cfs Diversion/1,500-cfs Release Delevan Pipeline (Section 3.1.4.4).

Operations. All operations activities would be the same as described for the proposed 2,000-cfs Diversion/1,500-cfs Release Delevan Pipeline (Section 3.1.4.4).

Maintenance. All maintenance activities would be the same as described for the proposed 2,000-cfs Diversion/1,500-cfs Release Delevan Pipeline (Section 3.1.4.4).

3.1.5.4 Delevan Pipeline Discharge Facility

Because Alternative B does not include the proposed Delevan Pipeline Intake Facilities, a separate release structure would be required at the Sacramento River to make controlled releases to the river. The proposed release structure (Delevan Pipeline Discharge Facility, Figure 3-13C) would be located at the same site as shown for the Delevan Pipeline Intake Facilities (Figure 3-13A). The diameter of the proposed Delevan Pipeline would be reduced in stages from 12-foot diameter to eight foot, then to four foot before reaching the proposed energy dissipating valve house. The valve house would be located just above the design Sacramento River flood level at the site, which is at an approximate elevation of 82 feet.

The energy dissipating valves would be 48-inch-diameter fixed cone valves located in confining vaults to control excessive spray and help dissipate the energy. From the valve structure, released water would flow down a short channel section before reaching a proposed baffle block spillway leading down to the river. The system is designed for a maximum release flow of 1,500 cfs. The baffle block spillway could control the release of water to the river regardless of the river level and provide aeration benefits.

The valve house, channel, and spillway would be located within the current river overbank area so that the facilities do not encroach within the flow area when the river is at its maximum design level. The downstream side of the spillway exposed to the river would be fitted with fish barrier racks to prevent migrating adults fish from entering the spillway chute. The clear spacing of the bars in the rack would be 1.5 inches.

At the maximum design flow, the width of the spillway structure would be designed to maintain the release velocity from the structure at or below two fps at the minimum river design level at an elevation of 51 feet.

The proposed Delevan Pipeline Discharge Facility would be located in a reach of the Sacramento River that is protected by a federal project levee system administered by U.S. Army Corps of Engineers (USACE) and the Central Valley Flood Protection Board. The top of the levee in the proposed Project area is at an elevation of 90 feet. Before the levee is breached and construction begins on the valve house and spillway, a setback levee would be constructed around the site. The setback levee would tie into the existing levee on the north and south sides of the site so that there is no interruption of flood protection during proposed Project construction. In addition, current levee regulations do not permit piping to pass through or under Project levees. For this reason, the piping would be elevated where it crosses the setback levee so that it is above elevation 90.0.

Construction. The total construction disturbance area would be approximately 7.7 acres. An additional area around the proposed construction site would be required for staging of materials, equipment, and construction offices. This area would be within the construction disturbance area for the proposed Delevan Pipeline. To isolate the construction area from the Sacramento River, a cellular sheet pile coffer dam would be installed in the river near the location of the discharge facility. Approximately 350 feet of sheet piles would be required to build the coffer dam. The coffer dam would extend approximately five to 10 feet into the water from the river bank. Installation of the coffer dam would involve driving interlocking metal sheet piles into the ground one section after another until the entire length of the intake structure is isolated from the river. The height of the coffer dam would match the height of the surrounding levees. The coffer dam is likely to remain in place throughout the duration of facility construction. The area behind the coffer dam would be dewatered prior to construction by pumping water out from behind the coffer dam. After construction of the discharge facility is complete, the coffer dam would be removed by pulling the sheet piles out of the river.

Construction of the proposed Delevan Pipeline Discharge Facility would include the following:

- Constructing the setback levee along with any slurry walls that might be required to control through seepage and under seepage.
- Constructing a coffer dam along the shore of the river to permit spillway construction in dry conditions.
- Excavation of the bank and backfilling of the area to construct the spillway, channel, and valve house. Approximately 6,000 cubic yards of excavation would be required.
- Backfilling around the structures and on the water side of the setback levee, as required.
- Placing rip rap rock slope protection for a minimum of 100 feet upstream and downstream of the spillway to control erosion.
- Site revegetation.

Operations. Proposed release operations would be such that a maximum 1,500 cfs would be discharged to the river channel. A SCADA system would control all of the different operational modes. The system would be located on-site and would broadcast status information to a manned remote location. The SCADA systems provide a means to control the release without staffing the on-site facilities.

Maintenance. The proposed Delevan Pipeline Discharge Facility would likely be staffed daily to maintain, operate, and monitor the facility. It is anticipated that employees would be on-site during release (predominantly in summer) activities.

3.1.5.5 Sites Pumping/Generating Plant (3,900-cfs)

The purpose of the proposed Sites Pumping/Generating Plant would be to pump water from the proposed Holthouse Reservoir to the proposed Sites Reservoir to fill it and to generate electricity during the release of water from Sites Reservoir to the Holthouse Reservoir. The Sites Pumping/Generating Plant would be located approximately 3,300 feet southeast of the proposed Golden Gate Dam (Figure 3-4).

The proposed Sites Pumping/Generating Plant would have a total pumping capacity of 3,916 cfs and a release capacity of 5,100 cfs. Table 3-12 summarizes the pump and pump/turbine configuration for the 3,900-cfs Plant.

Table 3-12
Proposed Sites Pumping-Generating Plant Configuration for Alternative B

Unit Type	Number of Units	Net Head (Feet)	Pumping Capacity Per Unit (cfs)	Generating Capacity Per unit (cfs)	Total Plant Pumping Capacity (cfs)	Total Plant Generating Capacity (cfs)
Pump – Francis Vane Dual Speed	2 (+1 Standby)	323	300	-	3,916	5,100
		195	300	-		
Pump/Turbine Reversible Francis, Dual Speed	4 (+1 Standby)	323/310	663	1,020		
		195/182	663	1,020		
Pump/Turbine Reversible Francis, Dual Speed	2	323/310	332	510		
		195/182	332	510		

The proposed Sites Pumping/Generating Plant has been designed as a conventional indoor-type pumping plant. The design includes an in-line arrangement of vertical pumping units with a reinforced concrete substructure and a steel superstructure. The size of each unit bay was determined based on the minimum required spacing between each unit. Two service bays have been incorporated on either side of the proposed Sites Pumping/Generating Plant and have been sized to allow for two units to be serviced simultaneously while the remainder of the plant continues operation.

The pumps would be connected to a complex intake/outflow manifold. When water would be drawn out of the proposed Holthouse Reservoir and pumped up to the proposed Sites Reservoir, the pumped water would flow through successive pipe connections until all eleven pipes coming from the pump units combine into a single 26-foot-diameter pipe. This pipe would then join the 26-foot-diameter pipe coming from the emergency bypass outlet, and the two pipes would connect to the 30-foot-diameter tunnel.

Additional proposed on-site facilities related to the proposed Sites Pumping/Generating Plant include:

- Approach channel
- Pressure tunnel
- Emergency release bypass outlet
- Electrical switchyard
- Maintenance buildings
- Electrical connection
- Access roads

The proposed Sites Pumping/Generating Plant would be connected to the proposed Holthouse Reservoir by an approximately 8,300 foot-long earthen approach channel (approach channel is discussed in

Section 3.1.1.9). On the other side of the pumping plant, connecting the channel to the proposed Sites Reservoir, would be an approximately 4,030-foot-long, 30-foot-diameter tunnel (discussed in Section 3.1.1.6).

An electrical switchyard (Sites Electrical Switchyard) would be required adjacent to the proposed Sites Pumping/Generating Plant that would step down the electrical voltage from high voltage lines to a lower voltage that could be used by the pumps and other machinery in the plant.

Construction. The total proposed footprint of the proposed Sites Pumping/Generating Plant and approach channel would be approximately 75 acres. An additional 20 acres of land adjacent to the proposed Sites Pumping/Generating Plant would likely be disrupted during construction.

Anticipated ground-disturbing activities include:

- Transportation of materials to the construction site
- Clearing and grading the construction workspace
- Placing construction materials at staging areas
- Excavating the approach channel and pumping plant
- Dewatering
- Constructing the forebay, pump house, and pump bay
- Site restoration after construction is complete

Operations. All proposed operations activities would be the same as described for the proposed 1.27-MAF Sites Reservoir pumping/generating plant (Section 3.1.4.5).

Maintenance. All proposed operations activities are the same as described for the proposed 1.27 MAF Sites Reservoir pumping/generating plant (Section 3.1.4.5).

3.1.5.6 Delevan Transmission Line

The proposed Delevan Transmission Line would carry electricity from an existing power source (PG&E 230-kV or WAPA 500-kV or WAPA 230-kV power lines) to the proposed Sites and TRR pumping/generating plants. Alternative B does not include a pump station at the Delevan Pipeline Intake. The transmission line would be the same as described in Section 3.1.4.6 for Alternative A, except there would be no transmission line between the proposed Delevan Pipeline Intake Facilities and the proposed TRR. There would be a slight difference in the alignment of the transmission line on the eastern edge of the proposed Sites Reservoir to the northernmost proposed recreation area (Saddle Dam Recreation Area) due to the differences in reservoir size and proposed Golden Gate Dam location between Alternatives A and B.

Construction. Construction of this facility would be the same as described in Section 3.1.4.6. However, the construction disturbance area for the transmission line would be approximately 100 acres because Alternative B does not include a transmission line between the proposed Delevan Pipeline Intake Facilities and the proposed TRR.

The proposed footings of the transmission towers would result in a permanent change in land use and loss of wildlife habitat. Assuming a worst-case scenario of 15 transmission towers, each with a concrete pad for a base for the length of the transmission line, the total permanent acreage that would change land use and result in a habitat loss would be approximately 0.5 acre of annual grassland habitat.

Operations. Operation of this proposed facility would be the same as described in Section 3.1.4.6.

Maintenance. Maintenance of this proposed facility would be the same as described in Section 3.1.4.6.

3.1.6 Alternative C—Proposed Facilities Unique to Alternative C

Alternative C would focus on meeting the proposed Project's primary objectives by constructing a proposed 1.81-MAF Sites Reservoir and relying on the existing T-C Canal (2,100-cfs diversion) and GCID Canal (1,800-cfs diversion), and a proposed Delevan Pipeline (2,000-cfs diversion/1,500-cfs release), to convey water to and from the reservoir. Alternative C would use the common features described in Section 3.1.1, in addition to other features already described for Alternatives A and B.

Alternative C combines several of the unique proposed features of Alternatives A and B, including

- Proposed 1.81-MAF Sites Reservoir Inundation Area – Same as Alternative B (Section 3.1.5.1)
- Proposed 1.81-MAF Sites Reservoir Dams – Same as Alternative B (Section 3.1.5.2)
- Proposed Delevan Pipeline Intake Facilities– Same as Alternative A (Section 3.1.4.3)
- Proposed Delevan Pipeline—2,000-cfs Diversion/1,500-cfs Release – Same as Alternative A (Section 3.1.4.4)
- Proposed Sites Pumping/Generating Plant (5,900-cfs) – Same as Alternative A (Section 3.1.4.5), except for the net head. The maximum water surface elevation for Alternative C would be approximately 40 feet higher than for Alternative A so the net head for the pumps and pump/turbines would be slightly larger compared to Alternative A. Table 3-13 summarizes the pump and pump/turbine configuration for the proposed 5,900-cfs Sites Pumping/Generating Plant.
- Proposed Delevan Transmission Line – The electrical transmission line for Alternative C would be similar to Alternative A (Section 3.1.4.6) with a slight difference in the alignment on the eastern edge of the proposed Sites Reservoir to the northernmost proposed recreation area (Saddle Dam Recreation Area) due to differences in reservoir size and the proposed Golden Gate Dam between Alternatives A and C.

Table 3-13
Proposed Sites Pumping-Generating Plant Configuration for Alternative C

Unit Type	Number of Units	Net Head (Feet)	Pumping Capacity Per Unit (cfs)	Generating Capacity Per unit (cfs)	Total Plant Pumping Capacity (cfs)	Total Plant Generating Capacity (cfs)
Pump – Francis Vane Dual Speed	2 (+1 Standby)	330	870	-	5,926	5,100
		202	870	-		
Pump – Francis Vane Dual Speed	2	330	435	-		
		202	435	-		
Pump/Turbine Reversible Francis, Dual Speed	4 (+1 Standby)	330/310	663	1,020		
		202/182	663	1,020		
Pump/Turbine Reversible Francis, Dual Speed	2	330/310	332	510		
		202/182	332	510		

3.2 Proposed Project Construction

Proposed Project construction is expected to last for more than eight years for any of the action alternatives. Several factors affect this schedule, including funding, environmental compliance, material and equipment availability, labor force constraints, and access road capacity limitations. Additional adjustments to the schedule would be required as the proposed Project moves forward.

At the peak of proposed Project construction, the construction labor force is expected to be approximately 400 workers. Table 3-14 provides a list of the typical construction equipment expected to be present on-site during construction of the major proposed facilities and estimated equipment days.

Construction activities are anticipated to occur between the hours of 6:00 a.m. and 7:00 p.m. Monday through Friday. Nighttime and weekend construction may occur on an as-needed basis. If nighttime construction is determined to be needed, construction lighting consistent with applicable federal, State, and local requirements would be used. Nighttime construction would not be conducted between the hours of 10:00 p.m. and 7:00 a.m. within 1,000 feet of occupied residences. Haul times through residential communities would be limited to the hours of 7:00 a.m. to 10:00 p.m. with air brake restrictions in residential communities.

Construction activities associated with the proposed Project would be confined to designated construction disturbance areas. Construction vehicles and equipment would also be parked within these construction disturbance areas. In addition, construction materials would be stored within the construction disturbance areas. Special or sensitive sites within the construction disturbance areas where construction equipment and materials would not be allowed would be clearly marked and fenced with orange barrier fencing before any construction or surface-disturbing activity begins. Construction personnel would be trained to recognize these markers and understand the equipment movement restrictions involved. Lath, fencing, or flags would be maintained until final cleanup and/or site restoration is completed, after which they would be removed.

3.2.1 Access Routes

Traffic-generating construction activities associated with the proposed Project would include trucks hauling equipment and materials to and from the work sites and the daily arrival and departure of the construction workers. Construction traffic on local roadways would include dump trucks, concrete trucks, and other delivery trucks. Dump trucks would be used for earth-moving and clearing, removal of excavated material, and import of other structural and paving materials. Other trucks would deliver heavy construction equipment, job trailer items, concrete forming materials, piping materials, piles, new facility equipment, and other miscellaneous deliveries.

The following are typical construction access routes to some of the major proposed Project features (routes are illustrated on Figures 3-3A and 3-3B):

3.2.1.1 Sites Reservoir Inundation Area

Central Reservoir Area

- From I-5, travel west on Maxwell Sites Road.

Table 3-14
Estimated Equipment Days for Construction of Proposed Project Features Included in the Action Alternatives

Equipment	Dams and Sites Reservoir Inundation Area	Recreation Areas	Gravel Roads	Paved Roads and Bridges	Sites P/G Plant, Tunnel, and Sites Inlet/Outlet Structure	Funks Reservoir Sediment Removal	Funks Reservoir and Holthouse Reservoir Complex	Pump Installation at the Red Bluff Pumping Plant	GCID Camal Facilities Modifications	TRR	TRR P/G Plant	TRR and Delevan Pipelines	Transmission Lines and Electrical Switchyards	Delevan Pipeline Intake/Discharge Facilities and P/G Plant	Field Office Maintenance Yard

Northern Reservoir Area

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and continue straight on proposed North Road (new permanent).

Southern Reservoir Area

- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), and turn right on Huffmaster Road.
- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), and turn right on proposed Lurline Road (new permanent) (this is the detour during construction).

3.2.1.2 Sites Reservoir Dams

Sites Dam

- From I-5, travel west on Maxwell Sites Road.

Golden Gate Dam

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on proposed Eastside Road (new permanent), and turn right on proposed O&M road (new permanent).
- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent), and turn left on proposed O&M road (new permanent).

Saddle Dams

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, continue straight on proposed North Road (new permanent) for Saddle Dams 7, 8, and 9, or turn left from proposed North Road onto proposed Saddle Dam Road (new permanent) for Saddle Dams 1, 2, 3, 4, and 5, or turn left from proposed North Road onto proposed O&M road (new permanent)for Saddle Dam 6, or turn left from County Road 69 onto proposed Eastside Road (new permanent) and turn right on proposed O&M road (new permanent) for the Golden Gate Saddle Dam.
- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent) and turn left on proposed O&M road (new permanent).

3.2.1.3 Recreation Areas

Saddle Dam

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, continue straight on proposed North Road (new permanent), and turn left on proposed Saddle Dam Road (new permanent).

Lurline Headwaters

- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), and turn right on proposed Lurline Road (new permanent, detour during construction).

Antelope Island

- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), turn right on Huffmaster Road, and turn left on proposed construction road (new temporary).
- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), turn right on proposed Lurline Road (new permanent, detour during construction), turn right on Huffmaster Road, and turn left on proposed construction road (new temporary).

Stone Corral

- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent), turn left on proposed Stone Corral Road (new permanent), and turn left on proposed Stone Corral Recreation Area Road (new permanent).

Peninsula Hills

- From I-5, travel west on Maxwell Sites Road to Sites Lodoga Road, and turn right on proposed Peninsula Road (new permanent campground spur road).
- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent), turn left on proposed Stone Corral Road (new permanent), across the proposed South Bridge (new permanent) onto Sites Lodoga Road, and turn right on proposed Peninsula Road (new permanent campground spur road).

3.2.1.4 Road Relocations and South Bridge

South Bridge

- From I-5, travel west on Maxwell Sites Road, and turn right on Peterson Road to reach central footings (this route is only available if the bridge is constructed before Sites Dam, which will block access on Maxwell Sites Road).
- From I-5, travel west on Maxwell Sites Road and continue straight on Sites Lodoga Road to reach the western approach/footings.
- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent), and turn left on proposed Stone Corral Road (new permanent) to reach the eastern approach/footings.

Com Road

- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), and turn right on proposed Lurline Road (new permanent, detour during construction), and turn right on proposed Com Road (new permanent).

Eastside Road

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on proposed Eastside Road (new permanent).
- From I-5, travel west on Maxwell Sites Road and turn right on proposed Eastside Road (new permanent).

Sulphur Gap Road

- From I-5, travel west on Maxwell Sites Road, and turn left on proposed Sulphur Gap Road (new permanent).

North Road

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, continue straight on proposed North Road (new permanent).
- From I-5, travel west on Maxwell Sites Road, and turn right on proposed Eastside Road (new permanent) and follow to proposed North Road (new permanent).

3.2.1.5 Sites Pumping/Generating Plant

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on proposed Eastside Road (new permanent).
- From I-5, travel west on Maxwell Sites Road and turn right on proposed Eastside Road (new permanent).

3.2.1.6 Sites Electrical Switchyard

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on proposed Eastside Road (new permanent), and turn left on proposed O&M road (new permanent).
- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent), turn right on proposed O&M road (new permanent).

3.2.1.7 Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on proposed Eastside Road (new permanent), and turn left on proposed O&M road (new permanent).
- From I-5, travel west on Maxwell Sites Road, turn right on proposed Eastside Road (new permanent), turn right on proposed O&M road (new permanent).

3.2.1.8 Sites Reservoir Inlet/Outlet Structure

- From I-5, travel west on Maxwell Sites Road, turn left onto proposed Sulphur Gap Road (new permanent), to proposed Lurline Road (new permanent), to Huffmaster Road, to Peterson Road.

3.2.1.9 Field Office Maintenance Yard

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on proposed Eastside Road (new permanent).
- From I-5, travel west on Maxwell Sites Road and turn right on proposed Eastside Road (new permanent).

3.2.1.10 Existing Funks Reservoir Dredging

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on proposed Eastside Road (new permanent).
- From I-5, travel west on Maxwell Sites Road and turn right on proposed Eastside Road (new permanent).

3.2.1.11 Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, turn left on proposed Eastside Road (new permanent), turn left on access road on south side of Funks Reservoir.
- From I-5, travel west on Maxwell Sites Road and turn right on proposed Eastside Road (new permanent), turn right on access road on south side of Funks Reservoir.

3.2.1.12 Pump Installation at the Red Bluff Pumping Plant

- From I-5, exit South Main Street (in Red Bluff) and travel south (South Main Street becomes Hwy 99W). Turn left onto Altube Avenue; the TCCA office is on the left.

3.2.1.13 GCID Canal Facilities Modifications

Headgate

- From I-5, travel east on SR 32 and turn left on Canal Road.

Railroad Siphon

- From I-5 northbound, exit County Road 53; immediately turn left onto SR 99; proceed 1.13 miles north to the intersection of GCID. Turn right at GCID; the siphon is approximately 200 feet east of SR 99 to the Union Pacific Railroad Siphon.

3.2.1.14 GCID Canal Connection to the Terminal Regulating Reservoir

- From I-5, travel west on Delevan Road, and turn left on McDermott Road or turn left on Noel Evan Road.

3.2.1.15 Terminal Regulating Reservoir

- From I-5, travel west on Delevan Road, and turn left on McDermott Road or turn left on Noel Evan Road.

3.2.1.16 Terminal Regulating Reservoir Pumping/Generating Plant and Terminal Regulating Reservoir Electrical Switchyard

- From I-5, travel west on Delevan Road, and turn left on McDermott Road or turn left on Noel Evan Road.

3.2.1.17 Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Pipeline Road, and Delevan Pipeline Electrical Switchyard

- From I-5, travel west on Delevan Road turn left on Sutton Road, McDermott Road or County Road D.

3.2.1.18 Delevan Transmission Line

Eastern End:

- From I-5, travel east on Maxwell Road, and turn left on SR 45.
- From I-5, travel east on SR 162, and turn right on SR 45.

Central Portion:

- From I-5, travel east on Maxwell Road, and turn left on Four Mile Road or Two Mile Road.
- From I-5, travel east on Delevan Road, and turn right on Four Mile Road or Two Mile Road.

Western Portion:

- From I-5, travel west on Delevan Road, and turn left on Sutton Road, McDermott Road, or County Road D.

3.2.1.19 Delevan Pipeline

Intake Facilities and Eastern End:

- From I-5, travel east on Maxwell Road, and turn left on SR 45.
- From I-5, travel east on SR 162, and turn right on SR 45.

Central Portion:

- From I-5, travel east on Maxwell Road, and turn left on Four Mile Road or Two Mile Road.
- From I-5, travel east on Delevan Road, and turn right on Four Mile Road or Two Mile Road.

Western Portion:

- From I-5, travel west on Delevan Road, and turn left on Sutton Road, McDermott Road, or County Road D.

Far Western Portion:

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on proposed Eastside Road (new permanent).
- From I-5, travel west on Maxwell Sites Road, and turn right on proposed Eastside Road (new permanent).

3.2.1.20 Delevan Pipeline Intake/Discharge Facilities

- From I-5, travel east on Maxwell Road, and turn left on SR 45.
- From I-5, travel east on SR 162, and turn right on SR 45.

3.2.1.21 Borrow Areas (Generally Within the Sites Reservoir Inundation Area or Adjacent on Logan Ridge)

- From I-5, travel west on County Road 68, turn left on County Road D, turn right on County Road 69, and turn left on proposed Eastside Road (new permanent).
- From I-5, travel west on Maxwell Sites Road, turn left on right on proposed Eastside Road (new permanent).

- From I-5, travel west on Maxwell Sites Road, turn left on proposed Sulphur Gap Road (new permanent), turn right on proposed Lurline Road (new permanent, detour during construction), turn right on Huffmaster Road, and travel straight on Peterson Road.
- From I-5, travel west on Maxwell Sites Road.

3.2.2 Environmental Management Program during Proposed Project Construction

Certain preventative measures, plans, and Best Management Practices (BMPs) would be incorporated into the proposed Project to avoid or minimize potential impacts to the environment during construction. These actions are described below.

3.2.2.1 DWR Environmental Site Assessment

All property considered for purchase, transfer, retirement, or sale in fee or easement for the proposed Project by DWR must undergo an environmental site assessment to determine the existence of any hazardous substances. Water Resources Engineering Memorandum (WREM) No. 59a "Policy for Environmental Site Assessment and Remediation of Lands and Improvements for Hazardous Substance Contamination" identifies the requirements for the site assessment. The goals of WREM 59a are to minimize DWR's liability for hazardous substance contamination and remediation, ensure that site assessments and remedial actions are performed in accordance with all applicable federal, State, and local statutes and regulations, as well as accepted industry standards and practices, and ensure the proper storage, handling, transport, and disposal of designated and hazardous waste.

3.2.2.2 Construction Management Plan

A Construction Management Plan would be developed to avoid or minimize potential impacts to public health and safety during proposed Project construction. The Plan would inform contractors and subcontractors of work hours; modes and locations of transportation and parking for construction workers; location of overhead and underground utilities; worker health and safety; truck routes; stockpiling and staging procedures; public access routes; the terms and conditions of all Project permits and approvals; and emergency response services contact information. The Plan would also include construction notification procedures for the Police, Public Works, and Fire departments in the cities and counties where proposed Project construction would be carried out. Construction notices would also be distributed to neighboring property owners.

3.2.2.3 Permit Terms and Conditions

DWR and Reclamation would require contractors and suppliers, general contractors, and all of the general contractors' subcontractors and suppliers to comply with all terms and conditions of all Project permits and approvals, and conditions attached to them. Compliance with applicable laws, policies, and plans for the proposed Project is discussed in Chapter 4 Environmental Compliance and Permit Summary.

3.2.2.4 Stormwater Pollution Prevention Plan

The proposed Project is subject to construction-related stormwater permit requirements of the federal Clean Water Act (CWA) National Pollutant Discharge Elimination System Program. DWR and Reclamation would obtain required permits through the CVRWQCB before any Project-related ground-disturbing construction activity occurs. As required by the stormwater permit, a Stormwater Pollution Prevention Plan (SWPPP) would be prepared and implemented before construction starts and throughout the proposed Project construction period that identifies BMPs to prevent and minimize the introduction of contaminants into surface waters.

The objectives of the SWPPP would be to (1) identify pollutants and their sources associated with proposed Project construction activities that may impact stormwater quality and identify BMPs to reduce pollutants in stormwater discharges during and after construction, and (2) identify non-stormwater discharges and develop a plan to eliminate, control, or treat all non-stormwater discharges. BMPs would include site management practices (i.e., good “housekeeping”), non-stormwater management; erosion and sediment controls; and an inspection, monitoring, and maintenance program. BMPs for the proposed Project could include, but would not be limited to, silt fencing, straw bale barriers, fiber rolls, storm drain inlet protection, hydraulic mulch, and stabilized construction entrances. The SWPPP would also include development of site-specific structural and operational BMPs to prevent and control impacts on runoff water quality, measures to be implemented before each storm event, inspection and maintenance of BMPs, and monitoring of runoff quality by visual and/or analytical means.

Other plans related to the SWPPP that would be prepared and implemented for the proposed Project include a Spill Prevention and Hazardous Material Management Plan, Erosion and Sediment Control Plan, and a Revegetation Plan.

Spill Prevention and Hazardous Materials Management

As part of the SWPPP, a Spill Prevention and Control Plan would be developed and implemented to minimize effects from spills of hazardous, toxic, or petroleum substances during construction of the proposed Project. The Spill Prevention and Control Plan would include measures to avoid the accidental release of chemicals, fuels, lubricants, and non-stormwater into channels. Spill prevention kits would always be in proximity when hazardous materials would be used (e.g., crew trucks and other logical locations). Feasible measures would be implemented so that hazardous materials would be properly handled by all reasonable means when working in or near any waterway. No fueling would be done within the ordinary highwater mark, immediate floodplain, or full pool inundation area, unless equipment would be provided so that any accidental fuel spill would not be able to enter the water, contaminate sediments that may come into contact with water, or damage wetland or riparian vegetation. Any equipment that was readily moved out of the channel would not be fueled in the channel or immediate floodplain. For all fueling of stationary equipment that is done at the construction sites, containments would be provided to the degree that any spill would not enter the channel or damage wetland or riparian vegetation. Equipment would not be serviced within the ordinary highwater mark or immediate floodplain, unless the equipment stationed in these locations could not be readily relocated (e.g., pumps, generators).

Additional BMPs designed to avoid spills from construction equipment and subsequent contamination of waterways would also be implemented. These may include, but not be limited to, the following:

- Storage of hazardous materials in double containment.
- Disposal of all hazardous and nonhazardous products in a proper manner.
- Monitoring of on-site vehicles for fluid leaks and regular maintenance to reduce the chance of leakage.
- Containment (a prefabricated temporary containment mat, a temporary earthen berm, or other measure can provide containment) of bulk storage tanks having a capacity of more than 55 gallons.

Erosion and Sediment Control Plan

An Erosion and Sediment Control Plan would be prepared and implemented to control short-term and long-term erosion and sedimentation effects, and to restore soils and vegetation in areas affected by proposed Project construction activities. The Plan would include all necessary requirements regarding erosion control, and would implement BMPs for erosion and sediment control, as required. Types of BMPs may include, but would not be limited to, earth dikes and drainage swales, streambank stabilization, and use of silt fencing, sediment basins, fiber rolls, and sandbag barriers.

Revegetation Plan

A Revegetation Plan would be prepared to be implemented in conjunction with other management plans (e.g., the Erosion and Sediment Control Plan). The Plan applies to any area included as part of a proposed Project action alternative that is subject to relocation or mitigation activities. The Plan would include elements to control erosion through using proactive design techniques so that revegetation requirements would be integrated into grading plans to create favorable planting environments that would aid plant establishment and natural regeneration. The Plan would emphasize the use of adapted native plant species that are able to grow and perpetuate without artificial intervention and maintenance. Whenever feasible, local native plant species would be used. The overall objectives of the Plan would be to reestablish native vegetation to control erosion; provide effective ground cover; minimize opportunities for non-native plant species to establish or expand; and provide habitat diversity over time. DWR and Reclamation would work closely with cooperating agencies, private landowners, and revegetation specialists to develop the site-specific planting patterns and species assemblages necessary for a revegetation effort of this magnitude.

3.2.2.5 Fisheries Conservation

The measures discussed below would be implemented to minimize potential Project-related adverse impacts to fish species.

Implement In-Stream Construction Work Windows

All proposed instream Project-related construction work would be timed to occur when sensitive fish species would not be present or are least susceptible to disturbance. DWR and Reclamation would initiate consultation with NMFS, USFWS, and CDFW to identify appropriate instream construction work windows or other methods to minimize impacts to sensitive fish species.

3.2.2.6 Water Quality Protection Measures

The measures discussed below would be implemented to minimize potential Project-related adverse effects to water quality.

Implement Construction Work Windows

All proposed Project construction activities that would occur instream and adjacent to waterways would be conducted during seasonal time periods when erosion and siltation from equipment use are least likely to occur, or are minimal. DWR and Reclamation would initiate consultation with appropriate regulatory agencies to identify appropriate time periods and acquire necessary permits related to water quality protection.

Permits and Regulations and Orders

Proposed Project activities will be conditioned upon compliance with all permits, regulations, and orders related to water quality protection. Relevant permits anticipated to be obtained for the proposed Project include a California Fish and Game Code 1602 Lake and Streambed Alteration Agreement, Regional Water Quality Control Board (RWQCB) Section 401 certification or waiver, and CWA Section 404 compliance through USACE as well as requirements within the NMFS and USFWS Biological Opinions.

Water Quality Best Management Practices

BMPs that would be implemented to avoid and/or minimize potential impacts associated with proposed Project construction are discussed below.

- **Minimize Potential Impacts Associated with Equipment Contaminants.** For proposed in-water work, all equipment would be steamed clean every day to remove hazardous materials before the equipment entered the water.
- **Minimize Potential Impacts Associated with Access and Staging.** Existing access roads would be used to the extent possible. Proposed equipment staging areas would be located outside of the Sacramento River ordinary high water mark and away from sensitive resources.
- **Remove Temporary Fills as Appropriate.** Temporary fill, such as for access, side channel diversions, and/or side channel cofferdams, would be completely removed after completion of proposed construction.
- **Remove Equipment from the Waterbodies Overnight and During High Flows.** The construction contractor would remove all equipment from the water on a daily basis at the end of the work day. The construction contractor would also monitor Reclamation's Central Valley Operations Office website daily for forecasted river flows to determine and anticipate any potential changes in releases. If flows are anticipated to inundate a proposed work area that would normally be dry, the construction contractor would immediately remove all equipment from the work area.

Asphalt Removal

Pursuant to DFG Code 5650 Section (a), all asphalt roadways and parking lots inundated by the proposed Project would be demolished and removed according to local standards. Asphalt would be disposed of at an approved and permitted waste facility or recycled at the proposed Project asphalt plant. Dirt roads inundated by the proposed Project would remain in place.

3.3 Proposed Project Operations and Maintenance

Proposed Project operations and maintenance activities would include any activities that must occur to operate and maintain each proposed facility. Operation activities include those related to the movement of water (such as proposed Sites Reservoir level fluctuations, or the intake or release of water through the proposed Delevan Pipeline Intake or Discharge facility), the generation/transmission of electricity, the use of roads during operations and maintenance activities, and the recreation activities that would be associated with operations of Sites Reservoir.

Maintenance for the proposed Project facilities would consist of activities, such as debris removal, dredging, vegetation control, rodent control, erosion control and protection, routine inspections (dams, tunnels, pipelines, pumping/generating plants, inlet/outlet works, fence, signs, gates), painting, cleaning, repairs, and other routine tasks to maintain facilities in accordance with design standards after construction and commissioning. Routine visual inspection of the proposed facilities would be conducted to monitor performance and prevent mechanical and structural failures of Project elements. Maintenance activities associated with proposed river intakes could include cleaning, removal of sediments, debris, and biofouling materials. These maintenance actions could require suction dredging or mechanical excavation around intake structures; dewatering; or use of underwater diving crews, boom trucks or rubber wheel cranes, and raft- or barge-mounted equipment.

Proposed operations and maintenance activities could occur on a daily, annually, periodically (as needed), and long-term basis. It is estimated that 60 operations and maintenance workers, working 10-hour days, would be needed to perform operations and maintenance activities.

Table 3-15 shows the estimated equipment and hours of operation for operations and maintenance of the proposed Project facilities for the action alternatives.

4. Environmental Compliance and Permit Summary

This chapter includes information about policies and regulations that are applicable to the proposed Project and relevant to the environmental impacts evaluated within the resource chapters. It includes identified regulatory requirements that could be applied to the proposed Project. The first section contains federal, State, and regional laws that are applicable to more than one environmental resource evaluated in this DEIR/EIS, followed by sections that are specific to each of the resource chapters (i.e., Chapters 6 through 31).

4.1 General

4.1.1 Federal Plans, Policies, and Regulations

4.1.1.1 National Environmental Policy Act

The National Environmental Policy Act (NEPA), which was signed into law on January 1, 1970, establishes a national environmental policy and goals for the protection, maintenance, and enhancement of the environment, and provides a process for implementing these goals by the federal agencies.

NEPA requires that all federal agencies use all practicable means to create and maintain conditions under which humans and nature can exist in harmony. NEPA further requires that federal agencies incorporate environmental considerations into their planning and decision making using an interdisciplinary approach.

NEPA's implementing regulations are administered by the Council on Environmental Quality (CEQ) (40 Code of Federal Regulations [CFR[1]] 1500 et seq.). Section 1502.14 of the CEQ Regulations for Implementing NEPA requires that EISs rigorously explore and objectively evaluate all reasonable alternatives to the project, including the No Action Alternative and reasonable alternatives not within the jurisdiction of the lead agency.

4.1.2 State Plans, Policies, and Regulations

4.1.2.1 California Environmental Quality Act

The California Environmental Quality Act (CEQA) statute was passed in 1970 shortly after the passage of NEPA. CEQA institutes a statewide policy of environmental protection which requires State and local agencies to analyze and disclose environmental impacts of all projects and to mitigate impacts to the extent feasible.

CEQA Guidelines §15126.6 requires that EIRs describe and evaluate a reasonable range of alternatives to a project, or to the location of a project, which would feasibly attain most of the basic project objectives and avoid or substantially lessen significant project impacts. CEQA also requires that the No Project Alternative be analyzed.

4.1.3 Local Plans, Policies, and Regulations

According to California Government Code §65300, every county and city in the State of California is required by law to adopt a general plan for the "physical development of the county or city, and any land

[1] The Code of Federal Regulations annual edition is the codification of the general and permanent rules published in the Federal Register by the departments and agencies of the Federal Government. It is divided into 50 titles that represent broad areas subject to Federal regulation.

outside its boundaries which bears relation to its planning". Called the "constitution for future development" by the California Supreme Court, the General Plan is a guideline for growth and policy decisions. The General Plan is intended to serve as a comprehensive long-term document establishing land use and development policy for the next 10 to 20 years.

4.1.3.1 Glenn County General Plan

The most recent General Plan for Glenn County was adopted in 1993 and provides a template for development in the unincorporated areas of the county, outside of the communities of Willows and Orland. The Plan addresses land use, transportation, housing, open space, conservation, safety, noise and economic development.

4.1.3.2 Colusa County General Plan

Colusa County recently adopted a new General Plan, replacing the previous 1989 General Plan. The 2012 Plan provides a framework for decisions on growth, development, and conservation of open space, consistent with the desires of the County's residents and businesses. The Plan contains specific elements including agriculture, transportation, community character, conservation, economic development, housing, land use noise, open space, public services and facilities, and safety. The Plan also includes a Sites Planning Area.

4.2 Chapter 6: Surface Water Resources

4.2.1 Federal Plans, Policies, and Regulations

4.2.1.1 Federal Regulations Related to CVP Authorization and Operations

In the early 1900s, the federal government and the State of California initiated several projects that coordinated water supply, flood control, and navigation benefits. One of the first California projects was proposed in 1920 by Colonel Marshall of the U.S. Geological Survey (USGS) (The Marshall Plan) to construct Shasta and Friant dams and associated facilities to provide water supplies and reduce groundwater overdraft in the San Joaquin Valley. In 1933, the State Legislature adopted the California Central Valley Project (CVP) Act to sell revenue bonds for the facilities. However, because of economic conditions, the bonds could not be sold, and federal government assistance was requested. The Federal Rivers and Harbors Act of 1935 appropriated funds and authorized the U.S. Army Corps of Engineers (USACE) to construct Shasta and Friant dams, power generating and transmission facilities, and the Contra Costa, Madera, and Friant-Kern canals. In 1937, Congress reauthorized the Rivers and Harbors Act, which included a provision to assign construction and operation of the CVP to the Reclamation Service (later known as the Bureau of Reclamation [Reclamation]). This resulted in the CVP being subject to Reclamation Law as defined in the Reclamation Act of 1902 (requiring water users to repay construction costs from which they received benefits) and all supplemental and amendatory acts thereof. Under Reclamation Law, the Secretary of the Interior administers the laws governing the distribution of benefits associated with construction, operation, and maintenance of federal reclamation facilities that provide water for irrigation farmland and other enumerated purposes.

Several other laws were adopted that provided reauthorization or further definition of authorizations for CVP facilities, operations, water service contracting, and environmental protections. One of the most recent laws, the Central Valley Project Improvement Act (CVPIA), substantially amended the CVP authorizations. CVP operations were also substantially modified through adoption of the Coordinated

Operating Agreement, CALFED Bay-Delta Authorization Act, implementation of the Trinity Record of Decision, and the San Joaquin River Agreement (SJRA).

Central Valley Project Improvement Act

The Reclamation Projects Authorization and Adjustment Act of 1992 includes Title 34: the CVPIA. The CVPIA amended the authorization of the CVP to include fish and wildlife protection, restoration, and mitigation as project purposes of the CVP having equal priority with irrigation and domestic uses of CVP water, and elevates fish and wildlife enhancement to a level having equal purpose with power generation. Section 3406(b)(2) of the CVPIA provides the basis for implementing upstream and Sacramento-San Joaquin Delta (Delta) actions for fish management purposes. Section 3406(b)(2) includes curtailing exports at Jones Pumping Plant for fishery management protection based on USFWS recommendations.

Among the changes mandated by the CVPIA are:

- Dedicating 800,000 acre-feet[2] annually to fish, wildlife, and habitat restoration – §3406(b)(2)
- Authorizing water transfers outside the CVP service area – §3405
- Implementing an anadromous fish restoration program – §3406(b)(1)
- Creating a restoration fund financed by water and power users – §3407
- Providing for the Shasta Dam temperature control device – §3406(b)(6)
- Implementing fish passage measures at the Red Bluff Diversion Dam – §3406(b)(10)
- Calling for planning to increase the CVP yield – §3406(j)
- Mandating firm water supplies for Central Valley wildlife refuges and wildlife habitat areas – §3406(d)
- Improving the Tracy Fish Collection Facility (a Reclamation facility that researches ways to improve fish protection around water diversion areas) – §3406(b)(4)
- Meeting federal trust responsibility to protect fishery resources in the Trinity River – §3406(b)(23)

Coordinated Operations Agreement

The CVP and State Water Project (SWP) use a common water supply in the Delta. The associated water rights are conditioned by the State Water Resources Control Board (SWRCB). These rights protect the beneficial uses of water individually and jointly for the SWP and CVP for the protection of beneficial uses[3] in the Sacramento Valley and the Delta Estuary. The Coordinated Operations Agreement (COA), signed in 1986, does the following:

- Defines the CVP and SWP facilities and their water supplies
- Sets forth procedures for coordination of operations

[2] An acre-foot is the amount of water that would fill a one acre plot of land up to one foot deep; approximately 325,000 gallons.

[3] Beneficial uses define the resources, services, and qualities of aquatic systems that are the goal of the SWRCB to protect and maintain high water quality. The SWRCB is charged with protecting all these uses from pollution to nuisances that may occur as a result of waste discharges in the region. Beneficial uses of surface waters, groundwater, marshes, and wetlands serve as a basis for establishing water quality objectives and discharge prohibitions.

- Identifies formulas for sharing joint responsibilities for meeting Delta standards as the standards existed in SWRCB D-1485 and other legal uses of water
- Identifies how unstored flow will be shared
- Sets up a framework for exchange of water and services between the SWP and CVP
- Provides for periodic review of the agreement.

In-basin uses, or legal uses of water in the Sacramento Basin, as defined by the COA, include water required under SWRCB D-1485 Delta standards for water quality protection for agricultural, municipal and industrial (M&I), and fish and wildlife use. The SWP and CVP are obligated to ensure water is available for these uses, but the degree of obligation depends on several factors and changes throughout the year. Balanced water conditions are defined in the COA as periods when releases from upstream reservoirs, plus unregulated flows, approximately equal the water supply needed to meet Sacramento Valley in-basin uses and exports. Excess water conditions are periods when the described flows exceed Sacramento Valley in-basin uses and exports. During excess water conditions, sufficient water is available to meet all beneficial needs, and the CVP and SWP are not required to supplement the supply with water from reservoir storage. These conditions must also be mutually agreed upon by both Reclamation and the California Department of Water Resources (DWR). Pursuant to Article 6(g) of the COA, Reclamation and DWR have the responsibility (during excess water conditions) to store and export as much water as possible, within physical, legal, and contractual limits. During balanced water conditions, the CVP and SWP share the responsibility in meeting in-basin uses. When water must be withdrawn from reservoir storage to meet in-basin uses, 75 percent of the responsibility is borne by the CVP and 25 percent is borne by the SWP. When unstored water is available for export while balanced water conditions exist, the sum of CVP stored water, SWP stored water, and the unstored water for export is allocated 45 and 55 percent to the SWP and CVP, respectively.

Implementation of the COA principles has evolved since 1986 because of changes in facilities, including the North Bay Aqueduct, as well as new water quality and flow standards established by SWRCB D-1641 and U.S. Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS) biological opinions. For example, water temperature controls at Shasta, Lewiston, and Whiskeytown dams have changed the pattern of storage and withdrawals for the purpose of improving temperature control and managing coldwater pool resources. Such constraints have reduced the CVP's capability to respond efficiently to changes in Delta export or outflow requirements. Periodically, temperature requirements have caused the timing of the CVP releases to be substantially mismatched with Delta export capability, resulting in loss of water supply. On occasion, and in accordance with Articles 6(h) and 6(i) of the COA, the SWP has been able to export water released by the CVP for temperature control in the Sacramento River. The installation of the Shasta Dam temperature control device has substantially improved Reclamation's ability to match reservoir temperature releases and Delta needs.

Other examples of requirements not included in the COA are the objectives in the 1995 Water Quality Control Plan (WQCP), Vernalis Adaptive Management Program (VAMP), and SWRCB in D-1641. The 1986 COA water supply sharing formula is now used to meet D-1641 Delta outflow and salinity-based standards. SWRCB D-1641 also contains "export limitation" criteria such as the export to inflow ratios, and San Joaquin River pulse period "export limits."

The 1986 COA affirmed the SWP's commitment to provide replacement export capacity for restrictions to CVP operations in May and June under SWRCB D-1485. The SWP provided export capacity (up to

195,000 acre-feet) at Banks Pumping Plant and eliminated the potential water delivery loss that would have been incurred by the CVP pursuant to the 1986 COA.

2009 National Marine Fisheries Service Biological Opinion

The 2009 National Marine Fisheries Service (NMFS) Biological Opinion (BO) concluded that the effects of the proposed operations are likely to jeopardize the continued existence of the following:

- Sacramento River winter-run Chinook salmon
- Central Valley spring-run Chinook salmon
- Central Valley steelhead
- Southern DPS of North American green sturgeon
- Southern Resident killer whale

The BO stated that the CVP and SWP have "both directly altered the hydrodynamics of the Sacramento-San Joaquin river basins and have interacted with other activities affecting the Delta to create an altered environment that adversely influences salmon and green sturgeon population dynamics. The altered environment includes changes in habitat formation, species composition, and water quality, among others".

NMFS developed Reasonable and Prudent Alternatives (RPAs) in accordance with federal Endangered Species Act (FESA) requirements. NMFS indicated that, based on the analyses presented in the BO, the "RPA cannot and does not include all steps that would be necessary to achieve recovery." Consequently, NMFS included focused actions designed to compensate for a particular stressor.

The RPAs to the proposed action are summarized below.

- A new year-round temperature monitoring program and reservoir storage management program for Shasta Reservoir to minimize effects to endangered winter-run Chinook salmon that spawn only in the Sacramento River.
- Long-term passage prescriptions at Shasta Dam and re-introduction of winter-run Chinook salmon to its native habitat in the McCloud River and/or upper Sacramento River.
- Maintenance of present flow and water temperature conditions in Clear Creek.
- Modified Red Bluff Diversion Dam (RBDD) gate operations while an alternative diversion structure is being built
- Short-term and long-term actions for improving juvenile rearing habitat in the lower Sacramento River and northern Delta
- Additional Delta Cross Channel gate closures to keep young fish out of artificial channels in the Delta and allow them to migrate safely towards the ocean
- New reverse flow levels in Old and Middle rivers to limit the strength of reverse flows and reduce entrainment at the CVP and SWP facilities
- Use of additional technological measures at the CVP and SWP facilities to enhance screening and increase fish survival

- Additional measures to improve survival of San Joaquin steelhead smolts, including increased San Joaquin River flows and export curtailments, and a new study of acoustic tagged fish in the San Joaquin River Basin to evaluate and refine these measures
- A new American River flow management standard, temperature management plan, additional technological fixes to temperature control structures, and, in the long-term, restoration of steelhead passage at Nimbus and Folsom dams
- A year-round minimum flow regime on the Stanislaus River necessary to minimize project effects to each life stage of steelhead, including new springtime flows that will support rearing habitat formation and inundation, and create pulses that allow salmon to migrate out successfully
- Development of Hatchery Genetic Management Plans to increase the diversity, and therefore, resiliency of salmon to withstand a wide range of conditions

The RPA actions that directly affect water supply operations are summarized below.

- **Clear Creek:** Modify releases from Whiskeytown Dam into Clear Creek to meet daily water temperature requirements and to provide periodic pulse flows for channel maintenance.
- **Upper Sacramento River and releases from Shasta Lake:** Manage reservoir storage volumes in Shasta Lake at the end of September to improve the potential for adequate water for coldwater pool maintenance in order to meet daily water temperature requirements in the fall and to provide adequate carryover storage to meet water temperature requirements in the following year. The RPA also included minimum instream flow targets and recommendations for modifications of water temperature requirements in drier water years that could be used for guidance to maintain adequate coldwater pool volumes.
- **Upper Sacramento River and Red Bluff Diversion Dam:** The RPA supported the current construction of the new diversion structure to eliminate use of the gates that block Sacramento River flows. The RPA also includes requirements for diversions until the new structure is completed.
- **Upper Sacramento River Flows at Wilkins Slough:** Instream flows historically were maintained at Wilkins Slough to provide adequate flows for navigation and more recently to provide adequate elevations for installed pumps. The RPA recommends modifications to this flow criterion.
- **American River:** The RPA supports the flows currently being discussed by Reclamation and other agencies for lower American River flow and water temperature management.
- **Stanislaus River:** The RPA requires modifications in operations of New Melones Reservoir to provide daily water temperature management and minimum instream flows in Stanislaus River.
- **Delta-Cross Channel (DCC) Gate Operations:** The RPA modifies the operations of the DCC Gate that diverts water from the Sacramento River toward the Clifton Court Forebay and the Jones Pumping Plant. The RPA modifies operations of the gate based on salinity in the southern Delta and presence of salmonids[4] in the Sacramento River near Knights Landing and the City of Sacramento. This could result in a reduction of exports.

[4]Salmonids- the family of fish that includes salmon

- **San Joaquin River:** Modification of the export to inflow ratio to reduce exports if the San Joaquin River flows at Vernalis are not adequate to meet the ratio criteria to protect water quality and reduce entrainment of juveniles.
- **Old and Middle River:** The RPA requires reductions in exports to reduce reverse flows when salmonids are present to protect water quality and reduce fish entrainment.

Bay-Delta Water Quality Control Plan

The Bay Delta Water Quality Control Plan outlines water quality objectives for the Delta.

CALFED Bay-Delta Authorization Act

The CALFED Bay-Delta Authorization Act authorized $395 million for a balanced program to increase California's water supply, reliability and quality and help restore sensitive water ecosystems.

The CALFED law was designed to ensure that California will be able to meet its water needs in a balanced manner – for farmers, for cities, and for the environment. Specifically, the law:

- Restores environmentally significant areas of the State, including the San Francisco Bay-Delta: Comprising more than 600 program elements including water purchases to improve river habitat, removal of dams that are no longer necessary and hinder fish migration, restoration of streams, and restoration of significant land habitat.
- Provides necessary water infrastructure to enable California to continue to lead the nation in economic growth and agriculture production: Including screens to protect fish, levee improvements to protect water quality and ensure beneficial land use, through-Delta conveyance importance, and additional ground and off-stream surface water storage.
- Ensures a safe, reliable source of drinking water for California's growing population, including smarter use of water supplies and facilities to reduce environmental impact of water exports

This approach balances the needs of agricultural, urban and environmental interests and helps to address the needs of the State's aging water infrastructure.

CALFED Bay-Delta Implementation Act

In the August 28, 2000 CALFED Record of Decision (ROD), Reclamation and other State and federal agencies committed to implementing a long-term plan to restore the Bay-Delta. This plan consists of many activities including storage, conveyance, ecosystem restoration, levee integrity, watersheds, water supply reliability, water use efficiency, water quality, water transfers, and science. The Implementation MOU, also signed August 28, 2000, continued the operations decision-making process that had evolved through the CALFED process. The ROD identified numerous programs to provide protection to fish in the Bay-Delta Estuary through environmentally beneficial changes in CVP and SWP pumping operations at no uncompensated water cost to CVP and SWP water users.

Trinity River Mainstem Fishery Restoration

In 1994, USFWS, as the NEPA lead agency, and Trinity County, as the CEQA lead agency, began the public process for developing the Trinity River Mainstem Fishery Restoration EIS/EIR. In December 2000, the Secretary of Interior signed the ROD for a variable annual flow regime, mechanical channel rehabilitation, sediment management, watershed restoration, and adaptive management. Based on the

ROD, 368,600 acre-feet to 815,000 acre-feet (depending on water year[5] type) is allocated annually for Trinity River flows. The amount of water released is scheduled in coordination with USFWS to best meet habitat, temperature, and sediment transport objectives in the Trinity River basin.

San Joaquin River Agreement and the Vernalis Adaptive Management Plan

The 1998 San Joaquin River Agreement (SJRA) was adopted through the SWRCB D-1641 agreement. It includes a 12-year experimental program providing for flows and Delta exports in the lower San Joaquin River. This study is conducted during a 31-day pulse flow period occurring April to May. The SJRA also provides for the collection of experimental data during that time to further the understanding of the effects of flows, exports, and a barrier at the head of Old River on salmon smolt survival. This experimental program is commonly referred to as the VAMP. The SJRA also provides water for flows at other times on the Stanislaus, Merced, and lower San Joaquin rivers. SJRA established a management and technical committee to oversee, plan, and coordinate implementation of activities required under the agreement. Reclamation, DWR, USFWS, California Department of Fish and Game (CDFG), and NMFS are signatories to the agreement; other signatories include San Joaquin River water rights holders, SWP and CVP water users, and other stakeholders.

The SJRA (1987) also provides for the collection of experimental data on the effects of flows, exports, and a barrier at the head of Old River. A barrier would deter salmon smolts (juvenile salmon) from entering Old River and direct them to the San Joaquin River where it has been shown that they have an increased survival rate. This experimental portion of the SJRA program is commonly referred to as the Vernalis Adaptive Management Program (VAMP). SWRCB indicates that VAMP experimental data will be used to create permanent objectives for the pulse flow period. The parties to the SJRA include several agencies that contribute flow to the San Joaquin River, divert from or store water on the tributaries to the San Joaquin River, or have an element of control over the flows in the lower San Joaquin River. These include Reclamation, Oakdale Irrigation District, South San Joaquin Irrigation District, Modesto Irrigation District, Turlock Irrigation District, Merced Irrigation District, and the San Joaquin River Exchange Contractors. VAMP is based on coordination among these participating agencies in carrying out their operations to meet an annual target flow objective at Vernalis.

The VAMP program has two distinct components: flow objectives and export restrictions. Flow increases could be provided using CVPIA §3406(b)(1), (b)(2), and (b)(3), which would contribute to fishery needs on the Stanislaus River. The export reduction involves a combined State and federal pumping limitation on the Delta pumps. Pumping reductions that cannot be recovered by adjustments in CVP operations are considered to be §3406(b)(2) water (e.g., it is reserved for fish and wildlife). Reductions of SWP pumping are limited to the amount that can be recovered through operations adjustments and the export of up to 48,000 acre-feet of transferred water to be made available from the Lower Yuba River Accord[6].

---

[5] The 12-month period starting October 1st and ending September 30th of the following year in which the surface-water supply is quantified. The water year is defined by the year in which it ends (i.e., October 1, 1998 through September 30, 1999 is the 1999 water year).

[6] The Lower Yuba River Accord provides higher minimum instream flows on the lower Yuba River, funds fisheries studies and restoration activities, enhances water supply reliability in Yuba County, and establishes long-term acquisition of water for the EWA. The "Interim Instream Flows and Fishery Studies in the Stanislaus River Below New Melones Reservoir" (1987 Agreement) specifies interim releases from the New Melones Dam to maintain instream flows as well.

4.2.1.2 Federal Water Quality Regulations Related to Water Supplies

Federal water quality regulations affect SWP and CVP water supplies indirectly through limitations on diversions to protect water quality needs of other beneficial uses.

Clean Water Act

The Federal Water Pollution Control Act was initially adopted in 1948. Modifications to a portion of the act in 1972, 1977, and 2002 became known as the Clean Water Act (CWA, 33 U.S.C. 1251 to 1376). The CWA establishes the basis for regulating discharges of pollutants into surface waters of the United States and regulating water quality standards for stated beneficial uses. Section 303 of the CWA requires states to adopt water quality standards for all surface waters of the United States. As defined by the CWA, water quality standards consist of two elements: (1) designated beneficial uses of the water body in question; and (2) criteria that protect the designated uses. Section 304(a) requires the U.S. Environmental Protection Agency (USEPA) to publish advisory water quality criteria that accurately reflect the latest scientific knowledge on the kind and extent of all effects on health and welfare that may be expected from the presence of pollutants in water. Where multiple uses exist, water quality standards must protect the most sensitive use.

The CWA is implemented by the USEPA. The USEPA is generally directly responsible for implementing CWA provisions, although the CWA also authorizes states to implement portions of CWA through a delegation process. California has this authority to identify beneficial uses and water quality criteria to protect those beneficial uses. SWRCB water rights decisions and orders have been issued to protect beneficial uses during operation of SWP and CVP facilities.

Several provisions of the CWA are implemented through other agencies, including Section 404 of the CWA that authorizes USACE to regulate discharge of dredging material and fill into “waters of the United States (including wetlands),” and The Safe Drinking Water Act (SDWA) of 1974, and amendments in 1986 and 1996, which directed the USEPA to establish national drinking water standards with maximum contaminant levels for a wide variety of constituents and provisions for a mandatory monitoring program for local water suppliers. The 1996 amendments expanded the focus of the SDWA from primarily treatment to source water protection to reduce contamination in municipal water supplies. Many of the SWP and CVP water users are municipalities that must comply with the SDWA and are concerned about water supply facility operations that may increase the potential for contamination.

4.2.2 State Plans, Policies, and Regulations

4.2.2.1 State Water Resource Control Board Water Rights and Water Quality Protection

California law recognizes several types of surface water rights, including riparian and appropriative rights[7]. A riparian right exists through ownership of land adjacent to a stream or other body of water. The right allows a water user to divert from the natural flow of a stream for use on land within the watershed of the source. Seasonal storage of water is not allowed under a riparian right. If there is insufficient water for the reasonable uses of all the riparian users, flows are shared relative to needs. Generally, riparian water users[8] have first priority to the use of the natural flow in a river. Remaining water is available to

[7] Appropriative rights pertain to the diversion of water for immediate use on non-riparian property (property not including or adjacent to a stream) or for storing the water for later use and requires a permit from the SWRCB

[8] Users who extract water for use on lands that directly border a stream; this use does not require a permit from the SWRCB.

appropriative water rights holders[9]. No permit or license is necessary to divert water under claim of riparian right; however, a record of water use should be filed with SWRCB.

Appropriative water rights are granted by the SWRCB based on the time of water right application. Appropriative water rights granted before 1914 ("pre-1914 appropriative water rights") do not require a permit or license; however, the pre-1914 water use is generally recorded with SWRCB. Post-1914 water rights require a permit or license from SWRCB or its predecessor agencies. All new appropriators must file an application with SWRCB and obtain a permit before diverting water. SWRCB determines whether the water will be put to beneficial use, the quantity and pattern of diversion, location of diversion, necessary conditions to protect the environment, the public trust, and prior water rights. If the water is diverted and applied to beneficial use in accordance with the terms of the permit for a period of years, a license may be issued by SWRCB confirming the extent of the permittee's right. The SWRCB has the authority to prevent waste and unreasonable use, prevent unreasonable method of use, unreasonable diversion of water, and to protect public trust uses of water. The SWRCB granted post-1914 appropriate water rights to Reclamation and DWR for the CVP and SWP, respectively.

Water Rights Protections for County of Origin and Upstream Watersheds

Initiation of the CVP in the 1920s by the State of California raised concerns for availability of water remaining in northern California following construction of storage and export facilities. These issues were discussed again in the 1950s as the SWP was being developed. In 1927, the State legislature adopted the Feigenbaum Act. This allows the State to file for unappropriated water[10] for general water resource development plans to avoid further filings by private parties for unappropriated water. The Feigenbaum Act was amended in 1931 to protect the availability of water for beneficial uses in the counties of origin.

Water Rights Decision 1422/Order 83-3 and Water Rights Decision 1275

Individual water rights for the CVP are granted by the SWRCB for the Sacramento, Trinity, American, San Joaquin, and Stanislaus rivers, and several of their tributaries. Water Rights D-1422 and SWRCB Water Rights Order 83-3 provide the water rights and primary operational criteria for New Melones Reservoir. D-1422 includes requirements for water quality conditions on the San Joaquin River at Vernalis.

Water rights for the SWP were granted in 1967 through Water Rights D-1275. This decision also included water quality criteria in the Delta to be implemented with the CVP and SWP.

4.2.2.2 Water Quality Control Plans for the Sacramento/San Joaquin River Basins, the San Francisco Bay Basin, and Development of the 1978 Delta Plan and Water Rights Decision 1485

In 1975 and 1976, the SWRCB adopted the Sacramento–San Joaquin Delta Basin and San Francisco Bay Basin plans, which included water quality standards. These plans formed the basis for the WQCP for the Delta and Suisun Marsh, which was adopted in 1978. This plan included salinity objectives in the Delta for protection of agricultural uses. In 1978, the SWRCB also adopted Water Rights Decision 1485 (D-1485) to implement portions of the plan through modifications to CVP and SWP operations. The 1978 Delta Plan considered the need to develop methods to improve circulation and change diversion to

---

[9] Users who extract water for delivery to a parcel of land that is not adjacent to the stream or other water source. This use requires a permit from the SWRCB.

[10] Unappropriated water is any usable water that is not claimed under prior rights.

protect water quality in the southern Delta. Reclamation and DWR protested many of the requirements of D-1485, including the ability of new water rights applicants to change Delta inflows that would need to be corrected through modification of CVP and SWP operations to continue to meet Delta water quality requirements. Alternatives to D-1485 and the 1978 Delta Plan were developed and discussed through the mid-1990s.

In the 1978 Delta Plan and D-1485, requirements were based on the Sacramento Valley 40-30-30 Index and San Joaquin Valley 60-20-20 Index. The Sacramento Valley 40-30-30 Index is computed through a weighted average of:

- The current water year's April through July unimpaired flow[11] forecast in the Sacramento Valley (weighted as 40 percent)
- The current water year's October through March unimpaired flow forecast in the Sacramento Valley (weighted as 30 percent)
- The previous water year's index (a cap of 10.0 million acre-feet is put on the previous year's index to account for required flood control reservoir releases during wet years weighted as 30 percent).

The Sacramento Valley unimpaired flow is a combination of flows for Sacramento River at Bend Bridge near Red Bluff, Feather River inflow to Lake Oroville, Yuba River flows at Smartville, and American River inflow to Folsom Lake. The criteria for water year classifications under the Sacramento Valley 40-30-30 Index are as follows:

- **Wet Year:** Weighted sum greater than or equal to 9,200,000 acre-feet
- **Above Normal Year:** Weighted sum less than 9,200,000 acre-feet and greater than 7,800,000 acre-feet
- **Below Normal Year:** Weighted sum less than 7,800,000 acre-feet and greater than 6,500,000 acre-feet
- **Dry Year:** Weighted sum less than 6,500,000 acre-feet and greater than 5,400,000 acre-feet
- **Critical Year:** Weighted sum equal to or less than 5,400,000 acre-feet

The San Joaquin Valley 60-20-20 Index is computed through a weighted average using:

- The current water year's April through July unimpaired flow forecast (weighted as 60 percent)
- The current water year's October through March unimpaired flow forecast (weighted as 20 percent)
- The previous water year's index with a maximum amount to reflect flood releases in wetter water years (weighted as 20 percent).

The Sacramento Valley unimpaired flow is a combination of flows for Stanislaus River inflow to New Melones Reservoir, Tuolumne River inflow to Don Pedro Reservoir, Merced River inflow to Exchequer Reservoir (Lake McClure), and San Joaquin River inflow to Millerton Lake.

The criteria for water year classifications under the San Joaquin Valley 60-20-20 Index are as follows:

- **Wet Year:** Weighted sum greater than or equal to 3,800,000 acre-feet
- **Above Normal Year:** Weighted sum less than 3,800,000 acre-feet and greater than 3,100,000 acre-feet
- **Below Normal Year:** Weighted sum less than 3,100,000 acre-feet and greater than 2,500,000 acre-feet

[11] Unimpaired flow is runoff that would have occurred had water flow remained unaltered in rivers and streams instead of stored in reservoirs, imported, exported, or diverted. The unimpaired flow forecast is the estimate of unimpaired flow that will be available for that water year.

- **Dry Year:** Weighted sum less than 2,500,000 acre-feet and greater than 2,100,000 acre-feet
- **Critical Year:** Weighted sum equal to or less than 2,100,000 acre-feet

Development of the 1995 and 2006 Water Quality Control Plans, and Orders 98-09 and 95-9

In 1994, representatives of the federal and State governments, urban and agricultural water users, and environmental interest groups agreed to implementation of the interim Bay-Delta protection plan. The 1995 Bay-Delta WQCP was adopted in 1995 and included provisions for operations of the CVP and SWP to be consistent with requirements of the USFWS 1995 Delta Smelt BO and NMFS 1995 Winter-Run Chinook Salmon BO. Water Rights Order 95-6 was subsequently adopted by SWRCB to eliminate inconsistencies between water rights permit conditions and the WQCP water quality objectives, and was extended through 1999 under Water Rights Order 98-09. Water Rights Order 95-9 also required CVP to release water from New Melones Reservoir to comply with salinity standards in the San Joaquin River at Vernalis. The WQCP and the CVPIA were several of the first plans that required the CVP and SWP to be operated in a manner to protect fish and wildlife as well as agricultural and urban water users. Many of the water quality provisions of these requirements were similar to those in D-1485. However, 1995 WQCP also included additional requirements for managing Delta salinity through X2[12] requirements, upper limits on exports, and operations of the DCC gates to protect fish. The WQCP also included water temperature standards for estuaries that were primarily developed to manage discharge of cooling water from thermal power plants.

The SWRCB undertook a proceeding to amend the 1995 WQCP. The SWRCB adopted a revised Bay-Delta Plan on December 13, 2006. There were no changes to the beneficial uses from the 1995 Plan to the 2006 Plan, nor were any new water quality objectives adopted in the 2006 Plan. A number of changes were made simply for consistency. The SWRCB initiated a Comprehensive Review of the Bay-Delta Plan entitled Water Rights and Other Requirements to Protect Fish and Wildlife Beneficial Uses and the Public Trust, in 2008.

4.2.2.3 State Water Resources Control Board Decision 1641 (D-1641)

With D-1641, adopted on December 29, 1999, the SWRCB implements the objectives of the 1995 Bay Delta WQCP and imposes flow and water quality objectives on the CVP and SWP. D-1641 specifies that, from February through June, the location of X2 must be west of Collinsville and must additionally be west of Chipps Island or Port Chicago for a certain number of days each month, depending on the previous month’s Eight River Index[13]. D-1641 specifies that compliance with the X2 standard may occur in one of three ways: (1) the daily average EC at the compliance point is less than or equal to 2.64 milliohms/cm; (2) the 14-day average EC is less than or equal to 2.64 milliohms/cm; or (3) the three-day average Delta outflow is greater than or equal to the corresponding minimum outflow.

In D-1641, the SWRCB assigned responsibilities to Reclamation and DWR for meeting these requirements on an interim basis. These responsibilities required that the CVP and SWP be operated to meet water quality objectives in the Delta, pending a water rights hearing to allocate the obligation to

[12] X2 is the location of the two parts per thousand salinity contour (isohaline), one meter off the bottom of the estuary, as measured in kilometers upstream from the Golden Gate Bridge.

[13] The Eight River Index refers to the sum of the unimpaired runoff for the following locations: Sacramento River flow at Bend Bridge, near Red Bluff; Feather River, total inflow to Oroville Reservoir; Yuba River flow at Smartville; American River, total inflow to Folsom Reservoir; Stanislaus River, total inflow to New Melones Reservoir; Tuolumne River, total inflow to Don Pedro Reservoir; Merced River, total inflow to Exchequer Reservoir; and San Joaquin River, total inflow to Millerton Lake.

meet the water quality and flow-dependent objectives among all users of the Sacramento and San Joaquin river basins with appropriative water rights with post-1914 priority dates. However, in lieu of this hearing, the SJRA and Sacramento Valley Water Management Agreement are settlements between Reclamation and DWR with water users upstream of the Delta, in which the CVP and SWP committed to continue to meet the D-1641 water quality requirements in return for other commitments by major upstream water-rights holders. After these agreements were executed, SWRCB cancelled the water rights hearing to allocate that responsibility.

The SWRCB revised D-1641on March 15, 2000. The requirements in the revised D-1641 address the standards for fish and wildlife protection, urban water quality, agricultural water quality, and Suisun Marsh salinity. D-1641 also authorizes the CVP and SWP to jointly use each other’s points of diversion in the southern Delta (also known as Joint Point of Diversion), with conditional limitations and required coordination plans, and modifies the Vernalis salinity standard in the WQCP.

The Joint Point of Diversion was authorized to meet a prioritized list of conditions. The highest priority was to convey CVP water in SWP facilities to several water service contractors located in the San Joaquin Valley, and to recover export reductions that were required to protect fish. The next priorities were for authorized purposes of current CVP and SWP water rights permits up to the physical capacity of the diversion facilities. The Joint Point of Diversion diversions are allowed only under excess conditions, as previously discussed, and after water rights and BO requirements for the Contra Costa Water District (CCWD) Los Vaqueros Project are met. The second priority also requires operations in accordance with a Fisheries Response Plan.

4.2.2.4 State Water Resources Control Board Regulations

Water quality regulations related to waste discharge and National Pollutant Discharge Elimination System (NPDES) permits are discussed in the Surface Water Quality section of this chapter. The following discussion is related to water quality regulations that affect water supplies of the CVP and SWP.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne Act) established surface and groundwater quality regulations that set limits on water quality constituents for the purpose of protecting beneficial uses[14] and provided the authority for the SWRCB to protect the State’s surface and groundwater. The nine Regional Water Quality Control Boards (RWQCBs) were established to oversee and implement specific water quality activities in their geographic jurisdictions.

The Porter-Cologne Act requires the RWQCBs to establish water quality objectives while acknowledging that water quality may change without unreasonably affecting beneficial uses. Therefore, water quality objectives are references as opposed to rules for meeting federal and State requirements for water quality control.

The Porter-Cologne Act also requires that each RWQCB develop basin plans that establish and periodically review the beneficial uses and water quality objectives for surface and groundwater bodies within its jurisdiction. Water quality objectives provide specific water quality guidelines to protect groundwater and surface water to maintain designated beneficial uses. The SWRCB, through its

[14] “Beneficial uses” of the waters of the State that may be protected against quality degradation include, but are not limited to, domestic, municipal, agricultural, and industrial supply; power generation; recreation; aesthetic enjoyment; navigation; and preservation and enhancement of fish, wildlife, and other aquatic resources or preserves.

RWQCBs, is the permitting authority in California to administer NPDES and waste discharge requirements for regulation of waste discharges in their respective jurisdictions.

The USEPA may allow a state to implement portions of the CWA. In 1972, the State Legislature amended the Porter-Cologne Act to give SWRCB the authority to implement those portions of the CWA. Portions of WQCPs that are consistent with and under the jurisdiction of the CWA also require approval by USEPA.

The Burns-Porter Act

The Burns-Porter Act of 1959, also known as the Water Resources Development Bond Act, authorized the sale of general obligation bonds to finance and develop the initial facilities of the State Water Resources Development System, which are now known as the SWP. The Burns-Porter Act also authorized the State of California to enter into contracts for the sale, delivery, or use of water made available by the State Water Resources Development System.

Delta Protection Act of 1959

The Delta Protection Act (California Water Code §12220) was adopted in 1959. This legislation incorporated by reference the county of origin and water protection acts. It found that maintenance of an adequate water supply in the Delta is necessary for the health, safety, and welfare of the people of the State. An adequate water supply is sufficient to maintain and expand agriculture, industry, urban, and recreational development and provides a common source of freshwater for export to areas of water deficiency (frequently referred to as the “Common Pool”) in the Delta. The legislation also declared that the CVP and SWP would provide salinity control and adequate water supply for users of water in the Delta. The legislation also defined the “Legal Delta” boundaries to include portions of Sacramento, San Joaquin, Yolo, Solano, and Contra Costa counties.

Delta Protection Act of 1992

The Delta Protection Act of 1992 (also known as the Johnston-Baker-Andal-Boatwright Delta Protection Act) established the Delta Protection Commission and defined the Commission’s principal jurisdiction. The Act declared that the Delta is a natural resource of statewide, national, and international significance, containing irreplaceable resources, and that it is the policy of the State to recognize, preserve, and protect those resources of the Delta for the use and enjoyment of current and future generations, in a manner that protects and enhances the unique values of the Delta as an evolving place (PRC §29701 to 2).

Monterey Agreement

In addition to the requirements established by SWRCB and other federal and State agencies, SWP operations are subject to requirements of their contracts. The SWP delivers the portion of available water supplies to each contractor as calculated each year. If excess water is available, Article 21 of the SWP contracts allows for delivery of the excess water (also known as “Article 21 Water”). However, as water supply availability frequently was reduced because of water quality, water rights, and environmental concerns, water deliveries have been reduced to many SWP water users. SWP contractors had raised issues with the allocation of surplus and carryover storage flows. In response to these issues, in 1994, DWR and SWP contractor representatives agreed to a set of 14 principles to modify the long-term SWP water supply contracts in a document that became known as the Monterey Agreement, which included principles to increase water supply reliability, improve financial management, and increase water management flexibility. A program EIR was completed and certified in 1995. Subsequent litigation related to the EIR required DWR to prepare a new EIR. The SWP operates under many of the provisions of the Monterey Agreement, including methods to allocate available water supplies, provisions for water transfers, and transfer of ownership for the Kern Fan Element (groundwater bank) to Kern County Water Agency to provide for more flexibility.

Monterey Plus

The Monterey Plus EIR is officially known as an EIR on the Monterey Amendment to the State Water Projects (Including Kern Water Bank Transfer) and Associated Actions as Part of a Settlement Agreement (Monterey Plus).

The objective of the Monterey Plus EIR is to resolve the underlying issues that led to the Monterey Amendment and implement the Settlement Agreement. Specific objectives of the Monterey Plus are to:

- Resolve conflicts and disputes among SWP contractors regarding water allocations and financial responsibilities for SWP operations;
- Restructure and clarify procedures for SWP water allocation and delivery during times of shortage and surplus;
- Reduce financial pressures on agricultural contractors in times of drought and supply reductions;
- Adjust the financial rate structure of the SWP to more closely match revenue needs;
- Facilitate water management practices and water transfers that improve reliability and flexibility of SWP water supplies in conjunction with local supplies;
- Resolve legal and institutional issues related to storage of SWP water in Kern County groundwater basins, and in other areas.

The Monterey Agreement provided in Principle 13 that the proposal was an integrated package. Contractors had to choose to participate in all the provisions of the Monterey Agreement or none. In other words, the Monterey Amendment resulted from a package deal of negotiated concessions that required achieving all of the above objectives in order to settle significant disputes among the contractors. Specific objectives of the Settlement Agreement are to:

- Communicate SWP supply reliability information to SWP contractors and local planning jurisdictions and clarify related SWP contract language;
- Enhance public review of SWP contract amendments and public participation in environmental review;
- Provide assurances regarding finality of certain Table A transfer and transfer of title to the Kern Fan Element land and assurances regarding environmental protection of Kern Fan Element lands;
- Increase SWP watershed enhancement activities in Plumas County and improve Plumas County's access to SWP water; and
- Provide funding to plaintiffs to implement the Settlement Agreement including watershed restoration projects.

Although the Settlement Agreement does not have the same language that the Monterey Agreement had with regard to an integrated package, the Settlement Agreement also was a package deal of negotiated concessions that required achieving all of the above objectives in order to settle significant disputes between the parties.

Suisun Marsh Protection Act and Plan (1974)

In 1974, the California Legislature passed the Nejedly-Bagley-Z'berg Suisun Marsh Protection Act (SMPA) of 1974, designed to preserve Suisun Marsh from residential, commercial, and industrial development. The act directed the San Francisco Bay Conservation and Development Commission (BCDC) and CDFG to prepare a protection plan for Suisun Marsh "to preserve the integrity and assure continued wildlife use" of the marsh. The objectives of the protection plan are to preserve and enhance the quality and diversity of the Suisun Marsh's aquatic and wildlife habitats, and to ensure retention of upland areas adjacent to the marsh in uses compatible with its protection.

Suisun Marsh Preservation Agreement (1987)

Since the early 1970s, the California Legislature, SWRCB, Reclamation, CDFG, Suisun Resource Conservation District (SRCD), DWR, and other agencies have worked to preserve beneficial uses of Suisun Marsh as mitigation for potential impacts of reduced Delta outflow on Delta salinity. On March 2, 1987, the SMPA (1987) was signed by DWR, Reclamation, CDFG, and SRCD, CVP, and SWP.

The purpose of the SMPA (1987) was to establish mitigation for impacts on salinity from the SWP, CVP, and other upstream diversions. The SMPA (1987) has the following objectives:

- To ensure that Reclamation and DWR maintain a water supply of adequate quantity and quality for managed wetlands within Suisun Marsh to mitigate adverse effects on these wetlands from CVP and SWP operations, as well as a portion of the adverse effects of other upstream diversions.
- To improve Suisun Marsh wildlife habitat on these managed wetlands.
- To define the obligations of Reclamation and DWR necessary to ensure the water supply, distribution, management facilities, and actions necessary to accomplish these objectives.
- To recognize that water users in Suisun Marsh (i.e., existing landowners) divert water for wildlife habitat management within the Suisun Marsh.
- Set a timeline for implementing the Suisun Marsh Protection Plan[15]
- Delineate monitoring and mitigation requirements
- Include provisions to recognize water uses in Suisun Marsh and improve wildlife habitat within the marsh

On June 20, 2005, a revised SMPA (1987) was signed to make channel water salinity requirements consistent with the SWRCB's Decision 1641 and replace additional large-scale water management facilities with landowner water and management activities to meet the SMPA (1987) objectives in the western portion of Suisun Marsh.

The two primary mechanisms for meeting salinity standards include the implementation and operation of facilities in the marsh and management of Delta outflow. The facilities include the Suisun Marsh Salinity

[15] The Suisun Marsh Protection Plan was prepared by the San Francisco Bay Conservation and Development Commission and CDFG in 1976. The Plan's objectives are to preserve and enhance the quality and diversity of the Suisun Marsh aquatic and wildlife habitats and to assure retention of upland areas adjacent to the Marsh in uses compatible with its protection.

Control Gates (SMSCGs) on Montezuma Slough (initiated in 1988) to restrict high salinity flows from Grizzly Bay into Montezuma Slough during incoming tides and to retain low salinity water, and the RRDS and Morrow Island Distribution System (constructed in 1979 and 1980) to provide low salinity water to a portion of the Suisun Marsh wetlands.

California Water Plan

Chapter 1 of Volume 2, Resource Management Strategies to the California Water Plan (CWP) – Update 2009, includes surface storage as a resource management strategy toward the management objective of helping to meet water-related resource management needs through an increase in water supply. Chapter 12 of Volume 2 includes the NODOS Project as a surface storage alternative identified in the CALFED ROD and recommends continued work efforts to complete environmental studies for the NODOS Project.

4.3 Chapter 7: Surface Water Quality

4.3.1 Federal Plans, Policies, and Regulations

4.3.1.1 Clean Water Act Section 303(d) Total Maximum Daily Load

Section 303(d) of the CWA establishes requirements for states to identify and prioritize water bodies that do not meet water quality standards and are not supporting their designated beneficial uses. As defined by the CWA, water quality standards consist of two elements: (1) designated beneficial uses of the water body in question; and (2) criteria that protect the designated uses. For these water quality–limited water bodies, states must calculate the total maximum daily load[16] (TMDL) for the contaminants of concern, set an allowable load to achieve water quality standards, and adopt a plan of implementation within the applicable water quality management plan. Placement on this list triggers development of a TMDL Program for each water body and associated pollutant/stressor on the list.

These waters are placed on the §303(d) List of Impaired Waters. This list defines low, medium, and high priority pollutants that require immediate attention by federal and State agencies. The RWQCBs are responsible for implementing the TMDL program in California. Completed or ongoing TMDLs in the Bay-Delta region include chlorpyrifos and diazinon, dissolved oxygen, mercury/methylmercury, pathogens, pesticides, organochlorine pesticides, salt and boron, and selenium.

4.3.1.2 Clean Water Act Section 402 NPDES Permit Compliance

The NPDES permit system pursuant to §402 of the CWA applies to discharges of wastes to surface waters of the U.S. Under California's Porter-Cologne Act, the SWRCB and associated RWQCBs regulate discharges of wastes to all waters of the State and land to protect both surface and groundwater.

In November 1990, the California Environmental Protection Agency (CalEPA) established regulations that provided stormwater permit requirements for specific categories of industries, including construction (Phase I Rule). Under Phase I, a stormwater permit was required for construction projects that disturbed five acres of land, and for large Municipal Separate Storm Sewer Systems (MS4s). In December 1999, the USEPA issued regulations (Phase II Rule) that expanded the NPDES program to require a stormwater discharge permit for construction activities with a disturbance area of one to five acres and for small MS4s. In California, the CalEPA has delegated responsibility for CWA implementation to the SWRCB.

[16] TMDL is the maximum amount of a specified pollutant that a waterbody can receive and still meet water quality standards, and an allocation of that load among the various sources of that pollutant.

4.3.1.3 Clean Water Act Section 404

Pursuant to CWA Section 404, a program was established to regulate the discharge of dredged and fill material into waters of the U.S., including some wetlands. Activities in waters of the U.S. that are regulated pursuant to this program include fills for development, water resource projects (e.g., dams and levees), infrastructure development (e.g., highways and airports), and conversion of wetlands to uplands for farming and forestry. Waters of the U.S. include navigable waters[17] of the U.S.; interstate waters; waters where their use, degradation, or destruction could affect interstate or foreign commerce; tributaries to any of these waters; and wetlands that meet any of these criteria or are adjacent to any of these waters or their tributaries. Wetlands are defined pursuant to §404 as those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support a prevalence of vegetation typically adapted for life in saturated soil conditions. Jurisdictional wetlands must meet three wetland delineation criteria: (1) hydrophytic vegetation (i.e., plants that grow in saturated soil), (2) hydric soil types (i.e., soils that are wet or moist enough to develop anaerobic conditions[18]), and (3) wetland hydrology.

Pursuant to §404(b)(1) of the CWA, the Least Environmentally Damaging Practicable Alternative (LEDPA) must be identified from among those alternatives considered in detail in an EIS/EIR. If a federal agency is a partner in the implementation of a project, then the Proposed Action/Project must be recognized as the LEDPA. A Section 404(b)(1) evaluation must be included with a project's Final EIS/EIR pursuant to the CWA, to provide required information on the potential effects of project activities regarding water quality and to provide rationale in support of identifying the LEDPA.

4.3.1.4 Rivers and Harbors Act Section 10

Section 10 of the Rivers and Harbors Act requires authorization from USACE for the construction of any structure in or over navigable waters of the U.S., the excavation/dredging or deposition of material in these waters, or any obstruction or alteration in navigable water.

4.3.1.5 Federal Antidegradation Policy

The Federal Antidegradation Policy is designed to provide the level of water quality necessary to protect existing uses and provide protection for higher quality and national water resources. The federal policy directs states to adopt a statewide policy that includes the following primary provisions:

1. Existing instream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected.

2. Where the quality of waters exceed levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds, after full satisfaction of the intergovernmental coordination and public participation provisions of the State's continuing planning process, that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located.

[17] Waters subject to the ebb and flow of the tide shoreward to the mean high water mark that may be used to transport interstate or foreign commerce.

[18] Conditions where there is no oxygen present in the soil.

3. Where high quality waters constitute an outstanding national resource, such as waters of national and State parks and wildlife refuges, and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected.

4.3.1.6 Federal Safe Drinking Water Act

The Federal SDWA was established to protect the public health and quality of drinking water in the United States, whether from aboveground or underground sources. The SDWA directed the USEPA to set national standards for drinking water quality. It required the USEPA to set Maximum Contaminant Levels (MCLs)[19] for a wide variety of potential drinking water pollutants. The owners or operators of public water systems are required to comply with primary (health-related) MCLs and are encouraged to comply with secondary (nuisance- or aesthetics-related) MCLs.

Federal SDWA standards apply to treated water as it is served to consumers. All surface waters require some form of treatment in order to meet drinking water standards. The degree of treatment needed depends on the quality of the raw water[20]. The highest quality raw surface waters need only to be disinfected before being served to consumers. More typically, raw water is treated in a conventional water treatment plant that includes sedimentation, filtration, and disinfection processes. Municipal water suppliers prefer raw water sources of high quality because their use minimizes risk to public health and minimizes the cost and complexity of treatment to meet SDWA standards.

Some constituents of Delta water are of particular concern to municipal contractors because they are either not removed, or only partially removed, by community-used water treatment processes. Constituents of concern include total dissolved solids (TDS)[21], chlorides, bromides, and organic compounds. These substances can be removed from raw water by advance water treatment processes, but to do so substantially increases the cost borne by municipalities.

The Department of Public Health (DPH) is designated by the USEPA as the primary agency to administer and enforce requirements of the Federal SDWA in California. Public water systems are required to monitor for regulated contaminants in their drinking water supply. California's drinking water standards (e.g., MCLs) are the same or more stringent than the federal standards and include additional contaminants not regulated by the USEPA.

4.3.1.7 Federal Surface Water Treatment Rule

The Federal Surface Water Treatment Rule is implemented in the State of California by the California Surface Water Treatment Rule, which satisfies three specific requirements of the Federal SDWA by: (1) establishing criteria for determining when filtration is required for surface waters; (2) defining minimum levels of disinfection for surface waters; and (3) addressing *Cryptosporidium* spp., *Giardia lamblia*, *Legionella* spp., *E. coli*, viruses, turbidity, and heterotrophic plate count by setting a treatment technique. A treatment technique is set in lieu of an MCL for a contaminant when it is not technologically or economically feasible to measure that contaminant. The Surface Water Treatment Rule applies to all drinking water supply activities in California, and implementation is overseen by DPH.

[19] The maximum concentration of a pollutant that is allowed in drinking water systems; the level below which there is no known or expected risk to health.

[20] Raw water is untreated water from either a surface or groundwater source.

[21] Total Dissolved Solids (TDS) are the total amount of mobile charged ions, including minerals, salts or metals dissolved in a given volume of water, expressed in units of mg per unit volume of water (mg/L), also referred to as parts per million (ppm).

National Toxics Rule

In 1992, pursuant to the CWA, the USEPA promulgated the National Toxics Rule (NTR) to establish water quality criteria for 14 states and two territories, including California, that had not complied fully with §303(c)(2)(B) of the CWA. As described in the preamble to the final NTR, when a state adopts water quality criteria consistent with the requirements of §303(c)(2)(B) of the CWA, and the USEPA approves, the USEPA will issue a rule amending the NTR to withdraw the federal criteria for that state. If the state's criteria are no less stringent than the promulgated federal criteria, the USEPA will withdraw its criteria and commence rulemaking without notice because additional comment on the criteria is unnecessary. However, if a state adopts criteria that are less stringent than the federally promulgated criteria, but in the USEPA's judgment fully meet the requirements of the CWA, the USEPA will provide an opportunity for public comment before withdrawing the federally promulgated criteria. The result is the California Toxics Rule (CTR) and the §303(d) list of impaired waters.

Long Term Management Strategy for the Placement of Dredged Material in the San Francisco Bay Region

The *Long-Term Management Strategy (LTMS) for the Placement of Dredged Material in the San Francisco Bay Region* is a cooperative effort of USEPA, USACE, the SWRCB, the San Francisco Bay RWQCB, and the San Francisco BCDC to develop a new approach to dredging and disposal of dredged materials in the San Francisco Bay Area. An average of six million cubic yards of sediment must be dredged every year to maintain safe navigation in and around San Francisco Bay, resulting in controversy surrounding appropriate management of such an effort. The following are the major goals of the LTMS:

- Maintain in an economically and environmentally sound manner those channels necessary for navigation in San Francisco Bay and Estuary and eliminate unnecessary dredging activities in the Bay and Estuary.
- Conduct dredged material disposal in the most environmentally sound manner.
- Maximize the use of dredged material as a resource.
- Establish a cooperative permitting framework for dredging and dredged material disposal applications.

The final policy environmental impact statement/programmatic environmental impact report for the LTMS addresses the salt ponds in and around south San Francisco Bay, mainly within the context of their role as habitat for the California least tern, snowy plover, California clapper rail, salt marsh harvest mouse, and California brown pelican. The presence of such species causes restrictions on potential management strategies, but disposal of dredged materials has potential benefits. For example, such disposal may create or restore seasonal wildlife habitats by raising and modifying topography, and thus improving wetland hydrology. Disposal of dredge material in the salt ponds would require a permit from the San Francisco BCDC.

Disinfectant and Disinfection Byproducts Rule

The 1986 amendments to the federal SDWA required USEPA to propose a rule for disinfectants and disinfection byproducts. The rule must balance the need for protection from cancer-causing chemicals (byproducts) with the need for protection from pathogenic microbes (bacteria, viruses, and protozoans) that are killed by disinfection. In 1992, USEPA began a rulemaking process called the "Reg-Neg" process. Negotiators in the process included staff members from State and local health and regulatory agencies, elected officials, consumer groups, environmental groups, and representatives from public water systems. The Reg-Neg process resulted in a two-stage approach for regulation development. The Stage 1 Disinfectant and Disinfection Byproduct Rule (DBP Rule) was promulgated in November 1998. Compounds affected under Stage 1 regulations of the DBP Rule include total trihalomethanes, total haloacetic acids, total organic carbon, bromate, chlorine, chloramines, chlorine dioxide, and chlorite.

The Stage 2 of the DBP Rule was promulgated in 2006. This final rule requires systems that deliver disinfected water to meet maximum contaminant levels as an average at each compliance monitoring location (instead of as a system-wide average as in previous rules) for two groups of DBPs, trihalomethanes and five haloacetic acids. The rule targets systems with the greatest risk and builds incrementally on existing rules. The rule also contains a risk-targeting approach to better identify monitoring sites where customers are exposed to high levels of DBPs.

Comprehensive Environmental Response, Compensation and Liability Act, as Amended

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) – or Superfund – provides federal funds to clean up uncontrolled or abandoned hazardous waste sites, accidents, spills, discharges, and other emergency releases of pollutants and contaminants into the environment. Through CERCLA, the USEPA was given power to seek out those parties responsible for any hazardous release, and assure their cooperation in the cleanup.

The Superfund Amendments and Reauthorization Act (SARA) of 1986 reauthorized CERCLA to continue cleanup activities around the country. Several site-specific amendments, definition clarifications, and technical requirements were added to the legislation, including additional enforcement authorities. Title III of SARA authorized the Emergency Planning and Community Right-to-Know Act.

Federal Insecticide, Fungicide, and Rodenticide Act, as Amended

The Federal Insecticide, Fungicide, and Rodenticide Act mandates that the USEPA regulate the sale and use of pesticides to protect human health and to protect the environment. The Act was initially passed in 1972 and has been repeatedly amended. Amendments to the Act strengthen the registration process, enforce compliance against banned or unregister chemicals, and provide a regulatory framework.

Federal Environmental Protection Agency Ambient Water Quality Criteria Recommendations for Rivers and Streams in Nutrient Ecoregion I

Ecoregional nutrient criteria are developed to represent surface waters that are minimally impacted by human activities and thus protect against the adverse effects of nutrient over-enrichment from cultural eutrophication. The USEPA's recommended process for developing such criteria includes physical classification of waterbodies, determination of current reference conditions, evaluation of historical data and other information (such as published literature), use of models to simulate physical and ecological processes or determine empirical relationships among causal and response variables (if necessary), expert judgment, and evaluation of downstream effects. The USEPA has used elements of this process to produce the information contained in this document. The causal (total nitrogen, total phosphorus) and biological and physical response (chlorophyll *a*, turbidity) variables represent a set of starting points for states and tribes to use in establishing their own criteria.

4.3.2 State Plans, Policies, and Regulations

The following State regulations apply to surface water quality, but are discussed in another section of this chapter, as indicated in parentheses:

- Porter-Cologne Water Quality Control Act (Surface Water Resources)
- State Water Resources Control Board Decision 1641 (D-1641) (Surface Water Resources)
- Water Quality Control Plan for the Sacramento/San Joaquin River Basins (Surface Water Resources)
- San Francisco Bay Basin Water Quality Control Plan (Surface Water Resources)

4.3.2.1 California Water Code, Section 13160

California Water Code, Section 13160, authorizes the SWRCB to act as the State water pollution control agency for purposes of compliance with Section 401 of the CWA. For an activity that may result in any discharge into navigable waters, Section 401 of the federal CWA requires a federal license or permit applicant to provide to the licensing or permitting agency a certification from the state in which the discharge originates that any such discharge will comply with State water quality standards and other appropriate requirements. The SWRCB administers the Section 401 program. Section 401 requires the SWRCB to find that there is a reasonable assurance that an activity will be conducted in a manner that will not violate applicable water quality standards and other appropriate requirements. Certification may be conditioned with other limitations to assure compliance with various CWA provisions.

4.3.2.2 State Water Resources Control Board Water Rights Decisions, Water Quality Control Plans, and Water Quality Objectives

The preparation and adoption of WQCPs is required by the California Water Code and supported by the CWA. According to Section 13050 of the California Water Code, WQCPs consist of a designation or establishment for the waters within a specified area of beneficial uses to be protected, water quality objectives to protect those uses, and a program of implementation needed for achieving the objectives. Because beneficial uses, together with their corresponding water quality objectives, can be defined per federal regulations as water quality standards, the WQCPs are regulatory references for meeting the State and federal requirements for water quality control. One substantial difference between the State and federal programs is that California's WQCPs establish standards for groundwater in addition to surface water. Adoption or revision of surface water standards is subject to the approval of the USEPA.

The SWRCB Water Rights Division has primary regulatory authority over water supplies and issues permits for water rights—specifying amounts, conditions, and construction timetables—for diversion and storage facilities. Water rights decisions implement the objectives adopted in water quality control plans and reflect water availability, recognize prior water rights and flows needed to preserve instream uses (such as water quality and fish habitat), and whether the diversion of water is in the public interest.

WQCPs adopted by RWQCBs are primarily implemented through the NPDES permitting system and issuance of waste discharge requirements to regulate waste discharges so that water quality objectives are met. Basin plans provide the technical basis for determining waste discharge requirements and authorize the RWQCBs to take regulatory enforcement actions if deemed necessary.

4.3.2.3 California Antidegradation Policy

The California Antidegradation Policy, formally known as the *Statement of Policy with Respect to Maintaining High Quality Waters in California* (SWRCB Resolution No. 68-16), restricts degradation of surface and ground waters. In particular, this policy protects water bodies where existing quality is higher than necessary for the protection of beneficial uses. Pursuant to the Antidegradation Policy, any actions that can adversely affect water quality in all surface and ground waters must (1) be consistent with maximum benefit to the people of the state, (2) not unreasonably affect present and anticipated beneficial use of the water, and (3) not result in water quality less than that prescribed in water quality plans and policies. Furthermore, any CFR §131.12) developed pursuant to the CWA.

4.3.2.4 Water Quality Control Plan for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary

The current WQCP in effect in the Delta is the 2006 WQCP for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary. The WQCP identifies beneficial uses of water in the Delta to be protected, water quality objectives for the reasonable protection of beneficial uses, and an implementation program to achieve the water quality objectives.

The 2006 WQCP adoption did not involve substantial changes to the prior 1995 WQCP. The 1995 WQCP was developed as a result of the December 15, 1994 Bay Delta Accord, which committed the SWP and CVP to new Delta habitat objectives. The new objectives were adopted by amendment through a water rights decision (D1641) for SWP and CVP operations. One key feature of the 1995 WQCP is the estuarine habitat objectives (X2) for Suisun Bay and the western Delta. The X2 standard refers to the position at which 2 ppt salinity occurs in the Delta estuary, and is designed to improve shallow water fish habitat in the spring of each year. The X2 standard requires specific daily or 14-day salinity, or three-day averaged outflow requirements, to be met for a certain number of days each month from February through June.

Other elements of the WQCP include export-to-inflow ratios intended to reduce entrainment of fish at the export pumps, DCC gate closures, minimum Delta outflow requirements, and San Joaquin River salinity and flow standards.

4.3.2.5 San Water Quality Control Plan for the North Coast

The North Coast WQCP was adopted in May 2011 and is a comprehensive plan. The plan describes water quality, water quality issues, and current and potential beneficial uses of water. The major components of the plan are beneficial uses, water quality objectives, implementation plans, and surveillance and monitoring.

4.3.2.6 Water Quality Control Plan for the Tulare Basin

The Tulare Basin WQCP was adopted in January 2014 and is a comprehensive plan. The plan describes surface and groundwater quality, water quality issues, and current and potential beneficial uses of water. The major components of the plan are beneficial uses, water quality objectives, implementation plans, plans and policies, and surveillance and monitoring. The plan addresses numerous water quality issues including; groundwater overdraft, agricultural chemical, well standards, oilfield waste water, and water transfers.

4.3.2.7 Central Valley Regional Water Quality Control Board Drinking Water Policy

A commitment of the CALFED Bay-Delta Program ROD was the development of a new drinking water policy for Delta waters. Currently, both the Bay-Delta WQCP and the Sacramento-San Joaquin Basin Plan lack numeric water quality objectives for several known drinking water constituents of concern, such as organic carbon and pathogens. In response to the CALFED commitment, the Central Valley RWQCB (CVRWQCB) is in the process of a multiyear effort to develop a drinking water policy for surface waters in the Central Valley. Existing policies and plans lack water quality objectives for several known drinking water constituents of concern, including DBP precursors and pathogens, and also lack implementation strategies to provide effective source water protection. The CVRWQCB Drinking Water Policy applies to Delta waters and any activities, such as discharges, that affect Delta water quality.

4.3.2.8 California Toxics Rule

As a result of a court-ordered revocation of California's statewide WQCP for priority pollutants in September 1994, CalEPA initiated efforts to promulgate additional numeric water quality criteria for California. In May 2000, CalEPA issued the CTR that promulgated numeric criteria for priority pollutants not included in the NTR. The CTR documentation carried forward the previously issued standards of the NTR, thereby providing a single document listing California's adopted and applicable water quality criteria for priority pollutants.

4.3.2.9 California Safe Drinking Water Act

In 1976, California enacted its own SDWA, requiring the Department of Public Health Services to regulate drinking water, including: setting and enforcing federal and State drinking water standards, administering water quality testing programs, and administering permits for public water system operations. The Federal SDWA allows the State to enforce its own standards in lieu of the federal standards so long as they are at least as protective as the federal standards. California's drinking water standards (e.g., MCLs) are the same or more stringent than the federal standards and include additional contaminants not regulated by the USEPA. Like the federal MCLs, California's primary MCLs address health concerns, while secondary MCLs address aesthetics, such as taste and odor. The California SDWA is administered by DPH primarily through a permit system.

4.4 Chapter 8: Fluvial Geomorphology and Riparian Habitat

4.4.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to fluvial geomorphology and riparian habitat, but are discussed in other section of this chapter, as indicated in parentheses:

- Coordinated Operations Agreement (Surface Water Resources)
- 2009 National Marine Fisheries Service Biological Opinion (Surface Water Resources)

4.4.1.1 Federal Endangered Species Act

FESA requires that both the USFWS and NMFS maintain lists of Threatened and Endangered Species. An "Endangered Species" is defined as "…any species which is in danger of extinction throughout all or a significant portion of its range." A "Threatened Species" is defined as "…any species that is likely to become an Endangered Species within the foreseeable future throughout all or a significant portion of its range". Section 9 of FESA makes it illegal to "take" (i.e., harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, collect, or attempt to engage in such conduct) any Endangered Species of fish, wildlife, or plants and contains similar provisions for most Threatened Species of fish, wildlife, and plants.

FESA also requires the designation of "critical habitat" for listed species. "Critical habitat" is defined as: (1) specific areas within the geographical area occupied by the species at the time of listing, if they contain physical or biological features essential to a species' conservation, and those features may require special management considerations or protection; and (2) specific areas outside the geographical area occupied by the species if the agency determines that the area itself is essential for conservation.

Section 7 of FESA requires all federal agencies to ensure that any action they authorize, fund, or carry-out is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of designated critical habitat. To ensure against jeopardy, each federal agency must consult with USFWS or NMFS, or both, if the federal agency determines that its action might affect a listed species. NMFS' jurisdiction under FESA is limited to the protection of marine mammals, marine fish, and anadromous fish; all other species are within the jurisdiction of USFWS.

If an activity would result in the take of a federally listed species, one of the following is required: (1) an Incidental Take Permit issued as part of an approved Habitat Conservation Plan (HCP) under Section 10(a) of FESA; or (2) an Incidental Take Statement issued pursuant to federal interagency consultation under Section 7 of FESA. Such authorization typically requires various measures to avoid and minimize species take, and to protect the species and avoid jeopardy to the species continued existence.

Where a federal agency is not authorizing, funding, or carrying out a project, take that is incidental to the lawful operation of a project may be permitted pursuant to Section 10(a) of FESA through approval of an HCP.

U.S. Fish and Wildlife Service Operations Criteria and Plan Biological Opinion

On December 15, 2008, the USFWS issued its biological opinion on the Operations Criteria and Plan (OCAP). The USFWS concurred with Reclamation's determination that the coordinated operations of the CVP and the SWP are not likely to adversely affect listed species, with the exception of delta smelt. The USFWS concluded that the coordinated operations of the CVP and the SWP, as proposed, were likely to jeopardize the continued existence of the delta smelt, and adversely modify delta smelt critical habitat. Although the opinion identified a number of stressors that affect delta smelt which are unrelated to CVP and SWP operations, their effects could not be assessed. Consequently, the USFWS developed RPAs as alternative actions to avoid the likelihood of jeopardizing the continued existence or the destruction or adverse modification of critical habitat for delta smelt. These actions include: (1) preventing/reducing entrainment of delta smelt at Jones and Banks pumping plants; (2) providing adequate habitat conditions that will allow the adult delta smelt to successfully migrate and spawn in the Bay-Delta; (3) providing adequate habitat conditions that will allow larvae and juvenile delta smelt to rear; and (4) providing suitable habitat conditions that will allow successful recruitment of juvenile delta smelt to adulthood. In addition, USFWS specified that it is essential to monitor delta smelt abundance and distribution through continued sampling programs through the Interagency Ecological Program (IEP).

4.4.2 State Plans, Policies, and Regulations

4.4.2.1 Senate Bill 1086

Senate Bill (SB) 1086 created the Sacramento River Conservation Area Advisory Council. The legislation required the development of a Sacramento River management plan which promotes the protection, restoration, and enhancement of both fisheries and riparian habitat while ensuring that other community needs are met, including agricultural production, public safety, public and private infrastructure, economic stability, and public recreation. The plan, the *Upper Sacramento River Fisheries and Riparian Habitat Management Plan,* was published in 1989.

4.4.2.2 California Endangered Species Act of 1982

The California Endangered Species Act (CESA) declares that deserving plant or animal species will be given protection by the State because they are of ecological, educational, historical, recreational, aesthetic, economic, and/or scientific value to the people of California. CESA established that it is State policy to conserve, protect, restore, and enhance endangered species and their habitats. CESA pertains only to State-listed rare, threatened, or endangered plant and wildlife species. CESA requires State agencies to consult with CDFG when preparing CEQA documents to ensure that agency actions do not jeopardize State-listed species.

4.5 Chapter 9: Flood Control and Management

4.5.1 Federal Plans, Policies, and Regulations

4.5.1.1 Executive Order 11988, Floodplain Management

Executive Order (EO) 11988 requires federal agencies to avoid, to the extent possible, the long and short-term adverse impacts associated with the occupancy and modification of floodplains and to avoid direct and indirect support of floodplain development wherever there is a practicable alternative. In accomplishing this objective, “each agency shall provide leadership and shall take action to reduce the risk of flood loss, to minimize the impact of floods on human safety, health, and welfare, and to restore and preserve the natural and beneficial values served by flood plains in carrying out its responsibilities” for the following actions:

- Acquiring, managing, and disposing of federal lands and facilities
- Providing federally-undertaken, -financed, or -assisted construction and improvements
- Conducting federal activities and programs affecting land use, including but not limited to water and related land resources planning, regulation, and licensing activities.

4.5.1.2 Clean Water Act Section 408

USACE’s §408 approval is required before approval and implementation of any proposed project that may affect any existing USACE (and/or Project) levee in the Central Valley and Delta. Section 2035 of the Federal Water Resources Development Act of 2007 requires that flood damage reduction projects be reviewed by independent experts if it is determined that a review is necessary to assure public health, safety, and welfare.

4.5.1.3 Federal Emergency Management Agency

The Federal Emergency Management Agency (FEMA) is responsible for maintaining minimum federal standards for floodplain management within the United States and territories of the United States. As discussed below, FEMA plays a major role in managing and regulating floodplains. FEMA is responsible for management of floodplain areas, which are defined as the lowland and relatively flat areas adjoining inland and coastal waters subject to a one percent or greater chance of flooding in any given year (the 100-year floodplain).

<u>**National Flood Insurance Program**</u>

The National Flood Insurance Program (NFIP) is administered primarily under two statutes: the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973. The Federal Insurance Administration under FEMA administers NFIP. NFIP has two main components: (1) floodplain management assistance and (2) flood insurance assistance. The purpose of flood insurance is to enable property owners to purchase insurance against losses from physical damage or the loss of buildings and their contents caused by floods, flood-related mudslides, or erosion. Insurance is available to property owners belonging to NFIP-participating communities. Participation in NFIP also makes communities eligible for federal flood disaster assistance. For a community to be eligible to participate in NFIP, the community must adopt a local floodplain management ordinance that meets or exceeds the minimum federal standards defined in 44 CFR 60 to 65. Participating communities must adhere to all floodplain management requirements, with oversight from FEMA, for all activities that may affect floodplains within the Special Flood Hazard Areas (SFHA).

Federal Emergency Management Agency Flood Zones

FEMA mapping provides important guidance in planning for flooding events and regulating development within identified flood hazard areas. FEMA's NFIP is intended to encourage State and local governments to adopt responsible floodplain management programs and flood measures. As part of the program, NFIP defines floodplain and floodway boundaries that are shown on Flood Insurance Rate Maps (FIRMs). DWR completed work to map the 200-year floodplain for many areas of California.

Flood Zone Regulations

SFHAs are subject to federal and State requirements, which are defined primarily by federal regulations at 44 CFR 60.3 and 44 CFR 65.12. The first citation requires the following:

These federal regulations are intended to address the need for effective floodplain management and provide assurance that the cumulative effects of floodplain encroachment do not cause more than a one foot rise in water surface elevation after the floodplain has been identified on the FIRM (local flood ordinances can set a more stringent standard). The absence of a detailed study or floodway delineation places the burden on the project proponent to perform an appropriate engineering analysis to prepare hydrologic and hydraulic analyses consistent with FEMA standards. These analyses would then be used to evaluate the proposed project together "with all other existing and anticipated development." Defining future anticipated development is difficult. The purpose of this requirement is to avoid inequitable encroachments into the floodplain.

FEMA Levee Design and Maintenance Regulations

For levees to be accredited by FEMA, and to allow communities to participate in Preferred Risk programs of NFIP, evidence must be provided that adequate design, operation, and maintenance systems are in place to provide reasonable assurance that protection from the base flood (one percent annual chance of exceedance or 100-year flood) exists. These requirements are outlined in 44 CFR, Volume 1, Chapter I, Part 65.10.

4.5.1.4 Federal Emergency Management Agency 100-year Protection Standard

The FEMA 100-year Protection Standard, often called the one percent annual chance flood level of protection, is based on criteria established in the CFR and is often used with established USACE criteria to meet certain freeboard, slope stability, seepage/under-seepage, erosion, and settlement requirements. Numerical hydrologic models are used to project surface water elevations at different locations in the rivers for the statistically probable 100-year flood event. Model runs are updated periodically to reflect changes in river bathymetry and historical hydrology. Meeting this level of flood protection means that communities will not require mandatory purchase of flood insurance for houses in the floodplain or be subject to building restrictions. This standard generally does not address seismic stability. Currently, FEMA 100-year criteria are based on historical conditions and do not include considerations for climate change or sea level rise. FEMA is currently completing a study on the *Impact of Climate Change on the National Flood Insurance Program* to determine how to accommodate these factors and the long-term implications.

4.5.1.5 U.S. Army Corps of Engineers

The following discussion provides an overview of USACE's regulatory responsibilities that apply to navigable waters and construction within the ordinary high water mark of other waters of the U.S. In addition, USACE constructs flood control and risk management projects and monitors their operations and maintenance. It also provides emergency response to floods. These functions are described below.

1936 Flood Control Act

USACE constructs local flood control and risk management projects and navigation projects. The Flood Control Act of 1936 established a nationwide policy that flood control on navigable waters or their tributaries is in the interest of the general public welfare and is, therefore, a proper activity of the federal government in cooperation with states and local entities. The 1936 Flood Control Act, its amendments, and subsequent legislation specify details of federal participation. Projects are either specifically authorized through legislation by Congress or through a small projects blanket authority. Typically, a feasibility study is done to determine federal interest before authorization or construction.

U.S. Army Corps of Engineers Rehabilitation and Inspection Program

The Rehabilitation and Inspection Program is a USACE program that provides for the inspection of flood-control projects, the rehabilitation of damaged flood-control projects, and the rehabilitation of federally authorized and constructed hurricane or shore-protection projects. Levees in the program are eligible for federally funded repair and rehabilitation for damage induced by flood events, provided funding is available. The project levees (those levees previously authorized or constructed under a federal flood-control project) are eligible for the program as long as the non-federal sponsor maintains the levees to certain federal standards. Repairs and rehabilitation are accomplished under provisions of Public Law 84-99, with some cost-sharing normally required for non-project levees. Non-project levees are managed and maintained by local districts, as opposed to project levees, which are part of a larger regional or State project, and managed and maintained by a federal or State agency.

Operations and Maintenance Controls, Flood Control Projects

The maintenance and operation of federal project levee structures is discussed in 33 CFR 208.10. According to these regulations, no improvement shall be passed over, under, or through the walls, levees, improved channels, or floodways, nor shall any excavation or construction be permitted within the limits of the project right-of-way, nor shall any change be made in any feature of the works without prior determination by the District Engineer of the Department of the Army or his or her authorized representative that such improvement, excavation, construction, or alteration will not adversely affect the function of the protective facilities. This regulation is the basis for requiring a permit prior to any construction at federal project levees. Types of alterations/modifications typically covered by a CFR 208 permit include bridges, pump houses, stairs, pipes, bike trails, and power poles.

Rivers and Harbors Act Section 14

33 United States Code 408 and Section 14 of the Rivers and Harbors Act provide that the Secretary of the Army, on the recommendation of the Chief of Engineers, may grant permission for the temporary occupation or use of any sea wall, bulkhead, jetty, dike, levee, wharf, pier, or other work built by the United States. This permission will be granted by an appropriate real estate instrument in accordance with existing real estate regulations. This regulation is used to require permits prior to modifications of federal project levees. Types of alterations typically requiring a Section 408 permit are major modifications such as degradations, raisings, and realignments.

4.5.2 State Plans, Policies, and Regulations

4.5.2.1 Central Valley Flood Protection Board Approval

The Central Valley Flood Protection Board (CVFPB) was previously known as the Reclamation Board. In 1855, California passed the Reclamation District (RD) Act providing for the sale of swamp lands. RDs were formed and were regulated so that construction of levees occurred along hydrologic boundaries (rather than along property lines). Islands in the Delta are ringed with levees that have their own districts for maintenance.

The CVFPB mission is to control flooding along the Sacramento and San Joaquin rivers and their tributaries in cooperation with USACE; to cooperate with various federal, State, and local agencies in establishing, planning, constructing, operating, and maintaining flood control works; and to maintain the integrity of the existing flood control system and designated floodways through the CVFPB’s regulatory authority by issuing permits for encroachments.

CVFPB is a major sponsor of federal flood risk management projects. It shares in construction cost; provides lands, easements, and rights-of-way; and assumes responsibility for operation and maintenance. CVFPB also approves or denies plans for reclamation, dredging, or improvements that alter any project levee. It has the authority to approve or deny any land reclamation plan (related to public works) or flood protection that involves excavation near rivers and tributaries, and has legal responsibility for oversight of the entire Central Valley flood management system.

4.5.2.2 Assembly Bill 1200

Assembly Bill (AB) 1200 highlighted the complex Delta water issues. AB 1200 amends Section 139.2 of the Water Code to read “The department shall evaluate the potential impacts on water supplies derived from the Delta based on 50-, 100-, and 200-year projections for each of the following possible impacts on the Delta”: subsidence; earthquakes; floods; changes in precipitation, temperature, and ocean levels; or any combination of these impacts.

The bill directs DWR and CDFG to report to the Legislature and Governor on the potential impacts of levee failures on Delta water supplies, options to reduce the impacts of these factors, and options to restore salmon and other fisheries that use the Delta estuary.

In response to the bill, DWR and CDFG have issued a report, *Risks and Options to Reduce Risks to Fishery and Water Supply Uses of the Sacramento/San Joaquin Delta*, dated January 2008. This report summarizes the potential risks to water supplies in the Sacramento-San Joaquin Delta attributable to future subsidence, earthquakes, floods, and climate change, and identifies improvements to reduce the impacts and options to deliver water.

4.5.2.3 Department of Water Resources' FloodSAFE California Initiative

In January 2005, Governor Arnold Schwarzenegger called for improved maintenance, system rehabilitation, effective emergency response, and sustainable funding to lower flood risks in California. In 2006, DWR launched FloodSAFE California, a multifaceted program to improve public safety through integrated flood management. Water Code Section 9602 (added by SB 5) requires a minimum level of flood protection for urban areas in the Sacramento and San Joaquin river watersheds. These areas must be able to withstand flooding that has a one-in-200 annual chance of occurrence. State Propositions 1E and 84, with legislative direction, allocated 67 percent of FloodSAFE funds to the Central Valley and Delta for repairs and improvements to levees and flood projects. FloodSAFE goals include reducing the frequency and size of flooding of communities, reducing the consequences of flooding, and protecting and enhancing ecosystems.

4.5.2.4 The State Plan of Flood Control Descriptive Document

DWR completed the State Plan of Flood Control (SPFC) Descriptive Document (November 2010) to meet the legislative requirements of California Water Code §9614, in part, for the Central Valley Flood Protection Plan (CVFPP). The SPFC Descriptive Document provides the first complete inventory and description of the SPFC as defined in §9110(f) of the California Water Code:

> *"State Plan of Flood Control" means the State and federal flood control works, lands, programs, plans, conditions, and mode of maintenance and operations of the Sacramento River Flood Control Project described in §8350, and of flood control projects in the Sacramento River and San Joaquin River watersheds authorized pursuant to Article 2 (commencing with §12648) of Chapter 2 of Part 6 of Division 6 for which the board or the department has provided the assurances of nonfederal cooperation to the United States, and those facilities identified in §8361."*

The State-federal flood protection system comprises federally- and State-authorized projects for which the CVFPB or DWR has provided assurances of cooperation to the United States federal government. These CVFPB- or DWR-provided assurances, coupled with State authorization, are an important distinction for what constitutes the State-federal flood protection system. Other flood protection facilities in the Sacramento River and San Joaquin River watersheds that are not covered by assurances to the federal government from the CVFPB or DWR are not part of the State-federal flood protection system or SPFC, but are included in the Sacramento-San Joaquin River Flood Management System defined in the California Water Code §9611.

4.5.2.5 Senate Bill 5

SB 5, signed into law in October 2007, updates the California Health and Safety Code to require DWR to propose updated requirements to the California Building Standards Code. The requirements proposed for adoption and approval by the California Building Standards Commission would be for construction in areas protected by the facilities of the CVFPP where flood levels are anticipated to exceed three feet for the 200-year flood event. Before DWR proposes the amendments to the California Building Standards Code, the Department is to consult with the CVFPB, the Division of the State Architect, and the Office of the State Fire Marshal.

4.5.2.6 Assembly Bill 162

AB 162 requires the land use element of the general plan of any city or county located within the boundaries of the Sacramento-San Joaquin Drainage District to identify and annually review those areas covered by the general plan that are subject to flooding as identified by flood plain mapping prepared by FEMA or DWR. The bill also requires, upon the next revision of the housing element, on or after January 1, 2009, the conservation element of the general plan to identify rivers, creeks, streams, flood corridors, riparian habitat, and land that may accommodate floodwater for purposes of groundwater recharge and stormwater management.

This bill also requires, upon the next revision of the housing element, on or after January 1, 2009, the safety element to identify, among other things, information regarding flood hazards and to establish a set of comprehensive goals, policies, and objectives, based on specified information for the protection of the community from, among other things, the unreasonable risks of flooding.

4.5.2.7 California Water Code

The Senate and Assembly bills identified above have resulted in various changes and additions to the California Water Code, including Section 8609. Section 8609 states that the board may designate floodways throughout the Sacramento and San Joaquin rivers drainage to control encroachments in, and to preserve the flow regimens of, floodways for the purpose of protecting public improvements, lives, land use values, and improvements created in reliance upon historical flooding patterns. “Sacramento and San Joaquin Rivers drainage,” or equivalent language, means all lands currently and historically drained by the Sacramento River and the San Joaquin River and their tributaries and distributaries.

California Water Code, Division 3: Dams and Reservoirs

California Water Code, Division 3: Dams and Reservoirs requires DWRs Division of Safety of Dams (DSOD) to supervise the construction, maintenance, and operation of dams and reservoirs to safeguard life and property from injury due to failure. The code section further requires DWR to evaluate the possibility that a dam or reservoir might be endangered due to seepage, earth movement or other conditions and to require the dam or reservoir owner to take appropriate actions to remove the danger to life and property. Federally owned dams and reservoirs are not under State jurisdiction, except as noted under federal law.

Sacramento-San Joaquin River Basin Comprehensive Study

The Comprehensive Study, which has been undertaken as a collaborative effort between USACE and DWR, released the first interim report in late 2002. The CVFPB will provide the administrative structure of the plan developed per the Comprehensive Study.

Sacramento River Flood Control Project

The Sacramento River Flood Control Project (SRFCP) is actually six interrelated projects undertaken by USACE, including reservoirs constructed on major rivers, which constitute the largest flood control system in the State. Project facilities extend from north of Colusa County southward to the Sacramento-San Joaquin Delta, approximately 230 miles along the Sacramento River corridor. Levees and associated facilities of the SRFCP have been constructed along five rivers, 15 creeks and 13 sloughs. In addition, human-made or human-modified facilities include six bypasses and 11 channels.

Sacramento River Bank Protection Project

As authorized by the Flood Control Act of 1970, the Sacramento River Bank Protection Project (SRBPP) is an ongoing construction and maintenance project. The SRBPP provides protection for existing flood control infrastructure, including levees, of the SRFCP.

4.5.3 Regional and Local Plans, Policies, and Regulations

4.5.3.1 Glenn County General Plan

Section 5.25 of the Glenn County General Plan identifies the following policies to address potential flood hazards:

- Recognize the special status of lands located within the designated floodways adopted by the State Reclamation Board.
- Support efforts to revise the FEMA FIRMs for the areas around Hamilton City, Willows, and Orland in order to improve their accuracy.
- Endeavor to avoid areas subject to flooding when considering approval of new development.
- Require the installation of storm drain and other flood protection/prevention improvements as a condition of all new development approvals.
- Encourage the formation of a countywide service area or individual storm drain maintenance districts to finance and construct needed flood control improvements.

4.5.3.2 Colusa County General Plan

The Colusa County General Plan identifies the following policies related to flood protection:

- **SAFE-1:** Floodplains should generally be maintained as open space. In these areas, their use for agriculture, recreation, preservation of vegetation and wildlife habitat, and scenery should be encouraged.
- **SAFE-2:** Urban development should be discouraged in the 100-year floodplain. Any habitable structure which is permitted shall be built so that the first floor of living area is above the 100-year flood elevation.
- **SAFE-3:** No critical or high-occupancy structures such as schools, hospitals, police, facilities, or fire stations should be built within the 100-year floodplain.
- **SAFE-4:** The County should support coordinated efforts to maintain levees along the Sacramento River and the 2047 canal.
- **SAFE-5:** Flood control policies in the Community Services Element should be supported to reduce the hazards associated with flooding.

4.5.3.3 Colusa County Code, Chapter 33: Flood Damage Prevention

It is the purpose of this chapter to promote the public health, safety, and general welfare, and to minimize public and private losses due to flood conditions in specific areas by provisions designed to:

(A) Protect human life and health;

(B) Minimize expenditure of public money for costly flood control projects;

(C) Minimize the need for rescue and relief efforts associated with flooding and generally undertaken at the expense of the general public;

(D) Minimize prolonged business interruptions;

(E) Minimize damage to public facilities and utilities such as water and gas mains; electric, telephone and sewer lines; and streets and bridges located in areas of special flood hazard;

(F) Help maintain a stable tax base by providing for the sound use and development of areas of special flood hazard so as to minimize future blighted areas caused by flood damage,

(G) Ensure that potential buyers are notified that property is in an area of special flood hazard; and

(H) Ensure that those who occupy the areas of special flood hazard assume responsibility for their actions.

To accomplish its purposes, this section includes methods and provisions to:

(A) Restrict or prohibit uses which are dangerous to health, safety, and property due to water or erosion hazards, or which result in damaging increases in erosion or flood heights or velocities;

(B) Control filling, grading, dredging, and other development which may increase flood damage;

(C) Require that uses vulnerable to floods, including facilities which serve such uses, be protected against flood damage at the time of initial construction;

(D) Control the alteration of natural floodplains, stream channels, and natural protective barriers, which help accommodate or channel floodwaters; and

(E) Prevent or regulate the construction of flood barriers which will unnaturally divert floodwaters or which may increase flood hazards in other areas.

A development permit shall be obtained before any construction or other development begins within any area of special flood hazard established in Section 33-3.2. Application for a development permit shall be made on forms furnished by the floodplain administrator and may include, but not be limited to: plans in duplicate drawn to scale showing the nature, location, dimensions, and elevation of the area in question; existing or proposed structures, fill, storage of materials, drainage facilities; and the location of the foregoing. Specifically, the following information is required:

(a) Proposed elevation in relation to mean sea level, of the lowest floor (including basement) of all structures in zone A, elevation of highest adjacent grade and proposed elevation of lowest floor of all structures; or

(b) Proposed elevation in relation to mean sea level to which any nonresidential structure will be flood-proofed, if required in Subsection 33-5.1(C)(3); and

(c) All appropriate certifications listed in Subsection 33.4.3(d) of this chapter; and

(d) Description of the extent to which any watercourse will be altered or relocated as a result of proposed development.

4.5.3.4 Colusa County Flood Control and Conservation District

The Colusa County Flood Control and Conservation District (District) is overseen by the County Board of Supervisors. The purpose of the District is to plan and obtain funding for flood control activities, measures, and projects within the County.

4.5.3.5 Colusa County Floodplain Administrator

The Colusa County Director of Public Works is appointed to administer, implement and enforce Chapter 33 (Flood Damage Prevention) of the Colusa County Code regulations relating to flood management.

The floodplain administrator must:

- Review all development permits to determine that all county, State, and federal permits have been obtained; that a development site is reasonably safe from flooding, and that the proposed development will not adversely alter existing base flood elevations
- Review other base flood data obtained from a federal, State, or other source before its use, and must submit the additional base flood data to the county for adoption
- Notify adjacent communities, DWR, the Federal Insurance Administration, and FEMA prior to the alteration or relocation of a watercourse
- Certify, maintain, and make available to the public documentation of floodplain development including lowest floor elevations and pad elevations for proposed structures, flood-proofing of non-residential structures, and floodway encroachments
- Make flood hazard map boundary location determinations

The floodplain administrator has the authority to take action to remedy code violations and to decide appeals regarding the enforcement and administration of Chapter 33 codes.

4.6 Chapter 10: Groundwater Resources

4.6.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to groundwater resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- National Environmental Policy Act (General)Federal Safe Drinking Water Act (42 USC 300f) (Surface Water Quality)
- Federal Antidegradation Policy (40 CFR 131.6) (Surface Water Quality)
- Clean Water Act (33 USC 1251–1376) (Surface Water Resources)

These regulations were not specifically promulgated to protect or administer regulations related to groundwater. However, their implementation may directly or indirectly affect groundwater conditions.

4.6.2 State Plans, Policies, and Regulations

The following State regulation is applicable to groundwater resources, but is discussed in another section of this chapter, as indicated in parentheses:

- California Environmental Quality Act (General)

California does not regulate the overall use, entitlement, and management of groundwater. Although statewide groundwater regulations have been considered several times in the past, the California Legislature considers groundwater management to be a local responsibility. Several State regulations do specifically address groundwater, and others include groundwater among other physical units, such as surface water. Most of the regulations that include groundwater among other regulated entities are presented in other sections. State regulations that specifically address groundwater as the primary objective or as a major component are presented below.

4.6.2.1 Area of Origin Statute Limitations (California Water Code 1220)

California Water Code 1220 prohibits the pumping of groundwater "for export within the combined Sacramento and Delta-Central Sierra Basins…unless the pumping is in compliance with a groundwater management plan that is adopted by [county] ordinance." The statute enables, but does not require, the board of supervisors of any county within any part of the combined Sacramento and Delta-Central Sierra Basin to adopt groundwater management plans (GWMPs).

4.6.2.2 Groundwater Management (Assembly Bill 3030)

AB 3030 (1992) enables local water agencies to develop and implement GWMPs to manage the groundwater resources in the jurisdiction of the participating parties. The State does not maintain a statewide program or mandate its implementation, but the legislation provides the guidelines and common framework through which groundwater management can be implemented. Groundwater management legislation was amended in 2002 with the passage of SB 1938, which provided additional groundwater management components supporting eligibility to obtain public funding for groundwater projects. In 2000, AB 3030 enabled the development of the Local Groundwater Assistance Grant Program which provides financial support to local public agencies that are developing groundwater management and monitoring programs in their area.

4.7 Chapter 11: Groundwater Quality

4.7.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to groundwater quality, but are discussed in other sections of this chapter, as indicated in parentheses:

- Federal Safe Drinking Water Act of 1974 (Surface Water Quality)
- Clean Water Act of 1977 (Surface Water Resources)
- Federal Antidegradation Policy (Surface Water Quality)
- Porter-Cologne Water Quality Control Act (Surface Water Resources)

4.7.2 State Plans, Policies, and Regulations

The following State regulations apply to groundwater quality, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Antidegradation Policy (Surface Water Quality)
- Water Quality Control Plan for California Regional Water Quality Control Board Central Valley Region (Surface Water Quality)
- Water Quality Control Plan for the San Francisco Bay/Sacramento San Joaquin Delta Estuary (Surface Water Quality)
- Water Quality Control Plan for Tulare Lake Basin (Surface Water Quality)
- Water Quality Control Plan for the North Coast Region (Surface Water Quality)
- Water Quality Control Plan for the Sacramento/San Joaquin River Basins (Surface Water Resources)
- San Francisco Bay Basin Water Quality Control Plan (Surface Water Resources)

4.7.2.1 California Code of Regulations – Underground Storage Tanks and Oil or Gas Wells

Title 23, Division 3, Chapter 16, Article 7 of the California Code of Regulations (CCR) describes the underground storage tank closure requirements which shall be accomplished in order to protect water quality. The requirements for permanent closure in place or removal apply to those underground storage tanks in which the storage of hazardous substances has ceased and tanks will not be used, or are not intended for use, for the storage of hazardous substances within the next 12 consecutive months.

Title 14, Division 2, Chapter 4, Article 3 of the CCR describes the rules and regulations governing the environmental protection measures that shall be taken when plugging and abandoning oil or gas wells. Requirements include the removal of all tanks, above-ground pipelines, debris, and other facilities and equipment.

4.7.3 Regional and Local Plans, Policies, and Regulations

The following local regulations apply to groundwater quality, but are described in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.7.3.1 Glenn County Groundwater Ordinance and Management Plan

The Glenn County groundwater management area includes areas of the county where irrigated agriculture is conducted, which is subdivided into 17 sub-areas and managed by individual sub-area, rather than at a countywide level. The Glenn County GWMP is based on established basin management objectives for minimum groundwater levels, minimum water quality, and maximum inelastic subsidence.

4.7.3.2 Colusa County Groundwater Management Plan

The Colusa County GWMP describes the groundwater management goals, basin management objectives, specific actions that will be implemented to manage groundwater resources, and a detailed groundwater management process that will be followed to achieve the groundwater management goals at a county-wide level. The plan is intended to be implemented in concert with the adopted groundwater management plans of existing water and irrigation districts, reclamation districts, cities, and public utility districts.

4.8 Chapter 12: Aquatic Biological Resources

4.8.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to aquatic biological resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Federal Endangered Species Act (Fluvial Geomorphology and Riparian Habitat)
- USFWS Operations Criteria and Plan Biological Opinion (Fluvial Geomorphology and Riparian Habitat)
- NMFS Operations Criteria and Plan Biological Opinion (Surface Water Resources)
- Clean Water Act (Surface Water Resources)
- Rivers and Harbors Act (Surface Water Quality)
- Central Valley Project Improvement Act (Surface Water Resources)
- National Environmental Policy Act (General)

4.8.1.1 Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act is the principal law governing marine fisheries in the United States. The purpose of this federal act is to conserve and manage anadromous fishery resources of the United States. The act establishes eight Regional Fishery Management Councils to prepare, monitor, and revise fishery management plans, which will achieve and maintain the optimum yield from each fishery. In California, the Pacific Fishery Management Council (PFMC) is responsible for achieving the objectives of the statute. The Secretary of Commerce has oversight authority. The statute was amended in 1996 to establish a new requirement to describe and identify “essential fish habitat” (EFH) in each fishery management plan. EFH is defined as “those waters and substrates necessary to fish for spawning, breeding, feeding, or growth to maturity.” EFH also includes all habitats necessary to allow the production of commercially valuable aquatic species, to support a long-term sustainable fishery, and contribute to a healthy ecosystem.

EFH has been established by the National Oceanic and Atmospheric Administration Fisheries for waters in California supporting anadromous fish. In 1999, the Pacific Fishery Management Council identified EFH for Central Valley Chinook salmon stocks to include the Sacramento and San Joaquin rivers.

4.8.1.2 U.S. Fish and Wildlife Service Recovery Plan for Sacramento-San Joaquin Delta Native Fishes

This recovery plan covers eight species of concern, including the delta smelt, longfin smelt, Sacramento splittail, Sacramento perch, green sturgeon, spring-, late fall-, and San Joaquin fall-run Chinook salmon. The basic goal of the plan is to establish self-sustaining populations of these species. The purpose and scope of the plan is to outline a strategy for the conservation and restoration of the Sacramento-San

Joaquin Delta that currently supports or has the potential to support Delta native fishes. It is intended to fulfill one of the primary purposes under Section 2 of FESA, which is to provide a means for the conservation of ecosystems upon which endangered and threatened species depend.

Since the Recovery Plan for Sacramento-San Joaquin Delta Native Fishes was released in 1996, new information regarding the status, biology, and threats to Delta native species has emerged. Ongoing revision of the plan will review the new information and develop a strategy for the conservation and restoration of Delta native fish through the identification of recovery actions that specifically address the threats to their existence.

4.8.1.3 National Marine Fisheries Service Recovery Planning for Salmon and Steelhead in California

In the Central Valley, NMFS is responsible for facilitating the development of recovery plans for:

- The Sacramento River Winter-run Chinook Salmon Evolutionarily Significant Unit (ESU)[22]
- The Central Valley Spring-run Chinook Salmon ESU
- Central Valley Steelhead Distinct Population Segment (DPS)
- The Southern DPS of North American Green Sturgeon

The California Central Valley Recovery Domain[23] extends from the upper Sacramento River Valley to the northern portion of the San Joaquin River Valley. The Public Draft Recovery Plan for the ESUs of Sacramento River winter-run Chinook salmon and Central Valley spring-run Chinook salmon and the DPS of Central Valley steelhead was released in October 2009. A recovery plan for green sturgeon will be developed in the future by NMFS.

The NMFS Technical Recovery Team has produced four documents on:

- Current and historical population distributions of winter- and spring-run Chinook salmon
- Historical population distributions of Central Valley steelhead
- Population viability
- Research and monitoring needs

These documents provided the foundation for the Public Draft Central Valley Salmonid Recovery Plan. The recovery plan's objective is to reintroduce salmonid populations in historic habitats and reduce threats to the populations.

For the Central Valley Chinook salmon ESUs and the steelhead DPS to achieve recovery, each diversity group must be represented, and population redundancy within the groups must be met to achieve diversity group recovery. Several priority recovery actions to address specific limiting factors were identified by NMFS to help meet recovery objectives:

- Protect and restore watershed and estuarine habitat complexity and connectivity

- Improve understanding of life stage survival through focused research and monitoring

---

22 Evolutionary significant unit- a population of organisms that is considered distinct for the purpose of conservation. This term is functionally the same as a distinct population segment, but this term is primarily used by USFWS.
23 California Central Valley Recovery Domain extends from the upper Sacramento River Valley to the northern portion of the San Joaquin River Valley.

- Establish at least two additional populations of winter-run Chinook salmon that are spatially diverse and secure from natural and human-made threats
- Develop more effective and efficient federal and State mechanisms to correct already documented threats to listed salmonids
- Collaboratively balance water supply and allocation with fisheries' needs through improving criteria for water drafting, storage and dam operations, water right programs, development of passive diversion devices and/or offstream storage, elimination of illegal diversions (accusation of diverting water without an appropriate permit) in priority watersheds and streams, and other such opportunities
- Screen appropriate water diversions and provide adequate downstream flows
- Provide outreach to federal action agencies regarding FESA Section 7(a)(1) and carry out programs to conserve and recover federally listed salmonids
- Identify and treat point and non-point source pollution to streams from wastewater, agricultural practices, and urban environments

4.8.1.4 Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (FWCA) gives the U.S. Secretary of Interior the authority to provide assistance to federal, State, public, or private agencies in developing, protecting, rearing, or stocking all wildlife, wildlife resources, and their habitats. Under the FWCA, whenever waters of any stream or other water body are proposed to be impounded, diverted, or otherwise modified by any public or private agency under federal permit, that agency must consult with the USFWS and, in California, the CDFG.

4.8.1.5 Anadromous Fish Restoration Program

An important goal identified to meet the fish and wildlife purposes of the CVPIA is the broad goal of restoring natural populations of anadromous fish (e.g., Chinook salmon, steelhead, green sturgeon, white sturgeon, American shad, and striped bass) in Central Valley rivers and streams to double their recent average abundance levels. The Anadromous Fish Restoration Program strives to achieve this goal by directing the Secretary of the Interior to develop and implement a program to ensure the sustainability of anadromous fish in Central Valley Rivers and streams.

4.8.1.6 CALFED Bay-Delta Program

In 1994, CALFED was initiated to address long-standing and unresolved conflicts over water use in the Sacramento–San Joaquin Delta. It was a collaborative program of 23 federal and State agencies. Its goal was to restore the ecological health of the Delta while ensuring an adequate supply for Delta water users, including the CVP and SWP.

4.8.1.7 National Invasive Species Act of 1996

The National Invasive Species Act reauthorizes and amends the Nonindigenous Aquatic Nuisance Prevention and Control Act of 1990 to mandate regulations to reduce environmental and economic impacts from invasive species and to prevent introduction and spread of aquatic nuisance species, primarily through ballast water[24].

4.8.1.8 Trinity River Restoration Program

The Trinity River Restoration Program (TRRP) was implemented in 2001 following the issuance of the TRRP ROD. The purpose of the TRRP is to restore and maintain the natural production of anadromous fish in the Trinity River Basin downstream of Lewiston Dam, including fishery restoration to pre-Trinity River Diversion (TRD) levels, and to meet the U.S. Government's tribal trust obligations. The TRRP includes actions that: (1) re-establish the natural physical processes that create and maintain high quality aquatic habitat; and (2) create spawning and rearing conditions downstream of the dams that best compensate for lost habitat upstream, including adequate water temperatures.

The goal of the TRRP is not to re-create pre-dam conditions; rather, the goal is to create a smaller, dynamic, alluvial channel exhibiting all the characteristics of the pre-dam river but at a smaller scale. This strategy is intended to best achieve the restoration goals and maintain the purpose and use of the TRD.

Components of the TRRP include flow management for geomorphic and riparian processes, flow management for temperature and habitat, channel and watershed restoration, coarse sediment management, and adaptive management and monitoring.

4.8.1.9 Central Valley Project Long-term Water Service Contracts and the State Water Project Operations Criteria and Plan

The long-term CVP and SWP OCAP serves as the operational standard by which Reclamation and DWR operate the CVP and SWP system. The OCAP describes how Reclamation and DWR operate the CVP and the SWP to divert, store, and convey water consistent with applicable law. Reclamation and DWR completed an update to the OCAP in 2008 to reflect recent operational and environmental changes occurring throughout the CVP and SWP system.

4.8.2 State Plans, Policies, and Regulations

The following State regulations are applicable to aquatic biological resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Endangered Species Act (Fluvial Geomorphology and Riparian Habitat)
- California Environmental Quality Act (General)
- Water Quality Control Plan for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary (Surface Water Quality)

4.8.2.1 California Department of Fish and Game Code Section 1602 (Streambed Alteration)

Section 1602 of the CDFG Code states that any entity proposing to substantially divert or obstruct the natural flow or alter streambed materials, channel, or bank in any river, stream, or lake must provide a detailed description and map of the proposed project location, name and description of the river, stream, or lake affected by streamflow diversions, and copies of applicable local, State, or federal permits and/or other documents already issued. The regulatory definition of a stream is a body of water that flows at least

[24] Ballast water is the water inside the hull of a boat used to provide stability and prevent the boat from capsizing

periodically or intermittently through a bed or channel having banks and supports wildlife, fish, or other aquatic life. This includes watercourses having a surface or subsurface flow that supports or has supported riparian vegetation. CDFG's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife.

4.8.2.2 The Salmon, Steelhead Trout, and Anadromous Fisheries Program Act

Enacted in 1988, the Salmon, Steelhead Trout and Anadromous Fisheries Program Act was implemented in response to reports that the natural production of salmon and steelhead in California had declined dramatically since the 1940s, primarily as a result of lost stream habitat on many streams in the State. The Salmon, Steelhead Trout, and Anadromous Fisheries Program Act declares that it is the policy of the State of California to increase the State's salmon and steelhead resources, and directs CDFG to develop a plan and program that strives to double the salmon and steelhead resources (CDFG Code §6902(a)). It is also the policy of the State that existing natural salmon and steelhead habitat shall not be diminished further without offsetting the impacts of lost habitat (CDFG Code §6902(c)).

4.8.2.3 Natural Community Conservation Planning Act

The Natural Community Conservation Planning Act (NCCPA) authorizes the NCCP program to design projects for and promote conservation of natural communities, while accommodating compatible land use. The NCCP program is broader in its orientation and objectives than CESA and FESA. Both ESA laws are designed to identify and protect individual species that have already significantly declined in number; the primary objective of the NCCP program is to conserve natural communities at the ecosystem level while accommodating compatible land use. The program seeks to prevent the controversies and gridlock caused by species' being listed. The intention of the plan is to provide protection for natural communities and the endangered, threatened, candidate, or other species known, or reasonably expected to be found in those communities. It does this by focusing on the long-term stability of wildlife and plant communities. Working with landowners, environmental organizations, and other interested parties, a local agency oversees the numerous activities that compose the development of a conservation plan. CDFG and USFWS provide the necessary support, direction, and guidance to NCCP participants.

4.8.2.4 California Department of Fish and Game Code Section 5937 (Flows Below Dams)

Fish and Game Code 5937 states that "the owner of any dam shall allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, allow sufficient water to pass over, around or through the dam, to keep in good condition any fish that may be planted or exist below the dam. During the minimum flow of water in any river or stream, permission may be granted by the department to the owner of any dam to allow sufficient water to pass through a culvert, waste gate, or over or around the dam, to keep in good condition any fish that may be planted or exist below the dam, when, in the judgment of the department, it is impracticable or detrimental to the owner to pass the water through the fishway."

4.8.2.5 California Department of Fish and Game Code Sections 5980–5993 (Fish Screening)

Sections 5980 to 5993 of the CDFG Code states that conduits with a maximum flow capacity greater than 250 cubic feet per second of water must be examined by CDFG. It is the responsibility of the owner of a conduit to install a screen when deemed by CDFG that it is necessary to prevent fish from passing into the conduit.

4.8.2.6 California Aquatic Invasive Species Management Plan

The California Aquatic Invasive Species Management Plan proposes management actions for addressing aquatic invasive species threats to the State of California. It focuses on the nonnative algae, crabs, clams, fish, plants and other species that continue to invade California's creeks, wetlands, rivers, bays and coastal waters.

4.8.3 Regional and Local Plans, Policies, and Regulations

4.8.3.1 Interagency Ecological Program Pelagic Organism Decline Studies and the CALFED State of the Bay-Delta Science Report

Since late 2004, scientific and public attention has focused on the unexpected decline of several pelagic (open-water) fishes (delta smelt, longfin smelt, juvenile striped bass, and threadfin shad) in the freshwater portion of the estuary known as the Delta. This decline has collectively become known as the Pelagic Organism Decline (POD). In 2005, the IEP formed a multi-agency POD Management Team tasked with designing and managing a comprehensive study to evaluate the causes of the decline and to synthesize and report the results. The IEP POD Team investigated three possible causes of POD (water project operations, contaminants, and invasive species). Final reports from the POD Management Team were issued in 2005 through 2010.

4.8.3.2 Delta Vision Strategic Plan

The intent of the Delta Vision Strategic Plan (Delta Vision) process is to identify a strategy for managing the Delta as a sustainable ecosystem that will continue to support environmental and economic functions which are critical to the people of California. The Delta Vision Blue Ribbon Task Force (Task Force), a Governor Schwarzenegger appointed panel, is charged with developing recommendations on priority actions that should be taken to achieve a sustainable Delta in the long-term. The Delta Vision has a broader focus than the CALFED Ecosystem Restoration Program, and the Task Force will issue recommendations that address the full array of natural resources, infrastructure, land use, and governance issues necessary to achieve a sustainable Delta. The Delta Vision is based on a growing consensus that:

(1) Environmental conditions and the current water conveyance configuration of the Delta are not sustainable for environmental and economic purposes

(2) Current land and water uses and related services dependent on the Delta are not sustainable based on current management practices and regulatory requirements

(3) Major "drivers of change" (e.g., seismic events, land subsidence, sea level rise, regional climate change, and urbanization) will impact the Delta in the future

(4) The current fragmented and complex governance systems within the Delta are not conducive to effective management of the Delta in light of these threats

(5) Failure to address these challenges and threats could result in significant environmental and economic consequences

The Task Force formulated seven goals. In addition to addressing legal actions and establishing a new governing structure, the goals recognize that enhancing the Delta's cultural, recreational, and agricultural values, and promoting statewide water conservation, would lead to improved water conveyance, storage, and operations; reduced risk; and ultimately, restoration of the ecosystem.

4.8.3.3 State Water Resources Control Board and the California Environmental Protection Agency Draft Development of Flow Criteria for the Sacramento-San Joaquin Delta Ecosystem

The SWRCB and CalEPA Draft Development of Flow Criteria for the Sacramento-San Joaquin Delta Ecosystem report (was produced in accordance with Water Code §85086. Water Code §85086, contained in the Delta Reform Act, was enacted as part of the comprehensive package of water legislation adopted in November 2009. Water Code §85086 requires the SWRCB to use the best available scientific information and a public process to develop new flow criteria for the Delta ecosystem to protect aquatic resources in the Delta. The purpose of the flow criteria is to inform planning decisions for the Delta Plan and the Bay Delta Conservation Plan. None of the determinations in the SWRCB Delta Flow Criteria Report have regulatory adjudicatory effect. The report includes flow criteria recommendations for the Sacramento River.

4.9 Chapter 13. Botanical Resources

4.9.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to botanical resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- National Environmental Policy Act (General)
- Federal Endangered Species Act (Fluvial Geomorphology and Riparian Habitat)

4.9.1.1 Executive Order 11312: Invasive Species

EO 11312 directs all federal agencies to prevent and control introductions of invasive nonnative species in a cost-effective and environmentally sound manner to minimize their economic, ecological, and human health impacts. EO 11312 established a national Invasive Species Council made up of federal agencies and departments and a supporting Invasive Species Advisory Committee composed of State, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the EO, including preparation of a National Invasive Species Management Plan.

4.9.2 State Plans, Policies, and Regulations

The following State regulations are applicable to botanical resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Environmental Quality Act (General)
- California Endangered Species Act (Fluvial Geomorphology and Riparian Habitat)

4.9.2.1 California Native Plant Society List

According to CDFG, species on California Native Plant Society (CNPS) Lists 1 or 2 must be treated as equivalent to State-listed species if they meet the definition of rare or endangered pursuant to CEQA §15380. CNPS states that "all of the plants constituting List 1B and List 2 meet the definitions of Sec.

1901, Chapter 10 (National Plant Protection Act) or Secs. 2062 and 2067 (CESA) of the CDFG Code, and are eligible for State listing. It is mandatory that they be fully considered during preparation of environmental documents relating to CEQA".

4.9.2.2 Natural Communities Conservation Planning Act

Sections 2800 to 2835 of the CDFG Code detail the State's policies on the conservation, protection, restoration, and enhancement of the State's natural resources and ecosystems. The intent of the legislation is to provide for conservation planning as an officially recognized policy that can be used as a tool to eliminate conflicts between the protection of the State's natural resources and the need for growth and development. In addition, the legislation promotes conservation planning as a means of coordination and cooperation among private interests, agencies, and landowners, and as a mechanism for multispecies and multi-habitat management and conservation.

4.9.2.3 California Department of Fish and Game Code Sections 1900 to 1913 – Native Plant Protection Act

The purpose of this regulation is to preserve, protect, and enhance endangered or rare native plants. The regulation states that CDFG shall establish criteria for determining if a native plant is endangered or rare through botanical research and field investigations, and the Fish and Game Commission may then designate endangered and rare plants. Designated endangered or rare plants shall not be taken or possessed.

4.9.2.4 Sections of the California Fish and Game Code Pertaining to Invasive and Noxious Plant Species

At least five code sections and their associated regulations address or relate to invasive and noxious plant species. These include CDFG Code Sections 2080 to 2089, 2118, 2270 to 2272, 2300, 6400 to 6403, 15000 et seq. The intent of these code sections is to regulate the importation and transportation of live wild animals and plants; restrict the placement of live aquatic animals or plants in State waters; and regulate the operation of aquaculture industries.

4.9.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to botanical resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.9.3.1 Colusa County Voluntary Oak Woodlands Management Plan

The purpose of Colusa County's Oak Woodland Management Plan is to provide a consistent policy for conservation and use of oak woodlands throughout the county. The document is expected to provide direction to landowners, the Colusa County Planning Department, and developers.

4.10 Chapter 14: Terrestrial Biological Resources

4.10.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to terrestrial biological resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- National Environmental Policy Act (General)
- Central Valley Project Improvement Act (Surface Water Resources)
- Federal Endangered Species Act (Fluvial Geomorphology and Riparian Habitat)
- Fish and Wildlife Coordination Act (Aquatic Biological Resources)
- Executive Order 11312: Invasive Species (Botanical Resources)

4.10.1.1 Migratory Bird Treaty Act

The Migratory Bird Treaty Act prohibits the taking, killing, possession, transportation, and importation of migratory birds, their eggs, parts, and nests, except when specifically authorized by the U.S. Department of the Interior (DOI).

4.10.1.2 Bald and Golden Eagle Protection Act

The Bald and Golden Eagle Protection Act (Eagle Act, as amended) prohibits the take of bald and golden eagles including individuals, parts, nests, eggs, nest trees, and nest territories.

4.10.2 State Plans, Policies, and Regulations

The following State regulations are applicable to terrestrial biological resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Environmental Quality Act (General)
- California Endangered Species Act (Fluvial Geomorphology and Riparian Habitat)

4.10.2.1 California Department of Fish and Game Code 3503

This CDFG Code states that it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, except as otherwise provided by this code or any regulation made pursuant thereto.

4.10.2.2 California Department of Fish and Game Code 3503.5

This CDFG Code states it is unlawful to take, possess, or destroy any birds in the orders Falconiformes or Strigiformes (birds-of-prey) or to take, possess, or destroy the nest or eggs of any such bird except as otherwise provided by this code or any regulation adopted pursuant thereto.

4.10.2.3 California Department of Fish and Game Code 3511

(a) (1) Except as provided in Section 2081.7 or 2835, fully protected birds or parts thereof may not be taken or possessed at any time. The following are fully protected birds:

(1) American peregrine falcon (*Falco peregrinus anatum*).
(2) Brown pelican (*Pelicanus occidentalis*).
(3) California black rail (*Laterallus jamaicensis coturniculus*).
(4) California clapper rail (*Rallus longirostris obsoletus*).
(5) California condor (*Gymnogyps californianus*).

(6) California least tern (*Sterna albifrons browni*).
(7) Golden eagle (*Aquila chrysaetos*).
(8) Greater sandhill crane (*Grus canadensis tabida*).
(9) Light-footed clapper rail (*Rallus longirostris levipes*).
(10) Southern bald eagle (*Haliaeetus leucocephalus leucocephalus*).
(11) Trumpeter swan (*Cygnus buccinator*).
(12) White-tailed kite (*Elanus leucurus*).
(13) Yuma clapper rail (*Rallus longirostris yumanensis*).

4.10.2.4 California Department of Fish and Game Code 4700

(a) (1) Except as provided in Section 2081.7 or 2835, fully protected mammals or parts thereof may not be taken or possessed at any time. The following are fully protected mammals:

(1) Morro Bay kangaroo rat (*Dipodomys heermanni morroensis*).
(2) Bighorn sheep (*Ovis canadensis*), except Nelson bighorn sheep (subspecies *Ovis canadensis nelsoni)* as provided by subdivision (b) of Section 4902.
(3) Northern elephant seal (*Mirounga angustirostris*).
(4) Guadalupe fur seal (*Arctocephalus townsendi*).
(5) Ring-tailed cat (Bassariscus *astutus*).
(6) Pacific right whale (*Eubalaena sieboldi*).
(7) Salt-marsh harvest mouse (*Reithrodontomys raviventris*).
(8) Southern sea otter (*Enhydra lutris nereis*).
(9) Wolverine (*Gulo luscus*).

4.10.2.5 California Department of Fish and Game Code 5050

(a) (1) Except as provided in Section 2081.7 or 2835, fully protected reptiles and amphibians or parts thereof may not be taken or possessed at any time. The following are fully protected reptiles and amphibians:

(1) Blunt-nosed leopard lizard (*Crotaphytus wislizenii silus*).
(2) San Francisco garter snake (*Thamnophis sirtalis tetrataenia*).
(3) Santa Cruz long-toed salamander (*Ambystoma macrodactylum croceum*).
(4) Limestone salamander (*Hydromantes brunus*).
(5) Black toad (*Bufo boreas exsul*).

4.10.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to terrestrial biological resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Colusa County General Plan (General)
- Glenn County General Plan (General)
- Colusa County Voluntary Oak Woodlands Management Plan (Botanical Resources)

4.11 Chapter 15: Wetlands and Other Waters of the U.S.

4.11.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to wetlands and other waters of the U.S., but are discussed in other sections of this chapter, as indicated in parentheses:

- Clean Water Act Sections 401 and 404 (Surface Water Resources, Surface Water Quality)
- Rivers and Harbors Act of 1899 (Surface Water Quality)
- Natural Communities Conservation Planning Act (Botanical Resources)

4.11.1.1 Executive Order 11990, Protection of Wetlands

EO 11990 requires each federal agency to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands which are under their jurisdiction. Further, the agencies are directed to avoid undertaking or providing assistance for any new construction located in wetlands unless the head of the agency finds that there is no practicable alternative to such construction and that the proposed action includes all practicable measures to minimize harm to the affected wetlands.

4.11.1.2 No Net Loss of Wetlands Policy

"No net loss" is the United States government's overall policy goal regarding wetlands preservation. The goal of the policy is to balance wetland loss due to economic development with wetlands reclamation, mitigation, and restorations efforts, so that the total acreage of wetlands in the country does not decrease, but remains constant or increases. No net loss as a goal for wetland's policy was recommended at the National Wetlands Policy Forum in 1987 and was first adopted by President George H.W. Bush administration in 1989. The policy, which represented compromise between development and conservation, was grounded on the needs to protect the wetlands by creating and restoring the wetlands.

4.11.1.3 Comprehensive Conservation Plans for National Wildlife Refuges

USFWS is directed to develop Comprehensive Conservation Plans (CCPs) to guide the management and resource use for each refuge of the National Wildlife Refuge System under requirements of the National Wildlife Refuge Improvement Act of 1997. Refuge planning policy also directs the process and development of CCPs. A CCP provides a description of the desired future conditions and long-range guidance necessary for meeting refuge purposes. It also guides management decisions and sets forth strategies for achieving refuge goals and objectives within a 15-year time frame.

4.11.2 State Plans, Policies, and Regulations

The following State regulations are applicable to wetlands and waters of the U.S., but are discussed in other sections of this chapter, as indicated in parentheses:

- Porter-Cologne Water Quality Control Act (Surface Water Resources)
- Suisun Marsh Preservation Agreement (Surface Water Resources)
- Suisun Marsh Protection Act and Suisun Marsh Protection Plan (Surface Water Resources)
- Delta Vision Strategic Plan (Aquatic Biological Resources)
- Delta Protection Act of 1992 (Surface Water Resources)

4.11.2.1 California Wetlands Conservation Policy

The goal of the California Wetlands Conservation Policy, adopted in 1993, is to ensure no overall net loss, and achieve a long-term net gain in the quantity, quality, and permanence of wetlands acreage and values in California, in a manner that fosters creativity, stewardship, and respect for private property.

4.11.3 Regional and Local Plans, Policies, and Regulations

4.11.3.1 Yolo Bypass Wildlife Area Land Management Plan

The Yolo Bypass Wildlife Area Land Management Plan was finalized in June 2008. The management plan is a general policy guide for the CDFG to manage the Yolo Bypass Wildlife Area. It is intended to contribute to habitat management that uses natural processes to create a sustainable system over the long term. The policies are based on an ecosystem approach to habitat management consistent with the principles of CALFED's Ecosystem Restoration Program, as implemented by the USFWS, NMFS, and CDFG.

4.12 Chapter 16: Geology, Minerals, Soils, and Paleontology

4.12.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to geology, minerals, soils, and/or paleontology, but are discussed in other sections of this chapter, as indicated in parentheses:

- Clean Water Act Section 402, National Pollution Discharge Elimination System Permits (Surface Water Quality)
- National Pollution Discharge Elimination System General Permit for Stormwater Discharges from Construction Sites (Surface Water Quality)

4.12.1.1 Antiquities Act of 1906

The Antiquities Act authorizes the President of the United States to designate National Monuments and provides criminal penalties (fines and/or imprisonment) for the unauthorized excavation, injury, or destruction of prehistoric or historic ruins and objects of antiquity located on federal land. This act applies to the public lands administered by federal agencies.

4.12.1.2 Archaeological Resources Protection Act of 1979 (16 USC 470aa to mm)

The Archaeological Resources Protection Act (ARPA) amends the Antiquities Act, sets a broad policy that archaeological resources are important to the nation and should be protected, and requires special permits before the excavation or removal of archaeological resources from federally managed lands and Indian lands. This act is applicable to public lands within the project boundary that are managed by federal agencies. ARPA also provides for maintaining the confidentiality of information on the nature and location of archaeological sites.

4.12.1.3 Omnibus Public Land Management Act of 2009

On March 31, 2009, President Obama signed into law the Omnibus Public Land Management Act (OPLMA) of 2009. Title 6, Subtitle D of the OPLMA, Paleontological Resources Preservation, requires the secretaries of the DOI (exclusive of Indian trust lands) and the U.S. Department of Agriculture (USDA) (insofar as U.S. Forest System lands are concerned) to "… manage and protect paleontological resources on Federal land using scientific principals and expertise… [and] develop appropriate plans for inventory, monitoring, and the scientific and educational use of paleontological resources …" The OPLMA further excludes casual collection from restrictions under the law, and then describes the requirements for permitting collection on federal lands, stipulations regarding the use of paleontological resources in education, continued federal ownership of recovered paleontological resources, and standards for acceptable repositories of collected specimens and associated data. The OPLMA also provides for criminal and civil penalties for unauthorized removal of paleontological resources from federal land, and for rewards for reporting the theft of fossils.

4.12.2 State Plans, Policies, and Regulations

The following State regulations are applicable to geology, minerals, soils, and/or paleontology, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Environmental Quality Act (General)
- Porter-Cologne Water Quality Control Act (Surface Water Resources)
- California Department of Fish and Game Code 1602 (Aquatic Biological Resources)
- California Water Code, Division 3: Dams and Reservoirs (Flood Control and Management)

4.12.2.1 Surface Mining and Reclamation Act of 1975 (Public Resources Code 2762 and 2714)

Mining activities are regulated in the State of California by the Surface Mining and Reclamation Act (SMARA) of 1975. This law's purpose is to create and maintain an effective and comprehensive surface mining and reclamation policy with regulation of surface mining operations to ensure that adverse environmental effects are prevented or minimized and that mined lands are reclaimed to a usable condition that is readily adaptable for alternative land uses. Production and conservation of minerals are encouraged, and consideration is given to values relating to recreation, wildlife, range and forage, and aesthetic enjoyment, while eliminating residual hazards to public health and safety. These goals are achieved through land use planning by allowing jurisdictions to balance the economic benefits of resource extraction with the need to provide other land uses.

It is also the intent of this process, through the adoption of local mineral resource management policies, that significant mineral resources be considered in future local land-use planning decisions. Public Resources Code Section 2762 directs that if a use is proposed that might threaten the potential recovery of minerals from an area that has been classified MRZ-2 (areas where adequate information indicates that significant mineral deposits are present or where it is judged that a high likelihood for their presence exists), the county (or city) must specify its reasons for permitting use, provide public notice of those reasons, and forward a copy of its statement of reasons to the State Geologist and the State Mining and Geology Board.

4.12.2.2 Seismic Hazards Mapping Act

The Seismic Hazards Mapping Act of 1990 was passed following the Loma Prieta earthquake to reduce threats to public health and safety by identifying and mapping known seismic hazard zones in California. The act directs the California Geological Survey of the Department of Conservation to identify and map areas prone to earthquake hazards of liquefaction[25], earthquake-induced landslides, and amplified ground shaking. The purpose of the maps is to assist cities and counties in fulfilling their responsibilities for protecting public health and safety.

4.12.2.3 Asbestos Airborne Toxic Control Measure for Surfacing Applications (amended 2000)

This California Air Resources Board (ARB) regulation serves to control the sale, use, or transport of materials derived from ultramafic (high in magnesium and iron) or serpentine[26] sources with the goal of reducing airborne emissions of asbestos found in these materials. The regulation does not include aggregate materials derived from alluvial sources.

4.12.2.4 Asbestos Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations 2002

This ARB regulation serves to limit ground disturbance in areas containing ultramafic rock or areas containing naturally occurring asbestos or serpentine.

4.12.2.5 Regulatory Design Codes for Buildings, Highways, and Other Structures

State and federal standards for minimum design regulate the construction of any buildings, highways, and other structures, and include the following:

- American Association of State Highway and Transportation Officials (AASHTO) Guide Specifications for Load and Resistance Factor Design (LRFD) Seismic Bridge Design, 1st Edition, 2009
- American Railway Engineering and Maintenance-of-Way Association Manual for Railway Engineering, Volume 2, Chapter 9, Seismic Design for Railway Structures, 2008
- American Society of Civil Engineers Minimum Design Loads for Buildings and Other Structures, ASCE-7-05, 2005
- California Amendments to AASHTO LRFD Bridge Design Specifications, Fourth Edition, 2008
- California Building Code (CBC), 2013 (CCR, Title 24, Part 2)
- Caltrans Seismic Design Criteria, latest edition
- DWR DSOD Guidelines for Use of the Consequence-Hazard Matrix and Selection of Ground Motion Parameters, 2002
- DWR Interim Levee Design Criteria for Urban and Urbanizing Area State-Federal Project Levees, 2009
- Federal Highway Administration (FHWA) Seismic Retrofitting Manual for Highways Structures, Parts 1 and 2, 2006
- USACE (Corps, CESPK-ED-G), Geotechnical Levee Practice, SOP EDG-03, 2004
- USACE Design and Construction of Levees, EM 1110-2-1913, 2000

25 Liquefaction- the process by which saturated, unconsolidated sediments are transformed into a substance that acts like a liquid. Earthquakes can cause soil liquefaction where loosely packed, water-logged sediments come loose from the intense shaking of the earthquake.
26 Serpentine- a mineral or rock consisting essentially of a hydrous magnesium silicate usually having a dull green color and often a mottled appearance

- USACE Engineering and Design, Earthquake Design and Evaluation for Civil Works Projects, ER 1110-2-1806, 1995
- USACE Engineering and Design – Earthquake Design and Evaluation of Concrete Hydraulic Structures, EM 1110-2-6053, 2007
- USACE Engineering and Design – General Design and Construction Considerations for Earth and Rock-Fill Dams, EM 1110-2-2300, 2004
- USACE Engineering and Design – Response Spectra and Seismic Analysis for Concrete Hydraulic Structures, EM 1110-2-6050,1999
- USACE Engineering and Design – Stability Analysis of Concrete Structures, EM 1110-2-2100, 2005
- USACE Engineering and Design – Structural Design and Evaluation of Outlet Works, EM 1110-2-2400, 2003
- USACE Engineering and Design – Time-History Dynamic Analysis of Concrete Hydraulic Structure, EM 1110-2-6051, 2003
- USACE Slope Stability, EM 1110-2-1902, 2003
- Reclamation. ACER Technical Memo No. 3. Criteria and Guidelines for Evacuating Storage Reservoirs and Sizing Low-Level Outlet Works, 1990.
- DOI and USGS Climate Change and Water Resources Management: A federal Perspective, Circular 1331

These standards establish minimum design criteria and construction requirements, including design of concrete and steel structures, levees, tunnels, pipelines, buildings, pumping stations, excavation and shoring, grading, and foundations.

4.12.2.6 Nonpoint Source Implementation and Enforcement Policy

The State's Nonpoint Source Implementation and Enforcement Policy describes how its nonpoint source plan is to be implemented and enforced, in compliance with Section 319 of the CWA (the Nonpoint Source Management Program), Coastal Zone Act Reauthorization Amendments, and the Porter-Cologne Act. In contrast to point-source pollution that enters water bodies from discrete locations, nonpoint source pollution enters water bodies from diffuse sources, such as land runoff, seepage, or hydrologic modification. Nonpoint source pollution is controlled through implementation of management measures such as operational controls. The nonpoint source pollution program contains recommended management measures for developing areas and construction sites, as well as wetland and riparian areas. Requirements for soil erosion and sediment controls to prevent nonpoint source pollution discharges to waterways may be incorporated into permits.

4.12.2.7 California Public Resources Code Chapter 1.7 Archaeological, Paleontological, and Historical Sites Section 5097.5)

(a) No person shall knowingly and willfully excavate upon, or remove, destroy, injure, or deface, any historic or prehistoric ruins, burial grounds, archaeological or vertebrate paleontological site, including fossilized footprints, inscriptions made by human agency, rock art, or any other archaeological, paleontological or historical feature, situated on public lands, except with the express permission of the public agency having jurisdiction over the lands. Violation of this section is a misdemeanor.

(b) As used in this section, "public lands" means lands owned by, or under the jurisdiction of, the State, or any city, county, district, authority, or public corporation, or any agency thereof.

4.12.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to geology, minerals, soils, and/or paleontology, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.13 Chapter 17. Faults and Seismicity

4.13.1 Federal Plans, Policies, and Regulations

4.13.1.1 National Earthquake Hazards Reduction Program Act of 2004

This act established the National Earthquake Hazards Reduction Program which was designed to develop and promote effective measures for earthquake hazard reductions, serve as a clearinghouse for data and standards related to earthquake effects on communities and structures, and to develop, operate and maintain the Advanced National Seismic Research and Monitoring System.

4.13.2 State Plans, Policies, and Regulations

The following State regulations are applicable to faults and seismicity, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Water Code, Division 3 Dams and Reservoirs (Flood Control and Management)
- Seismic Hazards Mapping Act of 1990 (Geology, Minerals, Soils, and Paleontology)

4.13.2.1 Alquist-Priolo Earthquake Fault Zoning Act of 1972

This act requires the State Geologist to provide maps of Earthquake Fault Zones to affected city, county, and State agencies to avoid development of structures for human occupancy across the trace of active faults. The act also facilitates the seismic retrofitting of existing buildings, including historic buildings, against ground shaking.

4.13.2.2 California Division of Mines and Geology Special Publication No. 42, Fault-Rupture Hazard Zones in California, 2007

Pursuant to the Alquist-Priolo Earthquake Fault Zoning Act, this report summarizes the various responsibilities under the Act, details the actions taken by the State Geologist and his staff to implement the Act, and provides earthquake fault zone maps.

4.13.2.3 California Division of Mines and Geology Special Publication No. 117A, Guidelines for Evaluating and Mitigating Seismic Hazards in California, 2008

Pursuant to the Seismic Hazards Mapping Act, this report presents guidelines for evaluating seismic hazards other than surface fault-rupture, and recommends mitigation measures as required by Public Resources Code Section 2695(a).

4.13.2.4 California Code of Regulations, Title 23 Waters, Division 2 DWR, Chapter 1 Dams and Reservoirs, Article 5

This section of the CCR states that, pursuant to Section 6056 of the Water Code, the DWR shall retain a board of three consultants to report to the Director on the safety of dams owned by DWR. The consulting board shall make independent findings with regard to conditions which may affect the safety of the dam and reservoir as specified in Section 6081 of the Water Code, and the board shall also make independent findings that the dam is safe to impound water, as specified in Section 6355 of the Water Code.

This section also states that DWR shall retain a consulting board (1) to review the adequacy of the design of a dam and reservoir DWR proposes to construct, or (2) to review the safety of the completed construction and the terms and conditions to be included in a certificate of approval for any dam owned by DWR as issued, renewed or modified, no later than six months following any such action. Where a board is retained to review the adequacy of the design of a dam and reservoir, it shall report its findings to the Director prior to the approval of an application to construct or enlarge the dam.

In addition, DWR shall retain a review board at least once every five years to review the operational performance of department owned dams. The Federal Power Commission’s five year independent review may be substituted if it is comparable to the review required by this article.

4.13.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to faults and seismicity, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.14 Chapter 18: Cultural Resources

4.14.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to cultural resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Antiquities Act of 1906 (Geology, Soils, Minerals, and Paleontology)
- Archaeological Resources Protection Act (Geology, Soils, Minerals, and Paleontology)

4.14.1.1 National Historic Preservation Act of 1966

Section 106 of the National Historic Preservation Act (NHPA) of 1966 and its implementing regulations require federal agencies to consider the effects of their undertakings, or those they fund or permit, on properties that may be eligible for listing, or that are listed in the National Register of Historic Places (NRHP). The 36 CFR Part 60.4 regulations describe the criteria to evaluate cultural resources for inclusion in the NRHP. Cultural resources can be significant on the national, State, or local level. Such resources are required to retain integrity and must exhibit an association with broad patterns of our history, be associated with an important person, embody a distinctive characteristic, or yield information that is historically significant.

The 36 CFR Part 800 regulations, implementing Section 106, call for considerable consultation with the State Historic Preservation Officer, Indian tribes, and interested members of the public throughout the process. The four principal steps are as follows:

- Initiate the Section 106 process
- Identify historic properties, resources eligible for inclusion in the NRHP
- Assess the effects of the undertaking to historic properties in the Area
- Resolve adverse effects

4.14.1.2 National Register of Historic Places

The NRHP is the official list of the Nation's historic places worthy of preservation. To be eligible for the register, the property must meet criteria related to age, integrity, and significance. All nominations to the register are reviewed by the State Office of Historic Preservation.

The NRHP is maintained by the Secretary of the Interior and includes districts, sites, buildings, structures, architecture, archaeology, engineering, culture, and objects of significance in American history. A property may be listed in the NRHP if it meets criteria for evaluation defined in 36 CFR 60.4:

The quality of significance in American history, architecture, archaeology, engineering, and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling, and association, and:

(A) That are associated with events that have made a significant contribution to the broad patterns of our history; or

(B) That are associated with the lives of persons significant in our past; or

(C) That embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess an artistic value, or that represent a significant and distinguishable entity whose components may lack individual distinction; or

(D) That have yielded, or may be likely to yield, information important to prehistory or history.

4.14.1.3 Protection of Historic Properties (USC 36 CFR 800)

This code section requires federal agencies to consider the effects of their undertakings on historic properties. Consultation early in the planning process allows identification of properties potentially affected by the undertaking and the development of measures to avoid, minimize, and mitigate adverse effects on historic properties.

4.14.1.4 Native American Graves Protection and Repatriation Act

The Native American Graves Protection and Repatriation Act (NAGPRA) provides for increased involvement of Native Americans in archaeology and historic preservation. NAGPRA addresses the rights of lineal descendants and Indian tribes to Native American human remains, funerary objects, sacred objects, and objects of cultural patrimony. These parties are to be consulted when such items are inadvertently discovered or intentionally excavated on federal or tribal lands. NAGPRA recognizes Native American "ownership" of these items. The NHPA amendments mandate tribal participation in the Section 106 process. A federal agency must consult with the tribal government or recognized representatives when its activities occur on a reservation and/or as part of an undertaking. Agencies also must consult with a tribe if an activity will affect a historic property to which the tribe attaches cultural or historic importance. More importantly, tribal historic preservation programs have the same legal status as State historic preservation programs. These stipulations are an acknowledgment that tribal sovereignty extends into the arena of cultural resource management and, therefore, are an extension of the government-to-government relationship between tribes and the federal government. The NHPA amendments also specify that "properties of traditional religious and cultural importance to Native Americans" qualify for inclusion in the NRHP. To a certain extent, this specification addresses the inability of the AIRFA to protect Native American sacred sites. This designation also expands the definition of "cultural resource" to include sites that may lack material remains.

4.14.2 State Plans, Policies, and Regulations

The following State regulations are applicable to cultural resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Environmental Quality Act (General)
- California Public Resources Code Chapter 1.7 Archaeological, Paleontological, and Historical Sites Section 5097.5 (Geology, Soils, Minerals, and Paleontology)

4.14.2.1 California Register of Historical Resources

The California Register of Historical Resources (CRHR) includes resources that are listed in or formally determined eligible for listing in the NRHP, as well as some California State Landmarks and Points of Historical Interest. Properties of local significance that have been designated under a local preservation ordinance (local landmarks or landmark districts) or that have been identified in a local historical resources inventory may be eligible for listing in the CRHR and are presumed to be significant resources for purposes of CEQA, unless a preponderance of evidence indicates otherwise. The eligibility criteria for listing in the CRHR are similar to those for NRHP listing, but focus on the importance of the resources to California history and heritage. A cultural resource may be eligible for listing in the CRHR if:

1. It is associated with events or patterns of events that have made a significant contribution to the broad patterns of local or regional history, or the cultural heritage of California or the United States; or
2. It is associated with the lives of persons important to local, California, or national history; or
3. It embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of a master, or possesses high artistic values; or
4. It has yielded, or has the potential to yield, information important to the prehistory or history of the local area, California, or the nation.

4.14.2.2 California Native American Historic Resource Protection Act

The California Native American Historic Resource Protection Act establishes the Native American Heritage Commission (NAHC) and its responsibilities and requires cooperation of State and local agencies in carrying out its duties with respect to Native American resources. The NAHC identifies and catalogs places of special religious or social significance to Native Americans and known graves and cemeteries of Native Americans on private lands, and performs other duties regarding the preservation and accessibility of sacred sites and burials and the disposition of Native American human remains and burial items. In the event of the discovery of human remains of Native American origin, the NAHC is responsible for the identification of the person or persons it believes to be the most likely descendant from the deceased Native American.

4.14.2.3 California Public Resources Code Section 5024.1

The Code Section requires State agencies to formulate policies to preserve and maintain State-owned historical resources under its jurisdiction. This includes those resources included in the NRHP as well as those resources potentially eligible for the register.

4.14.2.4 California Public Resources Code Section 5097.9-5097.991

These code sections provide protection to the exercise of Native American religion including protection of cemeteries, places of worship, religious or ceremonial sites, or sacred shrines on public property. City and County lands less than 100 acres are excluded from the provisions of the code section. The code section authorizes the establishment of a Native American Heritage Commission with the responsibility to identify and make recommendations regarding Native American sacred sites.

4.14.2.5 California Health and Safety Code Section 7050.5: Disturbance of Human Remains

Section 7050.5 of the California Health and Safety Code includes the following requirements:

Every person who knowingly mutilates or disinters, wantonly disturbs, or willfully removes any human remains in or from any location other than a dedicated cemetery without authority of law is guilty of a misdemeanor.

In the event of discovery or recognition of any human remains in any location other than a dedicated cemetery, there shall be no further excavation or disturbance of the site or any nearby area reasonably suspected to overlie adjacent remains until the coroner of the county in which the human remains are discovered has determined, in accordance with Chapter 10 (commencing with Section 27460) of Part 3 of Division 2 of Title 3 of the Government Code, that the remains are not subject to the provisions of Section 27491 of the Government Code or any other related provisions of law concerning investigation of the circumstances, manner and cause of any death, and the recommendations concerning the treatment and disposition of the human remains have been made to the person responsible for the excavation, or to his or her authorized representative. The coroner shall make his or her determination within two working days from the time the person responsible for the excavation, or his or her authorized representative, notifies the coroner of the discovery or recognition of the human remains.

If the coroner determines that the remains are not subject to his or her authority and if the coroner recognizes the human remains to be those of a Native American, or has reason to believe that they are those of a Native American, he or she shall contact the NAHC by telephone within 24 hours.

4.14.2.6 California Health and Safety Code Sections 8010 to 8011: California Native American Graves Protection and Repatriation Act

Sections 8010–8011 of the California Health and Safety Code establish a State repatriation policy that is consistent with and facilitates implementation of the federal NAGPRA. The policy requires that all California Indian human remains and cultural items be treated with dignity and respect and encourages voluntary disclosure and return of remains and cultural items by publicly funded agencies and museums in California. The policy provides for mechanisms to aid California Indian tribes, including non-federally recognized tribes, in filing repatriation claims and getting responses to those claims.

4.14.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to cultural resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.15 Chapter 19: Indian Trust Assets

Indian Trust Assets (ITAs) are legal interests in property held in trust by the United States for Indian Tribes or individuals. The Secretary of the Interior, acting as the trustee, holds many assets in trust. Examples of objects that may be trust assets are lands, minerals, hunting and fishing rights, and water rights. Although most ITAs are on reservations, they may also be found off of reservations. The United States has an Indian trust responsibility to protect and maintain rights reserved by or granted to Indian Tribes or Indian individuals by treaties, statutes, and executive orders. These are sometimes further interpreted through court decisions and regulations.

4.16 Chapter 20: Land Use

4.16.1 Federal Plans, Policies, and Regulations

4.16.1.1 Farmland Protection Policy Act

The Farmland Protection Policy Act of 1981 (FPPA) is a federal regulation that is intended to minimize the impact of federal programs with respect to the conversion of farmland to nonagricultural uses. The FPPA ensures that, to the extent possible, federal programs are administered to be compatible with State, local, and private programs and policies to protect farmland. It is administered by the USDA, Natural Resources Conservation Service (NRCS).

4.16.1.2 Wetlands Reserve Program

The NRCS administers the Wetlands Reserve Program (WRP). The WRP was established by Congress in the 1990 Farm Bill and has been reauthorized in the 1996, 2002, and 2008 Farm Bills. There have been WRP easements in California since 1992. The WRP is a voluntary program that offers landowners the opportunity to protect, restore, and enhance wetlands on their property. Landowners who are enrolled in the program retain the title to the land and the right to control access and recreational use of that land.

The WRP offers three options:

- Permanent Easement: this is a conservation easement in perpetuity. The USDA pays 100 percent of the easement value and up to 100 percent of the restoration costs.
- 30-Year Easement: this easement expires after 30 years. USDA pays up to 75 percent of the easement value and up to 75 percent of the restoration costs.
- Restoration Cost-Share Agreement: this is a 10-year agreement to restore or enhance the wetland functions and values without placing an easement on the enrolled acres. USDA pays up to 75 percent of the restoration costs.

Enrollment of land in the WRP limits the activities that can occur on that land, including digging, dredging, filling, leveling, and the installation of structures on, under, or over the easement area (except if those structures are for undeveloped recreational use).

4.16.2 State Plans, Policies, and Regulations

4.16.2.1 Important Farmland Inventory System and Farmland Mapping and Monitoring Program

The California Department of Conservation, Office of Land Conservation, maintains a statewide inventory of farmlands. These lands are mapped by the Division of Land Resource Protection as part of the Farmland Mapping and Monitoring Program. Lands are classified using a system that combines technical soil ratings and current land use into the following categories: Prime Farmland, Farmland of Statewide Importance, Unique Farmland, Farmland of Local Importance, Grazing Land, Urban and Built-up Land, Other Land, and Water. The definitions of these classifications are provided below.

Land Use Categories

- **Prime Farmland:** Farmland with the best combination of physical and chemical features able to sustain long term agricultural production. This land has the soil quality, growing season, and moisture supply needed to produce sustained high yields. Land must have been used for irrigated agricultural production at some time during the four years prior to the mapping date.
- **Farmland of Statewide Importance:** Farmland similar to Prime Farmland but with minor shortcomings, such as greater slopes or less ability to store soil moisture. Land must have been used for irrigated agricultural production at some time during the four years prior to the mapping date.
- **Unique Farmland:** Farmland of lesser quality soils used for the production of the State’s leading agricultural crops. This land is usually irrigated, but may include nonirrigated orchards or vineyards as found in some climatic zones in California. Land must have been cropped at some time during the four years prior to the mapping date.
- **Farmland of Local Importance:** Land of importance to the local agricultural economy, as determined by each county’s board of supervisors and a local advisory committee. The county-specific Board of Supervisors has the authority to adopt or recommend changes to this category of farmland.
- **Grazing Land:** Land on which the existing vegetation is suited to the grazing of livestock. This category was developed in Cooperation with the California Cattlemen’s Association, University of California Cooperative Extension, and other groups interested in the extent of grazing activities.
- **Urban/Built-Up Land:** Land occupied by structures with a building density of at least one unit to 1.5 acres, or approximately six structures to a 10-acre parcel. This land is used for residential, industrial, commercial, construction, institutional, public administration, railroad and other transportation yards, cemeteries, airports, golf courses, sanitary landfills, sewage treatment, water control structures, and other developed purposes.
- **Other Land:** Land not included in any other mapping category. Common examples include low density rural developments; brush, timber, wetland, and riparian areas not suitable for livestock grazing; confined livestock, poultry or aquaculture facilities; strip mines, borrow pits; and

waterbodies smaller than forty acres. Vacant and nonagricultural land surrounded on all sides by urban development and greater than 40 acres is mapped as Other Land.

- **Water:** Perennial water bodies with an extent of at least 40 acres.

4.16.2.2 California Land Conservation Act of 1965 (Williamson Act)

Preservation of farmland in California is encouraged by the California Land Conservation Act of 1965, more commonly known as the “Williamson Act” (Gov. Code §51250 et seq.). The Williamson Act enables local governments to form contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open space use. A landowner signs a contract with the County in which the land is located, voluntarily restricting land to agricultural and open space uses.

Some open space, defined by Government Code §51201 is generally eligible to be included as a compatible (not primary) use:

- Wildlife habitat areas, designated by the Board or Council in consultation with CDFG
- Some managed wetland areas, tidal submerged areas, and salt evaporation ponds
- Land supporting recreational use and open to the public, in its natural or agricultural state
- Land in scenic highway corridors
- Land enrolled in the federal Conservation Reserve Program or Conservation Reserve Enhancement Program are Open Space Uses

In return, landowners receive substantially reduced property tax assessments; assessments that are based upon generated income (i.e., farming and open space uses) as opposed to potential market value of the property. Local governments received a partial subvention (i.e., subsidy) of foregone property tax revenues from the State via the Open Space Subvention Act of 1972 (Government Code §16140, et seq.) through 2009. These payments have been suspended in more recent years due to revenue shortfalls.

The contract is renewed automatically annually, continuing indefinitely unless the owner or local government files for non-renewal. The minimum initial contract term is 10 years. Pursuant to the non-renewal process, the remaining contract term (nine years in the case of an original term of 10 years) is allowed to lapse, with the contract null and void at the end of the term. Property tax rates gradually increase during the nonrenewal period, until they reach normal (i.e., non-restricted) levels upon termination of the contract.

Pursuant to a set of specifically defined circumstances, a contract may be cancelled by the landowner without completing the process of term nonrenewal (Government Code §51281). Contract cancellation involves a comprehensive review and approval process, and the payment of a fee by the landowner equal to 12.5 percent of the full market value of the property in question. Landowners may petition a County Board of Supervisors or City Council for a Williamson Act contract cancellation. The County or City is required to send a copy of the petition to the Department of Conservation as a separate submittal from any CEQA document.

There are five sections pursuant to the Williamson Act statute that a landowner may petition a Board of Supervisors or City Council for a full or partial cancellation:

- §51282(b) Cancellation is Consistent with the Williamson Act
- §51282(c) Cancellation is in the Public interest
- §51282.3 Cancellation for Specified Alternate Use of the Land

- §51282.5 Cancellation of Land Zoned as Timberland Production
- §51297 Cancellation of Farmland Security Zone Contract

Local activities, such as eminent domain or city annexation, also result in the termination of Williamson Act contracts.

In 1998, the provisions of the Williamson Act were expanded by SB 1182 to strengthen agricultural land preservation incentives. The 1998 changes provided a 35 percent property tax discount to the Williamson Act valuation or Proposition 13 valuation, whichever is lower, and other incentives for farmland owners willing to maintain their land in agricultural land use for 20 years. This latter program creates Farmland Security Zones (also known as the “Super Williamson Act”) within agricultural preserves. Land enrolled under a Farmland Security Zone contract is restricted to agricultural and open spaces uses for a minimum initial contract term of 20 years. Land within a Farmland Security Zone cannot be annexed into cities, and school districts are prohibited from acquiring Farmland Security Zone lands for school facilities. Cancellations of Farmland Security Zone contracts are more expensive and difficult than Williamson Act contracts.

4.16.2.3 California State Planning and Zoning Laws

California Government Code §65300 et seq. establishes the obligation of cities and counties to adopt and implement General Plans. A city or county General Plan is a comprehensive, long-term, and general document that describes plans for the physical development of a city or county and any land outside its boundaries[27] that, in the city’s or county’s judgment, bears relation to its planning. The General Plan addresses a broad range of topics, including seven mandatory elements: land use, circulation, housing, conservation, open space, noise, and safety. In addressing these and other topics, the General Plan identifies the goals, objectives, policies, principles, standards, and plan proposals that support the city’s or county’s vision for the area. Although the General Plan serves as a blueprint for future development and identifies the overall vision for the applicable planning area, it remains general enough to allow for flexibility in the approach taken to achieve its goals.

California Government Code §65800 et seq. establishes that zoning ordinances, which are laws that define allowable land uses in a specific district, are required to be consistent with the General Plan and any applicable Specific Plan. Zoning codes implement the policies and provisions of the General Plans, identify permitted uses in each zone, regulate the use of land and the general design of structures, and establish minimum regulations and standards for developing land in each jurisdiction. When amendments to a General Plan are made, corresponding changes in the zoning codes may be required to ensure that the land uses designated in the General Plan also would be allowable by the zoning code.

4.16.3 Regional and Local Plans, Policies, and Regulations

4.16.3.1 Tehama County General Plan

The 2009 Tehama County General Plan includes countywide goals that it uses as a basis for evaluating development proposals and other land-use related activities within Tehama County. The General Plan includes policies and implementation measures that support its goals. The County has also developed

Individual Planning Area policies. The countywide and Central I-5 Corridor Planning Area goals are listed below.

Countywide Policies

- **Goal LU-1:** To plan development within the County in a manner which will provide opportunities for current and future residents to enjoy rural, community oriented living environments that are similar to those currently found in the County. Encourage higher densities, where appropriate, and promote in-fill development to discourage agricultural land conversion demands.
- **Goal LU-2:** To manage development and ensure that an individual(s) action(s) do not adversely impact the health, safety, and welfare of the County's citizens.
- **Goal LU-3:** To promote a development pattern which, whenever possible, maximizes the use of existing infrastructure prior to the construction of new infrastructure. Develop a land use pattern which, to the maximum extent feasible, minimizes the expenditure of public funds for infrastructure construction and maintenance.
- **Goal LU-4:** To designate lands for commercial and industrial development that are appropriate for these purposes and allows opportunities for business and industrial firms. Encourage compact development contiguous to existing urban centers, discourage linear and leapfrog development patterns.
- **Goal LU-5:** To promote a development pattern that will accommodate growth, consistent with other stated goals and for the growth projected for the planning period (2008 to 2028).
- **Goal LU-6:** To govern new development with subdivision, zoning, and other regulations that explicitly define government and private sector responsibilities and expectations with regard to an acceptable balance between public facility and service costs.
- **Goal LU-7:** To accommodate growth in a manner that preserves the predominate rural lifestyle and unique qualities that make the County an attractive place to live and that recognizes that a rural lifestyle does not always necessitate the provision of the full complement of services normally found in urban communities.
- **Goal LU-8:** To develop land use patterns which minimize travel to jobs and services.
- **Goal LU-9:** To accommodate cellular tower facilities while requiring siting provisions that protects the visual quality and character of the County.
- **Goal LU-10:** To promote development patterns that recognize the need to preserve water resources, consistent with other stated goals.

Central I-5 Planning Area Policies

- **Policy CI-5.1:** The development pattern shall recognize the predominantly agricultural land use of the planning area.
- **Policy CI-5.2:** Population growth shall be accommodated primarily in the Los Molinos area by a development pattern transitioning from higher densities in the developed portion of Los Molinos to lower densities moving outward to the surrounding rural areas.

- **Policy Cl-5.3:** The rural service center of Proberta and Gerber shall accommodate growth consistent with their agricultural support function and in a manner that preserves the agricultural value of lands surrounding these communities.
- **Policy Cl-5.4:** The County recognizes the special district service providers and will work with the districts to incorporate policies during the project review process.
- **Policy Cl-5.5:** The future development pattern shall recognize the existing rural residential small lot development in the vicinity of Bryne Avenue, Clement Avenue, and the Sacramento River.

Tehama County General Plan Land Use and Zoning Designations

The intent of the General Industrial land use classification is to provide for industrial land uses, including light and heavy manufacturing, industrial parks, support wholesale energy production, related office uses, and industrial uses of similar character. This designation allows for non-industrial firms that provide materials and services related to industrial uses. Additional non-industrial uses may be permitted on an interim basis with conditions that provide for reversion to industrial uses. Examples of uses include: light to heavy manufacturing, fabrication, storage and warehousing, processing of goods and resources, energy facilities, equipment sales and storage yards, business and office parks and other such uses, which because of their operations, may create noise, light or glare, dust, or odor that are not compatible with residential or service and retail commercial uses. Non-accessory residential uses shall be strongly discouraged.

The Tehama County zoning designation that is compatible with the General Industrial land use designation is the General Industrial District (M-2). Chapter 17-36 – M-2 General Industrial District, of the Tehama County, California, Code of Ordinances, Title 17-Zoning, indicates that the purpose of the M-2 General Industrial District classification is to provide opportunities for heavy industrial land uses and support facilities. This District is consistent with the General Industry category of the Development Pattern and Community Organization Element of the County General Plan.

Uses permitted in an M-2 District shall be as follows:

- Uses permitted in the M-1 District[28], except that dwellings, mobile homes, as defined in this title, and hotels may be permitted only upon the securing of a use permit
- The following specific uses, which shall be permitted only in M-2 Districts:
  - Wholesale lumber yards, lumber bills
  - Pottery kilns and ceramic works of heavy industrial types
  - Concrete batching plants
  - Blacksmith shops, casting foundries

[28] Uses permitted in the M-1 District include (A) uses permitted in C-3 District (i.e., General Commercial District classified facilities) except that dwellings, mobile homes, recreational vehicle parks, mobile home parks, and hotels may be permitted only upon the securing of a use permit; (B) The following uses of land and buildings, which shall be permitted in M-1 Districts: (1) Assembly and storage of goods, materials, liquids and flammable or explosive matter or materials which create dust, odor or fumes, including the following similar uses: (**a)** Wholesale and storage warehouses; (b) Feedyards and fuel yards; (2) Manufacturing, processing, fabricating, refining, repairing, packaging or treatment of goods, material or produce by electric power, oil or gas, except operations involving fish fats and oils, bones and meat products, or similar substances commonly recognized as creating offensive conditions in the handling thereof, including the following and similar uses: (a) Dyeing and dry-cleaning plants, (b) Rug cleaning plants, (c) Laundries, (d) Veterinary hospitals, (e) Construction and material yards, except gravel, rock and cement material yards, (f) Retail lumber yards; (C) The following when conducted within a building or enclosed within a solid wall or fence of a type approved by the planning commission and not less than six feet in height: (1) Body and fender repair shops, auto painting shops, (2) Cooperage and bottling works, (3) Sheet metal shops, welding shops, (4) Truck terminals; (D) Living quarters when accessory to the principal permitted use; (E) Mixed-use buildings.

- The following when enclosed with a solid wall or fence not less than six feet in height and of a type approved by the Planning Commission:
  - Building material storage yard, contractors storage yard
  - Junkyard
- Uses requiring Use Permits in an M-2 District shall be as follows: lawful uses not otherwise provided for in this chapter and not found to be similar to uses listed herein.

4.16.3.2 Glenn County General Plan

The 1993 Glenn County General Plan includes the following countywide goals that it uses as a basis for evaluating development proposals and other land-use related activities within Glenn County. The General Plan includes policies and implementation measures that support its goals. Provided below are the goals and policies that reflect Glenn County's approach to managing land use and agricultural land and timberland preservation.

Natural Resources

Agriculture/Soils: Goals and Policies

Goal: NRG-1 – Preservation of Agricultural: Goal Land

It shall be the policy of Glenn County to:

- **NRP-1:** Maintain agriculture as a primary extensive land use, not only in recognition of the economic importance of agriculture, but also in terms of agriculture's contribution to the preservation of open space and wildlife habitat.
- **NRP-2:** Support the concept that agriculture is a total, functioning system which will suffer when any part of it is subjected to regulation resulting in the decline of agricultural economics productivity, unmitigated land use conflicts, and/or excessive land fragmentation.
- **NRP-3:** Recognize the value of ricelands for waterfowl habitat, watershed management, and for groundwater recharge in an effort to preserve such lands and to maintain necessary water supplies in Glenn County.
- **NRP-5:** Continue participation in the Williamson Act: policy, and allow new lands devoted to commercial agriculture and located outside urban limit lines to enter the program, subject to the specific standards for inclusion contained in this General Plan.
- **NRP-8:** Assure that future land use decisions protect and enhance the agricultural economics industry while also protecting existing uses from potential incompatibilities.
- **NRP-9:** Encourage use of agricultural land preservation lands preservation tools such as incounty transfer of development rights, conservation easements, exclusive agricultural zoning and continuation of minimum parcel sizes.
- **NRP-11:** Monitor requests for subdivision of agricultural land preservationly developed and zoned parcels, located outside urban limit lines, in order to determine if present minimum parcel sizes are working effectively to discourage agricultural lands conversion.

- **NRP-12:** Review agricultural land conversion findings as described in NRP-11 with decision makers annually.
- **NRP-14:** Consult Important Farmland Maps and other sources of information on the relative value of agricultural lands when planning areas of growth, in order to direct growth and development toward lesser value agricultural lands.
- **NRP-15:** Recognize that, in order to realistically provide for the necessary diversity and growth required in the local economy, some lands presently committed to agriculture may be consumed by other development activities, and plan for and monitor such conversion to assure that it does not hinder or restrict existing agricultural operations. Priority shall be given to industries related to agriculture.
- **NRP-21:** Require notices of nonrenewal for Williamson Act lands as a condition of land division and boundary line changes, which result in parcel sizes below zoning minimums.

Goal: NRG-4 – Preservation, Maintenance and Restoration of Forestry Resources

It shall be the policy of Glenn County to:

- **NRP-63:** Preserve public and private timber lands and reserve them for that use, while at the same time encouraging compatible recreation and open space uses.

Community Development

Land Use/Growth: Goals and Policies

Goal: CDG-1 – Preservation of Agricultural Land

It shall be the policy of Glenn County to:

- **CDP-1:** Establish urban-rural interface areas within which all new development shall incorporate a buffer zone to separate the development from surrounding agricultural land. This requirement may be eliminated or modified if there are significant topographical differences, substantial vegetation, or existing physical barriers between urban and rural areas.
- **CDP-2:** Require that permanent well-defined buffer areas be provided as part of new nonagricultural development proposals located adjacent to agricultural land uses on Important Farmlands designated as prime, of statewide importance, unique, or of local importance. These buffer areas shall be dedicated in perpetuity, shall be of sufficient size to protect agriculture from the impacts of incompatible development and to mitigate the effects of agricultural operations on adjacent land uses, and shall be credited as open space.
- **CDP-10:** Encourage the preservation of agricultural lands, including those lands in production, and those which are potentially productive.
- **CDP-11:** Direct nonagricultural development to marginal agricultural lands, avoiding Important Farmlands, wherever feasible alternative sites have been identified.

Goal: CDG-3 – Appropriate Distribution and Regulation of Land Uses

It shall be the policy of Glenn County to:

- **CDP-20:** Assure that adequate provision is made in this General Plan for all types of uses and establish coherent land use patterns.
- **CDP-31:** Encourage commercial and industrial development in areas where adequate facilities and services exist or where facilities and services can be made available, including areas within incorporated cities, planned communities and along the I-5 corridor. Adequate facilities and services shall include community water and sewer if located within an incorporated city or urban limit line. In other areas, adequacy of sewer and water service shall be as determined by local health standards/regulations.

Glenn County Zoning Designations

AP – Agricultural Preserve Zone

The Agricultural Preserve Zone is to be applied to lands which are covered by a California Land Conservation Act (Williamson Act) contract with the county for the following purposes:

- To preserve the maximum amount of the limited supply of agricultural land which is necessary in the conservation of the county's economic resources and vital for a healthy agricultural economy of the county
- To protect the general welfare of the agricultural community for encroachments of unrelated agricultural uses which, by their nature, would be injurious to the physical and economic well-being of the agricultural community

The following uses and structures shall be permitted in the AP zone:

- One single-family residence for each parcel of land (refer to minimum residential construction standards)
- Second residence per each parcel of land (refer to minimum residential construction standards) providing that such residence may only be occupied by relatives of the owner or by employees who work on the property
- Accessory buildings such as garages, carports, greenhouses, gardening sheds, recreation rooms, storage of petroleum products for the use of persons residing on the property and any other structures that are customarily used in conjunction with and incidental to a principal use or structure
- Home occupations as defined in Chapter 15.780
- Growing and harvesting of fruit and nut trees, vines, vegetables, horticultural specialties and timber
- Growing and harvesting of field crops, grain and hay crops, and the growing of grass for pasture and grazing
- Livestock farming, including the raising, feeding, maintaining and breeding of horses, cattle, sheep, goats and similar livestock
- Operation of apiaries and dairies

- Curing, processing, packaging, packing, storage and shipping of agricultural products; however, those particular operations, uses and structures which create smoke, fumes, dust, odor and other hazards may be permitted only if a conditional use permit is first secured
- Accessory buildings or structures required for the storage of any crops, products, equipment or uses lawfully permitted or produced on the premises. Structures such as barns, stables, coops, tank houses, storage tanks, wind machines, windmills, silos and other farm buildings
- Game preserves and hunting clubs, private or public, but shall not include permanent facilities such as hotels, motels, restaurants, club houses
- Agricultural service establishments primarily engaged in performing agricultural animal husbandry services or horticultural services to farms
- Temporary landing of aircraft engaged in agricultural uses
- Dehydrators but not for the general public on a commercial basis
- Stands for the purpose of displaying and selling agricultural, floricultural or farming products which are grown or produced on the premises; provided, that there shall not be more than one stand per parcel of land. The stand shall be set back from the street or highway right-of-way a distance of at least twenty feet. Such stand must be of good frame construction
- Seasonal farmworker housing which meets the Seasonal Farmworker Housing Standards as set forth in Chapter 15.800 and approved for such use pursuant to Title 25 of the CCR. Seasonal farmworker housing shall also conform to such public health, building, and fire safety criteria as may be established by resolution or ordinance of the Board of Supervisors

The following uses and structures may be permitted in the AP Zone only if a conditional use permit has first been secured:

- Irrigation and flood control facilities, public utility and public service structures including electric transmission and distribution substations, gas regulator stations, communications equipment buildings, public service pumping stations and reservoirs over fifty acre-feet or over twenty-five feet high
- Agricultural labor camps
- Injection wells
- Confined animal facility
- Mining which meets the requirements of Government Code Sections 51238.1 or 51238.2

The following uses and structures may be permitted only if an administrative permit has first been secured:

- Natural gas wells
- Home occupation not in residential dwelling for parcels of at least 10 acres or more in size
- Agricultural Homestay Establishment

Site Area

- For prime land, the minimum area of any lot or parcel of land shall be thirty-six (36) acres or one quarter of one quarter section
- For nonprime land, the minimum area of any lot or parcel of land shall be one hundred forty-four (144) acres or one quarter section
- Variance for parcel size shall not be permitted
- The minimum area of any lot or parcel of land for each of the AP zones shall be as shown below:
  - AP-40 - Minimum Parcel Size 36 acres
  - AP-80 - Minimum Parcel Size 72 acres
  - AP-160 - Minimum Parcel Size 144 acres
- Non-contiguous parcels with a farmed area between 10 and 36 acres may be allowed if:
  - Parcel is in the same ownership as qualifying parcels but is not contiguous to the qualifying parcel, and
  - The contract contains a provision not allowing the non-contiguous parcel to be separated from the ownership of the qualifying parcels
  - The contract contains a provision not allowing construction of any residential use on the qualifying parcel

FA – Foothill Agricultural/Forestry Zone

This zoning classification is established for the following purposes:

- To provide areas for extensive agricultural activities
- To protect the timber and forest lands economically suitable for logging

The following uses and structures shall be permitted in the FA Zone:

- One single-family dwelling or mobile home for each one hundred sixty acres, private farm buildings, accessory buildings, and uses.
- Home occupations if a permit is secured pursuant to Chapter 15.780
- Growing and harvesting forest products
- Logging and sawmill operations and accessory buildings and uses
- Growing and harvesting of any agricultural crop or product
- The use of implements of husbandry, including aircraft when used in the growing of crops or raising of animals, except as may be regulated by other laws or regulations
- Game preserves and hunting clubs, private or public, but shall not include permanent facilities such as hotels, motels, restaurants, club houses
- Agricultural service establishments primarily engaged in performing agricultural animal husbandry services or horticultural services to farmers

- Temporary landing of aircraft engaged in agricultural uses
- Livestock farming, including the raising, feeding, maintaining and breeding of horses, cattle, sheep, goats and similar livestock
- Accessory buildings or structures required for the storage of any crops, products, equipment or uses lawfully permitted or produced on the premises
- The keeping of fowl and animals shall conform to all other provisions of law governing same. No pen, coop, stable, barn or corral used for fowl and animals shall be kept or maintained within fifty feet of any dwelling or other building used for human habitation, or within one hundred feet of the front lot line of the lot upon which it is located, or within twenty-five feet of the street side of a corner lot, or within one hundred feet of any parcel of land used for a public park, school or similar institution
- Stands for the purpose of displaying and selling agricultural, floricultural or farming products which are grown or produced on the premises, provided that there shall be not more than one stand per lot or parcel of land. The ground coverage of the stand shall not exceed three hundred square feet and it shall be set back from the street or highway right-of-way a distance of at least twenty feet. Such stand must be of good frame construction
- Windmills, tank houses, buildings or shelters for farm equipment and machinery, water wells, water reservoirs and storage tanks

The following uses and structures may be permitted in the FA Zone only if a conditional use permit has first been secured:

- Commercial storage and handling of agricultural chemicals
- Farm labor camps and structures for transient labor
- Commercial hog and pig farming
- Animal sales yards
- Commercial stables, riding academies
- Public and private nonprofit nursery schools, elementary schools, junior high schools, high schools, and colleges
- Churches, public playgrounds, and parks
- Sales and services to farmers or farm-related activities
- Government buildings and properties
- Kennels, animal hospitals, and veterinarian's offices
- Public utility buildings and public service or utility uses (transmission and distribution lines excepted), including but not limited to reservoirs, storage tanks, pumping stations, telephone exchanges, power stations, transformer stations, service yards, and parking lots
- Cemeteries, crematories, and mausoleums

- Commercial storage (storage for resale) of inflammable fluid or gas fuels in a quantity greater than five hundred gallons in any container less than two and one-half feet below the surface of the ground
- New confined animal facilities
- Confined animal facility expansion

The following uses and structures may be permitted only if an administrative permit has first been secured:

- Second residence per each parcel of land
- Natural gas wells
- Agricultural Homestay Establishment

The minimum area of any lot or parcel of land in the FA Zone shall be one hundred forty-four (144) acres.

4.16.3.3 Colusa County General Plan

The 2012 Colusa County General Plan includes the following countywide goals, objectives, and policies that it uses as a basis for evaluating development proposals and other land-use related activities within the County. Provided below are the goals, objectives, and policies that reflect Colusa County's approach to managing land use, agricultural land and timberland preservation, and open space uses.

Land Use Element

The Land Use Element provides for a development and resource conservation pattern that preserves and fosters the rural and agricultural character of Colusa County while allowing for economic development.

Goal LU-1: Maintain the Efficient and Harmonious use of Land in the County, Promoting a well Organized and Orderly Development Pattern, Avoiding Random, Haphazard Growth, Protecting Public Health and Safety, and Accommodating the Orderly and Sustainable Growth of Employment and Population

Objective LU-1A: Provide a Balanced Mix of Land Uses that Reflect the Needs of the County Residents and Businesses

- **Policy LU 1-2:** Ensure that the County designates a supply of developable industrial, commercial, and residential land sufficient to meet projected growth and economic needs over the planning period.
- **Policy LU 1-7:** The Land Use Map may be amended from time to time to ensure that there is an adequate supply of industrial, commercial, public service, residential, and other lands to serve the County's economic needs. However, agricultural and open space lands shall not be re-designated or developed for urban or residential uses unless:
  - The proposed use is necessary for the economic, agricultural, and social well-being of the County.
  - Residential uses are located away from areas of excessive noise, smoke, or dust, especially in those areas adjoining freeways or industrial uses.
  - The proposed use will not conflict with existing or anticipated uses in the vicinity.

- **Policy LU 1-27:** Participate in countywide, regional and other multi-agency planning efforts related to agriculture, water supply, tourism, open space, air quality, housing, green infrastructure, recreation, habitat conservation, energy, emergency preparedness and flood protection to ensure that the needs of the County's residents and businesses are not overlooked.

Goal LU-2: Maintain Agriculture as the Paramount Land Use in the County and Ensure Land Use and Planning Decisions Support a Strong Agricultural Economy

Objective LU-2A: Conserve and Protect Agricultural Land through a Variety of Strategies, including General Planning, Zoning, Taxation, and Easements

- **Policy LU 2-1:** Agriculture, upland, and resource conservation are the primary land use designations to be used outside of the communities and any adjacent Urban Reserve Areas.
- **Policy LU 2-2:** Ensure that future development and land use decisions protect the integrity of agriculture and do not in any way create a hardship for the county's farmers.
- **Policy LU 2-3:** Ensure that lands presently in agricultural uses that do not adjoin existing communities continue to be designated for agricultural uses and are protected through the county's land use regulations.
- **Policy LU 2-4:** Manage agricultural parcels of less than 20 acres, including antiquated subdivisions, to improve compatibility with surrounding agricultural uses, including:
  - Minimizing the impact of residential development near farms.
  - Encouraging lot mergers to achieve larger parcel sizes.
  - Locating dwelling units and structures near roads and in a way that minimizes interruption or fragmentation of agricultural lands.

Objective LU-2A: Only Permit Development on Agricultural Land that will Not Interfere with Viable Agricultural Operations

Agricultural and Upland (Agriculture General, Agriculture Transition, and Agriculture Upland) Policies

- **Policy LU 2-5:** Require lands designated Agriculture General, Agriculture Transition, or Agriculture Upland to remain designated for agricultural use, including businesses or uses that directly support County agricultural activities, for at least the duration of the planning period, with the exception of lands redesignated consistent with the requirements of Policy LU 1-7.
- **Policy LU 2-6:** Discourage the division of land in agricultural areas if the division is not for the purpose of farming or other agricultural activities or if the division precludes the future opportunity to farm the land.

Goal LU-3: Ensure that Future Development Achieves the County's Goals of Agricultural Conservation, Rural Character, Growth Focused Around Existing Communities and Uses Sustainable Practices through Application of Development Requirements

- **Policy LU 3-4:** Require transitional uses or a buffer between residential and industrial uses, residential and general agriculture uses, and residential and agriculture upland uses.

Goal LU-4: Provide Clear Land Use Objectives and Standards to Address the Unique Needs and Conditions Associated with the Proposed Sites Reservoir

Objective LU-4A: Provide for Orderly, Well-planned, and Compatible Growth associated with the Proposed Sites Reservoir and Surrounding Area

- **Policy LU 4-1:** Support the creation of Sites Reservoir.
- **Policy LU 4-2:** Participate in State and regional planning efforts related to the creation of Sites Reservoir to the greatest extent feasible.
- **Policy LU 4-3:** Ensure that future land use decisions regarding Sites Reservoir and the surrounding area recognize the needs of the County and existing property owners to address adequate access for existing landowners and persons who travel beyond the area, noise, habitat for displaced species, and recreation and tourist opportunities that are compatible with the surrounding region.
- **Policy LU 4-4:** Support the efforts of the Sites Reservoir Joint Powers Authority, with particular emphasis on landowner relocation assistance and ensuring financial compensation for landowners adversely impacted by the creation of Sites Reservoir.
- **Policy LU 4-5:** Future land use and zoning designations in the Sites Reservoir Planning Area should emphasize natural resource and wildlife habitat protection, recreational opportunities, open space preservation, and limited commercial development to support recreation and tourism. Year-round housing in the vicinity of Sites Reservoir should be discouraged.

Action LU 4-A: When the final boundaries for the proposed Sites Reservoir are determined and approved by the California Department of Water Resources, develop a Sites Area Plan to guide land uses in the Sites Reservoir Area. The plan shall include policies and actions to promote the economic and social viability of the area and shall designate a variety of land uses. Land uses in the plan shall include provisions for active and passive recreation, limited commercial uses oriented toward recreation and tourism, viewing points of the main scenic areas of the reservoir and any bridges, and seasonal housing and campgrounds in the areas immediately adjacent the reservoir. Additionally, the plan shall identify agricultural land to accommodate the needs of existing landowners and farmers and habitat land for displaced species. Access, noise, water, wastewater, and emergency services shall be considered in the designation of land uses.

Action LU 4-B: Actively participate in the Sites Project Joint Powers Authority, and any other state and regional entities formed to plan and develop the Sites Reservoir. Ensure that the County's needs for a range of land uses, adequate and convenient access to existing parcels, habitat for plants, wildlife, and special-status species, adequate and convenient access to communities (Lodoga, Stonyford, etc.), and recreation and tourist opportunities are addressed and that measures to promote the economic and social viability of the area and to reduce adverse noise, traffic, and other adverse impacts are identified and implemented.

Agricultural Element

The Agriculture Element contains goals, objectives, policies and action items geared towards the protection of agricultural lands, the expansion of agricultural operations, and the reduction of conflicts between agricultural and non-agricultural land uses.

Goal AG-1: Preserve and Protect Agricultural Land

Objective AG 1-A: Recognize that Agricultural Land is the County's Greatest Natural Asset and Take Appropriate Measures to Restrict the Conversion of Agricultural Lands to Non-Agricultural Use

- **Policy AG 1-1:** The following General Plan land use designations are considered agricultural lands: Agricultural General (AG), Agricultural Upland (AU), and Agricultural Transition (AT).
- **Policy AG 1-2:** Lands designated for agricultural uses shall remain designated for agriculture and not be rezoned or redesignated to an urban use unless all of the following criteria are met:
  - The lot(s) for which conversion is requested is adjacent to agriculture or agricultural support uses (e.g. receiving plants, hulling plants, warehousing, trucking, distribution, and other related activities.) on no more than two sides of the lot(s) or less than 50 percent of the perimeter of the lot(s) proposed for conversion.
  - The conversion will not be detrimental to existing agricultural operations.
  - The conversion land is within 500 feet of existing urban infrastructure (e.g., water supply lines and sewer lines) and conversion will constitute a logical contiguous extension of a designated urban area.
  - The lot(s) proposed for conversion include a buffer at the agricultural/urban transition zone to protect future users of the conversion lands from nuisances associated with typical agricultural practices.
  - No feasible alternative location (e.g., non-agricultural lands or less productive agricultural lands) exists.
  - The use would not have a significant adverse effect on existing or potential agricultural activities on surrounding agricultural lands.
- **Policy AG 1-3:** Land divisions that separate a residence or an agricultural processing facility from the agricultural land shall be prohibited, unless the lot split meets the minimum lot size requirement of the zoning district.
- **Policy AG 1-4:** Maintain agricultural parcel sizes that are large enough to sustain agricultural activities. The following minimum lot sizes shall apply to agricultural lands: Agricultural General- 40 acres, Agricultural Upland-80 acres, and Agricultural Transition -10 acres.
- **Policy AG 1-5:** Encourage lot mergers to meet minimum parcel size standards.
- **Policy AG 1-6:** Residential development on agricultural lands shall be limited to housing for family members and agricultural employee housing.

Goal AG-2: Maintain and Enhance Agriculture as the County's Most Critical Land Use, Economic Sector, and Resource

Objective AG 2-B: Allow Limited Recreation and Resource Production Uses on Agricultural Lands While Ensuring that Such Uses Do Not Adversely Affect Agricultural Activities

- **Policy AG 2-2:** Visitor-serving uses that support and are incidental to agricultural production, such as tasting rooms, including sales and promotion of products grown or processed in the County, educational activities and tours, incidental sales of items related to local area agricultural products, promotional events, and farm homestays, which allow visitors to visit a farm in the form of a vacation, that support and are secondary and incidental to local agricultural production, shall be allowed on agricultural lands provided the following findings are made:
  - The use promotes and markets only agricultural products grown or processed in the local area.
  - The use is compatible with and secondary and incidental to agricultural production activities in the area.
  - The use will not require the extension of sewer and water service.
  - The use is compatible with existing uses in the area.
  - The use will not adversely affect agricultural production in the area.
  - The use will not result in significant adverse traffic or air quality impacts.
  - The use will not be detrimental to the rural character of the area.
- **Policy AG 2-3:** Low-intensity recreational uses may be permitted on agricultural lands as long as they do not interfere with the principal use of the land for agricultural purposes. Examples include hunting, fishing, target shooting, horseback riding, hiking and exhibitions of working farms or ranches.

Objective AG 2-C: Preserve and Protect Water, Soil, and Natural Resources Necessary for Agricultural Operations

- **Policy AG 2-8:** Support and promote water development projects which provide additional sources of water for agricultural uses.
- **Policy AG 2-9:** Support the procurement of expanded and additional water rights which provide for contractual supply reliability for agricultural use.

Open Space and Recreation Element

Recreation is an important concern of County residents, and park facilities and recreational opportunities cannot exist without open space. This element addresses parks and recreation issues, goals, objectives, and policies.

Goal OSR-1: Preserve and Protect the Natural Resources and Scenic Beauty of the County

Objective OSR 1-A: Provide a Diverse and Accessible Range of Open Space Lands

- **Policy OSR 1-9**: Maintain open space for future water and drainage projects.

Objective OSR 1-E: Retain and Preserve Expansive Open spaces, Uninterrupted by Urban Development, both in the Valley Floor and in Upland Valleys

- **Policy OSR 1-23:** Ensure that open space buffers such as greenbelts, drainage features, parks, or other improved and maintained features are provided by new development projects, where appropriate, between new urban development and sensitive open space uses, such as agriculture and wildlife habitat. Buffers shall be adequately sized to reduce potential land use conflicts between adjacent uses.

Goal OSR-2: Increase Opportunities for Recreational Activities in Open Space

Objective OSR 2-A: Ensure Adequate and Increased Public Access is Available to Open Space Recreation Areas

- **Policy OSR 2-5**: Public access to the water and shoreline areas of lakes, reservoirs, rivers and streams, should be provided where appropriate.

Objective OSR 2-B: Increase Opportunities for County Residents and Visitors to Engage in a Broad Variety of Outdoor Recreation Activities

- **Policy OSR 2-13:** Encourage recreational uses that emphasize use of the waterways in locations directly on the Sacramento River, East Park Reservoir, and the proposed Sites Reservoir. Examples include fishing, canoeing, boating, and nature observation. With the exception of boat launches and docks, more active uses, such as parking, restrooms, and picnic areas, shall be located in areas away from the river and sensitive riparian habitat.
- **Policy OSR 2-14:** Encourage recreational uses that emphasize a range of outdoor activities, such as hiking, drive-in camping, hike-in camping, picnics, off-highway vehicle use, and nature observation, at the Mendocino National Forest, East Park Reservoir, proposed Sites Reservoir, Sacramento River, and other outdoor recreation areas.
- **Policy OSR 2-15:** Support the location and creation of Sites Reservoir in Colusa County (See Policies LU 4-1 through 4-5).
- **Policy OSR 2-16:** Require future water development projects, including reservoirs, marinas, and water-front developments, to include provisions for public access to the water and shoreline areas to the greatest extent feasible, without compromising private property rights.

Colusa County General Plan Land Use and Zoning Designations

The Agriculture General (AG)[29] land use designation identifies areas to be retained for agriculture and/or uses that are complementary to existing or nearby agricultural uses. This designation includes lands under agricultural preservation and/or conservation contracts and easements; land having present or future potential for agricultural production, and contiguous or intermixed smaller parcels on which non-compatible uses could jeopardize the long-term agricultural use of nearby agricultural lands. Lands designated Agriculture General are planned to be preserved for agricultural uses and the intent of the

[29] Agriculture Preserve (A-P) and Exclusive Agriculture (E-A) zoning districts are compatible with the Agriculture General land use designation.

designation is to preserve such lands for existing and future agricultural use and protect these lands from the pressures of development.

The Colusa County zoning classifications are presented below.

A-P – Agriculture Preserve Zone

The Agriculture Preserve or A-P Zone is intended to be applied in areas where agriculture is the natural and desirable primary land use and where the protection of agriculture from the encroachment of incompatible uses is essential to the general welfare.

- Principal Permitted Uses:
  - All general agricultural uses, including animal husbandry and all structures appurtenant to principal agricultural uses, main single-family dwelling for the landowner or the primary tenant of the property, nurseries and greenhouses, private farm airports, guest houses not rented or otherwise conducted as a business
- Uses Permitted with a Use Permit:
  - Single-family dwelling units for immediate relatives of the property owner, caretakers or farm labor housing
  - Commercial animal raising or farms
  - Agriculture auction and sales yards or collection yards
  - Agricultural products processing plants
  - Establishments for sale, rental or repair of farm equipment and supplies
  - Animal hospitals and kennels
  - Farm labor camps
  - Airports for commercial farm services
  - Residential mobile homes
  - Exploratory drilling and production of fossil fuels and geothermal power
  - Recreational uses such as gun and hunt clubs, boat landings, and resorts
- Other Regulations:
  - Minimum parcel size: eighty acres
  - Minimum parcel width: one hundred feet
  - Minimum parcel depth: two hundred feet
  - Minimum yards: front, twenty-five feet; side, ten feet; rear, twenty feet
  - Maximum building height (residential): thirty feet
  - Development standards as set forth in Article 8

E-A – Exclusive Agriculture Zone

The Exclusive Agriculture or E-A zoning classification is intended to be applied in agricultural lands with a General Plan land use designation of AG. The E-A Zone is to be applied to those areas where agricultural activities are the appropriate and desirable primary land use. The E-A Zone is to be applied to those areas where the protection of agriculture from the encroachment of incompatible uses is essential to the general welfare of the county citizens. The E-A Zone is to help maintain, protect, enhance, and propagate the county's agricultural resources. The E-A Zone is to protect and maintain a viable agricultural economy in the county. The E-A Zone is to protect agriculturalists from environmental impacts and pressures as they relate to groundwater, nonagriculture traffic, and encroachment from residential development resulting in common agriculture/residential conflicts related to noise, odors, spraying, vandalism, trespassing, and predation from wildlife habitating on nonmaintained adjacent ten-acre sized lots.

- Principal Permitted Uses:
  - All general agricultural uses, including farming, dairying, and pasturage
  - Horticulture, floriculture, aquaculture, and viticulture; the growing and harvesting of forestry products
  - Animal husbandry, and general keeping of animals, subject to the animal maintenance requirements of section 6.04
  - Nurseries and greenhouses
  - Private farm airports
  - Housing allowed as a permitted use as it is an appurtenant use to principal agricultural uses:
    - Primary residence, one single-family dwelling or modular home per parcel, for the landowner or primary tenant of the property whose principal income is derived from those agricultural activities upon which the house is located and other agricultural lands
    - Housing facilities (including mobile/modular homes) to accommodate up to twelve agricultural workers and their families employed by the owner or operator of premises or owners or operators of other agricultural lands
  - Buildings and uses accessory to the permitted uses, barns and other storage or shop buildings; those structures normally associated with a single-family residence use and in conjunction with or incidental to the residential use, including, but not limited to, a garage, workshop, shed, garden, private swimming pool, private tennis court, gazebo, spa, and other similar structures/uses
- Uses Permitted with a Use Permit:
  - Guest houses not rented or otherwise conducted as a business
  - Agriculture auction and sales or collection yards
  - Agriculture products processing plants
  - Agriculture chemicals manufacture, distribution, and storage
  - Establishments for sale, rental or repair of farm equipment and supplies
  - Establishments for repair of natural gas equipment and associated accessories associated with natural gas wells
  - Public and quasi-public uses

- Public tasting rooms in conjunction with a winery; provided, that such tasting room be considered accessory to the on-site winery
- Public or riding stables and academies
- Outdoor commercial recreational facilities on sites not less than five acres
- Kennels and animal hospitals
- Airports for commercial farm services
- Second dwelling unit, either a single-family dwelling unit or modular home for immediate relatives of property owner, or caretaker
- Oil and natural gas wells
- The erection, construction, alteration or maintenance of gas, electric, water, or communication transmission facilities
- Exploratory drilling and production of fossil fuels, geothermal power, and natural gas
- Recreational uses such as seasonal hunting and fishing camps, duck clubs with accessory structures, boat landings with accessory structures, and resorts

- Other Regulations:
  - Minimum parcel size: forty acres, including the existing and proposed rights-of-way of the county road or roads on which said parcel has frontage on the front, rear or side
  - Minimum parcel width: one hundred feet
  - Minimum parcel depth: two hundred feet
  - Minimum yards: front – twenty-five feet; side – twenty-five feet; rear – twenty-five feet
  - Maximum building height (residential): thirty feet
  - Development standards as set forth in Article 8. (Ordinance Number 722, §1.)

M – Industrial Zone

The industrial or M Zone is intended to apply to areas devoted to light manufacturing, heavy commercial uses, large administrative facilities and normal operations of industries, subject only to such regulations as are needed to control congestion and protect surrounding areas from significant environmental impacts.

- Principal Permitted Uses:
  - Food processing plants, fabrication or processing of metal, wood, fiber, plastic or pottery products
  - Administrative, business and professional offices, editorial, publishing and bookbinding
  - Manufacturing of electrical and electronic equipment; research and development laboratories
  - Warehouses, enclosed storage and distribution facilities

- Automotive and farm equipment sales, service, repair and rental facilities; farm and building supplies; truck terminals
- Industrial manufacturing uses

- Uses Permitted with a Use Permit:
  - Churches and other private institutions
  - Private recreation facilities
  - Commercial animal farms, animal hospitals and kennels
  - Animal products processing plants
  - Junk yards, garbage dumps, sewage plants
  - Smelting or reduction of metallic ores
  - Manufacturing, refining and storage by manufacturers or wholesalers or petroleum or petroleum products, acids, cement, explosives, fireworks, gas, glue, gypsum, and inflammable fluids or gasses
  - Drilling for oil or gas, or commercial excavation of sand, rock, gravel, or other natural materials
  - Manufacture of concrete, pottery, or asphaltic paving products
  - Energy production plants
- Other Regulations:
  - Minimum lot size, width, depth, and minimum yards: none
  - Maximum building height: fifty feet
  - Development standards as set forth in Article 8

F-W – Floodway Zone

The Floodway or F-W Zone is intended to be applied to lands which lie within stream or tidal channels and to adjacent areas which are periodically inundated, or which will be inundated by a “design flood.”

The regulations set forth in this section are intended to provide for the reasonably unrestricted passage of a “design flood” and to provide reasonable measures for the protection of life and property in floodway areas.

- Principal Permitted Uses:
  - General agriculture, but not including building or structures
  - Recreational uses on open land, including public and private parks and golf courses
- Uses Permitted with a Use Permit:
  - Private recreation facilities
  - Boat docks and launching facilities
  - Water, sewer, roadway, bridge, and other such facilities necessary for public health and safety

  - Minor or temporary structures incidental to agricultural or recreational uses, which will not impede flood flow and are of flood-proof design
  - Excavation of natural materials or construction of earthworks or water flow control devices
- Other Regulations:
  - None, except conditions in use permits
  - Development standards as set forth in Article 8

4.17 Chapter 21: Recreation Resources

4.17.1 Federal Plans, Policies, and Regulations

4.17.1.1 Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The purpose of the 1996 Shasta-Trinity National Recreation Area (NRA) management guide is to integrate past decisions that remain pertinent for managing the Shasta and Trinity units of the NRA with standards, guidelines, and management prescriptions incorporated from the April 1995 Shasta-Trinity National Forest Land and Resource Management Plan (LRMP). The LRMP establishes integrated land management direction, including time frames for implementing, monitoring, and evaluating projects, activities, programs, and budgeting in the Shasta-Trinity National Forest for a period of 10 to 15 years. The NRA management guide provides an analysis of direction from the LRMP, a summary of existing conditions, a description of desired future conditions, and a strategy of management recommendations, opportunities, and mitigation measures that will be used to implement the direction in the LRMP and achieve the desired future conditions.

4.17.1.2 Federal Water Project Recreation Act of 1965

This statute declares that recreation, fish and wildlife enhancement be given full consideration as purposes of federal water projects if non-federal public bodies agree: 1) to bear 50 percent of the cost of recreation enhancement and 25 percent of the cost of fish and wildlife enhancement, 2) to administer project lands and water bodies for these purposes, and 3) to bear all operation, maintenance, and replacement costs. This cost sharing is not required on federal lands under federal programs for fish and wildlife conservation.

4.17.1.3 Rehabilitation Act of 1973

This federal act extended and revised authorization of grants to states for vocational rehabilitation. One of the purposes of the act is to evaluate architectural and transportation barriers to handicapped individuals, develop new approaches, enforce statutory standards and requirements regarding barrier free construction of public facilities.

4.17.1.4 Architectural Barriers Act of 1968

The Architectural Barriers Act requires access to facilities designed, built, altered, or leased with federal funds. The Act is enforced by the Department of Defense, the Department of Housing and Urban Development, the General Services Administration, and the U.S. Postal Service to ensure, whenever possible, that physically handicapped persons will have ready access to, and use of, such buildings

4.17.1.5 Americans with Disabilities Act of 1990, as Amended

Public facilities must comply with the Americans with Disabilities Act (ADA) of 1990, as amended, to the extent possible. Needs and considerations regarding the disabled must be addressed and new facilities must comply with ADA standards.

4.17.1.6 San Luis Authorization Act

Congress passed the San Luis Authorization Act in 1960 to authorize the construction and operation of the San Luis Unit and to enable Reclamation to participate in the development of recreation facilities. The San Luis Unit is a part of the CVP and the SWP and is jointly operated by Reclamation and DWR. The principal purpose of the federal portion of the facilities is to furnish approximately 1.25 million acre-feet of water as a supplemental irrigation supply to 600,000 acres located in the western portion of Fresno, Kings, and Merced counties.

4.17.2 State Plans, Policies, and Regulations

4.17.2.1 State Water Code Section 11900-11901 (Implementing the Davis-Dolwig Act)

Chapter 10, Part 3, Division 6 of the California Water Code states that State facilities designed for the storage, conservation, or regulation of water shall be constructed in a manner consistent with the full utilization of their potential for the enhancement of fish and wildlife and to meet recreational needs. It specifies that providing for the enhancement of fish and wildlife and for recreation in connection with water storage, conservation, or regulation facilities benefits all of the people of California and that project construction costs attributable to such enhancement of fish and wildlife and recreation features should be borne by them. It further states that State recreation and the enhancement of fish and wildlife resources are among the purposes of State water projects; that the acquisition of real property for such purposes be planned and initiated concurrently with and as a part of the land acquisition program for other purposes of State water projects; and that facilities for such purposes be ready and available for public use when each State water project having a potential for such uses is completed. DWR is required to operate the SWP Facilities in accordance with this Act.

4.17.2.2 California Public Trust Doctrine

The California Public Trust Doctrine holds that certain resources are above private ownership and reside in the trust of the government for the benefit of the people. It is the duty of the government to administer these resources for the highest public interest. California courts have expanded the scope of the Doctrine to include recreation and environmental benefits. Additionally, the Doctrine has been expanded to include not only navigable waters, but all State-owned lands, fish, and wildlife.

Folsom Lake State Recreation Area General Plan and Amendment

The first Folsom Lake State Recreation Area (SRA) General Plan was approved in 1979. The plan was amended in 1996 to include additional facility recommendations for the Negro Bar (Lake Natoma), Willow Creek (Lake Natoma), and Beals Point (Folsom Lake) areas as part of the American River Bridge Crossing Project at Lake Natoma. The California Department of Parks and Recreation (State Parks) is updating the general plan for the Folsom Lake SRA.

The original 1979 general plan identifies the objectives for both Lake Natoma and Folsom Lake.

Lake Oroville State Recreation Area Resource Management Plan and General Development Plan and Amendment

In 1973, the Lake Oroville SRA Resource Management Plan and General Development Plan were approved. The plans outlined the allowable use intensities and planned development for each area in the SRA. In 1988, an amendment to the plan was approved to address three issues in the Lime Saddle area: acquisition of land, disposal of a parcel, and expansion of the existing Lime Saddle Marina.

San Luis Reservoir State Recreation Area General Development Plan and Amendment

The General Development Plan for the San Luis Reservoir SRA was approved in 1971, although the plan was not developed to the same level of detail used for later State Parks general plans. In 1986, the general development plan was amended to revise the land use designation for about 65 acres of land on the northern side of O'Neill Forebay from undesignated to a day and overnight use designation, thus allowing development of overnight facilities in the Meadows area and boat-in day-use and camping facilities in the Grant Line area. State Parks is updating the general plan for the San Luis Reservoir SRA.

4.17.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to recreation resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.18 Chapter 22: Socioeconomics

4.18.1 Federal Plans, Policies, and Regulations

4.18.1.1 Constitution of the United States: Fifth Amendment Takings Clause

The takings clause of the Fifth Amendment provides that "[n]o person shall be deprived of life, liberty, or property, without due process of law; nor shall private property be taken for public use, without just compensation." The takings clause does not prohibit the federal government from taking private property; it requires that property owners be compensated for the value of the property taken. According to the U.S. Supreme Court, the takings clause "was designed to bar Government from forcing some people alone to bear public burdens which, in all fairness and justice, should be borne by the public as a whole" (Armstrong v. United States [1960] 364 U.S. 40, 49). The taking of private property by the government can occur in a number of ways: by direct appropriation, by occupation or invasion, or by regulation (regulatory taking).

Government exactions may be considered unconstitutional takings if they do not meet the "reasonable relationship nexus" test, as set out in Dolan v. City of Tigard (1994) 512 U.S. 374 and Nollan v. California Coastal Commission (1987) 483 U.S. 825. In order for an exaction to be valid: (1) the legislation must serve a legitimate governmental purpose; and (2) the means used to achieve the objective must substantially advance the intended purpose.

4.18.1.2 Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970

Title II, Uniform Relocation Assistance, §201(b), establishes a uniform policy for the fair and equitable treatment of persons displaced as a direct result of programs or projects undertaken by a federal agency or with federal financial assistance. The primary purpose of this title is to ensure that such persons shall not suffer disproportionate injuries as a result of programs and projects designed for the benefit of the public as a whole and to minimize the hardship of displacement on such persons.

Title III, Uniform Real Property Acquisition Policy, §301**,** was developed “In order to encourage and expedite the acquisition of real property by agreements with owners, to avoid litigation and relieve congestion in the courts, to assure consistent treatment for owners in the many federal programs, and to promote public confidence in federal land acquisition practices.”

4.18.1.3 Housing and Community Development Act of 1974

Pursuant to §104(d) of the Housing and Community Development Act of 1974, as amended and the implementing regulations at 24 CFR Part 42, a residential anti-displacement and relocation assistance plan is required and must provide for: (1) one-for-one replacement of occupied and vacant occupiable low- and moderate-income dwelling units demolished or converted to another use in connection with a development project assisted under Parts 570 and 92; and (2) provide relocation assistance for all low- and moderate-income persons who occupied housing that is demolished or converted to a use other than for low- or moderate-income housing.

4.18.1.4 U.S. Department of Agriculture

The USDA administers and implements several programs that can influence both how the agricultural sector may react to proposed project activities and how large the direct economic effects on agriculture might be. These programs include the direct and countercyclical payments program, commonly referred to as the farm commodity programs, and the Conservation Reserve Program and similar programs. This section briefly describes important parts of the farm program.

The current farm commodity programs are defined in the Food, Conservation, and Energy Act of 2008, passed by Congress and signed into law in 2008. This law, commonly referred to as the Farm Bill, authorizes the programs for the next five years. At any time, Congress may, with the President’s approval, extend, modify, restructure, or eliminate one or more programs.

The current Farm Bill contains 15 titles that describe and authorize one or more specific programs. Key programs include:

- **Commodity Programs**. Certain agricultural commodities receive price supports and/or direct payments under the 2008 Farm Bill. These include corn, cotton, rice, small grains, grain sorghum, oilseeds, dry peas/lentils, and sugar crops (other crops also are included but are not grown in California). For the crop programs, benefits are paid to producers with eligible historical acreage (called Base Acres) of covered commodities. Some of these payments are available even if the program commodity is no longer grown on that base acreage; however, conversion of the land to nonagricultural uses generally eliminates all commodity program payments.

- **Conservation Reserve and Wetland Reserve Programs**. These programs provide annual payments to farmers willing to enter long-term contracts to maintain vegetative cover on eligible lands or to restore wetlands on previously agricultural land. They also provide cost-sharing and other financial assistance for soil conservation, water conservation, and wildlife conservation activities.

- **Marketing and Credit Assistance**. Numerous programs are designed to provide direct assistance, credit guarantees, and loans to support agriculture.
- **Crop Insurance and Disaster Assistance**. These programs provide subsidized crop insurance to farmers and provide disaster assistance payments to crop and livestock producers in declared disaster counties.

4.18.2 State Plans, Policies, and Regulations

4.18.2.1 California Constitution: Article 1 Declaration of Rights, Section 19

Pursuant to the California Constitution and other statutes, public agencies may use eminent domain power to: (1) acquire private property (real, business, personal, tangible, or intangible property); or (2) reduce the economic value of property for a public purpose (these are referred to as “damages”) if they pay “just compensation” to the owner. Just compensation includes: (1) the fair market value of the real property and its improvements; and (2) any diminution in value of the remaining property when property taken is part of a larger parcel.

4.18.2.2 California Relocation Assistance Act and the California Relocation Assistance and Real Property Acquisition Guidelines

Chapter 16, §7260 to 7277 of the California Government Code states that whenever programs or projects undertaken by a public entity result in the displacement of any person, the displaced person is entitled to payment for actual moving and related expenses as the public entity determines to be reasonable and necessary.

CCR Title 25, Chapter 6 provides guidelines to ensure that uniform, fair, and equitable treatment is afforded persons displaced from their homes, businesses, or farms as a result of the actions of a public entity in order that such persons shall not suffer disproportionate injury as a result of action taken for the benefit of the public as a whole.

4.18.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to socioeconomics, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.19 Chapter 23: Environmental Justice

4.19.1 Federal Plans, Policies, and Regulations

4.19.1.1 Executive Order 12898

EO 12898 provides that each federal agency shall make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations. The order calls for the fair treatment and meaningful involvement of all people, regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. "Fair treatment" means that no group of people, including racial, ethnic, or socioeconomic groups, should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal or commercial operations. Environmental justice is the fair treatment and meaningful involvement of all people – regardless of race, ethnicity, income, or education level – in environmental decision making. Environmental justice programs promote the protection of human health and the environment, empowerment via public participation, and the dissemination of relevant information to inform and educate affected communities.

4.19.1.2 Council on Environmental Quality Guidance (1997)

CEQ guidance for performing environmental justice analyses as part of the NEPA process provides definitions, thresholds, and overall methodological guidance for environmental justice analyses.

4.19.1.3 U.S. Department of the Interior Environmental Compliance Memorandum No. ECM 95-3

Memorandum No. ECM 95-3 provides guidance for complying with EO 12898 for DOI actions and programs. It stipulates that environmental documents prepared by DOI agencies shall analyze the impact of agency actions on minority and low-income populations. The memorandum directs agencies to evaluate the equity of the impacts imposed on these populations relative to the benefit of the action. The relevant environmental document should identify any such impacts, or the absence of impacts, on minority and low-income populations.

U.S. Department of the Interior Environmental Justice Strategic Plan – 1995

EO 12898 requires federal agencies to develop agency-specific environmental justice plans. The DOI Environmental Justice Strategic Plan – 1995 provides the following goals (1995):

- **Goal 1:** The Department will involve minority and low-income communities as we make environmental decisions and assure public access to our environmental information.
- **Goal 2:** The Department will provide its employees environmental justice guidance and with the help of minority and low-income communities develop training which will reduce their exposure to environmental health and safety hazards.
- **Goal 3:** The Department will use and expand its science, research, and data collection capabilities on innovative solutions to environmental justice-related issues (for example, assisting in the identification of different consumption patterns of populations who rely principally on fish and/or wildlife for subsistence).
- **Goal 4:** The Department will use our public partnership opportunities with environmental and grassroots groups, business, academic, labor organizations, and Federal, Tribal, and local governments to advance environmental justice.

4.19.1.4 U.S. Environmental Protection Agency Office of Environmental Justice's Environmental Justice Implementation Plan (1997)

The Environmental Justice Implementation Plan supplements EO 12898 and its associated Environmental Justice Strategic Plan by providing a timetable for undertaking revisions, as required by the EO, and identifying lead process owners and realistic measures of success.

4.19.1.5 Title VI of the Civil Rights Act of 1964

Title VI, 42 U.S.C. §2000d et seq., was enacted as part of the landmark Civil Rights Act of 1964. It prohibits discrimination on the basis of race, color, and national origin in programs and activities receiving federal financial assistance.

4.19.1.6 U.S. Environmental Protection Agency Final Guidance for Incorporating Environmental Justice Concerns in the EPA's National Environmental Policy Act Compliance Analyses (1998)

This framework serves as a guidance to incorporate environmental justice goals into the USEPA's preparation of EISs and environmental assessments (EAs) pursuant to NEPA. This framework emphasizes the importance of selecting an analytical process appropriate to the unique circumstances of the potentially affected community.

4.19.2 State Plans, Policies, and Regulations

The following State regulation is applicable to environmental justice, but is discussed in another section of this chapter, as indicated in parentheses:

- Delta Vision Strategic Plan (Aquatic Biological Resources)

4.19.2.1 Senate Bill 115 (Solis)

Approved in 1999, California SB 115 (Solis) adds §65040.12 to the Government Code and Part 3 to Division 34 of the Public Resources Code, both of which concern environmental justice. The bill provides that the Governor's Office of Planning and Research (OPR) is the coordinating agency in California State government for environmental justice programs.

4.19.2.2 California Government Code Section 65040.12

Pursuant to AB 1553, signed into law in October 2001, §65040.12 requires the OPR to:

1. Consult with the Secretaries of the CalEPA, the Resources Agency, and the Business, Transportation and Housing Agency, the Working Group on Environmental Justice established pursuant to §72002 of the Public Resources Code, any other appropriate State agencies, and all other interested members of the public and private sectors in this state.
2. Coordinate the office's efforts and share information regarding environmental justice programs with the CEQ, USEPA, the General Accounting Office, the Office of Management and Budget, and other federal agencies.
3. Review and evaluate any information from federal agencies that is obtained as a result of their respective regulatory activities under federal EO 12898, and from the Working Group on Environmental Justice established pursuant to §72002 of the Public Resources Code.

4. Establish guidelines for addressing environmental justice issues in City and County general plans, including planning methods for the equitable distribution of public facilities and services, industrial land uses, and the promotion of more livable communities.

4.19.2.3 California State Lands Commission Environmental Justice Policy (October 1, 2002)

The California State Lands Commission (CSLC) developed an Environmental Justice Policy to ensure equity and fairness in its own processes and procedures, and in October 2002, it adopted an amended policy. The policy ensures that "environmental justice is an essential consideration in its processes, decisions, and programs, and that all people who live in California have a meaningful way to participate in these activities". The CSLC implements the policy, in part, by identifying and communicating with relevant populations that could be adversely and disproportionately affected by CSLC projects or programs, and by ensuring that a range of reasonable alternatives is identified to minimize or eliminate environmental impacts affecting such populations. Pursuant to the agency's adopted environmental justice policy, CSLC's staff is required to report back to the Commission regarding how environmental justice is integrated into its programs, processes, and activities.

4.19.2.4 California Public Resources Code Sections 71110 to 71116

Public Resources Code §71110 to 71116 require the CalEPA to develop a model environmental justice mission statement for boards, departments, and offices in the agency. In addition, §71113 requires the CalEPA to convene a Working Group in Environmental Justice to develop a comprehensive environmental justice strategy. The sections also require this strategy to be reviewed and updated. Finally, §71116 establishes a small grant program for nonprofit organizations and federally recognized tribal entities to research environmental justice issues in their community and address larger environmental justice issues.

4.19.2.5 CALFED Environmental Justice Statement

The CALFED Bay-Delta Program states that potential effects of water management changes may accrue to rural communities and that public health and economic impacts may accrue to minorities and disadvantaged people throughout the Delta and vicinity as a result of water quality program actions. Specifically, CALFED identifies three overall guiding principles regarding environmental justice:

- The CALFED Program and its participating agencies are committed to seeking fair treatment of people of all races, cultures, and incomes, such that no segment of the population bears a disproportionately high or adverse health, environmental, social or economic impact resulting from CALFED's programs, policies, or actions.
- The CALFED Agencies will be responsible for ensuring this policy is carried out across all program areas through the development of environmental justice goals and objectives.
- The CALFED Agencies develop the capacity and process to understand, monitor, and address environmental justice issues as the program moves into implementation, including identifying and developing specific methods to address and mitigate environmental justice impacts.

4.19.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to environmental justice, but are discussed in other sections of this chapter, as indicated in parentheses:

- Tehama County General Plan (Land Use)
- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.20 Chapter 24: Air Quality

4.20.1 Federal Plans, Policies, and Regulations

4.20.1.1 Clean Air Act

The federal Clean Air Act (CAA) is the federal law passed in 1970, with amendments in 1977 and 1990. It forms the basis for the national air pollution control effort. Basic elements of the CAA include National Ambient Air Quality Standards (NAAQS) for major air pollutants, hazardous air pollutants standards, state attainment plans, motor vehicle emissions standards, stationary source emissions standards and permits, acid rain control measures, stratospheric ozone protection, and enforcement provisions.

4.20.1.2 National Ambient Air Quality Standards and Federal Air Quality Designations

Pursuant to the CAA, the USEPA established NAAQS for carbon monoxide (CO), ozone (O_3), nitrogen dioxide (NO_2), sulfur dioxide (SO_x as SO_2), particulate matter less than 10 microns in aerodynamic diameter (PM_{10}), particulate matter less than 2.5 microns in aerodynamic diameter ($PM_{2.5}$), and lead (Pb). These pollutants are referred to as criteria pollutants because numerical health-based criteria have been established that define acceptable levels of exposure for each pollutant. The NAAQS for these pollutants are provided in Chapter 24 Air Quality.

The USEPA has revised the NAAQS several times since their original implementation and will continue to do so as the health effects of exposure to pollution are better understood. As new NAAQS are adopted, ambient air quality monitoring data are reviewed by the regulatory agencies for each geographic area, and the USEPA uses the findings to designate the areas' pollutant-specific attainment status.

The USEPA designates areas as attainment[30], nonattainment[31], or unclassified[32] for individual criteria pollutants depending on whether the areas achieve (i.e., attain) the applicable NAAQS for each pollutant. An area can be designated as attainment for one pollutant (for example, NO_2) and nonattainment for others (for example, O_3 and PM_{10}). Unclassified areas are treated as attainment areas for regulatory purposes.

For some pollutants, there are numerous classifications of the nonattainment designation, depending on the severity of an area's nonattainment status. For example, the O_3 nonattainment designation has eight subclasses: basic, transitional, marginal, moderate, serious, severe 15, severe 17, and extreme.

Pursuant to the 1977 CAA amendments, states (or areas within states) with ambient air quality concentrations that do not meet the NAAQS are required to develop and maintain State Implementation

---

[30] Attainment Area: A geographic area considered to have air quality as good as or better than the national and/or State ambient air quality standards (NAAQS and CAAQS, respectively) (USEPA, 2006).

[31] Nonattainment Area: A geographic area identified by the USEPA and/or ARB as not meeting either NAAQS or CAAQS standards for a given pollutant (ARB, 2010).

[32] Unclassified Area: A geographic area that lacks monitoring data.

Plans (SIPs). The SIPs constitute a federally enforceable definition of the State's approach and schedule for the attainment of the NAAQS.

Finally, areas that were designated as nonattainment in the past but have since achieved the NAAQS are further classified as attainment maintenance areas. The maintenance classification remains in effect for 20 years from the date when the area is determined by the USEPA to meet the NAAQS. States must obtain USEPA approval of maintenance plans to ensure continued attainment over these 20-year time frames.

4.20.1.3 Federal General Conformity Requirements

The 1977 CAA amendments state that the federal government is prohibited from engaging in, supporting, providing financial assistance for, licensing, permitting, or approving any activity that does not conform to an applicable SIP. In the 1990 CAA amendments, the USEPA included provisions requiring federal agencies to ensure that actions undertaken in nonattainment or attainment maintenance areas are consistent with applicable SIPs. The process of determining whether a federal action is consistent with applicable SIPs is called "conformity" determination.

These conformity provisions were put in place to ensure that federal agencies would contribute to and not undermine efforts to attain the NAAQS. The USEPA has issued two conformity regulations: (1) a transportation conformity regulation that applies to transportation plans, programs, and projects and (2) a general conformity regulation that applies to all other federal actions. A conformity determination is a process that demonstrates how an action would conform to the applicable SIP, and is required only for the project alternative that is ultimately selected and approved. If the emissions cannot be reduced sufficiently and if air dispersion modeling cannot demonstrate conformity, then either a plan for mitigating or a plan for offsetting the emissions would need to be pursued. The general conformity determination is submitted in the form of a written finding that is issued after a minimum 30-day public comment period on the draft determination.

The USEPA general conformity regulation applies only to federal actions that result in emissions of "nonattainment or maintenance pollutants" or their precursors in federally-designated nonattainment or maintenance areas[33]. The general conformity regulation establishes a process to demonstrate that federal actions would be consistent with applicable SIPs and would not cause or contribute to new violations of the NAAQS, increase the frequency or severity of existing violations of the NAAQS, or delay the timely attainment of the NAAQS. The emission thresholds that trigger requirements of the general conformity regulation for federal actions emitting nonattainment or maintenance pollutants, or their precursors, are called *de minimis* levels.

4.20.1.4 Prevention of Significant Deterioration/New Source Review and New Source Performance Standards

The CAA and amendments also include regulations intended to prevent significant deterioration of air quality in attainment or maintenance areas, to provide for New Source Review (NSR) of major sources and modifications in nonattainment areas, and to establish emission performance standards for new stationary sources or new source performance standards (NSPS). Federal Prevention of Significant Deterioration (PSD)/NSR regulations apply to major (generally very large) stationary sources of emissions. NSPS apply to various types of new, modified, or reconstructed emissions units, and apply to

[33] The federal general conformity regulation does not apply to federal actions in areas designated as nonattainment for only the California ambient air quality standards.

such units regardless of whether these units are located at facilities that are "major" sources of emissions for PSD/NSR purposes.

4.20.1.5 Federal Regulations for Hazardous Air Pollutants

Hazardous Air Pollutants (HAPs) are defined as air pollutants that may cause serious human health effects, including mortality, but which are not regulated through issuance of a national ambient air quality standard.

The USEPA has developed regulations to evaluate and, if necessary, mitigate HAPs emissions sources. Prior to the 1990 CAA amendments, the USEPA established pollutant-specific National Emission Standards for Hazardous Air Pollutants (NESHAPs). NESHAPs were established for benzene, vinyl chloride, radionuclides, mercury, asbestos, beryllium, inorganic arsenic, radon 222, and coke oven emissions. The 1990 CAA amendments list 189 total pollutants that are defined as HAPs. For this list of pollutants, the USEPA is required to set standards for categories and subcategories of sources that emit HAPs, rather than for the pollutants themselves. The USEPA began issuing the new standards, referred to as Maximum Achievable Control Technology (MACT) standards, in November 1994. NESHAPs set before 1991 remain applicable.

The applicability of MACT standards is typically determined by each facility's Potential To Emit (PTE) HAPs from all applicable sources. The facility-wide PTE HAP applicability threshold values are 10 tons per year (tpy) for a single HAP and 25 tpy for any two or more HAPs.

4.20.1.6 Federal Standards for Mobile Sources

The USEPA's Office of Transportation and Air Quality regulates air pollution from motor vehicles and engines and the fuels used to operate them. The USEPA defines "mobile sources" to include cars, light-duty trucks, heavy-duty trucks, buses, recreational vehicles (such as dirt bikes and snowmobiles), farm and construction machines, lawn and garden equipment, marine engines, aircraft, and locomotives.

Starting in the 1970s, The USEPA has established progressively more stringent standards for CO, hydrocarbons (HCs), NO_x, and PM emissions from on-road vehicles. Since the early 1990s, the USEPA has developed similar standards for non-road engines and equipment, and also set tighter limits on sulfur allowed in fuels used for mobile sources. Emission standards set limits on the amount of pollution a vehicle or engine can emit, and are designed to force future vehicles and engines to meet stricter standards.

4.20.2 State Plans, Policies, and Regulations

4.20.2.1 California Clean Air Act

California air quality policies are regulated through the California Clean Air Act (CCAA) of 1988. The CCAA provides the State with a comprehensive framework for air quality planning regulation. Prior to passage of the Act, federal law contained the only comprehensive planning framework.

4.20.2.2 Mulford-Carrell Act

This 1967 act established the ARB. The ARB's mission is to promote and protect public health, welfare, and ecological resources through improved air quality. The ARB oversees the activities of local and regional air quality districts.

4.20.2.3 California Ambient Air Quality Standards and State Air Quality Designations

The ARB administers air quality policy in California, establishes statewide standards, and administers the State's mobile-source emissions control program, which is described below. In addition, the ARB oversees air quality programs established by State statute, and oversees programs to achieve the California Ambient Air Quality Standards (CAAQS). These standards are generally more stringent and apply to more pollutants than the NAAQS. In addition to the criteria pollutants, CAAQS have been established for visibility-reducing particulates, hydrogen sulfide, and sulfates. The CAAQS for these pollutants are provided in Chapter 24 Air Quality.

4.20.2.4 State Implementation Plans

Federal clean air laws require nonattainment areas with unhealthy levels of criteria air pollutants to develop SIPs to detail actions that will be undertaken to achieve the NAAQS. In addition, the CCAA requires local air districts in nonattainment areas of the State to prepare and maintain Air Quality Management Plans (AQMPs) to achieve compliance with CAAQS. These AQMPs also serve as a basis for preparing the SIP for the State of California, which must ultimately be approved by the USEPA and codified in the CFR.

SIPs are a compilation of new and previously submitted plans, programs (such as monitoring, modeling, and permitting), district rules, State regulations, and federal control requirements. Many of California's SIPs rely on the same core set of control strategies, including emission standards for cars and heavy trucks, fuel standards and requirements, and limits on emissions from consumer products. State law establishes the ARB as the lead agency for all purposes related to the SIP. Local air districts and other agencies, such as the Bureau of Automotive Repair, prepare SIP elements and submit them to ARB for review and approval. The ARB forwards SIP revisions to the USEPA for approval and publication in the Federal Register. The CFR Title 40, Chapter I, Part 52, Subpart F, Section 52.220 lists all of the items included in the California SIP. The promulgation of the new national 8-hour O_3 standard and $PM_{2.5}$ standards has resulted in additional statewide air quality planning efforts. The California Regional Haze Plan has been drafted to reduce regional haze and improve visibility in national parks and wilderness areas. Many additional California SIP submittals are pending USEPA approval.

In addition to the SIPs aimed at attainment of the NAAQS, the CCAA requires nonattainment areas to achieve and maintain the CAAQS by the earliest practicable date. Local air districts must develop plans to attain the State O_3, CO, SO_2, and NO_2 standards. The CCAA also requires that, by the end of 1994 and once every three years thereafter, the local air districts must assess their progress toward attaining the air quality standards. The triennial assessment is to report the extent of air quality improvement and the amounts of emission reductions achieved from control measures for the preceding three-year period. The districts must review and revise their attainment plans, if necessary, to correct for deficiencies in meeting progress, incorporate new data or projections, mitigate O_3 transport, and expedite adoption of all feasible control measures. In addition to the triennial progress assessment requirement, local air districts must prepare an annual progress report and submit the report to the ARB by December 31 of each year. At a minimum, the annual progress report contains the proposed and actual dates for the adoption and implementation of each measure listed in the previous three-year plan.

4.20.2.5 California Air Toxics Programs

In addition to the criteria pollutants, concern about non-criteria pollutants has increased in recent years. AB 1807 (the Tanner Bill, passed in 1983) established the California Air Toxics Program for identifying and developing emissions control and reduction methods for toxic air contaminants (TACs). The bill formally designated 18 substances as TACs. In 1993, the 189 HAPs identified by the USEPA were incorporated into California law as TACs. Other pollutants have been added more recently, such as particulate emissions from diesel-fueled engines (diesel PM), designated by California as a carcinogen. The California Air Toxics Program also includes provisions for public awareness and risk reduction.

Local agencies, such as air districts, are responsible for evaluating and controlling TAC emissions, especially when these emissions are released from projects near sensitive receptors. For example, AB 3205 requires that new or modified sources of TACs near schools provide public notice to the parents of school children before a permit to emit air pollutants is issued. One air toxics control measure adopted by the ARB in 2004 prohibited operation of diesel-fueled backup engines within 500 feet of a school during school hours, unless used in an emergency.

The Air Toxics “Hot Spots” Information and Assessment Act was enacted in September 1987. The act requires that toxic air emissions from stationary sources (facilities) be quantified and compiled into an inventory, that risk assessments be conducted according to methods developed by the California Office of Environmental Health Hazard Assessment (OEHHA), and that the public be notified of significant risks posed by nearby facilities. Since the amendment of the statute in 1992 by enactment of SB 1731, facilities that pose a potentially significant health risk to the public are required to reduce their risks.

4.20.2.6 California Mobile-Source Emission Control Programs

The ARB is responsible for developing statewide programs and strategies to reduce the emission of smog-forming pollutants and TACs by mobile sources. To attain the CAAQS, the CCAA mandates that the ARB achieve the maximum degree of emission reductions from all on- and off-road mobile sources. On-road sources include passenger cars, motorcycles, trucks, and buses; off-road sources include heavy-duty construction equipment, recreational vehicles, marine vessels, lawn and garden equipment, and small utility engines. On-road vehicle emission control programs overseen by the ARB include:

- Vehicle inspections
- Idling restrictions
- Regulations to require clean vehicle fleets
- Voluntary vehicle retirement programs
- Engine emissions standards

Additionally, exhaust emission standards have been adopted by the ARB and USEPA for off-road engines. ARB has extensive statewide programs underway to reduce particulate emissions from diesel-fueled engines, also known as diesel PM.

4.20.3 Regional and Local Plans, Policies, and Regulations

In California, air districts have been established to oversee the attainment of air quality standards within air basins as defined by the State. Each local air district has developed its own program and regulations to attain and maintain air quality standards while integrating federal and State requirements. The local air districts have permitting authority over all stationary sources of air pollutants within their district boundaries and provide the primary review of environmental documents prepared for projects with air quality issues. In many cases, the local air districts have established CEQA guidelines and significance thresholds for review of air-quality related impacts.

This section briefly describes applicable local air district rules and regulations, regional SIP and AQMP submittals, CEQA guidance documents, and air quality elements of General Plans for counties and cities in Glenn and Colusa counties.

4.20.3.1 Regional and Local Air Quality Management Plans

The Air Pollution Control Districts and Air Quality Management Districts for the counties located in the northern portion of the Sacramento Valley comprise the Northern Sacramento Valley Planning Area (NSVPA). The NSVPA Districts have jointly prepared and adopted a uniform AQMP for the purpose of achieving and maintaining healthful air quality throughout the air basin. The 2009 triennial update of the NSVPA Air Quality Attainment Plan (Plan) addresses the progress made in implementing the 2006 Plan and proposes modifications to the strategies necessary to attain the 1-hour ozone CAAQS at the earliest practicable date.

The 2009 Plan identifies those portions of the NSVPA designated as “non-attainment” for the CAAQS, and discusses the health effects related to the various air pollutants. All of the NSVPA Districts have been designated as non-attainment areas for the CAAQS for PM_{10}. Moreover, all of the Districts, with the exception of Colusa and Glenn counties, have been designated as non-attainment areas for the State standard for ozone. Colusa and Glenn counties have been designated as non-attainment transitional areas for ozone. Similar to the 1994, 1997, 2000, 2003 and 2006 Plans, the 2009 Plan focuses on the adoption and implementation of control measures for stationary sources, area-wide sources, and indirect sources, and addresses public education and information programs. The 2009 Plan also addresses the effect that pollutant transport has on the ability of the NSVPA to meet and attain the CAAQS.

According to the 2009 Triennial Plan, ozone violations in the NSVPA are caused, in part, by combustion sources and are occasionally influenced by smoke impacts from wildfires. The primary emission source is the internal combustion engine. The ozone problem is further aggravated by transport from the Broader Sacramento Area (BSA), which is comprised of Sacramento County and portions of El Dorado, Placer, Sutter, and Yolo counties. Ozone is formed by a photochemical reaction between nitrogen oxides and reactive organic gases. These ozone precursors are emitted as part of the exhaust of internal combustion engines in the NSVPA and BSA, and are transported northward via the prevailing winds. Due to the regional nature of the ozone problem and the fact that the NSVPA counties share the same air basin with BSA, the Attainment Plan is prepared in conjunction with the Sacramento Valley Air Quality Engineering and Enforcement Professionals and the Sacramento Valley Air Basin-wide Air Pollution Control Council’s Technical Advisory Committee.

The CCAA requires each District in which a CAAQS for ozone is exceeded to develop a plan and an emission control program to attain the State standard. The CCAA recognizes that ozone and ozone precursors can be transported by winds over long distances and thereby contribute to air quality problems outside of the District or air basin of origination. To address this, the CCAA requires upwind Districts to mitigate the impacts to downwind areas by pollutants that are originally emitted in the upwind Districts, even though the downwind District may have a shared or sole responsibility for air quality impacts. The CCAA directs the ARB to assess the impacts of such transport and to establish mitigation requirements for upwind Districts.

For transport mitigation, the CCAA requires that Districts within the areas of origin of transported air pollutants must include sufficient emission control measures in their ozone Attainment Plans to mitigate the impacts of their jurisdictional pollution sources on ozone concentrations in downwind areas. At a minimum, the Attainment Plans for Districts within the BSA must require the adoption and implementation of best available retrofit control technology on all existing stationary sources of ozone precursor emissions, as expeditiously as practicable. The plans must include measures sufficient to attain the State ambient air quality standard for ozone by the earliest practicable date, except during air pollution episodes. Implementation of these requirements will be through the BSA Districts' Attainment Plans.

4.20.3.2 Local Air District CEQA Guidance Documents Pertaining to Air Quality

Local air agencies may publish CEQA guidelines to assist local jurisdictions and lead agencies in complying with the requirements of CEQA regarding potentially adverse impacts to air quality. CEQA guidelines may or may not include thresholds of significance. Guidelines may provide useful information for calculating air pollution emissions, evaluating the health impacts of air pollutants, and identifying potential mitigation measures.

Air districts are required to develop and enforce local rules and regulations to attain and maintain healthful air within their jurisdiction. In past years, air districts were primarily concerned with emissions of criteria air pollutants, ozone precursors, odors, and toxic air contaminants.

The Glenn County Air Pollution Control District (GCAPCD) and the Colusa County Air Pollution Control District (CCAPCD) have developed plans and regulations to attain and maintain air quality standards while integrating federal and State requirements. For example, each of the agencies has developed regulations to cover new source review and permitting of stationary sources, agricultural burning, airborne toxic control measures, and federal operating permits.

The GCAPCD does not have CEQA guidelines; GCAPCD indicated that they would defer to the Butte County guidelines, if necessary, when reviewing the proposed Project. The Butte County AQMD published its CEQA Air Quality Handbook *Guidelines for Assessing Air Quality Impacts for Projects Subject to CEQA Review* in 2008. The CCAPCD also does not have CEQA guidelines, other than its New Source Review rules, and suggested that thresholds developed by the Tehama County Air Pollution Control District (TCAPCD) would represent similar values. Review of the Butte County and Tehama County thresholds indicates that they are the same values.

4.20.3.3 Glenn County and Colusa County General Plans

Glenn and Colusa counties have developed General Plans that include air quality policies. The 1993 Glenn County General Plan Update includes provisions to reduce air pollutant emissions, but the Draft EIR for the Update acknowledges that in nonattainment air basins, any emissions of nonattainment pollutants by new developments are considered to be a significant air quality effect, both directly and cumulatively. The Draft EIR indicates that many or most of the development projects that would be considered pursuant to the General Plan would potentially result in emissions of ozone precursors, which are associated with vehicular traffic, and PM_{10}, which can be emitted by construction activities, wood-burning appliances, yard burning, and incineration. The General Plan is intended to be compatible with the goals and policies of the local Air Quality Attainment Plan. Policies and implementation measures are included in the General Plan that require projects to incorporate all feasible emissions control measures, as specified in the Attainment Plan.

The 2012 Colusa County General Plan includes policies and action programs aimed at preserving air quality as part of the Conservation Element. The recommended measures include ongoing oversight by the CCAPCD for air monitoring, enforcement of local, State, and federal air quality rules, health risk assessment and mitigation of air toxics, and mitigation of significant impacts to the maximum extent feasible. The General Plan requires a compact development pattern to reduce vehicle trips and promote alternative transportation methods, and requires projects to mitigate significant air quality impacts associated with construction and operation.

4.21 Chapter 25: Climate Change and Greenhouse Gas Emissions

4.21.1 Federal Plans, Policies, and Regulations

4.21.1.1 Draft National Environmental Policy Act Guidance on Consideration of the Effects of Climate Change and Greenhouse Gas Emissions

The DOI has considered the issue of climate change in a manner consistent with other federal agencies, and discusses how to address and integrate the topic into NEPA documents. DOI recommends that agencies consider two ways to address climate change in NEPA documents, which are not mutually exclusive: (1) address the effect of climate change on proposed federal actions, and (2) evaluate how proposed federal actions (either individually or cumulatively) would affect climate change.

Agencies can use the NEPA process to reduce vulnerability to climate change impacts, adapt to changes in our environment, and mitigate the impacts of federal agency actions that are exacerbated by climate change.

This CEQ guidance document advises federal agencies that they should consider opportunities to reduce greenhouse gas (GHG) emissions caused by proposed federal actions and adapt their actions to climate change impacts through the NEPA process and to address these issues in their agency NEPA procedures. The document recommends a standard of 25,000 metric tons/year carbon dioxide equivalent (CO_2e) as GHG emissions. CEQ does not propose this standard as the threshold for significance, but rather as an indicator of the minimum level of GHG requiring NEPA analyses.

4.21.1.2 Greenhouse Gas Reporting Rule

In response to the fiscal year (FY) 2008 Consolidated Appropriations Act[34] which required the USEPA to develop "…mandatory reporting of greenhouse gases above appropriate thresholds in all sectors of the economy….", the USEPA issued the Greenhouse Gas Reporting Rule (74 FR 56260). The rule went into effect January 1, 2010, and requires reporting of greenhouse gas (GHG) data and other relevant information from large sources and suppliers in the United States. The GHG Reporting Rule applies to fossil fuel and industrial GHG suppliers, vehicle and engine manufacturers, and all facilities that emit 25,000 metric tons of CO_2e or more per year. Facility owners are required to submit an annual GHG emissions report with detailed calculations of facility GHG emissions. The GHG Reporting Rule also mandates recordkeeping and administrative requirements in order for the USEPA to verify annual GHG emissions reports.

4.21.1.3 Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202(a) of the Clean Air Act

The USEPA Administrator signed the Endangerment and Cause or Contribute Findings for Greenhouse Gases under Section 202(a) of the Clean Air Act on December 7, 2009, and the final rule became effective on January 14, 2010. The Endangerment Finding is based on Section 202(a) of the CAA, which

[34] Appropriates funds for FY2012 for military activities including, but not limited to: military personnel, operations and maintenance, procurement, research and development, and other related agencies and defense programs.

states that the USEPA Administrator should regulate and develop standards for “emission[s] of air pollution from any class or classes of new motor vehicles or new motor vehicle engines, which in [its] judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare.” The rule addresses Section 202(a) in two distinct findings. The first addresses whether or not the concentrations of the six key GHGs (i.e., CO_2, methane [CH_4], nitrous oxide [N_2O], hydrofluorocarbons [HFCs], perfluorocarbons [PFCs], and sulfur hexafluoride [SF_6]) in the atmosphere which threaten the public health and welfare of current and future generations. The second addresses whether or not the combined emissions of GHGs from new motor vehicles and motor vehicle engines contribute to atmospheric concentrations of GHGs, and therefore, to the threat of climate change.

The observed and projected results of climate change (e.g., higher likelihood of heat waves, wildfires, droughts, sea level rise, and higher intensity storms) are a threat to the public health and welfare. Therefore, GHGs were found to endanger the public health and welfare of current and future generations.

The finding cites that in 2006, motor vehicles were the second largest contributor to domestic GHG emissions (24 percent of total) behind electricity generation. In 2005, the United States was responsible for 18 percent of global GHG emissions.

Although the Endangerment Finding does not directly establish reduction goals or mandates for GHG emissions, the finding would obligates the USEPA to establish GHG emission standards for new motor vehicles, motor vehicle engines, and potential stationary sources (such as bioenergy production facilities) pursuant to the CAA. Any potential GHG emission standards resulting from the Endangerment Finding would be relevant to the GHG emission sources associated with proposed Project operations.

4.21.2 State Plans, Policies, and Regulations

4.21.2.1 California Environmental Quality Act Guidelines

CEQA requires lead agencies to consider the reasonably foreseeable adverse environmental effects of projects they are considering for approval.

In January 2009, OPR released preliminary draft CEQA Guidelines Amendments for GHGs consistent with the authority granted by CEQA and with CEQA case law. OPR’s recommendations for GHGs in the Guidelines Amendments fall within the existing CEQA framework for environmental analysis, which calls for lead agencies to determine baseline conditions and levels of significance, and to evaluate mitigation measures. For these reasons, OPR neither identifies a threshold of significance for GHG emissions nor prescribes assessment methodologies or specific mitigation measures. The Guidelines Amendments also encourage lead agencies to consider many factors in performing a CEQA analysis, but to preserve the discretion that CEQA grants lead agencies to make their own determinations based on substantial evidence. The Guidelines Amendments also encourage public agencies to make use of programmatic mitigation plans and programs from which to tier when they perform individual project analyses.

4.21.2.2 Senate Bill 97

SB 97 required OPR, by July 1, 2009, to prepare, develop, and transmit to the Resources Agency (now called the Natural Resources Agency), guidelines for the feasible mitigation of GHG emissions or the effects of GHG emissions, as required by CEQA, including but not limited to, effects associated with transportation or energy consumption. The Natural Resources Agency was required to certify and adopt those guidelines by January 1, 2010[35], and OPR is required to periodically update the guidelines to incorporate new information or criteria established by ARB pursuant to AB 32.

On December 30, 2009, the California Natural Resources Agency adopted amended guidelines to aid public agencies and developers in complying with CEQA. The guidelines expressly require that GHG emissions be included in the environmental impact analysis under CEQA.

4.21.2.3 Governor's Office of Planning and Research Technical Advisory on CEQA and Climate Change

In response to the requirements of SB 97, OPR released a technical advisory in June 2008 to provide interim advice to lead agencies regarding the analysis of GHGs in environmental documents. The advisory encourages lead agencies to identify and quantify the GHGs that could result from a proposed project, analyze the impacts of those emissions to determine whether they would be significant, and to identify feasible mitigation measures or alternatives that would reduce any adverse impacts to a less-than-significant level.

Without prescribing specific approaches, the advisory identified several methodologies for estimating project emissions and provided examples of mitigation measures that lead agencies could employ to reduce those emissions.

A consistent approach should be applied for the analysis of all such projects, and the analysis must be based on best available information. For these projects, compliance with CEQA entails three basic steps:

- Identify and quantify the GHG emissions
- Assess the significance of the impact on climate change
- If the impact is found to be significant, identify alternatives and/or mitigation measures that will reduce the impact below significance

The advisory discussed alternative project designs and locations that conserve energy and water, measures that reduce vehicle miles traveled by fossil-fueled vehicles, measures that contribute to established regional or programmatic mitigation strategies, and measures that sequester carbon to offset emissions from the project. The advisory recognized that mitigating GHGs at a project level may not be as effective as implementing a programmatic approach to mitigation. This approach requires public agencies to adopt a program of mitigation measures that apply broadly within the agency's jurisdiction, and are implemented at the project level when CEQA review is required.

4.21.2.4 Executive Order S-3-05

EO S-3-05 includes the following GHG reduction targets for California: by 2010, reduce GHG emissions to 2000 levels; by 2020, reduce GHG emissions to 1990 levels; and by 2050, reduce GHG emissions to 80 percent below 1990 levels. The final emission target of 80 percent below 1990 levels would put the State's emissions in line with estimates of the required worldwide reductions needed to bring about long-term climate stabilization and avoidance of the most severe impacts of climate change.

35 As directed by SB97, the Natural Resources Agency adopted Amendments to the CEQA Guidelines for GHG emissions on December 30, 2009. On February 16, 2010, the Office of Administrative Law approved the Amendments, and filed them with the Secretary of State for inclusion in the CCR. The Amendments became effective on March 18, 2010.

4.21.2.5 California Renewables Portfolio Standard Program

Established in 2002 pursuant to SB 1078 (required 20 percent renewable energy by 2017), accelerated in 2006 pursuant to SB 107 (accelerated 20 percent deadline to 2010), and expanded in 2011 pursuant to SB 2 (increased requirement to 33 percent by 2020), California's Renewables Portfolio Standard program requires investor-owned utilities, electric service providers, and community choice aggregators to increase procurement from eligible renewable energy resources to 33 percent of total procurement by 2020.

4.21.2.6 Assembly Bill 32 (California Global Warming Solutions Act of 2006)

AB 32, the California Global Warming Solutions Act of 2006, places caps on statewide GHG emissions equal to 1990 emissions levels. The statute requires that prior to January 1, 2008, ARB must: (1) identify the current level of GHG emissions by requiring statewide reporting and verification of GHG emissions from emitters; and (2) identify the 1990 levels of California GHG emissions. Pending these regulations, by June 30, 2007, ARB must publish a list of early-action GHG emission reduction measures and by January 1, 2010, must adopt regulations to implement those early-action measures. As of 2012, the ARB reported that these goals have been met and the State is on track to reach its 2020 goal. The 2020 goal is to attain 1990 emission levels (427 million metric tons [MMT] of CO_2e of GHGs).

4.21.2.7 Senate Bill 1368

SB 1368 requires the California Energy Commission (CEC) and the California Public Utilities Commission (CPUC), in consultation with ARB, to set performance standards for climate change pollutant emissions resulting from electric generation for long-term procurement by investor-owned and local publicly-owned utilities. This bill applies to individual utilities and requires compliance when funding new, or rehabilitating older, power generation facilities.

4.21.2.8 Executive Order S-1-07

EO S-1-07 requires that carbon intensity of transportation fuels be reduced by at least 10 percent by 2020. This mandates that ARB establish and certify such standards, including biennial reports on the goal progress.

4.21.2.9 Executive Order S-13-08

EO S-13-08 required the Natural Resources Agency[36] to conduct public workshops on sea level rise and requested that the National Academy of Sciences (NAS) complete a California Sea Level Rise Assessment Report. This EO dictates that the California Ocean Protection Council shall work with DWR, the CEC, California's coastal management agencies, and the SWRCB to conduct a review of the NAS assessment every two years, or as necessary.

4.21.2.10 Senate Bill 1771

SB 1771 requires that the nonprofit public benefit corporation known as the California Climate Action Registry administer a voluntary GHG emissions registry. CEC is required to provide technical guidance to the Registry on protocol development and to periodically update the State's inventory of GHG emissions, as well as serve as an information clearinghouse on climate change issues. The Registry consists of organizations that are actively reducing their GHG emissions.

---

[36] Includes the California Conservation Corps, the Department of Boating and Waterways, the Department of Conservation, CDFG, the Department of Forestry and Fire Protection, the Department of Parks and Recreation, the Department of Resources Recycling and Recovery, and DWR.

4.21.2.11 Climate Change Scoping Plan

In October 2008, ARB published the Climate Change Proposed Scoping Plan (CCPSP), which is the State's plan to achieve GHG reductions in California, as required by AB 32. The CCPSP was approved by ARB on December 11, 2008. The CCPSP contains the main strategies California will implement to achieve a reduction of approximately 169 MMT (approximately 30 percent) in CO2e emissions, relative to the State's projected 2020 emissions level of 596 MMT of CO2e under a business-as-usual scenario. The CCPSP includes ARB-recommended GHG reductions for each emissions sector of the State's GHG inventory. The largest recommended GHG reductions are:

- Improved emissions standards for light-duty vehicles (estimated reductions of 31.7 MMT of CO_2e)
- Implementation of the low-carbon fuel standard (15.0 MMT of CO_2e)
- Implementation of energy efficiency measures in buildings and appliances, and the widespread development of combined heat and power systems (26.3 MMT of CO_2e)
- A renewable portfolio standard for electricity production (21.3 MMT of CO_2e)

4.21.2.12 California Climate Change Adaptation Strategy

The 2009 California Climate Adaptation Strategy report summarizes the best known science on climate change impacts (public health, biodiversity and habitat, ocean and coastal resources, water management, agriculture; forestry, and transportation and energy infrastructure) in the state to assess vulnerability and outlines possible solutions that can be implemented within and across State agencies to promote resiliency.

4.21.2.13 California Cap and Trade Program

The Cap and Trade Program is a market-based regulation that sets a firm statewide limit on sources responsible for 85 percent of California's GHG emissions, and establishes a price signal needed to drive long-term investment in cleaner fuels and more efficient use of energy. The program is designed to provide covered entities the flexibility to seek out and implement the lowest-cost options to reduce emissions. California's Cap-and-Trade Regulation took effect on January 1, 2012, with amendments to the regulation effective September 1, 2012. The enforceable compliance obligation began on January 1, 2013.

4.21.2.14 Climate Action Plan Phase 1: Greenhouse Gas Emissions Reduction Plan

DWR developed a GHG Emissions Reduction Plan to guide its project development and decision making with respect to energy use and GHG emissions. The Plan details DWR's future plans for reducing GHG emissions consistent with the GHG emissions reduction targets established in AB 32, EO S-3-05, and DWR's own policies; the aggressive steps DWR will take to reduce its emissions by more than 80 percent below 1990 levels; and the steps that DWR will take to monitor its progress toward achieving these reductions. The Plan shows how DWR will achieve its near-term goal of reduced emissions by 50 percent below 1990 levels by 2020, and how DWR will achieve its long-term goal of reduced emissions by 80 percent below 1990 levels by 2050.

4.21.2.15 California Air Pollution Control Officers Association Guidance Documents on Addressing GHGs under CEQA and Quantifying GHG Mitigation Measures

The California Air Pollution Control Officers Association has prepared two reports intended as a resource for public agencies to address GHG emissions pursuant to CEQA and to quantify greenhouse gas mitigation measures. The reports are titled "CEQA & Climate Change: Evaluating and Addressing Greenhouse Gas

Emissions from Projects Subject to the California Environmental Quality Act, January 2008" and "Quantifying Greenhouse Gas Mitigation Measures, August 2010." These reports consider the application of thresholds and offer three alternative programmatic approaches toward determining whether GHG emissions are significant. These reports also evaluate tools and methodologies for estimating impacts and summarizing mitigation measures. They have been prepared with the understanding that the programs, regulations, policies, and procedures established by the ARB and other agencies to reduce GHG emissions may ultimately result in a different approach pursuant to CEQA than the strategies considered in these reports.

4.21.3 Regional and Local Plans, Policies, and Regulations

The following local regulation is applicable to climate change and greenhouse gases, but is discussed in another section of this chapter, as indicated in parentheses:

- Regional and Local Air Quality Management Plans (Air Quality)

4.22 Chapter 26: Navigation, Transportation, and Traffic

4.22.1 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to navigation, transportation, and traffic, but are discussed in other sections of this chapter, as indicated in parentheses:

- National Environmental Policy Act (General)
- Rivers and Harbors Act of 1899 (Surface Water Quality)

4.22.2 State Plans, Policies, and Regulations

The following State regulation is applicable to navigation, transportation, and traffic, but is discussed in other sections of this chapter, as indicated in parentheses:

- California Environmental Quality Act (General)

4.22.2.1 California Department of Transportation Regulatory Authority over the California State Highway System

The California Department of Transportation (Caltrans) has regulatory authority over the State highway system. Additionally, as part of a pilot program established by the Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users, Caltrans and FHWA have entered into a Memorandum of Understanding (MOU) in which certain authority pursuant to NEPA has been delegated to Caltrans in connection with the delivery of transportation projects. This MOU may apply to any potential effects to the State highway system from the proposed Project.

4.22.3 Regional and Local Plans, Policies, and Regulations

The following regulations are applicable to navigation, transportation, and traffic, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.23 Chapter 27: Noise

4.23.1 Federal Plans, Policies, and Regulations

4.23.1.1 Federal Guidance for Environmental Noise and Regulations for Specific Sources

Although no federal regulations limit overall environmental noise levels, federal guidance is provided by several federal agencies for specific sources (for example, aircraft or federally funded highways). The following federal agencies have such guidance: the Federal Energy Regulatory Commission (FERC), Federal Transit Administration, Federal Railroad Administration, FHWA, Federal Aviation Administration, USEPA, and the U.S. Department of Housing and Urban Development.

4.23.2 State Plans, Policies, and Regulations

4.23.2.1 California Noise Control Act of 1973

The California Noise Control Act of 1973 (Health and Safety Code §46000 to 46080) states that the Office of Noise Control should provide assistance to local communities in developing local noise control programs, and that the Office of Noise Control staff would also work with the OPR to provide guidance for the preparation of the required Noise Elements in city and county General Plans, pursuant to Government Code §65302(f). In preparing the Noise Element, a city or county must identify local noise sources and analyze and quantify, to the extent practicable, current and projected noise levels for various sources, including highways and freeways; passenger and freight railroad operations; ground rapid transit systems; commercial, general, and military aviation and airport operations; and other ground stationary noise sources. California Administrative Code, Title 4, has guidelines for evaluating the compatibility of various land uses as a function of community noise exposure.

4.23.2.2 Department of Water Resources Specification 05-16

Section 15070 of DWR Specification 05-16 suggests the following guidelines for DWR construction projects: Where ambient noise levels are less than 60 dBA and it is determined that construction related noise will cause noise levels to exceed 60 dBA, or where the ambient noise levels are greater than 60 dBA and it is determined that construction related noise will cause noise levels to exceed the ambient level by 5 dBA, a temporary sound wall shall be constructed between the sensitive area and the construction related noise source. The 60 dBA limit is not a regulatory requirement.

4.23.2.3 California Administrative Code Title 4

California Administrative Code Title 4 has guidelines for evaluating the compatibility of various land uses as a function of community noise exposure.

4.23.2.4 California Government Code §65302(f)

California Government Code §65302(f) requires City and County General Plans to include a Noise Element. The purpose of a Noise Element is to guide future development to enhance future land use compatibility.

4.23.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to noise, but are discussed in other sections of this chapter, as indicated in parentheses:

- Tehama County General Plan (Land Use)
- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.24 Chapter 28: Public Health and Environmental Hazards

4.24.1 Federal Agencies Responsible for Regulating Water Quality

The USEPA provides guidance and oversight to the State of California in regulating water quality, as it does for other states and tribes. The USEPA delegates authorities for establishing water standards and regulating controllable factors affecting water quality in the State. In California, this authority is delegated to the SWRCB. The SWRCB, in turn, delegates authority to its nine RWQCBs to implement the State's water quality management responsibilities in the nine geographic regions. Although the State generally takes the lead on developing and adopting water quality standards for California, the USEPA must approve new or modified standards. Thus, the USEPA, SWRCB, and the RWQCBs have worked together to establish existing water quality criteria/objectives and beneficial uses.

4.24.2 Federal Plans, Policies, and Regulations

The following federal regulations are applicable to public health and environmental hazards, but are discussed in other sections of this chapter, as indicated in parentheses:

- Clean Water Act (Surface Water Resources)
- Comprehensive Environmental Response, Compensation, and Liability Act (Surface Water Quality)
- Federal Insecticide, Fungicide, and Rodenticide Act (Surface Water Quality)
- Safe Drinking Water Act (Surface Water Quality)

4.24.2.1 Hazardous Materials Transportation Act of 1975

The objective of the Hazardous Materials Transportation Act is to improve the regulatory and enforcement authority of the Secretary of Transportation to protect the Nation adequately against risks to life and property which are inherent in the transportation of hazardous materials in commerce. The Act empowered the Secretary of Transportation to designate as hazardous material any particular quantity or form of a material that may pose an unreasonable risk to health and safety or property.

Regulations apply to any person who transports, or causes to be transported or shipped, a hazardous material; or who manufactures, fabricates, marks, maintains, reconditions, repairs, or tests a package or container which is represented, marked, certified, or sold by such person for use in the transportation in commerce of certain hazardous materials.

4.24.2.2 Resource Conservation and Recovery Act, as Amended

The Resource Conservation and Recovery Act (RCRA) provides the USEPA with the authority to control hazardous waste from cradle-to-grave. This includes the generation, transportation, treatment, storage, and disposal of hazardous waste. The 1984 Federal Hazardous and Solid Waste Amendments to the RCRA focus on waste minimization and phasing out land disposal of hazardous waste, as well as corrective action for releases. Other mandates of this law include increased enforcement authority for the USEPA, more stringent hazardous waste management standards, and a comprehensive Underground Storage Tank Program. The 1986 RCRA amendments enabled the USEPA to address environmental problems that could result from underground tanks storing petroleum and other hazardous substances. The RCRA also set forth a framework for the management of non-hazardous solid wastes. RCRA §3006 provides the USEPA with the authority to authorize State hazardous waste programs. Once authorized, the State program operates in lieu of the federal program, although the USEPA retains enforcement authority even after a State program has been authorized.

4.24.2.3 Toxic Substances Control Act

The Toxic Substances Control Act of 1976 gives the USEPA authority to require reporting, recordkeeping and testing requirements, and restrictions relating to chemical substances and/or mixtures. The Act addresses the production, import, use, and disposal of specific chemicals including polychlorinated biphenyls (PCBs), asbestos, radon, and lead-based paint.

4.24.3 State Plans, Policies, and Regulations

The following State regulation is applicable to public health and environmental hazards, but is discussed in another section of this chapter, as indicated in parentheses:

- California Safe Drinking Water Act (Surface Water Quality)

4.24.3.1 California Hazardous Substance Account Act of 1999

The California equivalent to CERCLA, the California Hazardous Substance Account Act, was adopted in 1999 and is codified in Division 20 of the Health and Safety Code, Chapter 6.8. It requires past and present owners and operators to assume liability for the remediation of hazardous waste sites within the State of California.

The Health and Safety Code Section 25356.1 requires the Department of Toxic Substances Control or the RWQCB to prepare or approve remedial action plans for sites where hazardous substances were released to the environment if they are listed as Superfund sites. The RWQCB has the responsibility to make decisions regarding cleanup and abatement goals and objectives for the protection of water quality.

4.24.3.2 California Land Reuse and Revitalization Act

This 2004 regulation provides immunity from liability for hazardous materials response costs, or damage claims to innocent landowners, bona fide purchasers, and contiguous property owners.

Similar to the 1996 CERCLA amendments, to encourage site cleanup, the California Land Reuse and Revitalization Act of 2004 was codified in the Health and Safety Code, Division 20, Chapter 6.82, Sections 25395.60 to 25395.105. This chapter encourages the development and redevelopment of urban properties, provides processes that ensure remediation to protect public health, safety, and the environment, and relieves innocent owners, bona fide prospective purchasers, and owners of property adjacent to contaminated sites of liabilities and responsibilities that should be borne by those who caused or contributed to the contamination.

4.24.3.3 California Underground Storage Tank Program

The California Underground Storage Tank Program is designed to prevent contamination from, and improper storage of, hazardous substances stored underground; to ensure that existing tanks are properly maintained, inspected, tested, and upgraded; and to ensure that new USTs meet appropriate standards. The California regulations are codified in the Health and Safety Code, Division 20, Chapter 6.7, Sections 25280 to 25299.8.

4.24.3.4 Aboveground Petroleum Storage Act of 2007

California adopted a statewide program to determine the amount and type of hazardous substances being stored in aboveground tanks under the Health and Safety Code Division 20, Chapter 6.67, Sections 25270 to 25270.23.

4.24.3.5 Toxic Injection Well Control Act of 1985

Injection of hazardous wastes is regulated pursuant to the Toxic Injection Well Control Act of 1985, Health and Safety Code Division 20, Chapter 6.5, Article 5.5, Sections 25159.10 to 25159.25. These regulations prohibit any injection of hazardous wastes into or above drinking water sources and prohibit injection of hazardous waste below drinking water sources, so as to prevent hazardous wastes from migrating to State drinking water, or otherwise endangering the environment.

4.24.3.6 Safe Drinking Water and Toxics Enforcement Act

The Safe Drinking Water and Toxics Enforcement Act (SDWTEA) was passed in August of 2003 and contains prohibitions preventing the contamination of drinking water with chemicals known to cause cancer or reproductive toxicity. The SDWTEA also requires a reasonable warning be provided before any person is exposed to chemicals known to cause cancer or reproductive toxicity.

4.24.3.7 California Hazardous Waste Control Act

Pursuant to this Act, the State is authorized to administer a hazardous waste program equivalent to the federal RCRA program. Generation, transportation, treatment, storage, and disposal of characteristic and listed hazardous wastes are regulated pursuant to the Health and Safety Code, Division 20, Chapter 6.5, Sections 25100 to 25250.28.

As part of hazardous waste regulation, the California Health and Safety Code, Division 20, Chapter 6.5, Article 13, Sections 25250 through 25250.28 regulates PCBs in used oil, and prohibits used oil recycling or reuse if the oil contains five parts per million or greater of PCBs.

4.24.3.8 California Solid Waste Program (Public Resources Code 43000 et seq., California Code of Regulations Titles 14 and 27)

Solid waste in California is regulated pursuant to Title 14, Division 7, and Title 27, Division 2 of the CCR. These regulations establish minimum standards for the handling and disposal of solid wastes. Both the SWRCB and the California Integrated Waste Management Board have oversight and approval authority over local enforcement agencies that permit and take enforcement action on solid waste management facilities. The Public Resources Code Sections 43200 to 43219, 43020, 43020.1, 43021, 43030, 43101 and 43103 created and govern the local enforcement agencies.

4.24.3.9 Hazardous Materials Release Response Plans and Inventory

California's equivalent to SARA was codified in the Health and Safety Code Division 20, Chapter 6.95, Sections 25500 to 25545. This code requires businesses to prepare plans relating to the handling and release or potential release of hazardous materials. It establishes minimum statewide standards for contents of plans, including location, type, quantity, and health risks of hazardous materials handled, used, stored, or disposed of, which could be accidentally released into the environment. It ensures firefighters, health officials, planners, public safety officers, health care providers, regulatory agencies, and other interested persons have access to the plans.

4.24.3.10 State Water Resources Control Board Resolution No. 92-49

SWRCB adopted Resolution Number 92-49, Policies and Procedures for Investigation and Cleanup and Abatement of Discharges, under Water Code Section 13304. This resolution establishes policies and detailed procedures for all investigations and remediation of any discharge that causes, or threatens to cause, conditions of soil, water pollution, or nuisance associated with migration of waste or fluid from waste management units. The resolution also requires coordination among other agencies including the DTSC, the USEPA, and local governances.

4.24.3.11 Mosquito Abatement Act of 1915

The Mosquito Abatement Act authorizes the formation of mosquito control districts in the State of California. It gives local governments the power to obtain revenues and form special districts to protect the public from the hazards of mosquito bites and mosquito-borne diseases.

4.24.3.12 California Health and Safety Code: Division 3, Chapter 1, Article 4, Sections 2040, 2041, 2060 to 2065 (Mosquito and Vector Control District Law)

Sections 2040 and 2041 of the California Health and Safety Code, Division 3, Chapter 1, Article 4 authorize mosquito control districts to conduct surveillance programs and studies, and take any and all necessary and proper actions to prevent the occurrence of, and abate or control, vectors and vectorborne diseases.

Sections 2060 to 2065 authorize mosquito control districts to abate a public nuisance by notifying the owner of the property that is causing the public nuisance, requiring the owner of the property to abate the nuisance within a specified time, and requiring the owner of the property to prevent the recurrence of the public nuisance. These sections also authorize the mosquito control districts to impose fines for non-compliance, and state that the owner of the property shall pay for the cost of abatement.

4.24.3.13 California Government Code: Title 3, Division 2, Part 2, Chapter 8, Article 3, Section 25842.5

This section of the California Government Code states that the Board of Supervisors may provide the same services and exercise the powers of mosquito abatement districts or vector control districts formed pursuant to the Mosquito Abatement and Vector Control District Law within both the unincorporated and incorporated territory of the county with the consent of the City Council and after holding a public hearing on the proposal. Notice of the hearing must be given, pursuant to Section 6061, in a newspaper of general circulation in the county.

4.24.3.14 California Mosquito-Borne Virus Surveillance and Response Plan

The California Mosquito-borne Virus Surveillance and Response Plan was developed to meet several objectives. Specifically, the Plan:

- Provides guidelines and information on the surveillance and control of mosquito-borne viruses in California, including West Nile, St. Louis encephalitis, and western equine encephalomyelitis viruses;
- Incorporates surveillance data into risk assessment models;
- Prompts surveillance and control activities associated with virus transmission risk level;
- Provides local and State agencies with a decision support system; and
- Outlines the roles and responsibilities of local and State agencies involved with mosquito-borne virus surveillance and response.

4.24.4 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to public health and environmental hazards, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.25 Chapter 29: Public Services and Utilities

4.25.1 Federal Plans, Policies, and Regulations

Federal regulatory agency involvement for public services and utilities is limited to review of a public service/utility provider's operation related to a specific resource area. Federal regulation can oversee issues such as the environment, energy, waterways, and fisheries. Associated agencies include USFWS, Reclamation, NMFS, USEPA, NRCS, USACE, U.S. Forest Service (USFS), USGS, and the Western Area Power Administration (WAPA).

The following federal regulation is applicable to public services and utilities, but is discussed in another section of this chapter, as indicated in parentheses:

- Americans with Disabilities Act (Recreation Resources)

4.25.1.1 Critical Infrastructure Information Act of 2002

The Critical Infrastructure Information Act (CIIA) is a component of the Homeland Security Act of 2002, which specifically addresses protection of high risk targets. The CIIA requires the Department of Homeland Security to evaluate and protect critical infrastructure including food and water systems, agriculture, health systems, emergency services, information and telecommunication, banking and finance, energy, transportation, chemical and defense industries, and national monuments and icons. The CIIA exempts disclosure of information regarding critical infrastructure from Freedom of Information Act requests due to the Homeland Security Act.

4.25.1.2 National Fire Protection Association 1710 Standard

This standard contains minimum requirements relating to the organization and deployment of fire suppression operations, emergency medical operations, and special operations to the public by substantially all-career fire departments[37]. The requirements address functions and objectives of fire department emergency service delivery, response capabilities, and resources. This standard also contains general requirements for managing resources and systems, such as health and safety, incident management, training, communications, and pre-incident planning. This standard addresses the strategic and system issues involving the organization, operation, and deployment of a fire department and does not address tactical operations at a specific emergency incident.

The National Fire Protection Association 1710 Standard recommends a response time of six minutes or less for 90 percent of the time for initial fire suppression and/or emergency medical response. This takes into account dispatch time (one minute), turnout time (one minute), and travel time (four minutes).

4.25.2 State Plans, Policies, and Regulations

4.25.2.1 Health and Safety Code Sections 13000 et seq.

State fire regulations are set forth in Sections 13000 et seq. of the California Health and Safety Code, and include regulations for building standards (as also set forth in the CBC), fire protection and notification systems, fire protection devices such as extinguishers and smoke alarms, high-rise building and childcare facility standards, and fire suppression training.

4.25.2.2 Health and Safety Code Section 13145 and 13146

The Department of Forestry and Fire Protection (CAL FIRE) provides wildland fire protection and implements the State Fire Marshal’s regulations. The State Fire Marshal is apart from CAL FIRE executive staff. California Health and Safety Code Section 13145 and 13146 authorizes, with some exceptions, local fire chiefs, or their designees, to enforce State Fire Marshal regulations.

Section 13145 states that the State Fire Marshal, the chief of any city, county, or city and county fire department or district providing fire protection services, or a Designated Campus Fire Marshal, and their authorized representatives, shall enforce in their respective areas building standards relating to fire and panic safety adopted by the State Fire Marshal and published in the California Building Standards Code and other regulations that have been formally adopted by the State Fire Marshal for the prevention of fire or for the protection of life and property against fire or panic.

Section 13146 states that the responsibility for enforcement of building standards adopted by the State Fire Marshal and published in the California Building Standards Code relating to fire and panic safety and other regulations of the State Fire Marshal shall be as follows:

(a) The city, county, or city and county with jurisdiction in the area affected by the standard or regulation shall delegate the enforcement of the building standards relating to fire and panic safety and other regulations of the State Fire Marshal as they relate to R-3 dwellings, as described in Section 1201 of Part 2 of the California Building Standards Code, to either of the following:

  (1) The chief of the fire authority of the city, county, or city and county, or his or her authorized representative.

[37] A department comprised 100 percent of career firefighters.

(2) The chief building official of the city, county, or city and county, or his or her authorized representative.

(b) The chief of any city, county, or city and county fire department or of any fire protection district, and their authorized representatives, shall enforce within its jurisdiction the building standards and other regulations of the State Fire Marshal, except those described in subdivision (a) or (d).

(c) The State Fire Marshal shall have authority to enforce the building standards and other regulations of the State Fire Marshal in areas outside of corporate cities and districts providing fire protection services.

(d) (d) The State Fire Marshal shall have authority to enforce the building standards and other regulations of the State Fire Marshal in corporate cities and districts providing fire protection services upon request of the chief fire official or the governing body.

(e) The State Fire Marshal shall enforce the building standards and other regulations of the State Fire Marshal on all University of California campuses and properties administered or occupied by the University of California. For each university campus or property the State Fire Marshal may delegate that responsibility to the person of his or her choice who shall be known as the Designated Campus Fire Marshal.

(f) Any fee charged pursuant to the enforcement authority of this section shall not exceed the estimated reasonable cost of providing the service for which the fee is charged, pursuant to Section 66014 of the Government Code.

4.25.2.3 Health and Safety Code, Section 13801 et seq.

Fire districts are formed and regulated pursuant to the California Health and Safety Code, Section 13801 et seq., also known as the Fire Protection District Law of 1987. The enabling legislation authorizes fire districts to provide fire protection, ambulance, and rescue services. Recognizing that the State's communities have diverse needs and resources, it was the intent of the Legislature in enacting this law to provide a broad statutory authority for local officials.

4.25.2.4 California Government Education Code Section 17620(a)

The governing board of any school district is authorized to levy a fee, charge, dedication, or other requirement against any construction within the boundaries of the district, for the purpose of funding the construction or reconstruction of school facilities.

4.25.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to public services and utilities, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.26 Chapter 30: Visual Resources

4.26.1 Federal Plans, Policies, and Regulations

4.26.1.1 National Scenic Byways Program

The National Scenic Byways Program is part of the U.S. Department of Transportation, FHWA. The program is a grass-roots collaborative effort established to help recognize, preserve and enhance selected roads throughout the United States. Since 1992, the National Scenic Byways Program has funded 3,049 projects for State and nationally designated byway routes in 50 states, Puerto Rico, and the District of Columbia. The U.S. Secretary of Transportation recognizes certain roads as All-American Roads or National Scenic Byways based on one or more archeological, cultural, historic, natural, recreational, and scenic qualities.

4.26.2 State Plans, Policies, and Regulations

The following State regulation is applicable to visual resources, but is discussed in another section of this chapter, as indicated in parentheses:

- Delta Protection Act of 1992 (Surface Water Resources)

4.26.2.1 California Scenic Highway Program

The stated intent of the California Scenic Highway Program (Streets and Highways Code Sections 260 to 263) is to protect and enhance the natural scenic beauty of California's highways and adjacent corridors, through special conservation treatment. Official designation requires a local governing body to enact a Corridor Protection Program that protects and enhances scenic resources along the highway. A properly enforced program can:

- Protect the scenic corridor from encroachment of incompatible land uses such as junkyards, dumps, concrete plants, and gravel pits.
- Mitigate activities within the corridor that detract from its scenic quality by proper siting, landscaping, or screening.
- Prohibit billboards and regulate on-site business signs so that they do not detract from scenic views.
- Make development more compatible with the environment and in harmony with the surroundings.
- Regulate grading to prevent erosion and cause minimal alteration of existing contours and to preserve important vegetative features along the highway.
- Preserve views of hillsides by minimizing development on steep slopes and along ridgelines.
- Prevent the need for noise barriers (sound walls) by requiring a minimum setback for residential development adjacent to a scenic highway.

4.26.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to visual resources, but are discussed in other sections of this chapter, as indicated in parentheses:

- Tehama County General Plan (Land Use)
- Glenn County General Plan (General)
- Colusa County General Plan General)

4.27 Chapter 31: Power Production and Energy

4.27.1 Federal Plans, Policies, and Regulations

The following federal regulation is applicable to power production and energy, but is discussed in another section of this chapter, as indicated in parentheses:

- Clean Air Act (Air Quality)

4.27.1.1 Federal Power Act of 1920

The Federal Power Act (16 U.S.C. 791 to 828c; Chapter 285, June 10, 1920; 41 Stat. 1063) (FPA) was first passed in 1920 and has undergone several major amendments since. The FPA governs all interstate power and transmission system transactions, and it established FERC (originally called the Federal Power Commission) to regulate the interstate wholesale transmission market and to license all non-federal hydroelectric projects.

4.27.1.2 Public Utility Regulatory Policies Act of 1978

The Public Utility Regulatory Policies Act (PURPA) established an independent electric generator market, allowing non-utility companies to build power plants and obligating utilities to purchase renewable and higher efficiency power and energy from independent producers at the price it would otherwise cost the utility to produce the power and energy itself, based on its “avoided cost.” This act was largely responsible for the development of the renewable energy industry in the U.S. for the next 25 years.

4.27.1.3 Electric Consumers Protection Act of 1986

The Electric Consumers Protection Act of 1986 specifies that in addition to the power and development purposes for which licenses are issued, FERC shall give “equal consideration” to power and water facility development, energy conservation, recreational uses, and protection, mitigation of damage to and enhancement of fish and wildlife (including spawning grounds and habitat) as well as preservation of other aspects of environmental quality (16 U.S.C. 797(f)).

4.27.1.4 Energy Policy Acts of 1992 and 2005

The Energy Policy Acts established open access requirements for all transmission system owners and gave authority to FERC to mandate construction of new facilities to accommodate all access requests that are in the public’s interest. The 1992 Act amended Section 211 of the FPA (16 U.S.C. 824j) subsection (a) to read: “Any electric utility, federal power marketing agency, or any other person generating electric energy for sale or resale, may apply to the Commission for an order under this subsection requiring a transmitting utility to provide transmission services (including any enlargement of transmission capacity necessary to provide such services) to the applicant…[and that] the Commission may issue such order if it finds that such order meets the requirements of Section 212, and would otherwise be in the public interest." The Act specifies that the costs of such improvements can be recovered through the provider's rates and tariffs, but that "such rates, charges, terms, and conditions shall promote the economically efficient transmission and generation of electricity and shall be just and reasonable, and not unduly discriminatory or preferential."

The 2005 act authorized FERC to certify a national electric reliability organization to enforce mandatory reliability standards for the bulk-power system, under which the Western Electricity Coordinating Council has authority through the North American Electric Reliability Council and, ultimately, FERC to enforce electric reliability standards for bulk power transactions on the interconnected transmission system in the western half of North America. The 2005 act further strengthened transparency in the wholesale power market by granting FERC the authority to publish power, energy and interstate transmission service prices, and gave FERC approval authority over the sale or merger of entities under its jurisdiction greater than $10 million in value.

The 2005 act also repealed the requirement under PURPA that utilities must purchase power from all qualifying facilities and small power producers at a rate based on the utilities' avoided cost, providing FERC finds that a competitive electricity market exists and a qualifying facility has adequate access to wholesale markets; and it repealed the Public Utility Holding Company Act of 1935, which restricted the structure of holding companies of investor-owned utilities, but mandated that utilities give access to their books and records to FERC and State utility regulators.

4.27.2 State Plans, Policies, and Regulations

The following State regulations are applicable to power production and energy, but are discussed in other sections of this chapter, as indicated in parentheses:

- California Global Warming Solutions of 2006 (Climate Change and Greenhouse Gas Emissions)
- California Clean Air Act (Air Quality)
- California Renewables Portfolio Standard Program (Climate Change and Greenhouse Gas Emissions)

4.27.2.1 Warren-Alquist State Energy Resources Conservation and Development Act

The Warren-Alquist State Energy Resources Conservation and Development Act, also called the Warren-Alquist Act, was passed in 1974. The Warren-Alquist Act established the CEC and granted it statutory authority.

4.27.2.2 The Electric Utility Industry Restructuring Act of 1996 (Assembly Bill 1890)

AB 1890 attempted to establish a direct access market for all customers of the investor-owned utilities (IOUs) in the State, allowing customers to purchase energy services from other utilities or third-party providers. It established the Power Exchange, through which all IOUs purchased all power and energy services on the day-ahead and day-of market, and established the Independent System Operator (ISO) as the operator of the State's privately owned transmission system, which includes contracting for various reliability services to maintain required reliability standards. The attempt failed, and the direct access and Power Exchange provisions were repealed later in 2001, but the California ISO still maintains operational control of the interconnected IOU transmission system, including contracting of reliability services, as well as conducts planning for transmission system improvements.

4.27.2.3 California Integrated Energy Policy of 2002 (SB 1389)

SB 1389 requires the CEC to conduct assessments and forecasts of all aspects of energy industry supply, production, transportation, delivery and distribution, demand, and prices. These assessments and forecasts will be used by the CEC to develop energy policies that conserve resources, protect the environment, ensure energy reliability, enhance the State's economy, and protect public health and safety.

4.27.2.4 California Clean Water Act 316(b) Once-Through Cooling Policy

On May 4, 2010, the SWRCB adopted a Policy regarding the Use of Coastal and Estuarine Waters for Power Plant Cooling (Policy). The administrative record for the Policy was approved by the Office of Administrative Law on September 27, 2010. The Policy became effective on October 1, 2010 when the California Environmental Quality Act Notice of Decision was submitted to the Secretary of Resources.

The Policy establishes technology-based standards to implement federal Clean Water Act §316(b) and reduce the harmful effects associated with cooling water intake structures on marine and estuarine life. The Policy applies to the 19 existing power plants (including two nuclear plants) that currently have the ability to withdraw over 15 billion gallons per day from the State's coastal and estuarine waters using a single-pass system, also known as once-through cooling. Closed-cycle wet cooling has been selected as Best Technology Available. Permittees must either reduce intake flow and velocity or reduce impacts to aquatic life comparably by other means.

The Policy is implemented through an adaptive management strategy by which the standards can be achieved without disrupting the critical needs of the State's electrical generation and transmission system. A Statewide Advisory Committee on Cooling Water Intake Structures has been established to review implementation plans and schedules and provide recommendations to the SWRCB at least annually. The SWRCB will consider the Statewide Advisory Committee's recommendations and make modifications to the Policy, as appropriate. The permittees' NPDES permits will be reissued or modified to conform with the Policy.

4.27.3 Regional and Local Plans, Policies, and Regulations

The following local regulations are applicable to power production and energy, but are discussed in other sections of this chapter, as indicated in parentheses:

- Glenn County General Plan (General)
- Colusa County General Plan (General)

4.27.3.1 Regional Clean Air Incentives Market (RECLAIM) Program for NO_x and SO_x of 1993

RECLAIM is a market incentive program designed to allow facilities flexibility in achieving emission reduction requirements for oxides of nitrogen (NOx), and oxides of sulfur (SOx) pursuant to the Air Quality Management Plan using methods which include, but are not limited to: add-on controls, equipment modifications, reformulated products, operational changes, shutdowns, and the purchase of excess emission reductions.

4.28 Chapter 34: Growth-Inducing Impacts

4.28.1 Federal Plans, Policies, and Regulations

4.28.1.1 National Environmental Policy Act Regulations

The CEQ regulations require an EIS to consider indirect effects of a project, which are often related to growth-inducing effects (40 CFR 1508.8(b)), as described below:

> *"Indirect effects, which are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable. Indirect effects may include growth-inducing effects and other effects related to induced changes in the pattern of land use, population density or growth rate, and related effects on air and water and other natural systems, including ecosystems."*

4.28.2 State Plans, Policies, and Regulations

4.28.2.1 California Environmental Quality Act Guidelines

CEQA Guidelines (§15126.2(d)) require that an EIR evaluate the growth-inducing impacts of a project. The EIR must:

> *"Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth (a major expansion of a waste water treatment plant might, for example, allow for more construction in service areas). Increases in the population may tax existing community service facilities, requiring construction of new facilities that could cause significant environmental effects."*

> *"Discuss the characteristic of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment."*

5. Guide to the Resource Analyses

5.1 Introduction

This chapter is included to help readers understand how the impact analyses are presented for the resource discussions in Chapters 6 through 31. The resource chapters included in this EIR/EIS were prepared by a multi-discipline team of resource specialists using data from site visits, field surveys, and technical studies conducted for the Project; and information obtained from published environmental and planning documents, books, websites, journal articles, and communications with technical experts.

Chapters 6 through 31 of this EIR/EIS are organized by environmental resource area. Each chapter discusses the Environmental Setting[1]/Affected Environment[2], the Environmental Impacts[1]/Environmental Consequences[2] (short- and long-term impacts/direct and indirect impacts,) of implementing the No Project[1]/No Action[2] Alternative and the three action alternatives (Alternatives A, B, and C), and, where appropriate, Mitigation Measures. Also discussed for each environmental resource area are the assumptions considered and methodologies used, the regulatory setting, and the references that were consulted during the preparation of the resource analyses.

Chapters 6 through 31 are organized into the following resource areas:

- Chapter 6: Surface Water Resources
- Chapter 7: Surface Water Quality
- Chapter 8: Fluvial Geomorphology and Riparian Habitat
- Chapter 9: Flood Control and Management
- Chapter 10: Groundwater Resources
- Chapter 11: Groundwater Quality
- Chapter 12: Aquatic Biological Resources
- Chapter 13: Botanical Resources
- Chapter 14: Terrestrial Biological Resources
- Chapter 15: Wetlands and Other Waters of the U.S.
- Chapter 16: Geology, Minerals, Soils, and Paleontology
- Chapter 17: Faults and Seismicity
- Chapter 18: Cultural Resources
- Chapter 19: Indian Trust Assets
- Chapter 20: Land Use
- Chapter 21: Recreation Resources
- Chapter 22: Socioeconomics
- Chapter 23: Environmental Justice
- Chapter 24: Air Quality
- Chapter 25: Climate Change and Greenhouse Gas Emissions
- Chapter 26: Navigation, Transportation, and Traffic
- Chapter 27: Noise
- Chapter 28: Public Health and Environmental Hazards
- Chapter 29: Public Services and Utilities

---

[1] This terminology is applicable to the California Environmental Quality Act (CEQA).
[2] This terminology is applicable to the National Environmental Policy Act (NEPA).

- Chapter 30: Visual Resources
- Chapter 31: Power Production and Energy

For some of these resource areas, an appendix has been prepared. All appendixes are listed in the EIR/EIS Table of Contents, and are included at the end of this EIR/EIS.

5.1.1 Approach to the Resource Analyses

5.1.1.1 CEQA and NEPA Requirements

The California Environmental Quality Act (CEQA) and the State *CEQA Guidelines* §15125(a) indicate that "the description of the environmental setting shall be no longer than is necessary to an understanding of the significant effects of the proposed project and its alternatives."

CEQA Guidelines §15126 indicates that "all phases of a project must be considered when evaluating its impact on the environment: planning, acquisition, development, and operation". *CEQA Guidelines* §15126.2(a) indicates that "an EIR shall identify and focus on the significant environmental effects of the proposed project. Direct and indirect significant effects of the project on the environment shall be clearly identified and described, giving due consideration to both the short-term and long-term effects. State *CEQA Guidelines* §15126.4 requires that an EIR describe feasible measures which could minimize significant adverse impacts, and sets forth mitigation measure considerations.

The Council on Environmental Quality (CEQ) regulations for implementing the National Environmental Policy Act (NEPA) specify that an "EIS shall succinctly describe the environment of the area(s) to be affected or created by the alternatives under consideration. The descriptions shall be no longer than is necessary to understand the effects of the alternatives. Data and analyses in a statement shall be commensurate with the importance of the impact, with less important material summarized, consolidated, or simply referenced" (Title 40, Section 1502.15 of the Code of Federal Regulations [40 CFR 1502.15]).

40 CFR 1502.16 indicates that, for the environmental consequences analysis, "the discussion will include the environmental impacts of the alternatives including the proposed action." It shall include "any environmental effects which cannot be avoided should the proposal be implemented." It shall also include discussions of: direct effects and indirect effects and their significance; possible conflicts between the proposed action and the objectives of federal, regional, State, and local (and in the case of a reservation, Indian tribe) land use plans, policies, and controls for the area concerned; and the means to mitigate adverse environmental impacts. "40 CFR 1502.14(f) requires the inclusion of "appropriate mitigation measures not already included in the proposed action or alternatives".

DWR and Reclamation prepared this EIR/EIS in accordance with the above-listed regulations.

5.1.1.2 Establishment of the Environmental Setting/Affected Environment Baseline Date

In determining the "Environmental Setting/Affected Environment " baseline date for environmental analyses in this EIR/EIS, DWR and Reclamation consulted the *CEQA Guidelines* and the CEQ NEPA regulations (40 CFR Part 1500).

CEQA Guidelines §15125(a) indicates than "an EIR must include a description of the physical environmental conditions in the vicinity of the project as they exist at the time the Notice of Preparation

(NOP) is published, or if no NOP is published, at the time environmental analysis is commenced, from both a local and regional perspective. The environmental setting will normally constitute the baseline physical conditions by which a Lead Agency determines whether an impact is significant.

CEQA Guidelines §15126.2(a) indicates that “the lead agency should normally limit its examination to changes in the existing physical conditions in the affected area as they exist at the time the NOP is published, or where no NOP is published, at the time environmental analysis is commenced.”

The CEQ regulations do not specify a baseline physical condition time period.

The NOP for the Project was published on November 5, 2001, and the Notice of Intent (NOI) for the Project was published on November 9, 2001. Lead agencies have the discretion, where appropriate, to fully or partially update baseline physical conditions beyond the time of the issuance of the NOP and NOI. Because the preparation of this environmental document has occurred over several years, it is appropriate to delay the Environmental Setting/Affected Environment date to include programs, projects, or policies that have been implemented during the document’s preparation. Changes in the regulatory environment since November 2001, such as the regulations discussed below, preclude using November 2001 as the baseline for environmental analyses in this EIR/EIS.

The December 2008 U. S. Fish and Wildlife Service (USFWS) and June 2009 National Marine Fisheries Service (NMFS) Biological Opinions (BOs) for the Operations Criteria and Plan (OCAP) established a new regulatory framework for water management and operations within the Sacramento Valley and the Sacramento-San Joaquin Delta. These BOs fundamentally changed State and federal project operations, which affected water supply reliability and substantially increased water supplies dedicated to environmental enhancement purposes. For these reasons, June 2009 (following the release of NMFS’ BO) was selected as the Project’s Environmental Setting/Affected Environment (i.e., Existing Conditions) date.

The environmental and social conditions in June 2009 within the Project’s three study areas[3] that could be affected by the three action alternatives were used to establish the Environmental Setting/Affected Environment that is presented in each of the environmental resource evaluations (Chapters 6 through 31). The information necessary to characterize the setting was obtained from technical studies performed for the Project, information that was obtained from published environmental and planning documents, books, websites, journal articles, field surveys, site visits, and communications with technical experts. In addition, the resources analyses considered regulations that are in effect; descriptions of the regulations for each resource are provided in Chapter 4 Environmental Compliance and Permit Summary.

[3]The three study areas for the EIR/EIS analyses are the Extended, Secondary, and Primary study areas. They are discussed in Chapter 1 Introduction. The data presented in the various resource chapters for the three study areas were presented at a level of detail that was appropriate for each individual discussion.

5.1.1.3 Project Facilities Evaluated

Analysis of the action alternatives within each resource area included consideration of each of the following Project facilities that are components of the alternatives:

- Sites Reservoir Inundation Area (1.27-MAF reservoir or 1.81-MAF reservoir)
- Sites Reservoir Dams (Golden Gate Dam, Sites Dam, and saddle dams)
- Recreation Areas (Antelope Island, Lurline Headwaters, Stone Corral, Peninsula Hills, Saddle Dam[4])
- Road Relocations and South Bridge
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Complex
- Holthouse Reservoir Electrical Switchyard
- Glenn-Colusa Irrigation District Canal Facilities Modifications
- Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir
- Terminal Regulating Reservoir
- Terminal Regulating Reservoir Pumping/Generating Plant
- Terminal Regulating Reservoir Electrical Switchyard
- Terminal Regulating Reservoir Pipeline
- Terminal Regulating Reservoir Pipeline Road
- Delevan Transmission Line
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard
- Delevan Pipeline Intake Facilities
- Delevan Pipeline Discharge Facility
- Project Buffer

Combinations of these Project facilities were used to create action Alternatives A, B, and C. In the resource chapters, DWR and Reclamation described the potential impacts associated with the construction, operation, and maintenance of each of the Project facilities listed above for each of the three action alternatives.

5.1.1.4 Alternatives Analysis

For this analysis, DWR and Reclamation defined the No Action Alternative as the conditions that existed as of June 2009 (known as the Existing Conditions, and characterized in Chapters 6 through 31 as the Environmental Setting/Affected Environment), plus the programs that were adopted and the facilities that were permitted or are being constructed during the early stages of development of the EIR/EIS. As indicated in Chapter 3, the No Project Alternative (for CEQA) and the No Action Alternative (for NEPA) are the same alternative. Thus, in this EIR/EIS, it is called the No Project/No Action Alternative.

[4] Although five recreation areas were evaluated in this EIR/EIS, fewer than five recreation areas may be developed if the Project is approved.

For every resource discussion presented in Chapters 6 through 31, for the purpose of CEQA compliance:

- The No Project Alternative (CEQA term) was compared to the Environmental Setting (known as Existing Conditions)
- Alternatives A, B, and C were compared to the Environmental Setting (known as Existing Conditions)

For every resource discussion presented in Chapters 6 through 31, for the purpose of NEPA compliance:

- Alternatives A, B, and C were compared to the No Action Alternative (NEPA term).

To reduce redundancy in the analyses of Alternatives A, B, and C, the analysis for Alternative A was presented first in the discussion, and then the analyses for alternatives B and C indicate if their impacts would be the same, or similar to, Alternative A. If they were not similar, those analyses then described how they differed from Alternative A.

The analysis of each resource began with an examination of the Existing Conditions that may be affected by implementation of the alternatives. The effects of the alternatives, pursuant to CEQA, were defined as the changes to Existing Conditions that were attributable to construction, operation, and/or maintenance of the alternatives.

In conducting the analysis for this EIR/EIS, the authors considered the comments that were received during the Project's scoping period, relied on available published studies and reports, and conducted independent investigations, as needed. The specific documents considered and relied upon are cited for each resource in Chapter 37 References.

Each identified impact has been numbered in accordance with the naming convention presented in Table 5-1. Included in each impact discussion is the reasoning indicating *whether* and *why* there would be an impact and the level of significance of each impact, when compared to Existing Conditions and the No Project/No Action Alternative.

*Each resource impact is numbered, with the first impact numbered “1”.

5.1.1.5 Types of Impacts

Mechanisms that could cause impacts are discussed for each resource. General categories of impact mechanisms are construction and future operation and maintenance. Project-related impacts are categorized as follows, to describe the intensity or duration of the impact:

- **A temporary impact** would last less than three to four years and typically would occur only during Project construction. Construction impacts would occur during the defined construction period and include all activities that would occur to construct each Project facility. For the purposes of this analysis, the initial filling of Sites Reservoir and Project access road construction was considered a construction-related impact. The construction disturbance area includes each Project facility footprint plus the land area around that footprint that would be used for materials laydown, soil stockpiling, equipment storage, construction vehicle parking, equipment/vehicle maintenance, spoil disposal, construction debris, batch plants, materials delivery, access roads, actual construction activity disturbance, and any other activity conducted during the construction period for a Project purpose that would cease after the Project facilities are built. The total construction disturbance area is larger than the permanent long-term disturbance area that is caused by each Project facility footprint.
- **A short-term impact** would occur during Project construction and could last from the time construction ceases to within three to five years after Project construction.
- **A long-term impact** would last longer than five years after the completion of Project construction. In some cases, a long-term impact could be a permanent impact. Project operational and maintenance impacts include any activities that must occur to operate and maintain each Project facility. These activities and their associated impacts are long-term and permanent. Operation activities include those related to the movement of water (such as Sites Reservoir level fluctuations, or the intake or release of water through the Delevan Pipeline Intake or Discharge facility), the generation/transmission of electricity, the use of roads during operation and maintenance activities, and the recreation activities that would be associated with operation of the reservoir. Maintenance activities include the upkeep of all of the facilities.

- **A direct impact** is an impact that would be caused by an action and would occur at the same time and place as the action.
- **An indirect impact** is an impact that would be caused by an action but would occur later in time or at another location, yet is reasonably foreseeable in the future.

5.1.1.6 Determination of Significance of Impacts

CEQA Guidelines §15382 define the term "significant effect on the environment" as "a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project including land, air, water, minerals, flora, fauna, ambient noise, and objects of historic or aesthetic significance." The *CEQA Guidelines* further state that the determination of whether a project could have a significant effect on the environment requires careful judgment on the part of the public agency involved and that this judgment should be based, to the extent possible, on "scientific and factual data" [§15064(b)]. CEQA also states that there is no predetermined definition of "significant effect" because the significance of an activity can vary with the setting. For example, an activity that might not have a significant effect in an urban area could be considered significant in a rural area [§15064(b)].

For the purposes of the analyses conducted in this EIR/EIS of Alternatives A, B, and C, a combination of the CEQA Appendix G Environmental Checklist Form criteria were used, along with professional judgment that considered current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. The specific criteria for determining impact significance are listed within the impact discussion in each resource chapter.

The level of significance of the impacts for Alternatives A, B, and C was classified based on the following impact definitions:

- **Potentially Beneficial Effect:** The alternative would potentially improve the environment. No mitigation is required.
- **Beneficial Effect:** The alternative would improve the environment. No mitigation is required.
- **No Impact:** No change in the environment would result from implementing the alternative. No mitigation is required.
- **Less-than-Significant Impact:** No substantial adverse change in the environment would result from implementing the alternative. No mitigation is required.
- **Potentially Significant Impact:** A substantial adverse change in the environment may result from implementing the alternative; however, additional information is needed regarding the extent of the impact. For CEQA purposes, a potentially significant impact is treated as if it were a significant impact. Mitigation measures are identified, when feasible, to reduce effects to the environment.
- **Significant Impact:** A substantial adverse change in the physical conditions of the environment would result from implementing the alternative. Significant impacts are identified by the evaluation of project effects using specified significance criteria. Mitigation measures are identified, when feasible, to reduce effects to the environment.

5.1.1.7 Mitigation Measure Development and Implementation

Mitigation measures were presented, where feasible, to avoid, minimize, rectify, reduce, or compensate for significant and potentially significant impacts of the alternatives, in accordance with §15126.4 of the *CEQA Guidelines* and NEPA regulations (40 CFR 1508.20). To aid the reader, each mitigation measure was identified numerically to correspond with the number of the impact being mitigated by the measure.

When “significant” or “potentially significant” impacts were identified, feasible mitigation measures were formulated to eliminate or reduce the intensity of the impacts and focus on the protection of sensitive resources. The effectiveness of a mitigation measure was subsequently determined by evaluating the impact remaining after the application of the mitigation, and reaching one of two conclusions: (1) the mitigation reduced the impact to a less-than-significant level; or (2) no feasible mitigation exists to reduce the impact to a “less-than-significant level,” and therefore, the impact was determined to be “significant and unavoidable”. No mitigation measures were needed or proposed when an impact was determined to be “less than significant.” Implementation of more than one mitigation measure may be needed to reduce an impact below a level of significance. The mitigation measures recommended in this EIR/EIS are identified within each resource chapter (Chapters 6 through 31) and are presented in the Mitigation Monitoring Plan (Appendix 1A).

5.1.1.8 Topics Eliminated from Further Analytical Consideration

CEQA and the State *CEQA Guidelines* provide for the identification and elimination from detailed study the effects that are not significant or that have been covered by prior environmental documentation (Public Resources Code, §21002.1; State *CEQA Guidelines*, §15143). The NEPA regulations provide similar provisions (40 CFR 1501.7(a)(3)).

During initial scoping with the public and governmental agencies, and based on information obtained through literature review, agency correspondence, consultations, and field data collection, it was determined that no resources were able to be eliminated from detailed study. Therefore, analysis of all resources required by CEQA and NEPA is included in this Draft EIR/EIS.

However, during preparation of the impact analyses, it became evident that some of the CEQA significance criteria were not applicable to the Project, or that some discussions were not relevant to the analysis. DWR and Reclamation described those situations in a “Topics Eliminated from Further Analytical Consideration” subsection in the appropriate resource chapters.

5.1.1.9 Tools, Analytical Methods, and Applications

Each resource chapter includes a description of the methodology used to identify and assess the potential environmental impacts that would result from implementation of the alternatives. For those resources that used modeling output, a brief overview of the modeling tools and output is provided below.

Several modeling tools and analytical methods were used to characterize and analyze the changes in water operations in the SWP and CVP systems for each alternative. These tools represent the best available technical tools for purposes of conducting the analyses. The overall flow of information between the models and the general application and use of output for the resource evaluations are shown in Figure 5-1. Table 5-2 provides a description of the various modeling tools and an overview of how they were used for the impact analyses.

The models were used to compare and contrast the effects among alternatives with various operating scenarios. The models incorporated a set of base assumptions; the assumptions were then modified to reflect the operations associated with each of the alternatives. The output of the models was used to show the comparative difference in the conditions among the different alternative scenarios. The model output does not predict absolute conditions in the future; rather, the output is intended to show what type of changes would occur. This type of model is described as comparative rather than predictive. Because of the comparative nature of these models, these results are best interpreted using various statistical measures, such as long-term and water year-type averages, and probability of exceedance.

The output from these models supports the comparative analysis of various resources, such as water quality, land use, economics, and energy. Additional detailed discussions of the modeling tools and assumptions are provided in the appendixes that are mentioned in Table 5-2.

Table 5-2
Overview of NODOS EIR/EIS Modeling Tools, Analytical Methods, and Applications

Model Name	Description of Model
Surface Water Resources	
SWP and CVP Hydrology and System Operations Model (CALSIM II)	Simulates operations of the SWP, CVP, and other facilities in the Central Valley and approximates changes in storage reservoirs, river flows, and exports from the Delta. Inputs describe assumptions of hydrology at projected levels of land and water use, existing and proposed facilities, and riverine and Delta regulatory conditions. SWP and CVP operations are consistent with the Biological Assessment on the Continued Long-term Operations of the Central Valley Project and the State Water Project (U.S. Bureau of Reclamation. 2008) as modified by the December 2008 USFWS BiOp (U.S. Fish and Wildlife Service. 2008) and the June 2009 NMFS BiOp (National Marine Fisheries Service. 2009). The model and assumptions are described in Appendixes 6A and 6B.
Artificial Neural Network (ANN)	Mimics the flow-salinity relationships as modeled in the Delta Hydrodynamics and Salinity Model (DSM2), and provides a rapid transformation of this information into a form usable by the Statewide CALSIM II model. ANN is implemented in CALSIM II to inform the operations of the upstream reservoirs and the Delta export pumps to satisfy particular salinity requirements.
Upper Sacramento River Daily Operations Model (USRDOM)	Simulates daily reservoir operations and daily river flows for the upper Sacramento River from Shasta Dam to Knights Landing, including the facilities and tributaries within this region; includes the Trinity River section of the Central Valley Project, the Sutter Bypass region (and other bypasses), and the conveyance and storage facilities of the proposed Project. Uses CALSIM II outputs. The model is described in Appendix 6C.
Surface Water Quality	
Upper Sacramento River Water Quality Model (USRWQM)	Simulates the temperature regime of the Upper Sacramento River. The USRWQM, as modified for use in the NODOS Investigations, extends from Keswick Dam to Knights Landing and includes the Sacramento River, Sacramento River at Red Bluff Diversion Dam, Black Butte Dam, Stony Creek, T-C Canal, GCID Canal, Colusa Basin Drain, a proposed Delevan pipeline, the proposed Holthouse Reservoir, and the proposed Sites Reservoir. Provides estimate of daily average riverine temperature conditions. Uses USRDOM outputs. The model is described in Appendix 7E.
Preliminary Sites Reservoir Discharge Temperature Model	Simulates the temperature regime in the proposed Sites Reservoir and the discharge of flows to the Sacramento River. Provides simulated daily average temperature conditions of discharge and blended flow in the Sacramento River. Uses USRDOM and USRWQM outputs. The model is described in Appendix 7E.

Table 5-2
Overview of NODOS EIR/EIS Modeling Tools, Analytical Methods, and Applications

Model Name	Description of Model
Reclamation Monthly Temperature Models (Reclamation Temperature)	Simulates the temperature regime in the Trinity, Feather, American, Lower Sacramento, and Stanislaus river basins and upstream reservoirs. Provides simulated monthly reservoir and stream temperatures used for evaluating the effects of operations on mean monthly water temperatures in the basin. Uses CALSIM II outputs. The model is described in Appendix 7E.
Delta Hydrodynamics Model (DSM2 HYDRO)	Simulates one-dimensional hydrodynamics of the Sacramento–San Joaquin Delta; models Delta channel flows, stages, and cross-section average velocities under tidal conditions. DSM2 is simulated on a 15-minute time step to address the changing tidal dynamics of the Delta system; however, one-dimensional and simplified boundary conditions limit use of results to monthly statistics. Uses outputs from CALSIM II. The model is described in Appendix 7D.
Delta Salinity Model (DSM2 QUAL)	Simulates salinity based on Electrical Conductivity (EC) calibration; one-dimensional and simplified boundary conditions limit use of results to monthly statistics. Uses outputs from DSM2 HYDRO. The model is described in Appendix 7D.
Fluvial Geomorphology and Riparian Habitat, Botanical Resources, and Terrestrial Biological Resources	
Sedimentation and River Hydraulics - Capacity (SRH-Capacity)	Simulates water and sediment budgets of the river system at the watershed scale. The model links sediment sources and transport with geomorphic change and accounts and predicts the sediment loads from tributaries and sediment balance in the main stem of the river. The study area is the Sacramento River from River Mile 295 (downstream of Keswick Dam) to River Mile 80 (near Knights Landing). The study area has been divided into 23 sub-reaches based on hydraulic conditions and river slope. Hydraulics conditions are averaged in each reach and then transport capacity in each reach is computed using the sediment size fraction. SRH-Capacity uses daily flow data from 19 tributaries and computes sediment load in these reaches to estimate sediment balance in the mainstem. Uses outputs from USRDOM. The model is described in Appendix 8A.
Sedimentation and River Hydraulics – Meander (SRH-Meander)	Simulates the bed topography, flow field, and bank erosion rate in curved channels with an erodible bed. In each time step, SRH-Meander first calculates the flow field. It then computes the channel bank erosion rate. Finally, the channel alignment is updated with the erosion rate, followed by a channel cutoff if needed. The model can be used to predict the channel migration in meandering rivers. Uses outputs from USRDOM. The model is described in Appendix 8A.
Sedimentation and River Hydraulics - Vegetation (SRH-1DV)	Simulates river hydraulics, sediment transport, erosion, deposition, and vegetation growth. Cottonwood growth and survival at different cross-sections along the Sacramento River is simulated between Keswick Dam and Colusa. The river is divided into five reaches. SRH-1DV uses groundwater data at several locations and river stage data at River Mile 183 and River Mile 193. Flow rates for the model are required at Hamilton City and Ord Ferry. Uses outputs from USRDOM. The model is described in Appendix 8A.
Riparian Habitat Establishment Model (RHEM)	Simulates the growth of riparian vegetation on point bars. Integrates the simultaneous effects of river stage, precipitation, evaporation, and plant transpiration on soil water content in the root zone. Uses these results to determine the plant survival by simulating the plant's ability to maintain sufficient transpiration to support continued root and shoot growth from germination through the initial establishment stage. Uses outputs from USRDOM and SRH. The model is described in Appendix 8A.

Table 5-2
Overview of NODOS EIR/EIS Modeling Tools, Analytical Methods, and Applications

Model Name	Description of Model
Sacramento River Ecological Flows Tool (SacEFT)	A decision analysis tool that incorporates physical models of the Sacramento River with biophysical habitat models for three species that use riparian habitats along the Sacramento River to evaluate the ecological consequences of management-related changes in flow regime and channel restoration activities. Includes flow and habitat relationships for bank swallows and channel erosion/migration for large woody debris deposition and removal, western pond turtle, and Fremont cottonwood. The model is described in Appendix 8B.
Aquatic Biological Resources	
Reclamation Mortality Models (Reclamation Mortality and SacSalMort)	Estimates the fraction of population lost each year for winter-, spring-, fall-, and late-fall-run Chinook salmon due to thermal conditions only. Uses reach level empirical degree-day equations for the Trinity, Sacramento, Feather, American, and Stanislaus rivers. Uses monthly average outputs from Reclamation Temperature Model. Customized version for the Sacramento River (SacSalMort) uses daily outputs from USRWQM. The model is described in Appendix 12J.
Salmonid Population Model (SALMOD)	Simulates dynamics of freshwater life history of anadromous and resident salmonid populations using streamflow, water temperature, and habitat type. Provides potential fish production values reflecting the suitability of riverine habitat for winter-, spring-, fall-, and late-fall-run Chinook salmon. Simulates salmon habitat conditions in the Sacramento River between Keswick Dam and Bend Bridge. Uses outputs from USRDOM and USRWQM. The model is described in Appendix 12K.
Winter Run Chinook Life Cycle Model (IOS)	Simulates multiple life stages of winter-run Chinook salmon within the Sacramento River system. Life-cycle model provides a quantitative framework to evaluate the effects of flow, temperature, diversions, and habitat conditions on individual cohorts and overall population of winter-run Chinook salmon. The IOS model tracks daily salmon numbers from six different life stage categories (eggs, alevins, fry, smolts, subadults, and adults). The model is spatially explicit including detailed reaches of the Sacramento River, Delta migratory corridors, and the Pacific Ocean. Uses outputs from USRDOM, USRWQM and DSM2. The model is described in Appendix 12L.
Delta Passage Model (DPM)	Simulates detailed accounting of migratory pathways and reach-specific mortality for four runs (winter-, spring-, fall-, and late-fall) of Chinook salmon smolts traveling through a simplified network of reaches and junctions in the Delta. The DPM operates on a daily time step using simulated daily average flows and Delta exports as model inputs. The DPM does not attempt to represent sub-daily flows or diel salmon smolt behavior in response to the interaction of tides, flows, and specific channel features. The DPM for winter-run Chinook salmon is incorporated as a module of the IOS model. Uses outputs from DSM2. The model is described in Appendix 12M.
Sacramento River Ecological Flows Tool (SacEFT)	A decision analysis tool that incorporates physical models of the Sacramento River with biophysical habitat models for three Sacramento River fish species to evaluate the ecological consequences of management-related changes in flow regime and channel restoration activities. Includes flow and habitat relationships for Chinook salmon, steelhead, and green sturgeon. Constituent focal species "sub-models" provide performance measures specific to the species evaluated. Multi-year roll-ups of annual performance allow users to quickly zoom in on the much smaller set of performance measures, which differ significantly across management scenarios. Uses outputs from CALSIM II, USRDOM, and USRWQM. For fisheries analyses in the NODOS Investigations, the SacEFT was used to evaluate potential impacts on steelhead and green sturgeon. The model is described in Appendix 8B.

Table 5-2
Overview of NODOS EIR/EIS Modeling Tools, Analytical Methods, and Applications

Model Name	Description of Model
Recreation Resources	
Recreation-Day Benefit Values	Benefit values combine two equally weighted factors: (1) variety and quality of recreation, and (2) aesthetic qualities of the site. Factors considered in determining the variety and quality of recreation at a reservoir include the types of activities available, quality of the experience, quality of development, and operation and maintenance of the facilities and area. Aesthetic factors include reservoir operation, geologic, topographic, aquatic, vegetative, climate, and other environmental factors. Based on guidelines described in DWR's Economics and Recreation Planning Manuals and in Supplementary Procedures for Application of DWR's Guidelines for Evaluation of General Recreation, developed jointly by DWR and DPR (California State Parks, 1967).
Socioeconomics	
Statewide Agricultural Production (SWAP) model	Simulates the decisions, production, and economics of agricultural producers in California's Central Valley. The model includes up to 27 crop production regions in the Central Valley and 20 categories of crops. Surface water supplies are estimated by hydrologic models and groundwater use and pumping lift are estimated based on assumptions about groundwater availability. SWAP model versions consider responses under average hydrologic conditions and responses during drought. The model maximizes the producer and consumer surplus to determine an optimal market solution. Uses outputs from CALSIM II. The model is described in Appendix 22E.
Least Cost Planning Simulation Model (LCPSIM)	Simulation/optimization model that assesses the economic benefits and costs of increasing urban water service reliability (supply/demand balance) at the regional level. The total cost of the optimized regional water management plan is used in a comparative analysis to determine the potential economic benefit or cost of a proposed action. Models are available for the South Bay and South Coast regions. Uses outputs from CALSIM II. The model is described in Appendix 22D.
Other Municipal Water Economics Model (OMWEM)	Urban water supply valuation for other urban areas using assumptions associated with availability of surface and groundwater supplies. Uses outputs from CALSIM II. The model is described in Appendix 22D.
Lower Colorado River Basin Water Quality Model (LCRBWQM)	Assesses the regional economic effects of water salinity within the SWP system and Colorado River Aqueduct throughout the urban coastal region of southern California. Assesses the benefit of a change in average annual regional salinity costs based on demographic data; water deliveries; TDS concentration; and costs for typical household, agricultural, industrial, and commercial water uses. Uses mathematical functions that define the relationship between TDS and items in each affected category, such as the useful life of appliances, specific crop yields, and costs to industrial and commercial customers. Uses long-term volume and salinity load information based on CALSIM II and DSM2 results. The model is described in Appendix 22E.
Bay Area Water Quality Economics Model (BAWQM)	Assesses the benefit of a change in average annual regional salinity costs based on households in the South Bay region. Uses mathematical functions that define the relationship between TDS and items in each affected category, such as the useful life of appliances. Uses long-term volume and salinity load information based on CALSIM II and DSM2 results. The model is described in Appendix 22E.
IMPLAN	IMPLAN develops input-output estimates of the economic impacts of various activities. For water resources planning, IMPLAN estimates the income and employment effects upon local communities from water project construction and the regional effects of water transfers. Uses outputs from SWAP. The model is described in Appendix 22C.

Table 5-2
Overview of NODOS EIR/EIS Modeling Tools, Analytical Methods, and Applications

Model Name	Description of Model
Reporting Metrics Tool (RMT)	Developed for the NODOS Feasibility Report and EIR/EIS, RMT is a spreadsheet model that reports system operations and economics metrics. The reports are a summary of system specifications for scenarios evaluated, modeled operations, and modeled economics impacts at a range of detail. The reported system operations metrics include yield and water supply, water quality, and hydropower. The reported economics metrics include Project costs, agricultural and M&I water supply, and M&I water quality. The system operations metrics are characterized by user type, and because the modeled economics metrics do not include the entire modeled operations metrics, extensions are made in the RMT to provide estimates for these reporting gaps. Uses outputs from SWAP, LCPSIM, OMWEM, LCRBWQM, BAWQM and other Project-specific information. The model is described in Appendix 22B.
Air Quality and Greenhouse Gas Emissions	
Off-Road Emissions Model (OFFROAD 2007)	The OFFROAD Model estimates the relative contribution of gasoline-, diesel-, compressed natural gas, and liquefied petroleum gas-powered vehicles to the overall emissions inventory of the state. The model is described in Appendix 24A.
Emissions & Generation Resource Integrated Database (eGRID)	The eGRID is a comprehensive source of data on the environmental characteristics of almost all electric power generated in the United States. These environmental characteristics include air emissions for nitrogen oxides, sulfur dioxide, carbon dioxide, methane, and nitrous oxide; emissions rates; net generation; resource mix; and many other attributes. Uses outputs from Reclamation Long Term Generation (LT-GEN), State Water Project Power Model (SWP Power) and Project Power. The model is described in Appendix 24A.
URBan EMISsions (URBEMIS 2007)	URBEMIS 2007 estimates air pollution emissions from a wide variety of land use projects. The model uses the California Air Resources Board's EMFAC2007 model for on-road vehicle emissions and the OFFROAD2007 model for off-road vehicle emissions. The model is described in Appendix 24A.
EMission FACtors (EMFAC 2007)	The EMFAC model is used to calculate emission rates from all motor vehicles, such as passenger cars to heavy-duty trucks, operating on highways, freeways and local roads in California. The model is described in Appendix 24A.
Power Production and Energy	
Reclamation Long Term Generation (LT-GEN)	Computes the power generation and capacity for CVP power plants and project use (pumping plant demand) for CVP pump stations at a monthly time step based on the operations defined by a CALSIM II simulation. Simplified factors are used to separate peak and non-peak generation and load. Includes calculations of transmission losses. Net-revenue is estimated based on price forecasts. Uses outputs from CALSIM II. The model is described in Appendix 31B.
State Water Project Power Model (SWP Power)	Computes the power generation and capacity for SWP power plants and project use (pumping plant demand) for SWP pump stations at a monthly time step based on the operations defined by a CALSIM II simulation. Simplified factors are used to separate peak and non-peak generation and load. Net-revenue is estimated based on price forecasts. Uses outputs from CALSIM II. The model is described in Appendix 31B.
NODOS Power	Computes the power generation and capacity for proposed Project power plants and use (pumping plant demand) for proposed Project pump stations at a monthly time step based on the operations defined by a CALSIM II simulation. Simplified factors are used to separate peak and non-peak generation and load. Net-revenue is estimated based on price forecasts. Uses outputs from CALSIM II. The model is described in Appendix 31B.

Table 5-2
Overview of NODOS EIR/EIS Modeling Tools, Analytical Methods, and Applications

Model Name	Description of Model
DWR-PARO Optimization Modeling	A DWR-PARO Power Planning Study was completed to analyze the current/designed components, and operational scenarios of the Project from a power planning perspective. The Study was aimed at optimizing Project operations to maximize its power portfolio's value (revenues-obligations). The Study is implemented using current power market information and regulations, and available power portfolio models/tools to better evaluate energy costs and revenues of the Project. The Study considered short time step pump-generation operations in addition to long-term water operations. Uses outputs from CALSIM II. The model is described in Appendix 31A.

5.1.1.10 Limitations of the Modeling Tools and Analytical Methods

All modeling tools and analytical methods used in the environmental consequences analyses have limitations. The limitations related to the modeling tools are documented in each of the Appendixes referenced in Table 5-2. There are other uncertainties reflected in the EIR/EIS analyses presented in this document from conducting the environmental studies associated with a large, complex, and evolving project over a period of many years. Biological and cultural resource surveys were conducted over a period of many years. These surveys have limitations in that survey access was not obtained for all parcels for all resource surveys. These surveys are adequate for impact assessment, but some surveys may need to be updated to meet regulatory agency guidelines to confirm final mitigation.

5.1.1.11 Sensitivity Analysis

One limitation of the environmental consequences analyses is that the water operations in the SWP and CVP systems for each alternative were evaluated only at the 2009 climate and sea level conditions. A sensitivity analysis was prepared to evaluate the potential impact of climate and sea level conditions on the results of the surface water models, CALSIM II, and test the conclusions of the environmental consequences analyses subject to the findings of this sensitivity analyses (Appendix 25B).

North-of-the Delta Offstream Storage Project

6. Surface Water Resources

6.1 Introduction

This chapter describes Existing Conditions (the environmental setting) and Project-related changes to surface water resources in the Extended, Secondary and Primary study areas. Detailed descriptions and maps of these three study areas are provided in Chapter 1 Introduction, and summarized descriptions are included in this chapter. Surface water resources generally include reservoirs, rivers, creeks, and human-made diversions, such as flood bypasses and canals.

The chapter also includes a description of the current and future operations and resulting surface water resources characteristics of California's major water systems that are relevant to the Project: the Central Valley Project (CVP), the State Water Project (SWP), and associated tributary rivers and streams. A schematic showing the layout of these two water systems, with the relative location of the proposed Project, is shown in Figure 6-1. A comparison of these characteristics has been made between Existing Conditions, the No Project/No Action Alternative, and the three action alternatives (Alternatives A, B, and C). Unless noted, all numbers shown related to storages, flows, exports, and deliveries in this chapter are generated from the CALSIM-II computer simulation model.

This chapter describes changes in the surface water resources associated with Existing Conditions, the No Project/No Action Alternative, and the three action alternatives, but does not assess impacts or evaluate the significance of surface water changes, except for evaluating changes in the surface water resources metrics (CVP and SWP deliveries) used to evaluate water supply reliability impacts and significance (refer to Section 6.5).

All other impact and significance determinations that rely on the surface water resources data that are presented in this chapter are described and evaluated in other resource chapters (e.g., changes in reservoir storage and river flows). Chapter 5 Guide to the Resources Analyses describes the relationship between this chapter and subsequent analyses included in other chapters. Appendixes 6A and 6B describe the assumptions and the analytical framework used, and presents maps showing the specific locations used for surface water and surface water quality analyses.

6.2 Environmental Setting/Affected Environment

6.2.1 Extended Study Area

The Extended Study Area includes San Luis Reservoir, which is jointly operated by both the CVP and SWP. The Extended Study Area also includes the service areas of the CVP (operated and maintained by the U.S. Bureau of Reclamation [Reclamation]) and the SWP (operated and maintained by the California Department of Water Resources [DWR]).

6.2.1.1 San Luis Reservoir

The San Luis Unit, which is part of the CVP and the SWP, was authorized in 1960. Reclamation and DWR constructed and operate this unit jointly. Some features of the San Luis Unit are "joint-use facilities" of the federal government and the State. The joint-use facilities are O'Neill Dam and Forebay, B.F. Sisk San Luis Dam, San Luis Reservoir, William R. Gianelli Pumping/Generating Plant, Dos

Amigos Pumping Plant, Los Banos and Little Panoche reservoirs, San Luis Canal from O'Neill Forebay to Kettleman City, and the associated switchyard facilities.

Completed in 1967 and dedicated on April 20 of that year, B. F. Sisk Dam (which created San Luis Reservoir) is a zoned earthfill structure 382 feet high with a crest length of 18,600 feet; it contains 77,656,000 cubic yards of material. The dam's crest is 30 feet thick; the maximum base width is 2,420 feet. The reservoir filled for the first time on May 31, 1969. San Luis Reservoir is one of the largest offstream reservoirs in the nation. The reservoir has a capacity of slightly more than 2 million acre-feet (MAF), and is used to store surplus water from the Sacramento-San Joaquin Delta. Reservoir fill and release cycles are similar to other large reservoirs in California, with storage peaking in March (approximately 1.5 MAF average) and at annual minimum levels in August (548,000 acre-feet average). Releases are made through the San Luis Pumping/Generating Plant.

The pumping/generating units lift water from O`Neill Forebay and discharge it into the main reservoir. When not pumping, these units generate electricity by reversing flow through the turbines. Water for irrigation is released into the San Luis Canal, and flows by gravity to Dos Amigos Pumping Plant, where it is lifted more than 100 feet to permit gravity flow to the end of the San Luis Canal at Kettleman City, from which the water continues to flow in the California Aqueduct to southern California. During irrigation months, water from the California Aqueduct flows through O`Neill Forebay into the San Luis Canal instead of being pumped into San Luis Reservoir. Two detention reservoirs, Los Banos and Little Panoche, control cross drainage along the San Luis Canal. The reservoirs also provide recreation and flood control benefits (Reclamation, 2011).

Table 6-1 shows Existing Conditions for average monthly San Luis Reservoir (CVP and SWP) storage over the long term and by water year type for Existing Conditions. Refer to Appendix 6B for San Luis Reservoir surface water elevation and surface area data tables.

6.2.1.2 CVP and SWP Deliveries

The CVP provides water to a range of service contract types delivering Municipal and Industrial (M&I), Agricultural, Settlement, Exchange, and Wildlife Refuge water supplies throughout California's Central

Valley. Settlement and Exchange contractors have the highest degree of reliability due to water rights senior to the CVP. Water service contractors and wildlife refuges are subject to shortages according to water availability and their geographic location. Due to conveyance constraints, water service contractors and wildlife refuges south of the Delta have a lower degree of reliability than water service contractors and wildlife refuges north of the Delta.

California is divided into 10 hydrologic regions (Figure 6-2) that correspond to the State's major water drainage basins (DWR, 2005). Table 6-2 shows the Existing Conditions for CVP deliveries for the hydrologic regions within the Extended Study Area by water service type.

Table 6-2
Central Valley Project Annual Deliveries (TAF)

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:
TAF = thousand acre-feet
M&I = Municipal and Industrial
Ag = Agricultural

Existing Conditions CVP deliveries reflect the delivery capability of the CVP system, including existing facilities, regulatory requirements, and contractual commitments. Settlement and Exchange deliveries comprise the greatest portion of deliveries for the Sacramento River and San Joaquin River regions, respectively. Agricultural service comprises the majority of the deliveries in San Francisco Bay Region and all of the deliveries in the Tulare Lake Region. Generally, deliveries diminish as conditions get drier. Agricultural service contracts also incur the greatest change in deliveries based upon water year type. For example, Agricultural service deliveries in Critical Years within the Tulare Lake Region (152,000 acre-feet) are 16 percent of the deliveries in Wet years (956,000 acre-feet).

As part of the Central Valley Project Improvement Act (CVPIA), the CVP provides Firm Level 2 Supplies to State Wildlife Refuges, National Wildlife Refuges (NWR), and private wetlands in the Grassland Resource Conservation District (RCD) identified in the CVPIA.

In addition, pursuant to CVPIA, Reclamation is negotiating long-term water supply contracts/agreements for Level 4 Supplies with the California Department of Fish and Game, Grasslands Water District (representing the Grassland RCD), and memoranda of understanding (MOUs) with the U.S. Fish and Wildlife Service (USFWS).

These contracts/agreements and MOUs will provide long-term water supplies (up to 25 years) to specified State wildlife areas, private wetlands in the Grassland RCD, and the NWRs identified in the CVPIA. These Level 4 supplies are in addition to the Firm Level 2 Supplies provided by the CVP.

Table 6-3 shows Existing Conditions for total Wildlife Refuge Water Supply deliveries for the hydrologic regions within the Extended Study Area. These include CVP Contract and Acquisitions supplies.

Table 6-3

[c]L4 = Level 4 refuge water supply - the increased amount of water above Level 2 needed to achieve optimum waterfowl habitat management.
[d]Based on CALSIM-II modeling over an 82-year simulation period.
[e]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Note:
TAF = thousand acre-feet

The SWP provides water to a range of service contract types delivering M&I and agricultural water supplies to service areas in northern California, including the Feather River Service Area (FRSA), the San Francisco Bay Area, the San Joaquin Valley, the Central Coast, and southern California. FRSA contractors are located north of the Delta and hold pre-SWP priority senior delivery rights.

Table 6-4 shows Existing Conditions for SWP contract deliveries for the hydrologic regions within the Extended Study Area by water service type. Existing Conditions SWP deliveries reflect the delivery capability of the SWP system, including existing facilities, regulatory requirements, and contractual commitments. Total deliveries of the SWP system are dominated by Agricultural Service in the Tulare Lake Region and M&I Service in the South Coast Region. Deliveries are diminished as conditions become drier, based upon water year type. For example, South Coast M&I Service deliveries in Critical years (757,000 acre-feet) are 50 percent of those deliveries in Wet years (1,517,000 acre-feet).

6.2.2 Secondary Study Area

The Secondary Study Area is defined as the CVP and SWP reservoirs, rivers, creeks, and associated floodplains that could be affected by Project operations, located in 22 counties.

The Secondary Study Area includes the following reservoirs, rivers, creeks, and floodplains: Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay. They are discussed below.

6.2.2.1 Trinity Lake

The Trinity River Division consists of Trinity Dam and Lake, Trinity Power Plant, Lewiston Dam and Lake, Lewiston Power Plant, Clear Creek Tunnel, Judge Francis Carr Powerhouse, Whiskeytown Dam and Lake, Spring Creek Tunnel and Power Plant, Spring Creek Debris Dam and Reservoir, as well as related pumping and distribution facilities.

The Trinity Dam and facilities transfer water from the Trinity River basin to the Sacramento River Basin. Water from the Trinity River Basin is stored, regulated, and diverted through a system of dams, reservoirs, tunnels, and power plants. The system diverts the water south into Clear Creek, the Sacramento River, and the Central Valley.

Trinity Dam regulates flows and stores water for various uses. Completed in 1962, Trinity Dam is an earthfill structure 538 feet high with a crest length of 2,450 feet. The dam forms Trinity Lake. Trinity Lake, located approximately 50 miles west of the City of Redding, has a capacity of approximately 2.4 MAF and is operated for a variety of purposes: irrigation water supply, flood control, improved Sacramento River navigation, domestic and industrial water supply, electric power generation, fish and wildlife conservation, creation of recreation opportunities, and water quality enhancement. Releases from Trinity Dam through the downstream Trinity Power Plant are regulated downstream at Lewiston Reservoir for downstream flow requirements and diversions through the Clear Creek Tunnel to Keswick Reservoir. The outflow from Trinity and Lewiston reservoirs also provides water to meet temperature objectives for special-status species in the Trinity and upper Sacramento rivers.

The minimum instream flow requirements downstream of Lewiston Dam on the Trinity River that were stipulated in the Trinity River Record of Decision (ROD) (Reclamation, 2000) affect storage within Trinity Lake.

Storage varies between approximately 1.3 MAF (October) and 1.8 MAF (April), based upon the long-term average end-of-month storage. The variation from average is most significant in Critical year types, where end-of-month storage is reduced by up to 55 percent in November; Critical Year November storage is approximately 590,000 acre-feet, and long-term average November storage is approximately 1.3 MAF (Reclamation, 2011).

Table 6-6 shows Existing Conditions for average monthly Trinity Lake storage over the long term and by water year type. Refer to Appendix 6B for Trinity Lake surface water elevation and area data tables.

Note:
TAF = thousand acre-feet

6.2.2.2 Lewiston Lake

Lewiston Dam was constructed by Reclamation from 1960 to 1963. Lewiston Lake is formed by Lewiston Dam on the Trinity River. It has a capacity of approximately 14,600 acre-feet. Lewiston Power Plant is located at the base of Lewiston Dam. It diverts water through the Clear Creek Tunnel to Whiskeytown Lake. The power plant began operating in 1964.

Although developed primarily for irrigation, this multiple-purpose project also provides flood control, improves Sacramento River navigation, supplies domestic and industrial water, generates electric power, conserves fish and wildlife, creates opportunities for recreation, and enhances water quality.

Lewiston maintains and regulates river releases and provides power to the adjacent Trinity River Fish Hatchery. Energy in excess of hatchery loads is sold to Pacific Gas and Electric Company (Reclamation, 2011).

6.2.2.3 Trinity River

The Trinity River, located in northwest California, is the largest tributary to the Klamath River. Water export and energy generation from the Trinity River were envisioned as early as 1931 when plans for diverting Trinity River water to the Sacramento River were included as part of the California State Water Plan.

The 2000 Trinity River ROD stipulated specific releases to the Trinity River downstream of Lewiston Dam to meet instream flow requirements. The total volume of water released to the Trinity River ranges from approximately 369,000 acre-feet to 815,000 acre-feet, depending on the annual water-year type (hydrology) determined as of April 1st (Reclamation, 2000). Table 6-7 shows the annual flow volumes, peak flows, and peak flow durations by water type[1].

[1] The water year types included in the Trinity ROD are probability-based and classified by ranges of annual Trinity River Basin water year runoff. This classification is different from the water year types presented in all other tables of this chapter, which are based on the historical record of WY1922 through WY2003 and defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 2000).

Table 6-7
Trinity River Record Of Decision
Annual Flow Volumes and Peak Flows

Water Year Type	Volume (AF)	Peak Flow (cfs)	Peak Flow Duration (days)
Extremely Wet	815,000	11,000	5
Wet	701,000	8,500	5
Normal	647,000	6,000	5
Dry	453,000	4,500	5
Critically Dry	369,000	1,500	36

Notes:
cfs = cubic feet per second
AF = acre-feet

Source: Reclamation, 2000.

The release schedules based on water year type have a minimum release of 450 cubic feet per second (cfs) between October 1st through October 15th, and 300 cfs from October 16th through April 21st. Release schedules are variable, based upon water year type between April 22nd and July 21st. Releases across all water year types are then fixed at a minimum of 450 cfs from July 22nd through September 30th (Reclamation, 2000).

Table 6-8 shows Existing Conditions for average monthly Trinity River flow downstream of Lewiston Lake over the long term and by water year type. Trinity River long-term average flows by month vary between 365 cfs in November and 3,779 cfs in May.

Table 6-8
Trinity River Monthly Flow Downstream of Lewiston Reservoir (cfs)
Existing Conditions
Long-Term Average and Average by Water Year Type

Analysis Period	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep

Critical (15%)	342	300	300	300	300	300	575	2,092	783	450	450	450

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).
Note:
cfs = cubic feet per second

The Trinity River ROD release schedules are clearly reflected in the monthly flows by water year type. For example, the 300 cfs minimum flow requirement is reflected in the Below Normal, Dry, and Critical water years during November through March. The 450 cfs minimum flow requirement during August and September is clearly reflected across all water years.

6.2.2.4 Klamath River Downstream of the Trinity River

The Klamath River begins in the southeastern part of Oregon and flows approximately 263 miles southwest through northern California, flowing through the southern Cascade Range to empty into the Pacific Ocean. The Trinity River is the largest tributary of the Klamath River. The Trinity River joins the Klamath River at Weitchpec approximately 44 miles upstream of the Pacific Ocean.

The Trinity River confluence also marks the point where Klamath River flows slow down dramatically. For the remainder of its course, it flows generally northwest through the Hoopa Valley and Yurok Indian reservations, passing the town of Klamath and flowing out to sea 16 miles south of Crescent City. The mouth of the Klamath River is located at the community of Requa.

6.2.2.5 Clear Creek

Since 1964, a portion of the flow from the Trinity River Basin has been exported to the Sacramento River Basin through CVP facilities. Water is diverted from the Trinity River at Lewiston Dam via the 11-mile-long Clear Creek Tunnel and passes through the Judge Francis Carr Powerhouse as it is discharged into Whiskeytown Lake on Clear Creek.

Table 6-9 shows Existing Conditions for average monthly Clear Creek Tunnel flow over the long term and by water year type. The long-term average monthly flow in the Clear Creek Tunnel ranges from 92 cfs (February) to 1,866 cfs (August). The relative timing of flow in the Clear Creek Tunnel is unnatural because higher flows occur in summer and lower flows occur in winter.

Note:
cfs = cubic feet per second

6.2.2.6 Whiskeytown Lake

Whiskeytown Dam was constructed in 1963 by Reclamation. Located approximately eight miles west of Redding, it was one of the first units of the Trinity River Diversion of the CVP to be constructed. The earthfill dam, located on Clear Creek, is 282 feet high and 4,000 feet long. Crest elevation is 1,228 feet. Whiskeytown Dam regulates Trinity River flows discharged from the Judge Francis Carr Powerhouse and regulates the runoff from the Clear Creek drainage area. Whiskeytown Lake has a capacity of approximately 241,000 acre-feet.

Whiskeytown Lake is normally operated to regulate inflows for power generation and recreation, support upper Sacramento River temperature objectives, and provide releases to Clear Creek, consistent with CVPIA Anadromous Fish Restoration Program (AFRP) objectives.

Historically (1964 to 1992), approximately 1.3 MAF of water has been diverted annually from Whiskeytown Lake to Keswick Reservoir. This represents approximately 17 percent of the flow measured in the Sacramento River at Keswick.

Operations at Whiskeytown Lake during flood conditions are complicated by its operational relationship with the Trinity River, Sacramento River, and Clear Creek. On occasion, imports of Trinity River water to Whiskeytown Lake may be suspended to avoid increasing flows under high flow conditions in the Sacramento basin. Heavy rainfall events occasionally result in spillway discharges to Clear Creek.

Water rights permits issued by SWRCB for diversion from Trinity River and Clear Creek specify minimum downstream releases from Lewiston and Whiskeytown dams, respectively (Reclamation, 2011).

6.2.2.7 Spring Creek

The Spring Creek Tunnel diverts water from Whiskeytown Lake on Clear Creek to the Spring Creek Power Plant. The tunnel is 18.5 feet in diameter and approximately 2.4 miles long, including the 0.6-mile-long 17-foot-diameter Rock Creek Siphon. The Spring Creek Power Plant (a peaking plant that has been operating since 1964) is located at the foot of the Spring Creek Debris Dam. Water from the plant is discharged to Keswick Reservoir.

Spring Creek also flows into the Sacramento River and enters at Keswick Reservoir. Flows on Spring Creek are partially regulated by the Spring Creek Debris Dam.

The Spring Creek Debris Dam, located on Spring Creek upstream of the Spring Creek Power Plant tailrace, is an earthfill structure that is 196 feet high with a crest length of 1,110 feet. Spring Creek Reservoir has a capacity of approximately 5,800 acre-feet. It controls debris that would otherwise enter the power plant tailrace, and provides important fishery and water quality benefits by controlling contaminated runoff resulting from old mine tailings on Spring Creek (Reclamation, 2011).

6.2.2.8 Shasta Lake

Shasta Dam was constructed in 1945 by Reclamation as an integral element of the CVP for six purposes: irrigation water supply, M&I water supply, flood control, hydropower generation, fish and wildlife conservation, and navigation. Shasta Dam is located on the upper Sacramento River approximately nine miles northwest of Redding. Shasta Lake has a storage capacity of approximately 4.5 MAF. Shasta Lake captures runoff from approximately 6,665 square miles. Shasta Power Plant, a peaking power plant, is located downstream of Shasta Dam on the Sacramento River. Pertinent data for Shasta Dam and Lake are shown in Table 6-11.

Table 6-11
Shasta Dam and Lake Pertinent Data

	Elevation (feet)	Area (acres)	Capacity (TAF)
Inactive Pool	840	6,700	587
Bottom Flood Control Pool[a]	1,019	24,000	3,252
Gross (Full) Pool[b]	1,067	29,500	4,552

[a]Maximum Controlled Release: 81,800 cfs
[b]Spillway Capacity: 186,000 cfs

Note:
TAF = thousand acre-feet

Source: Reclamation, 2011.

Shasta Lake has an average annual inflow of 5.9 MAF. The flood control storage space is 1.3 MAF. Inflows to the lake generally increase during November through March, with maximum storage occurring in April or May following the months of highest inflow. After the spring snowmelt has ended, typical June through October flow into the reservoir is less than 5,000 cfs. Seasonal storage and releases average approximately 1.5 MAF with year-to-year carryover averaging about 2.8 MAF.

The entire outflow from Shasta Lake flows into, and is regulated through, Keswick Reservoir, which is located approximately nine miles downstream of Shasta Dam. Releases from Shasta Reservoir are managed to meet minimum fish flows and temperature requirements, flood control requirements, salinity control, and water supply demands of CVP contractors (Reclamation, 2011).

Shasta Lake is the largest reservoir in California, and as such, is the foundation storage facility of the CVP system. The operation of Shasta Lake has greatly changed the natural flow conditions of the Sacramento River downstream of Keswick Reservoir. Flood peaks are reduced in the winter and spring, and discharges are increased during the summer and fall for irrigation, fish, and other uses.

A temperature control device (TCD) was installed at Shasta Dam between 1996 and 1998 to both minimize power losses and control the water temperature downstream of Shasta Lake to protect salmon.

The new TCD has allowed for warmer water withdrawals in the spring/early summer, resulting in conservation of the deep cold water pool for colder withdrawals in the late summer/early fall to meet downstream temperature requirements.

Table 6-12 shows Existing Conditions for average monthly Shasta Lake storage over the long term and by water year type. Over the long-term average, Shasta Lake end-of-month storage varies between 2,549,000 acre-feet in November and 3,939,000 acre-feet in May.

Note:
TAF = thousand acre-feet

Water in storage in Shasta Lake is reduced, especially in Critical water years, up to 58 percent in October (from 2,571,000 acre-feet long-term average to 1,084,000 acre-feet during Critical water years). Refer to Appendix 6B for Shasta Lake surface water elevation and area data tables.

6.2.2.9 Keswick Reservoir

Since 1964, flow from the Trinity River has been imported to Whiskeytown Lake and then to Keswick Reservoir. Keswick Dam and Reservoir is located approximately nine miles downstream from Shasta Dam and five miles west of the City of Redding. Keswick Power Plant is located at Keswick Dam. Keswick Reservoir has a storage capacity of approximately 24,000 acre-feet.

Keswick Reservoir receives inflows from Whiskeytown Lake on Clear Creek and regulates all outflows from Shasta Lake that flow into and through the reservoir. Keswick Dam controls runoff from 45 square miles of drainage area. Nearly all releases from Keswick Dam are made through its generating facilities. On occasion, however, outflows during flood operations are made through the flood control outlets and over the spillway. During these instances, the existing power plant is bypassed for much of the flood release.

Releases from Keswick Reservoir are managed to meet minimum fish flow and temperature requirements, flood control requirements, salinity control requirements, and water supply demands of CVP contractors (Reclamation, 2011).

6.2.2.10 Sacramento River

The Sacramento River is the largest river in California. Runoff from the upper Sacramento River and its tributaries are regulated by Shasta Dam and Lake, and then by Keswick Dam and Reservoir.

Downstream of Keswick Reservoir, the Sacramento River is also influenced by tributary stream runoff from precipitation and snowmelt; diversions for agricultural, municipal, and industrial purposes; agricultural and municipal discharges; and a flood damage reduction system that includes levees, floodplains (including the Yolo, Sutter, and Colusa bypasses), and weirs.

The Sacramento River flood channel capacity between Red Bluff and Chico Landing near the mouth of Stony Creek is approximately 260,000 cfs. The Sacramento River Flood Control Project levees begin near Ord Bend. From Ord Bend to below Butte City, the Sacramento River flood channel capacity is approximately 160,000 cfs. Floodwaters exceeding the channel capacity between Chico Landing and Colusa Weir overflow into the Butte Sink area and then to the Sutter Bypass. The capacity of the Sacramento River decreases to approximately 110,000 cfs downstream of Moulton Weir, and to approximately 48,000 cfs downstream of Colusa Weir (USACE, 1960).

Annual diversions from the Sacramento River upstream of the Feather River average approximately 1.7 MAF. Major diversions occur at the Red Bluff Diversion Dam (RBDD) into the Tehama-Colusa (T-C) and Corning canals, and at the Glenn-Colusa Irrigation District (GCID) Canal at Hamilton City. Surface water demands along the Sacramento River between Red Bluff and Colusa are more than 2.3 MAF annually, including water supplies for Sacramento Valley refuges, agricultural activities, and urban uses.

The Sacramento River channel downstream of Colusa is quite different than upstream of Colusa. Downstream of Colusa, the gradient of the river decreases, the channel becomes deeper and narrower, the capacity decreases, and the bed material is finer (SRAC, 1998). The river is also contained by levees with excess flow bypassed through spills at Tisdale, Fremont, and Sacramento weirs. The bypassed flow goes into the Sutter Bypass and the Yolo Bypass. The Feather River joins the Sacramento River at the community of Verona, and the American River joins at the City of Sacramento. The Sacramento River then flows south, joining with the San Joaquin River in the Delta, and out to the Pacific Ocean.

Numerous small and large streams flow into the Sacramento River. The major tributaries feeding into the Sacramento River are listed in Table 6-13.

Table 6-13
Major Tributaries of the Sacramento River Downstream of Shasta Dam

West Side	East Side
Clear Creek	Cow Creek and Bear Creek
Cottonwood Creek	Battle Creek

	Feather River
	American River

Table 6-14 shows Existing Conditions for average monthly Sacramento River flow downstream of Keswick Reservoir over the long term and by water year type. Long-term average Sacramento River monthly streamflow downstream of Keswick Reservoir varies between 6,248 cfs in October and 10,154 cfs in February. Streamflow downstream of Keswick Reservoir varies by year type, similar to Shasta Lake storage. Critical water year streamflow is decreased by up to 65 percent in February (3,591 cfs), compared to long-term average flow (10,154 cfs). Wet water year streamflow is increased by up to 92 percent in January (15,878 cfs), compared to long-term average flow (8,252 cfs).

6.2.2.11 Glenn-Colusa Irrigation District Canal

The GCID's Main Pump Station, located approximately five miles northwest of Hamilton City, diverts water into the existing GCID Canal for distribution to over 130,000 acres of irrigated lands within the GCID service area. The approximately 65-mile-long Canal terminates at the Colusa Basin Drain (CBD) near the town of Williams, California.

GCID's system has undergone significant infrastructure and operational changes; infrastructure changes have included a major expansion of the GCID Fish Screen (completed in 2001) and several improvements along the Canal to allow year-round water delivery operations. Two major operational changes included a shift to year-round water delivery to provide water in the fall and winter to the federal Sacramento National Wildlife Refuge complex, as well as to meet increased fall and winter season water demands for rice straw decomposition purposes.

The existing Canal is an unlined earthen channel with capacity varying from 3,000 cfs at the upstream end to 300 cfs at its terminus. Approximately 40 miles of the Canal, from the Main Pump Station south to the proposed Terminal Regulating Reservoir (TRR), would be used for conveying water to the proposed Sites Reservoir. The 40-mile section of the Canal has six main reaches. There are 40 major structures within this area, including bridges, siphons, and check structures.

Table 6-18 shows Existing Conditions for average monthly GCID Canal Intake flow over the long term and by water year type. Long-term average monthly GCID Canal flow ranges from 52 cfs (February) to 2,818 cfs (June).

6.2.2.12 Tehama-Colusa Canal

Constructed in 1980 by Reclamation, the T-C Canal is a lined canal that is approximately 111 miles long. It extends from the RBDD in Tehama County to south of the community of Dunnigan in Yolo County. It is operated by the Tehama-Colusa Canal Authority (TCCA) through a Joint Powers Authority comprised of 17 water districts. TCCA delivers water to the 17 water districts' irrigation service areas in Tehama, Glenn, Colusa, and northern Yolo counties. Since the canal operation began, fall and winter diversions have increased due to increased water demands for rice straw decomposition purposes.

Water from the Sacramento River enters the T-C Canal Intake at the RBDD. Canal capacity is 2,530 cfs at the start and 1,700 cfs at the terminus. Canal flows enter Funks Reservoir approximately 66 canal miles downstream from the RBDD. The canal capacity at Funks Reservoir is 2,100 cfs.

Table 6-19 shows Existing Conditions for average monthly T-C Canal Intake flow over the long term and by water year type. Long-term average monthly T-C Canal Intake flow ranges from 0 cfs (December and January) to 830 cfs (July).

6.2.2.13 Lake Oroville and the Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay)

The Oroville Facilities include Oroville Dam and Lake Oroville, three power plants (Hyatt Pumping-Generating Plant, Thermalito Diversion Dam Power Plant, and Thermalito Pumping-Generating Plant), Thermalito Diversion Dam, the Feather River Fish Hatchery and Fish Barrier Dam, Thermalito Power Canal, Oroville Wildlife Area, Thermalito Forebay and Forebay Dam, Thermalito Afterbay and Afterbay Dam, transmission lines, as well as several recreational facilities. The Oroville Facilities were developed as part of the SWP and are operated by DWR.

The mainstem of the Feather River is regulated by Oroville Dam. The dam and its two saddle dams were completed in 1968 and formed Lake Oroville, a 3.5-MAF capacity storage reservoir with a surface area of approximately 16,000 acres at its normal maximum operating level.

The Oroville hydroelectric facilities have a combined licensed generating capacity of approximately 762 megawatts (MW). The facilities consist of the Hyatt Pumping-Generating Plant, the Thermalito Diversion Dam Power Plant, and the Thermalito Pumping-Generating Plant.

The Thermalito Afterbay is used to release water into the Feather River downstream of the hydroelectric facilities. It helps regulate the power system, provides storage for pump-back power operations, and provides recreational opportunities. Several local irrigation districts receive water from the Afterbay during the May through August season.

Operation of the Oroville facilities varies depending upon hydrology and the objectives DWR is trying to meet. Lake Oroville stores winter and spring runoff for release to the Feather River, as necessary, for project purposes. Typically, releases to the Feather River are managed to conserve water while meeting a variety of water delivery requirements, including flow, temperature, fisheries, recreation, diversions, and water quality. Power production is scheduled within the boundaries specified by the water operations criteria.

During the wintertime, the Oroville Facilities are operated pursuant to flood control requirements specified by the U.S. Army Corps of Engineers (USACE). Pursuant to these requirements, Lake Oroville is operated to maintain up to 750,000 acre-feet of storage space to allow for the capture of significant inflows.

Annual operations are conducted for multi-year carryover. The current methodology is to retain half of the Lake Oroville storage above a specific level for subsequent years. Currently, that level has been established at 1 MAF; however, this does not limit drawdown of the reservoir below that level. If hydrology is drier than expected, or requirements greater than expected, additional water would be released from Lake Oroville. The operations plan is updated regularly to reflect changes in hydrology and downstream operations. Project operations are directly constrained by downstream operational constraints and flood management criteria.

An August 1983 agreement between DWR and DFG titled, "*Agreement Concerning the Operation of the Oroville Division of the State Water Project for Management of Fish & Wildlife*," sets criteria and objectives for flow and temperatures in the low-flow channel and the reach of the Feather River between Thermalito Afterbay and Verona where the Feather River joins the Sacramento River. This agreement: (1) establishes minimum flows between Thermalito Afterbay Outlet and Verona, which vary by water year type; (2) requires flow changes under 2,500 cfs to be reduced by no more than 200 cfs during any 24-hour period, except for situations such as flood management or failures; (3) requires flow stability during the peak of the fall-run Chinook spawning season; and (4) sets an objective of suitable temperature conditions during the fall months for salmon and during the later spring/summer for shad and striped bass. In addition, the 2006 Feather River Settlement Agreement established minimum flows of 800 cfs during October through March and 700 cfs during April through August across all water year types in the low-flow channel.

Table 6-20 shows Existing Conditions for average end-of-month Lake Oroville storage over the long term and by water year type. The long-term average end-of-month Lake Oroville storage ranges from 1,812,000 acre-feet (October) to 3,015,000 acre-feet (May). In Critical water years, storage in Lake Oroville is reduced by more than 50 percent in July (1,153,000 acre-feet), as compared to long-term average (2,426,000 acre-feet). Refer to Appendix 6B for Lake Oroville surface water elevation and area data tables.

6.2.2.14 Feather River

Lower Feather River flows vary as water released at the Oroville Dam facilities travels down to the confluence with the Sacramento River at Verona. At the upper extent, the approximate eight-mile low flow section contains mainly riffles and runs. The low-flow section also has a series of remnant gravel pit pools/ponds that connect to the main channel. This stretch is fairly confined by levees as it flows through the City of Oroville. The 2006 Feather River Settlement Agreement established minimum flows of 800 cfs during October through March and 700 cfs during April through August across all water year types in the low-flow channel. From the downstream end of the low-flow section, the Feather River is fairly active and meanders its way south to Marysville. However, this stretch is bordered by active farmland, which confines the river into an incised channel in certain stretches.

Table 6-21 shows Existing Conditions for monthly Feather River flow downstream of the Thermalito Complex for averages over the long term and by water year type. The long-term average monthly flow in the Feather River downstream of the Thermalito Complex ranges from 2,282 cfs (November) to 6,079 cfs (March).

Downstream from Wilkins Slough, the Feather River enters the Sacramento River upstream of Verona. Between Wilkins Slough and Verona, floodwater is diverted at two places: Tisdale Weir into the Tisdale Bypass, and Fremont Weir into the Yolo Bypass. The bypass system routes floodwater away from the Sacramento River mainstem to discharge into the Delta.

6.2.2.15 Sutter Bypass

The Sutter Bypass is a narrow floodwater bypass that conveys Sacramento River flood flows. The bypass is an expansive land area for agriculture in Sutter County. In times of high water, Sacramento River water enters the bypass through the Butte Slough outfall and the Tisdale Weir (when the stage exceeds 45.45 feet) and inundates the bypass with as much as 12 feet of water.

The Sutter Bypass receives water from natural runoff areas south of Chico, overflow and weir flow from the Sacramento River, and drainage from the east side of the bypass through Wadsworth Canal and pumping plants. The bypass meets the Feather River upstream of the confluence with the Sacramento River near the Fremont Weir. The Fremont Weir is a floodway; when the water level in the Sacramento

River reaches a high level, water flows over the Fremont Weir into the Yolo Bypass. The Feather River and Sutter Bypass flow in a joint channel to the Sacramento River.

Table 6-22 shows Existing Conditions for average monthly Tisdale Weir flow into the Sutter Bypass over the long term and by water year type. Over the long-term average, Tisdale Weir flow into the Sutter Bypass ranges from 0 cfs (July to September) to 3,232 cfs (February). Flows occur even in some Critical water years during December through March. Refer to Appendix 6C for detailed tables of weir flows into the Sutter Bypass.

6.2.2.16 Yolo Bypass

The Yolo Bypass is an approximately 59,000-acre land area that conveys Sacramento River flood waters around Sacramento during times of high runoff. Flow is diverted from the Sacramento River into the bypass when the stage exceeds 33.5 feet (corresponding to 56,000 cfs at Verona). Diversion of the majority of the Sacramento River, Sutter Bypass, and Feather River floodwaters to the Yolo Bypass controls Sacramento River flood stages at Verona. During large flood events, up to 80 percent of Sacramento River flows are diverted into the bypass. The Yolo Bypass parallels the lower Sacramento River reach to the west. Flows enter this river reach at various points. First, flows from the Natomas Cross Canal enter the Sacramento River approximately one mile downstream from the Feather River mouth. The American River flows into the Sacramento River in the City of Sacramento. When Sacramento River system flood flows are the highest, a portion of the flow is diverted into the Yolo Bypass at the Sacramento Weir, located approximately three miles upstream from the American River confluence in downtown Sacramento. At the downstream end, Yolo Bypass flows reenter the Sacramento River near Rio Vista. As the river enters the Delta, Georgiana Slough branches off from the mainstem of the Sacramento River, routing a portion of the flow into the central Delta.

Table 6-26 shows Existing Conditions for average monthly Yolo Bypass flow over the long term and by water year type. Flow in the Yolo Bypass is mostly related to weir spills from the Sacramento River, as described above. Some of the flow is from Westside streams, such as Cache Creek. Long-term average monthly flow in the Yolo Bypass ranges from a monthly low of 47 cfs (July) to 12,548 cfs (February). Refer to Appendix 6B for detailed tables of weir flows into the Yolo Bypass.

6.2.2.17 Folsom Lake and Lake Natoma

The Folsom Facilities were developed as an integral part of the CVP. The facilities consist of Folsom Lake, which is formed by Folsom Dam, and Lake Natoma, which is formed by Nimbus Dam.

Construction of Folsom Dam was completed in 1956 and impounds Folsom Lake. Total Folsom Lake storage capacity is approximately 1 MAF.

Folsom Lake is a multiple-purpose facility. It is managed to provide flood control, recreation, hydroelectric power generation, M&I water supply, Delta water quality protection, and minimum fish protection flows in the American River and the Sacramento-San Joaquin Delta. It is located on the American River approximately 15 miles northeast of the City of Sacramento, near the City of Folsom, and approximately 30 miles upstream of the confluence of the Sacramento and American rivers.

Nimbus Dam is located seven miles downstream from Folsom Dam and impounds Lake Natoma. Lake Natoma reregulates the releases made through the Folsom Power Plant. Lake Natoma has a storage capacity of approximately 8,760 acre-feet (Reclamation, 2011).

Flood control requirements and regulating criteria are specified by USACE and described in the *Folsom Dam and Lake, American River, California Water Control Manual* (USACE, 1987).

Since 1996, Reclamation has operated the facilities according to modified flood control criteria, which reserve 400,000 to 670,000 acre-feet of flood control space in Folsom Lake and in a combination of three upstream reservoirs. This flood control plan, which provides additional protection for the lower American River, is implemented through an agreement between Reclamation and Sacramento Area Flood Control Agency (SAFCA). The terms of the agreement allow some of the empty reservoir space in Hell Hole, Union Valley, and French Meadows reservoirs to be treated as if it were available in Folsom Lake.

Table 6-27 shows Existing Conditions for average end-of-month Folsom Lake storage over the long term and by water year type. The long-term average end-of-month storage in Folsom Lake ranges from 445,000 acre-feet (November) to 844,000 acre-feet (May). In Critical water years, storage in Lake Oroville is reduced by up to 53 percent in July (1,153,000 acre-feet), as compared to long-term average (2,426,000 acre-feet). Critical water year storage in Folsom Lake is reduced up to 54 percent in October (227,000 acre-feet), as compared to long-term average (489,000 acre-feet). Refer to Appendix 6B for Folsom Lake surface water elevation and area data tables

6.2.2.18 American River

Downstream of Folsom Lake, the river passes through an urbanized area that is buffered by a riparian park, known as the American River Parkway. The river flows approximately 31 miles from Folsom Lake to the river's confluence with the Sacramento River.

Table 6-28 shows Existing Conditions for average monthly American River flow downstream of Nimbus Dam over the long term and by water year type. The long-term average monthly flow in the American River downstream of Nimbus ranges from 1,601 cfs (October) to 5,173 cfs (February).

6.2.2.19 Sacramento-San Joaquin Delta

The Sacramento-San Joaquin Delta (Delta), located to the east of San Francisco Bay, is the point of confluence for the Sacramento and San Joaquin rivers. The Delta encompasses the legal limits of the Delta, as defined in California Water Code Section 12220. Water flows out of the Delta, into Suisun Bay, then San Pablo Bay, and finally San Francisco Bay before flowing to the Pacific Ocean. Salty ocean water and fresh river water commingle in the Delta, creating the largest estuary on the west coast of North America. Water from more than 40 percent of the State's land area flows into the Delta (Reclamation, 2009).

Hundreds of miles of waterways divide the Delta into islands, some of which are below sea level. The Delta relies on more than 1,000 miles of levees to protect these islands.

The Delta supports several beneficial uses, including water supply to local and south of Delta municipalities and agricultural uses; ecological support for fisheries, including wetlands and important habitat; in-Delta agriculture; flood management; water quality management; and a major conveyance for transporting fresh water from northern to southern portions of the State (Delta Vision Blue Ribbon Task Force, 2008). The Delta is critical to California's economy, supplying drinking water for two-thirds of Californians and irrigation water for more than seven million acres of the most highly productive agricultural land in the world, providing approximately 45 percent of the nation's produce. However, many water projects, including export pumps for the SWP and CVP, diversions for Delta area and Bay area municipalities, and regional agricultural users, also divert Delta waters, and thereby influence Delta hydrology and water quality (Reclamation, 2009).

Operation of the CVP and SWP is coordinated according to their respective water right permits, and a series of other governing laws, regulations, and agreements that have been developed to ensure compliance with specific hydrology, water quality, and ecosystem requirements while meeting the water supply contract obligations. CVP and SWP operations are adjusted to meet Delta flow and water quality standards by increasing releases of stored water in project reservoirs, or altering export pumping, gate positions, and other Delta facility operations. Water Rights Decision 1641 and Order WR 2001-05 contain water right requirements for Reclamation and DWR to implement the Bay-Delta Water Quality Control Plan flow and water quality objectives. The Coordinated Operations Agreement defines how Reclamation and DWR share their joint responsibility to meet Delta water quality standards and meet the water demands of senior water right holders. Depending on specific conditions of the fisheries populations and presence in the Delta each year, CVP/SWP exports can be restricted on a seasonal basis pursuant to biological opinions issued by the National Marine Fisheries Services (NMFS) and USFWS.

Flows through the Delta are maintained to meet Bay-Delta water quality standards arising from DWR's water rights permits. These standards are designed to meet several water quality objectives, such as salinity, Delta outflow, river flows, and export limits. The purpose of these objectives is to attain the highest water quality, which is reasonable, considering all demands being made on the Bay-Delta waters. In particular, they protect a wide range of fish and wildlife, including Chinook salmon, delta smelt, striped bass, and the habitat of estuarine-dependent species.

The primary factors that affect Delta hydrology are: (1) twice-daily tidal cycles, which result in inflow and outflow through the Delta and San Francisco Bay; (2) freshwater inflow from the Sacramento and San Joaquin rivers; and (3) water management activities, including SWP and CVP reservoir storage and releases, as well as water exports from the south Delta. Additionally, winds and salinity/freshwater mixing behaviors generate several secondary currents. Although these currents are generally of low velocity, they are significant in terms of transporting contaminants and mixing different sources of water.

The CVP and SWP are the largest Delta water users and exporters. Water is exported via pumping and aqueduct facilities located at Clifton Court Forebay, the Banks Pumping Plant, the Jones Pumping Plant, and the North Bay Aqueduct. Local agencies, such as Contra Costa Water District (CCWD), municipalities, private entities, and agricultural users also operate their own diversion programs and infrastructure.

The Delta includes approximately 540,000 acres of agricultural land which, during the summer irrigation season, is supplied by Delta surface water. Water use in the Delta region averages approximately 1.7 MAF per year with the majority of that going to agricultural uses. Most of the agricultural water is diverted directly by farmers through unscreened diversions pursuant to riparian or pre-1914 water rights. Agricultural users operate their own diversions at more than 1,800 locations and divert a net rate (total diversions minus return flows) estimated at over 4,000 cfs, for a total of approximately 1.5 MAF of water consumed annually. Agricultural return flows are collected by canal systems and pumped back into Delta waterways. Given the agricultural return flows, actual diversions exceed the net water consumed by 50 percent or more. There is also a small amount of urban water use, including diversions by CCWD, the City of Antioch, and industries along the Pittsburg-Antioch shoreline.

Table 6-29 shows Existing Conditions for average monthly Sacramento-San Joaquin Delta outflow over the long term and by water year type. The long-term average monthly Delta outflow ranges from 6,015 cfs (October) to 51,555 cfs (February).

The Delta Cross Channel (DCC) is a gated diversion channel in the Sacramento River near Walnut Grove and Snodgrass Slough. Flows into the DCC from the Sacramento River are controlled by two 60-foot by 30-foot radial gates. When the gates are open, water flows from the Sacramento River through the DCC to channels of the lower Mokelumne and San Joaquin rivers toward the interior Delta. The DCC operation improves water quality in the interior Delta by improving circulation patterns of good quality water from the Sacramento River toward Delta diversion facilities. Reclamation operates the DCC in the open position to (1) improve the transfer of water from the Sacramento River to the export facilities at the Banks and Jones pumping plants, (2) improve water quality in the southern Delta, and (3) reduce salt water intrusion rates in the western Delta. During the late fall, winter, and spring, the gates are often periodically closed to protect out-migrating salmonids from entering the interior Delta. In addition, whenever flows in the Sacramento River at Sacramento reach 20,000 to 25,000 cfs on a sustained basis, the gates are closed to reduce potential scouring and flooding that might occur in the channels on the downstream side of the gates.

Note:
cfs = cubic feet per second

Water management activities, especially export pumping, can affect the direction of flow in Delta channels. Net flow of Delta waters is naturally westward from the San Joaquin and Sacramento rivers across the Delta and toward San Francisco Bay. However, during certain tidal, river inflow, and south Delta export pumping conditions, the direction of net flow within specific western Delta channels may be eastward (creating a reverse flow).

The combined Old and Middle river flows are used as a measure of net reverse flow conditions (exclusive of tides) downstream of the Jones and Banks pumping plants within the south Delta. CVP and SWP export pumping causes reverse flows in the southward direction down Old and Middle rivers and other central and south Delta channels. A negative flow value indicates reverse flow conditions.

Table 6-31 shows Existing Conditions for average monthly Old and Middle river flows over the long term and by water year type. The long-term average monthly flow in Old and Middle rivers ranges from -9,589 cfs (July) to 840 cfs (April). Positive flow values are shown in April and May for the long-term average and over all water years except for Dry and Critical. All other months and water years show negative flow values, which indicate reverse flows.

6.2.2.20 Suisun Bay, San Pablo Bay, and San Francisco Bay

San Francisco Bay is a shallow productive estuary through which water from the Sacramento and San Joaquin rivers enters the Pacific Ocean. Specifically, both rivers flow into Suisun Bay, which flows through the Carquinez Strait to meet with the Napa River at the entrance to San Pablo Bay. San Pablo Bay connects at its south end to San Francisco Bay. However, the entire group of interconnected bays is often referred to as the “San Francisco Bay”.

The outlet of San Francisco Bay at Golden Gate Bridge is located 74 km from Chipps Island, the interface between the Delta and Suisun Bay. The Suisun Marsh is located north of Suisun Bay and east of Carquinez Strait; it is an extensive mosaic of variably controlled tidal marshlands. Tributaries to San Pablo Bay include the Napa, Sonoma, and Petaluma rivers. Numerous lesser streams collectively drain the Bay Region.

San Francisco Bay has a surface area of approximately 400 square miles at mean tide level. Most of the Bay’s shoreline has a mild slope, which creates a relatively large intertidal zone. The volume of water in the Bay changes by approximately 21 percent from mean higher-high tide to mean lower-low tide. The overall average depth of the Bay is approximately 20 feet, with the Central Bay averaging 43 feet and the South Bay averaging 15 feet. San Francisco Bay is surrounded by approximately 130 square miles of tidal flats and marshes.

Average net Delta outflow into the Bay Region, as measured at Chipps Island, is approximately 20,400 cfs, or 15 MAF per year. Average natural freshwater inflow to the Delta varies by a factor of more than 10 between the highest month in winter or spring and the lowest month in fall. During summer months of Critically Dry water years, net Delta outflow can decrease to 3,000 cfs.

In addition to Delta outflow, San Francisco Bay receives freshwater inflow from the Napa, Petaluma, and Guadalupe rivers, and from Alameda, Coyote, Walnut, and Sonoma creeks, as well as several smaller streams. The total average annual inflow volume of these tributaries (excluding the Delta) is approximately 350,000 acre-feet. Stream flow is highly seasonal, with more than 90 percent of the annual runoff occurring during November through April.

Suisun Bay and the adjacent 80,000-acre Suisun Marsh are located near the downstream end of the Delta. Suisun Bay is the area where the effects of mixing fresh water and salt water are typically most pronounced.

Downstream of Carquinez Strait are the San Pablo and central San Francisco bays. Carquinez Strait separates these bays from Suisun Bay and the Delta, and allows tides to play a leading role in their salinity and circulation. These embayments can become fresh, especially at the surface, during extremely high freshwater flows. During these high flows, the entrapment zone can be temporarily relocated downstream to San Pablo Bay. During periods of low freshwater flows and high tides, these embayments are saline.

The South Bay is different from the other parts of the system. This area is not in the main path of Delta outflows. Thus, except during sustained high-outflow periods, water quality is not significantly affected by Delta outflow. During low Delta outflow periods, evaporation, combined with limited tidal flushing, can cause salinity levels to be higher in the South Bay than in the ocean outside of the Golden Gate.

The Bay Region receives unallocated and minimum required outflows from the Delta Region. These can range from the minimum required flow of less than four to nearly 60 MAF, depending on precipitation and diversions. This water is used in the Bay Region primarily for ecological and water quality maintenance purposes.

The location of the mixing zone between fresh water from the Delta and saline water from the Bay varies with the amount of Delta outflow, as well as tides. The mixing zone is pushed downstream during periods of high Delta outflow and can move upstream into the Delta if Delta outflow is low, or during spring neap tides.

To track and regulate this movement, a standard has been developed, called X2, which represents the mean distance in kilometers (km) from the Golden Gate Bridge where salinity concentration and electrical conductivity requirements are met. The X2 position approximates the location of the entrapment zone, which is an area of high biological productivity.

The Water Quality Control Plan (WQCP) for the San Francisco Bay/Sacramento-San Joaquin Delta defines requirements for maintaining X2 at Port Chicago and Chipps Island (SWRCB, 1999).

6.2.3 Primary Study Area

The Primary Study Area is considered to be the footprint of the Project facilities, the land immediately surrounding them that could be affected by construction and/or maintenance activities (construction disturbance area), and the land parcels surrounding those areas that would be purchased as a Project buffer.

The Primary Study Area is located entirely within Glenn and Colusa counties. The primary surface water resources in this study area are Funks Creek, Stone Corral Creek, Funks Reservoir, CBD, and other small tributaries. They are discussed below.

6.2.3.1 Funks Creek

Funks Creek headwaters begin in the foothills west of the town of Maxwell. Funks Creek flows into Funks Reservoir at the T-C Canal, both of which are operated by TCCA. The drainage area of Funks Creek at Funks Dam is 43 square miles. The last stream gage that was operated on Funks Creek washed out in 1985 and was not replaced due to the constantly degrading channel. Peak winter flows of approximately 2,000 cfs are common (Weathers, pers. comm., 2005). Because the topography and soil composition of the watershed are similar to those of Stone Corral Creek, where stream flow records are available, and given the comparable drainage areas of the two watersheds, it is reasonable to assume that the 100-year discharge on Funks Creek would be similar to that of Stone Corral Creek.

6.2.3.2 Stone Corral Creek

The drainage area of the Stone Corral Creek watershed is 38.2 square miles. The USGS collected 25 years of discharge measurements near the town of Sites from 1958 through 1985 with periodic interruptions. During that time, there were three years of zero flow: 1972, 1976, and 1977. The maximum mean daily flow of 2,230 cfs occurred on December 24, 1983. The instantaneous peak flow was 5,700 cfs on January 26, 1983. The 100-year discharge upstream of Sutton Road (aka Cemetery Road) is 3,560 cfs. A summary of the flow statistics is shown in Table 6-33 (FEMA, 2003).

Table 6-33
Stone Corral Creek Daily and Monthly Flows Near Sites, USGS 11390672
Period of Record 4/1/1958 – 9/30/1964 and 10/1/1965 – 9/30/1985

Note:
cfs = cubic feet per second

6.2.3.3 Funks Reservoir

Funks Reservoir is located on Funks Creek approximately seven miles northwest of the town of Maxwell, in Colusa County. Constructed in 1975 by Reclamation, Funks Reservoir has a designed storage capacity of approximately 2,200 acre-feet with a surface area of 232 acres. The T-C Canal connects to Funks Reservoir with an inlet at the northeast end adjacent to the dam spillway and an outlet to the southeast end. Both the inlet and outlet have a gated release. The Funks Reservoir spillway is designed to pass 25,000 cfs. Both Funks Reservoir and the T-C Canal are operated and maintained by TCCA (Reclamation, 2012).

The typical summer releases from Funks Reservoir to the lower portions of T-C Canal range from 500 cfs to 1,000 cfs. Total flows of 50 cfs to 200 cfs for off-peak limited agricultural releases are needed between November and February, and possibly into March, depending on the weather (DWR, 2003).

6.2.3.4 Colusa Basin Drain

Runoff from 11 stream systems draining the foothill and valley floor watersheds contribute flow to the CBD. The CBD flows southward through Glenn, Colusa, and Yolo counties and enters the Sacramento River at the town of Knights Landing. This natural historic drainage system for the Colusa Basin has been almost entirely cut off from receiving floodwaters from the Sacramento River by an extensive levee system (except when flood flows on the Sacramento River exceed 300,000 cfs near Ord Ferry). In general, the CBD conveys flood flows from November through March, and agricultural irrigation and drainage flows from April through October. The northern half of the CBD is unleveed. Beginning south of Colusa, left bank (looking downstream) levees extend southward to the CBD’s confluence with the Sacramento River. A DWR gaging station located at State Route (SR) 20 near the City of Colusa has been operating since 1924. The drainage area at SR 20 is 973 square miles, and the average annual runoff is 497,000 acre-feet. A summary of the flow statistics is shown in Table 6-34.

6.2.3.5 Other Local Creeks

Numerous small tributaries exist within the Primary Study Area. Grapevine Creek starts on the west side of the proposed Sites Reservoir inundation area and flows north and into the reservoir area near Sites Lodoga Road. It also flows into Funks Creek approximately seven miles upstream of Funks Reservoir. Antelope Creek starts on the west side of the proposed reservoir inundation area, south of the headwaters of Grapevine Creek. Antelope Creek flows south, then east, and then north through the southern portion of the proposed reservoir inundation area, and joins with Stone Corral Creek near the town of Sites. North of the Sites Reservoir inundation area, Hunters Creek flows to the east. Southeast of Sites Reservoir, Lurline Creek flows to the east. Both Hunters and Lurline creeks flow into the CBD.

6.3 Evaluation of Changes to Surface Water Resources

6.3.1 Regulatory Setting

Surface water resources are regulated at the federal, State, and local levels through regulations that pertain to water quality, flood control, protection of fish and wildlife, power generation, the beneficial uses of water, water rights, and regulations that define the sharing of water between the CVP and SWP. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

6.3.1.1 Federal Plans, Policies, and Regulations

- Central Valley Project Improvement Act
- Coordinated Operations Agreement
- 2009 National Marine Fisheries Service Biological Opinion
- Bay-Delta Water Quality Control Plan
- CALFED Bay-Delta Authorization Act
- CALFED Bay-Delta Implementation Act
- Trinity River Mainstem Fishery Restoration

- San Joaquin River Agreement and the Vernalis Adaptive Management Plan
- Clean Water Act

6.3.1.2 State Plans, Policies, and Regulations

- State Water Resources Control Board Water Rights and Water Quality Protection
  - Water Rights Protections for County of Origin and Upstream Watersheds
- Water Rights Decision 1422/Order 83-3 and Water Rights Decision 1275
- Water Quality Control Plans for the Sacramento/San Joaquin River Basins, the San Francisco Bay Basin, and Development of the 1978 Delta Plan and Water Rights Decision 1485
- Development of the 1995 and 2006 Water Quality Control Plans and Orders 98-09 and 95-9
- State Water Resources Control Board Decision 1641
- Porter-Cologne Water Quality Control Act
- The Burns-Porter Act
- Delta Protection Act of 1959
- Delta Protection Act of 1992
- Monterey Agreement
- Monterey Plus
- Suisun Marsh Protection Act and Plan (1974)
- Suisun Marsh Preservation Agreement (1987)
- California Water Plan

6.3.2 Assessment Assumptions and Methodology

The following assumptions and methods were used to describe the changes in surface water resources associated with implementation of the No Project/No Action Alternative and Alternatives A, B, and C.

6.3.2.1 Key Assumptions Associated with the No Project/No Action Alternative

Below is a summary of key assumptions included in the No Project/No Action Alternative, which directly influence the changes in surface water resource metrics between the No Project/No Action Alternative and Existing Conditions. A more detailed explanation of key assumptions between alternatives can be found in Appendix 6A.

- An increase in demands and build-out of facilities associated with CVP contracts of approximately 253,000 acre-feet per year north of the Delta at the future level of development. This is a result of an increase in CVP M&I service contracts related primarily to urban M&I use within the American River Basin (198,000 acre-feet), especially in the communities in El Dorado, Placer, and Sacramento counties. A summary of the CVP demands between the No Project/No Action Alternative and the Existing Conditions is shown in Table 6-35.

- An increase in demands associated with SWP contracts, up to full contract amounts, south of the Delta at the future level of development. SWP M&I demands, which with the existing level of development, vary on hydrologic conditions between 3.0 to 4.1 MAF per year, and with the future condition are at maximum contract amounts in all hydrologic conditions. This represents a potential 25 percent increase on average in south of the-Delta demands pursuant to SWP M&I contracts between existing and future levels of development. A summary of the SWP demands between the No Project/No Action Alternative and the Existing Conditions is shown in Table 6-35.
- An increase in non-Project water rights demand of 184,000 acre-feet in the American River Basin.
- New urban intake/Delta export facilities include:
  - Freeport Regional Water Project (FRWP)
  - City of Stockton Delta Water Supply Project, 30 mgd capacity
  - Delta-Mendota Canal – California Aqueduct Intertie
  - Contra Costa Water District's Middle River Intake and Pump Station (previously known as the Alternative Intake Project) and Los Vaqueros expanded storage capacity, 160,000 acre-feet
  - South Bay Aqueduct rehabilitation, to 430 cfs capacity, from junction with California Aqueduct to Alameda County FCWSD Zone 7
- An increase in supplies firm Level 2 for wildlife refuges of approximately 32,000 acre-feet per year north of the Delta and a decrease of approximately 24,000 acre-feet south of the Delta and an increase of Level 4 supplies of for wildlife refuges of approximately 50,000 acre-feet per year (17,000 acre-feet north of the Delta and 33,000 acre-feet south of the Delta) at the future level of development. However, Firm Level 2 supplies are met by CVP contract supply and Level 4 supplies are met through local water acquisitions in both existing and future levels of development.
- Both Existing Conditions and the No Project/No Action Alternative modeling assumptions reflect the best representation of the Reasonable and Prudent Actions (RPAs) in the 2008 U.S. Fish and Wildlife Service (USFWS) and 2009 NOAA National Marine Fisheries Service (NMFS) Biological Opinions (BiOps).
  - USFWS BiOp RPA actions considered include:
    - Action 1: Adult Delta smelt migration and entrainment (RPA Component 1, Action 1 – First Flush)
    - Action 2: Adult Delta smelt migration and entrainment (RPA Component 1, Action 2)
    - Action 3: Entrainment protection of larval and juvenile Delta smelt (RPA Component 2)
    - Action 4: Estuarine habitat during Fall (Fall X2 Action) (RPA Component 3)
    - Action 5: Temporary spring head of Old River barrier and the Temporary Barrier Project (RPA Component 2)
  - NMFS BiOp RPA actions considered include:
    - Action I.1.1: Clear Creek spring attraction flows
    - Action I.3.1: Operations after May 14, 2012: Operate RBDD with Gates Out

- Action I.4: Wilkins Slough operations
- Action II.1: Lower American River flow management
- Action III.1.3: Stanislaus River flows downstream of Goodwin Dam
- Action IV.1.2: Delta Cross Channel gate operations
- Action IV.2.1: San Joaquin River flow requirements at Vernalis and Delta export restrictions
- Action IV.2.3: Old and Middle River flow management

Table 6-35 shows a summary of CVP and SWP demands for Existing Conditions and the No Project/No Action Alternative grouped by north-of-the-Delta and south-of-the-Delta regions. Key differences in project demands are reflected in the changes seen between Existing Conditions and the No Project/No Action Alternative. For a general discussion of the CVP and SWP project contractors and demands, refer to Section 6.2.1.2.

Table 6-35
Summary of CVP and SWP Demands (TAF/Year)
No Project/No Action Alternative Compared to Existing Conditions

	Summary of SWP and CVP Demands under Existing Conditions		Summary of SWP and CVP Demands under No Project/No Action Alternative	
Project Contractor Type	**North-of-the-Delta**	**South-of-the-Delta**	**North-of-the-Delta**	**South-of-the-Delta**

Notes:
SWP = State Water Project
CVP = Central Valley Project
TAF = thousand acre-feet

6.3.2.2 Methodology

Analyses to support the description of changes to surface water resources associated with implementation of the alternatives were developed based upon CALSIM II operations simulations. CALSIM II is the DWR and Reclamation operations simulation model developed for the CVP and SWP water resources system. CALSIM II is described in Appendix 6B.

The use of CALSIM II allows Project planners to describe the comparative changes or effects to the CVP and SWP water resources system associated with adding a new surface storage reservoir located north of the Delta. For the simulation of Existing Conditions, all characteristics of the CVP and SWP remained the same. For the simulation of the No Project/No Action Alternative, reasonably foreseeable projects and changes (such as increasing demands) were added to the Existing Conditions baseline. Subsequently, simulations of the CVP and SWP were performed with the addition of Project action alternatives A, B, and C to facilitate a comparison of surface water resources with and without the proposed Project.

The metrics chosen to evaluate differences between Existing Conditions, the No Project/No Action Alternative, and Alternatives A, B, and C were for those locations at which a relative change could occur due to implementation of the alternatives. In addition, one metric was chosen to represent changes at each evaluation location discussed. For example, storage was chosen to represent changes at reservoirs, although reservoir surface water elevation and surface area changes were also modeled.

Detailed data of all surface water resources modeling locations and metrics are included in Appendix 6B. In addition, maps showing the specific locations used for surface water and surface water quality modeling are included in Appendix 6B.

6.3.3 Topics Eliminated from Further Analytical Consideration

Metrics at several modeled locations were omitted from discussion throughout this chapter where it would have been redundant to represent changes resulting from implementation of the alternatives, or where no change would be expected to occur from implementation of the alternatives.

6.3.4 Changes Associated with the No Project/No Action Alternative

This section describes changes between the No Project/No Action Alternative and Existing Conditions. Environmental effects associated with the changes described below are discussed in other resources chapters.

6.3.4.1 Extended Study Area – No Project/No Action Alternative

San Luis Reservoir

Table 6-36 shows the differences between the No Project/No Action Alternative and the Existing Conditions for monthly San Luis Reservoir storage. Table 6-36 presents data for averages over the long term and by water year types.

Over the long term, storage would be reduced in most months, when compared to Existing Conditions. Small increases would occur in February, March, and April. Larger reductions in storage would occur in May through January. The largest reduction in storage (6.6 percent) would occur in November. The greatest storage reductions would occur in Wet water years, and the greatest storage increases would occur in Critical water years with June through November, all increasing by more than 20 percent (roughly 100,000 acre-feet or more). The largest reduction (18.4 percent) would occur in August of Wet water years, and the largest increase by water year type (30.7 percent) would occur in September of Critical water years.

Notes:
Percent Difference (%) = Relative Difference of the monthly average.
TAF = thousand acre-feet

CVP Deliveries

No Project/No Action Alternative vs. Existing Conditions

Table 6-37 shows the differences between the No Project/No Action Alternative and Existing Conditions for annual CVP deliveries within the Extended Study Area by hydrologic region and water service type. Table 6-37 presents data for the long-term averages and combined Dry and Critical water years average.

Table 6-37
Annual CVP Deliveries (TAF)[a]

		Dry and Critical	283	307	-24 (-8%)
Total For All Regions					
Total CVP Supplies	Contract Delivery (Settlement, Ag, M&I and Refuges from CVP – does not include Refuge Level 4 supply from acquisitions)	Long-Term	4,868	4,659	209 (4%)
		Dry and Critical	4,164	4,001	163 (4%)

[a]Based on CALSIM-II modeling over an 82-year simulation period.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Notes:

Ag = Agricultural
CVP = Central Valley Project
EXC = existing conditions
M&I = Municipal and Industrial
TAF = thousand acre-feet

The total deliveries for all regions over the long-term average show that an increase of 209,000 acre-feet (four percent) would occur. By hydrologic region, the long-term average shows that substantial M&I increases would occur in the Sacramento and San Francisco Bay regions. M&I deliveries in the Sacramento River hydrologic region would increase by 126,000 acre-feet (149 percent). This increase is due primarily to increase in urban M&I use within the American River Basin. To a lesser extent, M&I deliveries would also increase by 65,000 acre-feet (29 percent) in the San Francisco Bay Region. The only noticeable change in Ag deliveries would be a reduction (10,000 acre-feet [5 percent]) in the Sacramento Region. Wildlife Refuge Level 2 deliveries would also decrease in both the San Joaquin (20,000 acre-feet [7 percent]) and Tulare Lake (3,000 acre-feet [21 percent]) regions. Sacramento Hydrologic Region CVP settlement contractors' deliveries would increase by 23,000 acre-feet (one percent). San Joaquin River Exchange contractors' deliveries would remain the same.

The total deliveries throughout all hydrologic regions for the combined Dry and Critical water years average show that an increase of 163,000 acre-feet (four percent) would occur. Examining the Dry and Critical water years average by region indicates that substantial reliability improvements would occur with similar M&I delivery increases in the Sacramento (100,000 acre-feet [135 percent]) and San Francisco Bay (94,000 acre-feet [42 percent]) regions. Ag deliveries show that reductions would occur in all four regions, ranging from 7 percent (11,000 acre-feet) in the San Joaquin River and San Francisco Bay regions to 17 percent (19,000 acre-feet) in the Sacramento River region. Sacramento Hydrologic Region CVP settlement contractors' deliveries would increase by 26,000 acre-feet (one percent). San Joaquin River Exchange contractors' deliveries would remain the same.

SWP Deliveries

No Project/No Action Alternative vs. Existing Conditions

Table 6-38 shows the differences between the No Project/No Action Alternative and Existing Conditions for SWP deliveries by hydrologic region and water service type. Table 6-38 presents data for the long-term averages and combined Dry and Critical water years average.

The total deliveries for all regions over the long-term average show that an increase of 21,000 acre-feet (one percent) would occur. The long-term averages indicate that M&I delivery increases in the San Francisco Bay (9,000 acre-feet [four percent], South Coast (48,000 acre-feet [four percent]) and South Lahontan (6,000 acre-feet [two percent]) regions would occur, while all other M&I deliveries would decrease.

The total deliveries throughout all hydrologic regions for the combined Dry and Critical water years average shows that a reduction of 134,000 acre-feet (five percent) would occur. Dry and Critical water years averages show M&I reductions for all regions, with the largest reductions occurring in the South Coast (57,000 acre-feet [five percent]), San Francisco Bay (16,000 acre-feet [10 percent]) and South Lahontan (23,000 acre-feet [10 percent]) regions. Dry and Critical water years averages also show that Ag reductions would occur in the Tulare Lake (32,000 acre-feet [six percent]) region.

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:
Percent Difference (%) = Relative Difference of the monthly average.
TAF = thousand acre-feet

The long-term average shows that slight changes would occur, with the greatest change being an increase (0.5 percent) in April. By water year type, storage generally would increase during drier years, with a maximum increase (1.6 percent) occurring during February of Critical water years.

Lewiston Lake

For the purposes of evaluation, Lewiston Lake is assumed to continue to operate as it has historically (as a regulating reservoir). As a regulating reservoir, Lewiston Lake is operated to manage inflows that vary hourly for power generation needs and manage releases that vary daily for meeting downstream flow needs and diversions through the Clear Creek Tunnel to Whiskeytown Lake. Water levels in the reservoir vary over a day and over the span of a week. The regulating operations of Lewiston Lake or Whiskeytown Lake would not be significantly changed by the Project. The modeling performed considered only flow variations on a monthly basis.

Trinity River

Table 6-40 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Trinity River flow downstream of Lewiston Lake. It presents data for averages over the long term and by water year types.

Table 6-40

[a]Based on CALSIM-II modeling over an 82-year simulation period.

[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

In general, flow changes would be minimal for both the long term and by water year type. Over the long term, the greatest change would be a reduction (6.7 percent) in March. By water year type, the greatest change would be a reduction (12.4 percent) in April of Wet water years. There would be no change in flows in Below Normal, Dry, and Critical water years because flow would be controlled by minimum flow requirements.

Klamath River Downstream of the Trinity River

Changes to Klamath River flows downstream of the Trinity River were not modeled. The Klamath River is relatively far downstream of the Trinity River, and flow changes were modeled on the Trinity River downstream of Lewiston Reservoir.

Changes to the Trinity River downstream of Lewiston Lake would be limited to slight reductions in spring flood spills. Flow changes and associated impacts would be even smaller downstream given the other flows coming together in the lower part of the watershed.

Clear Creek Tunnel

Table 6-41 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Clear Creek Tunnel flow. It presents data for averages over the long term and by water year types.

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Over the long term, flows show that both increases and decreases would occur, with a maximum reduction (10.2 percent) occurring during January and a maximum increase (8.8 percent) occurring during May.

Whiskeytown Lake

For the purposes of evaluation, Whiskeytown Lake is assumed to continue to operate as it has historically (as a regulating reservoir). As a regulating reservoir, Whiskeytown Lake is operated to manage inflows that vary hourly for power generation needs and manage releases that vary daily for meeting downstream flow needs. Water levels in the reservoir vary over a day and over the span of a week. The regulating operations of Whiskeytown Lake would not be significantly changed by the Project. The modeling performed considered only flow variations on a monthly basis.

Clear Creek Downstream of Whiskeytown Lake

Table 6-42 shows the differences between the No Project/No Action Alternative and the Existing Conditions for monthly Clear Creek flow downstream of Whiskeytown Lake. It presents data for averages over the long term and by water year types.

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes
cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

The long-term average shows that slight increases for most months would occur, with no reductions. Critical water years show that substantial increases would occur during October through December, with a maximum increase (three percent) occurring during December.

Spring Creek

For the purposes of this evaluation, the Spring Creek Detention Dam on Spring Creek was assumed to operate as it has historically as a debris dam. Flows between Whiskeytown, Shasta, and Keswick dams were not considered to be more adverse due to detention dam operations. Whiskeytown Lake and Keswick Reservoir are regulating reservoirs. These reservoirs are operated to manage inflows that vary hourly for power generation needs and manage releases that vary daily for meeting downstream flow needs. Water levels in these reservoirs vary over a day and over the span of a week. The regulating operations of Whiskeytown Lake and Keswick Reservoir would not be significantly changed by the Project. Therefore, Spring Creek Detention Dam flows would not be altered in response to the changes due to the Project. The modeling performed considered only flow variations on a monthly basis and did not include the Spring Creek Detention Dam.

Shasta Lake

Table 6-43 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Shasta Lake storage. It presents data for averages over the long term and by water year types.

Over the long term, there would be slight storage variations, with the largest change being a reduction (0.8 percent) in September. By water year type, the greatest increases (1.9 percent) would occur during September and October of Critical water years, and the largest reduction (1.6 percent) would occur during September of Above Normal water years. This type of change, where storage would generally decrease in wetter years and increase in drier years, is associated with greater deliveries in the No Project/No Action Alternative, when compared to Existing Conditions, and some reduced allocations in drier years.

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Over both the long term and by water year type, flows would decrease during October through December and increase during June through September, with relatively minor changes. The long-term average shows that a maximum reduction (3.7 percent) would occur during November and a maximum increase (two percent) would occur during September. By water year type, the largest flow reduction (12.1 percent) would occur in November of Dry water years, while flows show that a maximum increase (4.9 percent) would occur during September of Above Normal water years.

Table 6-45 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Sacramento River flow downstream of RBDD. It presents data for averages over the long term and by water year types.

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

A comparison indicates slight changes in monthly flow overall. Flow changes over both the long term and by water year type would follow a pattern similar to those downstream of the Keswick Reservoir, although the changes would be relatively minor. Flows would decrease during October through December and increase during June through September. Over the long term, flows would show a maximum reduction (1.9 percent) during November and a maximum increase (2.2 percent) during September. By water year type, the largest flow decrease (7.4 percent) would occur in November of Dry water years, and flows show that a maximum increase (5.1 percent) would occur during September of Above Normal water years.

Table 6-46 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Sacramento River flow downstream of Hamilton City. It presents data for averages over the long term and by water year types.

[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:
cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

A comparison of the No Project/No Action Alternative and Existing Conditions indicates overall slight changes would occur in monthly flow downstream of Hamilton City. Over both the long term and by water year type, flow changes would follow a pattern similar to those upstream, and would be, therefore, relatively minor. Flows would decrease during October through December and increase during June through September. The long-term averages show that a maximum reduction of 2.5 percent would occur during November and a maximum increase of 1.2 percent would occur during September. By water year type, the largest flow reduction (7.8 percent) would occur during November of Dry water years, and flows would increase 4.1 percent during September of Above Normal water years.

Table 6-47 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Sacramento River flow downstream of the proposed Delevan Pipeline Intake. It presents data for averages over the long term and by water year types.

[a]Based on CALSIM-II modeling over an 82-year simulation period.

[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

A comparison of the No Project/No Action Alternative and Existing Conditions indicates that overall slight changes in monthly flow would occur. Over both the long term and by water year type, flow changes would follow a pattern similar to those upstream. Flows would decrease during October through December, and would fluctuate between slight increases and decreases during the remainder of the year. The long-term averages show that a maximum reduction (2.1 percent) would occur during November and a maximum increase (1.2 percent) would occur during September. By water year type, the largest flow decrease (7.6 percent) would occur during November of Dry water years and the largest flow increase (3.9 percent) would occur during September of Above Normal water years.

GCID Canal Intake

Table 6-48 shows the differences between the No Project / No Action Alternative and Existing Conditions for monthly GCID Canal Intake flow at Hamilton City. It presents data for averages over the long term and by water year types.

Over both the long term and by water year type, the largest canal flows (by volume) would be made during April through August, which are relatively dry months when demands are high. Over the long term, flows would increase during November through February with a peak diversion increase (26.9 percent) in February. However, flows (by volume) are relatively small to begin with during these months.

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:
cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Across both the long-term average and by water year type, T-C Canal Intake flows show relatively no change or small decreases, when compared to Existing Conditions, but with flows still peaking over the dry summer months of June and July.

Lake Oroville

Table 6-50 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Lake Oroville storage. It presents data for averages over the long term and by water year types.

[a]Based on CALSIM-II modeling over an 82-year simulation period.
[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:
Percent Difference (%) = Relative Difference of the monthly average.
TAF = thousand acre-feet

Storage would decrease for both the long term and all water year types. Over the long term, the maximum reduction (2.8 percent) would occur during September. By water year type, the maximum reduction (3.5 percent) would occur during September and October of both Wet and Critical water years.

Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay)

For the purposes of evaluation, the Thermalito Complex is assumed to continue to operate as it has historically (as a regulating reservoir complex). As a regulating reservoir, the Thermalito Complex is operated to manage inflows that vary hourly for power generation needs and manage releases that vary daily for meeting downstream flow needs and diversions into irrigation canals. Water levels in the reservoir vary over a day and over the span of a week. The regulating operations of the Thermalito Complex would not be significantly changed by the Project. The modeling performed considered only flow variations on a monthly basis.

Feather River

Table 6-51 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Feather River flow downstream of the Thermalito Complex. It presents data for averages over the long term and by water year types.

[a]Based on CALSIM-II modeling over an 82-year simulation period.

[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Across both the long term and water year type averages, flows would decrease during October through March and increase during the remainder of the year. Over the long-term average, a maximum increase (4.4 percent) would occur during September and a maximum decrease (4.1 percent) would occur during October. By water year type, a maximum increase (19.1 percent) would occur during August of Wet water years and a maximum reduction (16.1 percent) would occur during March of Dry water years.

Sutter Bypass

Table 6-52 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Tisdale Weir flow into the Sutter Bypass. It presents data for averages over the long term and by water year types.

Notes:
cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Over the long term and by water year type, flows show that increases and decreases would occur with variation occurring between months. The flows over the Sacramento and Freemont weirs would occur during high flow, flood conditions in the Sacramento River and could vary widely from day to day and through a month. The flows shown in Table 6-56 are averages for each month and water year type. For a change shown in the table, the increases and decreases in flows could have either occurred in many months or in few months depending on how high flow, flood conditions changed with the No Project/No Action Alternative. Appendix 6B and Appendix 6C include detailed modeling results for all of the weirs along the Sacramento River. These variations in flow conditions are evaluated in more detail in Chapter 12 Aquatic Biological Resources.

Folsom Lake

Table 6-57 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Folsom Lake storage. It presents data for averages over the long-term and by water year types.

Over both the long-term and by water year type, storage would decrease with a maximum long-term average reduction (2.9 percent) in August. The reductions between the No Project/No Action Alternative and Existing Conditions are due to the inclusion of new and increased diversions represented in the No Project/No Action Alternative modeling assumptions. More specifically, an increase in urban M&I use within the American River Basin is not included in Existing Conditions, but is included in the No Project/No Action Alternative and Alternatives A, B, and C.

TAF = thousand acre-feet

Lake Natoma

For the purposes of evaluation, Lake Natoma is assumed to continue to operate as it has historically (as a regulating reservoir). As a regulating reservoir, Lake Natoma is operated to manage inflows that vary hourly for power generation needs and manage releases that vary daily for meeting downstream flow needs and diversions into the Folsom South Canal. Water levels in the reservoir vary over a day and over the span of a week. The regulating operations of Lake Natoma would not be significantly changed by the Project. The modeling performed considered only flow variations on a monthly basis.

American River

Table 6-58 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly American River flow downstream of Lake Natoma. It presents data for averages over the long term and by water year types.

Expected flow changes correspond with the trends seen in Folsom Lake storage upstream, with flows decreasing during nearly all months over both the long-term and by water year types. The expected reductions between the No Project/No Action Alternative and Existing Conditions are due to the inclusion of new diversions represented in the No Project/No Action Alternative modeling assumptions, as discussed for Folsom Lake, which draw off of both the American River and Sacramento River.

The long-term average shows a maximum reduction (8.4 percent) occurring during September. Comparing by water year types, flows would decrease more as years become drier. Maximum reductions would occur during August and September for all water year types, with a maximum reduction (18.3 percent) occurring in September of Critical water years.

[a]Based on CALSIM-II modeling over an 82-year simulation period.

[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Over the long-term average, outflow shows that little change would occur, with a maximum increase (1.1 percent) occurring in July and a maximum reduction (1.7 percent) occurring in May. During Wet and Above Normal water years, outflows would decrease during most months.

Table 6-60 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Delta Cross Channel flow. It presents data for averages over the long term and by water year types.

Table 6-60

[a]Based on CALSIM-II modeling over an 82-year simulation period.

[b]As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 1999).

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Changes over the long-term average would be relatively minor during all months. By water year type, Wet and Above Normal water years show that increases in reversed (negative) flow conditions would occur during several months.

Table 6-62 shows the differences between the No Project/No Action Alternative and Existing Conditions for monthly Banks and Jones pumping plant exports. It presents data for averages over the long term and by water year types.

Over the long-term average, changes in exports would be relatively minor and fluctuate between increases and reductions. By water year type, maximum reductions would occur in August of both Dry (10.7 percent) and Critical (15 percent) years.

Table 6-62
Total Banks Pumping Plant (SWP) and Jones Pumping Plant (CVP) Monthly Exports (cfs)

Notes:

cfs = cubic feet per second
Percent Difference (%) = Relative Difference of the monthly average.

Suisun Bay, San Pablo Bay, and San Francisco Bay

For the Suisun Bay, San Pablo Bay, and San Francisco Bay region, detailed evaluation was limited to evaluating the changes in Delta outflow, as shown in Table 6-59. Further evaluation of changes in Delta outflow on Suisun Bay, San Pablo Bay, and San Francisco Bay is included Chapter 7 Surface Water Quality and Chapter 12 Aquatic Biological Resources.

6.3.4.3 Primary Study Area – No Project/No Action Alternative

Funks and Stone Corral Creeks

Funks and Stone Corral creeks were not modeled for the No Project/No Action Alternative because the No Project/No Action Alternative does not include any modifications to Existing Conditions that would substantially affect Funks and Stone Corral creek flows.

Funks Reservoir

Changes to Funks Reservoir were not modeled for the No Project/No Action Alternative because the No Project/No Action Alternative does not include any modifications to Existing Conditions that would affect Funks Reservoir. Funks Reservoir was assumed to operate as it has historically (regulating water levels between the canals).

Colusa Basin Drain

CBD flows were not modeled for the No Project/No Action Alternative because the No Project/No Action Alternative does not include any modifications to Existing Conditions that would substantially affect CBD flows.

Other Local Creeks

Grapevine, Antelope, Hunters, and Lurline creeks were not modeled for the No Project/No Action Alternative because the No Project/No Action Alternative does not include any modifications to Existing Conditions that would substantially affect these creek flows.

6.3.5 Changes Associated with Alternatives A, B, and C

This section describes the changes to surface water resources associated with implementation of Alternatives A, B, and C.

The alternatives would be significantly integrated with the CVP and SWP systems. Consequently, the alternatives would affect operations and resultant storage, flows, and diversions associated with the CVP and SWP systems and respective streams and waterways.

Major differences in operational effects between Alternatives A, B, and C would result primarily from differences in the storage capacity of Sites Reservoir (1.27 MAF for Alternative A and 1.81 MAF for Alternatives B and C) and differences in diversion capabilities (Alternatives A and C include a 2,000 cfs Delevan Pipeline diversion and release facility, and Alternative B includes a 1,500 cfs Delevan Pipeline release-only facility).

Changes in metrics are presented comparing the alternatives to Existing Conditions and the No Project/No Action Alternative. To simplify the comparisons between the alternatives, expected changes associated with implementation of Alternatives A, B, and C relative to Existing Conditions and the No Project/No

Action Alternative are presented in summary tables. The summary tables show the long-term average and the combined Dry and Critical water years' average. Detailed modeling results with data for all water year types are included in Appendix 6B.

6.3.5.1 Extended Study Area – Alternatives A, B, and C

Changes in CVP and SWP deliveries between Alternatives A, B, and C, when compared to the No Project/No Action Alternative, are addressed in Section 6.5. Changes in San Luis Reservoir storage from Alternatives A, B, and C, when compared to Existing Conditions and the No Project/No Action Alternative, are discussed below.

San Luis Reservoir

Alternatives A, B, and C Compared to Existing Conditions

Table 6-63 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly San Luis Reservoir storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-63
San Luis Reservoir End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to Existing Conditions

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]				
		Change from Existing Conditions (TAF)					Change from Existing Conditions

Aug	548	-58 (-11%)	-59 (-11%)	-69 (-13%)	Aug	408	-14 (-4%)	-13 (-3%)	-39 (-9%)
Sep	617	-27 (-4%)	-24 (-4%)	-41 (-7%)	Sep	442	2 (0%)	26 (6%)	-23 (-5%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Operations and criteria that affect San Luis Reservoir storage include CVP and SWP allocations, storage over the normally wet winter season, and the rate of drawdown between March (usually the beginning of the delivery season) and August.

Over the long-term averages, Alternatives A, B, and C show that storage would increase during January through April and would decrease during May through October, with maximum reductions occurring during July and August. Alternative C would result in the largest reductions (11 to 13 percent) among alternatives.

Over the Dry and Critical water year averages, Alternative A shows that storage would increase during January through June (as much as 8 percent), and storage would decrease during July through December. Alternative B shows that storage would increase in January through July and September and November, and storage would decrease in August and October. Alternative C shows that storage would increase in January through May, and storage would decrease in June through December. Alternative C would result in the largest storage reductions among the three alternatives.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-64 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly San Luis Reservoir storage. It presents data for averages over the long-term and combined Dry and Critical water years averages.

Table 6-64
San Luis Reservoir End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to the No Project/No Action Alternative

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]

Jul	583	-29 (-5%)	-29 (-5%)	-45 (-8%)	Jul	548	-101 (-19%)	-100 (-18%)	-139 (-25%)
Aug	513	-24 (-5%)	-25 (-5%)	-34 (-7%)	Aug	462	-68 (-15%)	-67 (-14%)	-92 (-20%)
Sep	584	7 (1%)	9 (2%)	-7 (-1%)	Sep	500	-57 (-11%)	-33 (-7%)	-81 (-16%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.
Note:
TAF = thousand acre-feet

Over the long-term averages, Alternatives A and B show that storage would increase during September through May, with maximum increases (up to 10 percent) occurring during November, and storage would decrease during June through August. Alternative C shows that storage would increase during October through March and decrease during April through September. Alternative C shows the greatest storage reductions among the alternatives.

Over the Dry and Critical water years averages, Alternatives A, B, and C generally show that storage decreases would occur during most months. The three alternatives show that substantial reductions would occur in June and July (as much as 25 percent), with Alternative C showing the greatest reductions among the alternatives.

6.3.5.2 Secondary Study Area – Alternatives A, B, and C

As described for the No Project/No Action Alternative, operations for the regulating reservoirs that are located within the Secondary Study Area (i.e., Lewiston Lake, Whiskeytown Lake, Keswick Reservoir, the Thermalito Complex, and Lake Natoma) were not modeled. These reservoirs are assumed to continue to operate as they have historically (as regulating reservoirs), and therefore, would not experience changes in operation. In addition, Spring Creek and Suisun, San Pablo, and San Francisco bays were not modeled. Spring Creek Detention Dam is assumed to continue to operate as it has historically as a debris dam, and any changes in inflow to the bays would not be discernible.

Changes in operations resulting from implementation of Alternatives A, B, and C at the remaining facilities within the Secondary Study Area, when compared to Existing Conditions and the No Project/No Action Alternative, are discussed below.

Trinity Lake

Alternatives A, B, and C Compared to Existing Conditions

Table 6-65 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Trinity Lake storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-65
Trinity Lake End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to Existing Conditions

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]				
Month	Existing Conditions	Change from Existing Conditions: Alternative A	Alternative B	Alternative C	Month	Existing Conditions	Change from Existing Conditions: Alternative A	Alternative B	Alternative C

Sep	1,373	44 (3%)	43 (3%)	51 (4%)	Sep	937	68 (7%)	58 (6%)	78 (8%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Increased Trinity Lake coldwater pool storage is a Project objective. An increase in the coldwater pool at Trinity Lake is considered an improvement for salmonids downstream of the dam, especially during Dry and Critical water year types.

Over the long-term averages, Alternatives A, B, and C show that increases (two to four percent) in storage would occur during all months.

Over the Dry and Critical water years averages, the alternatives show that the greatest storage increases would occur (8 to 11 percent) in the early winter (October through December).

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-66 shows the differences between Alternatives A, B and C and the No Project/No Action Alternative for monthly Trinity Lake storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that increases (two to four percent) in storage would occur during all months.

Over the Dry and Critical water years averages, the alternatives show that the greatest storage increases would occur (8 to 11 percent) in the early winter (October through December).

Trinity River

Alternatives A, B, and C Compared to Existing Conditions

Table 6-67 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Trinity River flow downstream of Lewiston Reservoir. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that almost no change or reductions in flows would occur, primarily during December through April. Trinity River ROD flow criteria are reflected in Existing Conditions minimum flows (450 cfs) during August and September.

Over the Dry and Critical water years averages, the alternatives show that mostly no change in flows would occur, when compared to Existing Conditions, for almost all months except that minor increases (up to five percent) would occur during October and December. Trinity River ROD flow criteria are reflected in the minimum flows for Dry and Critical water year types, with flows of 300 cfs during November through March and flows of 450 cfs during August and September.

Table 6-67

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C show that reductions in flows (up to four percent) would occur primarily during December through February, and remaining months show that either no change or slight increases would occur. Trinity River ROD flow criteria are reflected in Existing Conditions minimum flows (450 cfs) in August and September.

Over the Dry and Critical water years averages, the alternatives show that mostly no change would occur, when compared to Existing Conditions, for almost all months except that minor increases in flows (three to five percent) would occur during October and December. Trinity River ROD flow criteria are reflected in the minimum flows for Dry and Critical water year types, with flows of 300 cfs during November through March and flows of 450 cfs during August and September.

Klamath River Downstream of the Trinity River

Changes to Klamath River flows downstream of the Trinity River were not modeled. The Klamath River is relatively far downstream of the Trinity River, and flow changes were modeled on the Trinity River downstream of Lewiston Reservoir.

Changes to the Trinity River downstream of Lewiston Reservoir are limited to slight reductions in spring flood spills. Flow changes would be smaller downstream at its confluence with the Klamath River, and would not be discernible considering the other flows coming together in the lower part of the watershed.

Clear Creek Tunnel

Alternatives A, B, and C Compared to Existing Conditions

Table 6-69 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Clear Creek Tunnel flow. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-69
Clear Creek Tunnel Monthly Flow (cfs)
Alternatives A, B, and C Compared to Existing Conditions

Sep	1,660	-31 (-2%)	83 (5%)	7 (0%)	Sep	1,245	23 (2%)	277 (22%)	47 (4%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C show that relatively large increases in flows (some 20 percent or more) would occur during December through March. During the remainder of the year, flows for the alternatives show that minor changes would occur, except that noticeable decreases would occur during November.

Over the Dry and Critical water years averages, the alternatives show that greater increases in flows would occur during December through March. The alternatives also show that noticeable flow reductions would occur during October and November.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-70 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Clear Creek Tunnel flow. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-70
Clear Creek Tunnel Monthly Flow (cfs)
Alternatives A, B, and C Compared to the No Project/No Action Alternative

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]				
Month	No Project/No Action Alternative	Change from No Project/No Action Alternative			Month	No Project/No Action Alternative	Change from No Project/No Action Alternative		
		Alternative A	Alternative B	Alternative C			Alternative A	Alternative B	Alternative C

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C show that relatively large increases in flows (some 20 percent or more) would occur during December through March. During the remainder of the year, flows for the alternatives show that minor changes would occur, except that noticeable decreases would occur during October and November.

Over the Dry and Critical water years averages, the alternatives show that greater increases in flows would occur during December through March. The alternatives also show that noticeable decreases would occur during October and November.

Clear Creek Downstream of Whiskeytown Lake

Alternatives A, B, and C Compared to Existing Conditions

Table 6-71 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Clear Creek flow downstream of Whiskeytown Lake. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that minor increases in flows would occur during all months.

Over the Dry and Critical water years averages, the alternatives show that greater increases in flows would occur during most months, when compared to the long-term average.

Table 6-71

[a]Based on CALSIM II modeling over an 82-year simulation period.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

[d]These increased flows in July would not occur under the alternatives; these results are due to a poorly formulated constraint in CALSIM-II due to NODOS alternative operating criteria. These flows should have been directed down the Sacramento River at Keswick Dam. Correcting these flows would not result in material difference in any other analysis of the EIR/EIS. These higher flows should be disregarded in evaluating changes in Clear Creek flows.

Note:
cfs = cubic feet per second

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-72 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Clear Creek flow downstream of Whiskeytown Lake. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that no noticeable change in flows would occur during most months.

Over Dry and Critical water years averages, the alternatives show that no change in flows would occur during most months.

Table 6-72

Shasta Lake

Alternatives A, B, and C Compared to Existing Conditions

Table 6-73 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Shasta Lake storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Improved coldwater pool storage in Shasta Lake is a Project operational objective. Storage improvements would provide a measure of improvement of the reliability of the coldwater pool, and storage improvements during relatively drier years are especially important.

Over the long-term averages, Alternatives A, B, and C show that slight increases in storage (maximum four percent) would occur during almost all months.

More important to the reliability of the coldwater pool are improvements in Dry and Critical water years. Over the Dry and Critical water years averages, the alternatives show that larger increases in storage would occur, when compared to Existing Conditions, than when comparing the long-term averages. The greatest relative storage increases for the alternatives (8 to 11 percent) would occur during October.

Table 6-73
Shasta Lake End of Month Storage (TAF)
Alternatives A, B, and C Compared to Existing Conditions

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]				
		Change from Existing Conditions					Change from Existing Conditions

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-74 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Shasta Lake storage. It presents data for averages over the long term and combined Dry and Critical water years averages. The long-term average shows that all three alternatives would have increases (a maximum of four percent) during all months.

Table 6-74
Shasta Lake End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to the No Project/No Action Alternative

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]				
		Change from No Project/No Action Alternative					Change from No Project/No Action Alternative		
Month	No Project/No Action Alternative)	Alternative A	Alternative B	Alternative C	Month	No Project/No Action Alternative	Alternative A	Alternative B	Alternative C

Sep	7,909	-125 (-2%)	80 (1%)	-68 (-1%)	Sep	5,579	-85 (-2%)	188 (3%)	-88 (-2%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Sacramento River flows would be modified with implementation of the alternatives, when compared to Existing Conditions. Some changes would be directly related to Project operational objectives, such as increased coldwater pool releases from Shasta Lake for temperature improvements and stabilizing flows downstream of Keswick Reservoir to improve salmonid conditions. Other changes would be caused in a more indirect manner and are associated with other Project objectives, such as improved water supply reliability, improved Delta water quality, and other ecosystem enhancement objectives.

Over the long-term averages, Alternatives A, B, and C show that flows would increase from Existing Conditions during December through February. Flows would decrease for the alternatives during the remainder of the year.

Over the Dry and Critical water years averages, the alternatives show that noticeable increases would occur during January and February (14 to 17 percent). Flows would decrease for the three alternatives in April (18 to 19 percent) and May (11 to 12 percent).

Table 6-76 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Sacramento River flow downstream of the RBDD. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-76

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Refer to the above discussion related to changes in Sacramento River flow downstream of Keswick Reservoir. The flow downstream of RBDD also reflects the effect of T-C Canal diversions to Project storage. These changes would continue downstream.

Over the long-term averages, the alternatives show that the most noticeable flow reductions would occur during January through April. Alternative B, which does not include the proposed Delevan Pipeline Intake Facilities, shows that the greatest relative decreases (11 percent) would occur in March, when compared to Alternatives A and C.

Over the Dry and Critical water years averages, the alternatives show that the most noticeable flow reductions would occur during January through April. All three alternatives show relatively similar flow reductions (14 to 17 percent) during March and April.

Table 6-77 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Sacramento River flow downstream of Hamilton City. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-77

[a]Based on CALSIM II modeling over an 82-year simulation period.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

cfs = cubic feet per second

Refer to the above discussion related to changes in Sacramento River flow downstream of Keswick Reservoir. The flow downstream of Hamilton City also reflects the diversions to Project storage associated with the GCID Canal conveyance.

Over the long-term averages, flows would decrease for all three alternatives during January through April, with the greatest reductions occurring during March (8 to 15 percent). Alternative B, which does not include the proposed Delevan Pipeline Intake Facilities, shows that the greatest decrease in flows would occur during March, when compared to Alternatives A and C. Alternatives A and C show that the most noticeable increase would occur during July (13 to 14 percent), when compared to Alternative B.

Over the Dry and Critical water years averages, all three alternatives show that the greatest flow reductions would occur during March and April (20 to 21 percent in March). Alternatives A and C would show the most noticeable increase in July (10 to 12 percent), when compared to Alternative B.

Table 6-78 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Sacramento River flow downstream of the proposed Delevan Pipeline Intake. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-78

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

The flow downstream of the proposed Delevan Pipeline Intake reflects the effect of diversions to Project storage.

Over the long-term averages, flows would decrease for all three alternatives during December through April, with the greatest decreases occurring during March (8 to 12 percent). All three alternatives show that noticeable flow increases would occur during July through October.

Over the Dry and Critical water years averages, all three alternatives show that a similar trend would occur, with reductions in flows during December through March. The greatest reductions would occur during March (14 to 19 percent). All three alternatives show that the greatest flow increases would occur during July through September.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-79 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Sacramento River flow downstream of Keswick Reservoir. It presents data for averages over the long term and combined Dry and Critical water years averages.

Sacramento River flows would be modified with implementation of Alternatives A. B, and C, when compared to the No Project/No Action Alternative. Some changes would be directly related to Project operational objectives, such as increased temperature releases from Shasta Lake and stabilizing flows downstream of Keswick Reservoir to improve salmonid conditions. Other changes would be caused in a more indirect manner and would be associated with other Project objectives, such as improved water supply reliability, improved Delta water quality, and other ecosystem enhancement objectives.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

cfs = cubic feet per second

Over the long-term averages, all three alternatives show that increased flows from the No Project/No Action Alternative would occur during November through February. Flows would decrease slightly for all three alternatives during the remainder of the year.

Over the Dry and Critical water years averages, all three alternatives show that noticeable increases would occur during January and February (14 to 17 percent), and there would be noticeable reductions in flows for all three alternatives during April (17 to 18 percent) and May (11 to 12 percent).

Table 6-80 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Sacramento River flow downstream of RBDD. It presents data for averages over the long term and combined Dry and Critical water years averages.

The flow downstream of RBDD reflects the effect of T-C Canal diversions to Project storage.

Over the long-term averages, the alternatives show that the most noticeable flow reductions would occur during January through April. Alternative B, which does not include the proposed Delevan Pipeline Intake Facilities, shows that the greatest relative reductions (12 percent) would occur during March, when compared to Alternatives A and C.

Over the Dry and Critical Years averages, the alternatives show that the most noticeable flow decreases would occur during January through April. All three alternatives show relatively similar flow decreases (14 to 17 percent) during March and April.

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

The flow downstream of Hamilton City also reflects the diversions to Project storage associated with the GCID Canal conveyance.

Over the long-term averages, flows would decrease for all three alternatives during January through April, with the greatest reductions occurring during March (9 to 15 percent). Alternative B, which does not include the proposed Delevan Pipeline Intake Facilities, shows the greatest reduction in flows during March, when compared to Alternatives A and C. Alternatives A and C show that the most noticeable increase would occur during July (12 to 13 percent), when compared to Alternative B.

Over the Dry and Critical water years averages, the alternatives show that the greatest flow reductions would occur during March and April (20 to 21 percent in March). Alternatives A and C show that the most noticeable increase would occur during July (9 to 11 percent), when compared to Alternative B.

Table 6-82 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Sacramento River flow downstream of the proposed Delevan Pipeline Intake Facilities. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-82

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

cfs = cubic feet per second

Flows downstream of the proposed Delevan Intake Facilities reflect the effects of diversions to and from Project storage. Generally, flows would decrease during December through April, and would increase during the remainder of the year, which corresponds with diversions to and from Project storage.

Over the long-term averages, flows would decrease for all three alternatives during December through April, with March showing the greatest reductions (8 to 12 percent). All three alternatives show that noticeable flow increases would occur during July through October.

Over the Dry and Critical water years averages, the three alternatives show that a similar trend of reductions in flows during December through March. The greatest reductions would occur during March (15 to 20 percent). All three alternatives show that the greatest flow increases would occur during July through September.

T-C Canal Intake

Alternatives A, B, and C Compared to Existing Conditions

Table 6-83 shows the differences between Alternatives A, B, and C and Existing Conditions for the monthly T-C Canal Intake flow at RBDD. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-83

[a]Based on CALSIM II modeling over an 82-year simulation period.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Notes:

cfs = cubic feet per second

Percent changes are not shown for November through April because the T-C Canal diversions associated with Existing Conditions during this period are zero or very low, and diversions to fill the proposed Sites Reservoir for the alternatives would typically be highest during these months. The percent change in these months would be very large and meaningless.

Over the long-term averages, Alternatives A, B, and C show that the T-C Canal Intake flows would increase during the predominantly wet months November through April, reflecting the diversions needed to fill the proposed Sites Reservoir. In contrast, the intake flows generally would decrease during May through September with the highest reductions occurring in June and July. These reductions in T-C Canal Intake flows would be a result of one of the Project's ecosystem objectives of increasing flows in the

Sacramento River from spring through fall by reducing diversions at the T-C Canal and GCID Canal intakes and providing supplemental flows through releases from the proposed Delevan Pipeline.

Over the Dry and Critical water years averages, the alternatives show that a similar flow pattern of increases would occur during the normally wet months November through April and would decrease noticeably during June and July.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-84 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for the monthly T-C Canal Intake flow at RBDD. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-84

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Notes:

cfs = cubic feet per second

Percent changes are not shown for November through April because the T-C diversions associated with the No Project/No Action Alternative during this period are zero or very low, and diversions to fill the proposed Sites Reservoir for the alternatives would typically be highest during these months. The percent change in these months would be very large and meaningless.

Over the long-term averages, Alternatives A, B, and C show that the T-C Canal Intake flows would increase during November through April, reflecting the diversions needed to fill the proposed Sites Reservoir. In contrast, the intake flows generally would decrease during May through September with the highest reductions occurring in June and July. These reductions in T-C Canal Intake flows would be a result of one of the Project’s ecosystem objectives of increasing flows in the Sacramento River from spring through fall by reducing diversions at the T-C Canal and GCID Canal intakes and providing supplemental flows through releases from the proposed Delevan Pipeline.

Over the Dry and Critical water years averages, the alternatives show that a similar flow pattern of increases would occur during the normally wet months November through April and would decrease noticeably during June and July.

GCID Intake at Hamilton City

Alternatives A, B, and C Compared to Existing Conditions

Table 6-85 shows the differences between Alternatives A, B, and C and Existing Conditions for the monthly GCID Canal Intake flow at Hamilton City. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that GCID Canal Intake flows would increase during December through March, reflecting the diversions needed to fill the proposed Sites Reservoir. In contrast, flows would generally decrease during May through July with the highest reductions occurring in June and July (34 to 35 percent in July for Alternatives A and C). These reductions in GCID Canal Intake flows would be a result of one of the Project's ecosystem objectives of increasing flows in the Sacramento River from spring through fall by reducing diversions at the T-C Canal and GCID Canal intakes and providing supplemental flows through releases from the proposed Delevan Pipeline.

Over the Dry and Critical water years averages, the alternatives show that a similar flow pattern of increases would occur during the predominantly wet months December through March. All three alternatives show that flows would noticeably decrease during June and July (39 to 41 percent in June).

Jul	2,798	-1,030 (-37%)	-426 (-15%)	-1,053 (-38%)	Jul	2,658	-916 (-34%)	-239 (-9%)	-947 (-36%)
Aug	2,066	-103 (-5%)	55 (3%)	-226 (-11%)	Aug	1,928	-105 (-5%)	-11 (-1%)	-275 (-14%)
Sep	548	-61 (-11%)	-54 (-10%)	-82 (-15%)	Sep	508	3 (1%)	-11 (-2%)	-32 (-6%)

[a]Based on CALSIM II modeling over an 82-year simulation period.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Notes:

cfs = cubic feet per second

Percent changes are not shown for December through March because GCID Canal diversions associated with the No Project/No Action Alternative during this period are low, and diversions to fill the proposed Sites Reservoir for the alternatives would typically be highest during these months. The percent change in these months would be very large and meaningless.

Over the long-term averages, Alternatives A, B, and C show that GCID Canal Intake flows would increase during December through March, reflecting the diversions needed to fill the proposed Sites Reservoir. In contrast, flows would generally decrease during May through November with the highest reductions occurring in June and July (37 to 38 percent in July for Alternatives A and C). These reductions in GCID Canal Intake flows would be a result of one of the Project's ecosystem objectives of increasing flows in the Sacramento River from spring through fall by reducing diversions at the T-C Canal and GCID Canal intakes and providing supplemental flows through releases from the proposed Delevan Pipeline.

Over the Dry and Critical water years averages, the alternatives show that a similar flow pattern of increases would occur during the predominantly wet months December through March. All three alternatives show that noticeable flow reductions would occur during June and July (40 to 41 percent in June).

Lake Oroville

Alternatives A, B, and C Compared to Existing Conditions

Table 6-87 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Lake Oroville storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-87
Lake Oroville End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to Existing Conditions

Aug	2,135	-9 (0%)	-8 (0%)	-11 (-1%)	Aug	1,262	40 (3%)	57 (4%)	53 (4%)
Sep	1,883	-39 (-2%)	-42 (-2%)	-45 (-2%)	Sep	1,172	14 (1%)	15 (1%)	14 (1%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Over the long-term averages, Alternatives A, B, and C show that storage changes would be small, with increases occurring during December through July, and reductions occurring in the remaining months.

Over the Dry and Critical water years averages, the alternatives show that small, but positive, storage increases would occur during nearly all months, with the greatest increases occurring during July and August. Relative increases would be greater than those expected over only the long-term averages.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-88 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Lake Oroville storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-88
Lake Oroville End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to the No Project/No Action Alternative

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]

Sep	1,831	13 (1%)	9 (1%)	7 (0%)	Sep	1,154	32 (3%)	33 (3%)	32 (3%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of Oct 1921 - Sep 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of Oct 1921 - Sep 2003.

Note:

TAF = thousand acre-feet

Over the long-term averages, Alternatives A, B, and C show that small storage increases would occur during all months.

Over the Dry and Critical water years averages, the alternatives show that small storage increases would occur during nearly all months, with the greatest increases occurring during June and July. Relative increases would be greater than those expected over the long-term averages.

Feather River

Alternatives A, B, and C Compared to Existing Conditions

Table 6-89 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Feather River flow downstream of the Thermalito Complex. It presents data for averages over the long term and combined Dry and Critical water years averages.

During September, long-term averages for all three alternatives show that an increase in flows would occur (9 percent for Alternative A, 11 percent for Alternatives B and C), and in October, all three alternatives show that a decrease would occur (between 8 and 12 percent).

During Dry and Critical water years, the same is true; there would be an increase during September for the alternatives (between 16 and 31 percent) and then a reduction in October for all three alternatives (between 9 and 18 percent).

Table 6-89
Feather River Monthly Flow Downstream of the Thermalito Complex (cfs)
Alternatives A, B, and C Compared to Existing Conditions

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-90 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Feather River flow downstream of the Thermalito Complex. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that maximum flow increases would occur (five to six percent) during September, and maximum decreases (seven to nine percent) would occur during October and December.

Over the Dry and Critical water years averages, the alternatives show that noticeable decreases in flows (8 to 13 percent) would occur during October and December, and would also decrease (9 to 15 percent) during April and May. Flows would increase noticeably (27 to 28 percent) during August and September, when compared to the long-term average August and September flows.

Table 6-90

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Sutter Bypass

Alternatives A, B, and C Compared to Existing Conditions

Table 6-91 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Tisdale Weir flow into the Sutter Bypass. It presents data for averages over the long term and combined Dry and Critical water years averages.

Tisdale Weir flows show that reductions would occur during the wetter months (generally November through April), which reflect the Sacramento River diversions for the proposed Project.

Over the long-term averages, Alternatives A, B, and C show that flow reductions would occur during the wetter months (generally November through April), with maximum flow decreases occurring during November with implementation of Alternatives A and C.

Over the Dry and Critical water years averages, the alternatives show that flow reductions would occur during November through March.

Table 6-91
Tisdale Weir Monthly Flow (cfs)
Alternatives A, B, and C Compared to Existing Conditions

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Table 6-92 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Colusa Weir flow into the Sutter Bypass. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-92

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Colusa Weir flows show that reductions would occur during the wetter months (generally November through April), which reflect the Sacramento River diversions for the proposed Project.

Over the long-term averages, Alternatives A, B, and C show that noticeable flow reductions would occur, primarily during January through March, and that flows would increase for the three alternatives during December.

Over the Dry and Critical water years averages, the alternatives show that noticeable flow reductions would occur primarily during January through March, and that flows would increase for the alternatives during December.

Table 6-93 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Moulton Weir flow into the Sutter Bypass. It presents data for averages over the long term and combined Dry and Critical water years averages.

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Ord Ferry flows show that reductions would occur during the wetter months (generally November through April), which reflect the Sacramento River diversions for the proposed Project.

Over the long-term averages, Alternatives A, B, and C show that noticeable flow reductions would occur during January through March. Flows would increase slightly for all three alternatives during December.

Over the Dry and Critical water years averages, the alternatives show that a slight increase in flows would occur during December.

Yolo Bypass

Alternatives A, B, and C Compared to Existing Conditions

Table 6-99 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Yolo Bypass flow. It presents data for averages over the long-term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that slight increases and generally reductions in flows would occur, with a maximum reduction (10 percent) occurring during November. During September, there would be an increase (28 percent) in flows for all three alternatives.

Over the Dry and Critical water years averages, the alternatives show that the largest reduction in flows would occur during March (31 percent).

Table 6-99

Note:
cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C show that flows would generally decrease with a maximum reduction (12 percent) occurring during November. During September and October, there would be flow increases (26 and 39 percent, respectively).

Over the Dry and Critical water years averages, the alternatives generally show that flows would decrease in October (6 to 10 percent) and December through March (5 to 39 percent). There would be a maximum increase in flows in November (42 percent).

Folsom Lake

Alternatives A, B, and C Compared to Existing Conditions

Table 6-101 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Folsom Lake storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-101
Folsom Lake End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to Existing Conditions

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]

Sep	509	9 (2%)	9 (2%)	11 (2%)	Sep	359	9 (2%)	22 (6%)	14 (4%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

TAF = thousand acre-feet

Generally, minor positive and negative changes in storage would occur for the long-term average. The maximum increase (two percent) would occur during July, and the maximum reduction of four TAF would occur during June. Over the long-term averages, Alternatives A, B, and C show that a slight increase would occur during September (two percent).

Over Dry and Critical water year averages, Alternatives A and C show that Folsom Lake storage would increase by one to five percent in all months. Alternative B shows that storage generally increases in all months by up to five percent, except in May where there is a small reduction of three TAF.

Table 6-102 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Folsom Lake storage. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-102
Folsom Lake End-of-Month Storage (TAF)
Alternatives A, B, and C Compared to the No Project/No Action Alternative

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]

Aug	582	23 (4%)	15 (3%)	23 (4%)	Aug	380	22 (6%)	29 (8%)	26 (7%)
Sep	496	22 (5%)	22 (4%)	24 (5%)	Sep	348	19 (6%)	32 (9%)	25 (7%)

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Generally, storage in Folsom Lake would increase in nearly every month for the long-term averages and Dry and Critical years average for Alternatives A, B, and C, when compared to the No Project/No Action Alternative. Storage changes would be positive during all months over the long-term average, with a maximum increase (five percent) occurring in July. Over the Dry and Critical water years averages, the alternatives show that similar increases in storage would occur in every month, with maximum increases of seven to nine percent.

American River

Alternatives A, B, and C Compared to Existing Conditions

Table 6-103 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly American River flow downstream of Lake Natoma. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-103
American River Monthly Flow Downstream of Lake Natoma (cfs)
Alternatives A, B, and C Compared to Existing Conditions

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Generally, over the long-term average, flows in the American River downstream of Lake Natoma for Alternatives A, B, and C would decrease in all months and would correspond to the general increase in Folsom Lake storage. The maximum flow decrease (14 percent) would occur in July. For Dry and Critical water years, flows in the American River downstream of Lake Natoma for Alternatives A, B, and C would generally decrease in all months with maximum decreases occurring during June through September (9 to 16 percent).

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-104 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly American River flow downstream of Lake Natoma. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, flows in the American River downstream of Lake Natoma for Alternatives A, B, and C would decrease in June and July with a maximum reduction (11 percent) expected to occur in July. Flows in all other months would increase or decrease slightly.

For Dry and Critical water years, flows in the American River flow downstream of Lake Natoma for Alternatives A, B, and C would decrease in June and July with a maximum reduction (nine percent) expected to occur in July. Flows in all other months would increase or decrease slightly.

[a]Based on CALSIM II modeling over an 82-year simulation period.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

cfs = cubic feet per second

Sacramento-San Joaquin Delta

Alternatives A, B, and C Compared to Existing Conditions

Table 6-105 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Sacramento-San Joaquin Delta outflow. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternative A shows that very slight changes would occur during all months. Alternatives B and C (which include the 1.81-MAF Sites Reservoir) show that slight decreases in outflow would occur during November through May, and that outflow increases would occur during June through October. The increased Delta outflows during June through October would be due to supplemental releases from the proposed Sites Reservoir for Delta water quality improvements.

Over the Dry and Critical water years averages, Alternative A shows that a mix of slight changes would occur during all months. When compared to Existing Conditions, Alternatives B and C show that greater fluctuations between positive and negative outflow changes would occur (than for Alternative A), with noticeably more positive outflows occurring during July through October.

Table 6-105
Sacramento-San Joaquin Delta Monthly Outflow (cfs)
Alternatives A, B, and C Compared to Existing Conditions

Long-Term Average[a, b]					Dry and Critical Water Years Average[a, c]

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C generally show that minor flow increases and minor flow reductions would occur, with increases (three to five percent) that would occur during August and September.

Over the Dry and Critical water years averages, the alternatives show that similar flow increases would occur during August and September (four to seven percent).

Table 6-107 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Old and Middle river flows. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-107

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C show that minor negative changes in flows would occur (which indicates increased reverse flows), except for maximum increases in reverse flows during September and November.

Over the Dry and Critical water years averages, the alternatives show that a mix of flow changes would occur, with the only relatively large change being maximum increases in reverse flows during September and November.

Table 6-108 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly Banks and Jones pumping plant exports. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that slight increases in exports would occur, with the greatest export increases occurring during September (10 to 11 percent) and November (10 to 14 percent).

Over the Dry and Critical water years averages, the alternatives show that a mix of changes in exports would occur, with the only noticeable changes being greater flow increases during September (8 to 13 percent) and November (9 to 11 percent).

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-109 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Sacramento-San Joaquin Delta outflow. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Delta outflows for Alternatives A, B, and C show that decreases would occur during the wetter winter months (November through March) and relatively substantial increases would occur during July and August.

Over the Dry and Critical water years averages, the outflows of the alternatives show that relatively substantial decreases would occur during January through March. The alternatives also show that increases would occur during July through September.

Table 6-110 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Delta Cross Channel flow. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C generally show that no change or minor decreases in flows would occur, except for minor increases (four to six percent) during August and September.

Over the Dry and Critical water years averages, the alternatives show that similar flow increases would occur during August and September (7 to 11 percent).

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
cfs = cubic feet per second

Over the long-term averages, Alternatives A, B, and C show that minor negative changes in flows would occur (which indicates increased reverse flows), except that maximum increases in reverse flows would occur during September and November.

Over the Dry and Critical water years averages, the alternatives show a mix of flow changes, with the only relatively large change being maximum increases in reverse flows during August, September, and November.

Table 6-112 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly Banks and Jones pumping plant exports. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A, B, and C show that substantial pumping export increases (9 to 16 percent) would occur during September through November.

Over the Dry and Critical water years averages, the alternatives show that substantial pumping export increases would occur during August (17 to 23 percent), September (11 to 16 percent), and November (13 to 15 percent).

6.3.5.3 Primary Study Area – Alternatives A, B, and C

Funks Creek and Stone Corral Creek

With implementation of either Alternative A, B, or C, Sites and Golden Gate dams would impound Funks and Stone Corral creeks. After Project construction is complete, maintenance flows up to a maximum of 10 cfs would be maintained in both Funks and Stone Corral creeks downstream of Sites Reservoir (refer to Chapter 9 Flood Control and Management and Chapter 3 Description of the Proposed Project/Proposed Action and Alternatives for additional details).

Funks Reservoir

The existing Funks Reservoir is a reregulating reservoir that balances water level operations of the T-C Canal upstream and downstream of Funks Creek. With implementation of the Project, Funks Reservoir would be expanded to form Holthouse Reservoir by constructing a new dam (Holthouse Dam) and reservoir to the east of Funks Reservoir, and breaching the existing Funks Dam so that the new and existing reservoirs would act as one unit with an enlarged active storage capacity of approximately 6,500 acre-feet and a surface area of approximately 450 acres. Holthouse Reservoir would be required for the Project to facilitate balancing and regulating Sites Reservoir inflows and outflows through the Sites Pumping/Generating Plant, and to provide sufficient supplemental storage to allow simultaneous pump back power generation.

Colusa Basin Drain

The CBD conveys runoff and agricultural return flows from approximately one million acres of watershed in the Colusa Basin and discharges the flows to the Sacramento River at Knights Landing. The CBD also collects flood flows from the local creeks within the Primary Study Area. During high flows, flows in the CBD are diverted to Yolo Bypass through the Knights Landing Ridge Cut.

The operation of Sites Reservoir would reduce potential flood flow impacts primarily from Funks and Stone Corral creeks, as well as from Grapevine and Antelope creeks, which are located within the proposed Sites Reservoir Inundation Area. Flows from these creeks would be regulated by Sites and Golden Gate dams through releases of low maintenance flows. Hunters and Lurline creeks, which flow into the CBD, would not be affected by Sites Reservoir's operation.

The CBD would, therefore, change from an unregulated sporadic flow that is responsive to local storms to a regulated low maintenance flow resulting from the reduced drainage from Funks, Stone Corral, Grapevine and Antelope creeks once Sites Reservoir becomes operational.

Other Local Creeks

Many small tributaries exist within the Primary Study Area, including Grapevine Creek, Antelope Creek, Hunters Creek, and Lurline Creek.

Grapevine and Antelope creeks are located within the proposed Sites Reservoir Inundation Area; flows from both of these creeks would be reduced with operation of Sites Reservoir.

Hunters Creek (located north of Sites Reservoir) flows to the east. Lurline Creek (located southeast of Sites Reservoir) flows to the east. Hunters and Lurline creeks flow into the CBD. The operation of Sites Reservoir would not affect Hunters and Lurline creeks.

Sites Reservoir

Alternatives A, B, and C Compared to Existing Conditions

Table 6-113 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly storage at the proposed Sites Reservoir. It presents data for averages over the long term and combined Dry and Critical water years averages.

Table 6-113

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Across both the long-term averages and water year types, reservoir storage would decline to a minimum in November, increase during December through April to its maximum, and then decrease during May through October.

Although Alternatives B and C would both include the larger reservoir size (1.81-MAF), Alternative C would have more water in storage in Sites Reservoir than Alternative B. This increased storage would result from differences in diversion and conveyance capacities between the alternatives associated with the Delevan Pipeline Intake Facilities and the Delevan Pipeline Discharge facility.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-114 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly storage at the proposed Sites Reservoir. It presents data for averages over the long term and combined Dry and Critical water years averages.

Across both the long-term averages and water year types, reservoir storage would decline to a minimum in November, increase during December through April to its maximum, and then decrease during May through October.

Although Alternatives B and C would both include the larger reservoir size (1.81-MAF), Alternative C's reservoir would have more water in storage in Sites Reservoir than Alternative B. This increased storage would result from differences in diversion and conveyance capacities between the alternatives associated with the Delevan Pipeline Intake Facilities and the Delevan Pipeline Discharge facility.

Delevan Pipeline Intake Facilities

Alternatives A, B, and C Compared to Existing Conditions

Table 6-115 shows the differences between Alternatives A, B, and C and Existing Conditions for monthly flow at the proposed Delevan Pipeline Intake. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages, Alternatives A and C show that increases would occur during the late winter (December through March) and late summer (June and July). Over the Dry and Critical water years averages, Alternatives A and C show that an increase in diversions would occur during December through July. During June and July, upstream GCID and T-C canal flows would be supplemented by Delevan Pipeline flows.

Alternative B does not include the Delevan Pipeline Intake Facilities.

Table 6-115

Note:

cfs = cubic feet per second

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-116 shows the differences between Alternatives A, B, and C and the No Project/No Action Alternative for monthly flow at the proposed Delevan Pipeline Intake. It presents data for averages over the long term and combined Dry and Critical water years averages.

Over the long-term averages and across all water year types with implementation of Alternatives A and C, flows would increase during the predominantly wet months of December through March, reflecting the withdrawals needed to fill the proposed Sites Reservoir. Pipeline releases would increase during the dry summer months of June and July. During June through August, upstream GCID and T-C canal flows would be supplemented by Delevan Pipeline flows.

In contrast, Alternative B does not include the Delevan Pipeline Intake Facility.

Table 6-116

[a]Based on CALSIM II modeling over an 82-year simulation period.
[b]Long-Term is the average quantity for the period of October 1921 through September 2003.
[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:

cfs = cubic feet per second

6.4 Evaluation of Changes to Operational Flexibility

The existing State and federal water systems, SWP and CVP, respectively, have become relatively rigid in terms of timing, location, and quantity of stored and released water. This lack of flexibility creates difficulty in addressing many of the challenges facing California's water managers, including drought impacts, flood risk, declining ecosystems, impaired water quality, and climate change. As described in Chapter 1 Introduction, having more water in storage would improve the operational flexibility of California's major water systems and would give water managers the ability to develop more solutions to respond to California's water resources challenges.

Changes in CVP and SWP storage associated with implementation of Alternatives A, B, and C, when compared to Existing Conditions and the No Project/No Action Alternative, are discussed below.

6.4.1 Total North-of-the-Delta CVP and SWP Reservoir Storage

Table 6-117 shows the differences in total annual North-of-the-Delta storage between Alternatives A, B, and C, when compared to Existing Conditions and the No Project/No Action Alternative. It presents data for averages over the long term and combined Dry and Critical water years averages. Total North-of-the-Delta storage combines the Trinity Lake, Shasta Lake, Lake Oroville, Folsom Lake, and the proposed Sites Reservoir storages.

A comparison of the long-term averages and Dry and Critical water years averages of the total North-of-the-Delta storage for Alternatives A, B, and C with Existing Conditions and the No Project/No

Action Alternative indicates that there would be additional operational flexibility provided by the proposed Sites Reservoir.

Table 6-117
Total Annual North-of-the-Delta Storage[a] (TAF)

Long-Term Average[b, c]					Dry and Critical Water Years Average[b, d]				
	Existing Conditions	Change from Existing Conditions: Alternative A	Alternative B	Alternative C		Existing Conditions	Change from Existing Conditions: Alternative A	Alternative B	Alternative C
Annual	7,628	927 (12%)	1,167 (15%)	1,373 (18%)	Annual	6,070	791 (13%)	953 (16%)	1,173 (19%)
	No Project/No Action Alternative	Change from No Project/No Action Alternative: Alternative A	Alternative B	Alternative C		No Project/No Action Alternative	Change from No Project/No Action Alternative: Alternative A	Alternative B	Alternative C
Annual	7,591	964 (13%)	1,205 (16%)	1,410 (19%)	Annual	6,040	821 (14%)	983 (16%)	1,203 (20%)

[a]For Existing Conditions and the No Project / No Action Alternative, total annual storage combines Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake storage. For Alternatives A, B, and C, the storage for the same four reservoirs is combined with the proposed Sites Reservoir storage.
[b]Based on CALSIM II modeling over an 82-year simulation period.
[c]Long-Term is the average quantity for the period of October 1921 through September 2003.
[d]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Note:
TAF = thousand acre-feet

Alternatives A, B, and C show that substantial increases in total North-of-the-Delta storage would occur. Some of the increase in total North-of-the-Delta storage would be associated with increases at the existing reservoirs, and some would be associated with water in storage at the proposed Sites Reservoir. Over the long-term averages, total storage would increase, when comparing Alternatives A, B, and C, reflecting the differences in Sites Reservoir design capacity as well as differences in conveyance to the reservoir.

For example, over the long-term average, Alternative A includes the smaller Sites Reservoir (with a storage capacity of 1.27 MAF) and would result in the smallest total North-of-the-Delta storage increase of 927 TAF (12 percent), when compared to Existing Conditions, and 964 TAF (13 percent), when compared to the No Project/No Action Alternative.

Alternatives B and C both include the larger 1.81-MAF Sites Reservoir, and over the long-term average both show that larger total North-of-the-Delta storage increases would occur when compared to Existing Conditions (increases of 1,167 TAF [15 percent], and 1,373 TAF [18 percent], respectively) and the No Project/No Action Alternative (increases of 1,205 TAF [16 percent], and 1,410 TAF [19 percent], respectively).

Over the Dry and Critical water years average, Alternative A would result in a total North-of-the-Delta storage increase of 791 TAF (13 percent), when compared to the Existing Conditions, and 821 TAF (14 percent), when compared to the No Project/No Action Alternative. Alternative B would result in a total North-of-the-Delta storage increase of 953 TAF (16 percent), when compared to the Existing Conditions, and 983 TAF (16 percent), when compared to the No Project/No Action Alternative. Alternative C would result in a total North-of-the-Delta storage increase of 1,173 TAF (19 percent), when compared to the Existing Conditions, and 1,203 TAF (20 percent), when compared to the No Project/No Action Alternative.

Although Alternatives B and C would have the same reservoir storage size, the approximately 200 TAF storage difference between those alternatives reflects the difference in intake and conveyance capacity to Sites Reservoir between Alternative C and Alternative B. Alternative C includes the 2,000 cfs Delevan

Pipeline Intake Facilities; whereas, Alternative B has no diversion capability at the Delevan Pipeline (it instead has the Delevan Pipeline Discharge Facility).

6.5 Water Supply Impacts

6.5.1 Water Supply Reliability

Water supply reliability is defined as delivering a specific quantity of water with a determined frequency to a particular location at a particular time. Reliability indicates an acceptable level of dependability of water delivery to the users receiving it. Local, regional, California, and federal governments, and water suppliers, all have a role in water resource sustainability and improving water supply reliability for the existing and future population and the environment.

Water supply reliability is complicated by the need for consistent and efficient delivery of water to environmental, agricultural, and urban users. During prolonged droughts, water supplies are less reliable, which increases competition and can lead to conflict between water users.

Climate change threatens to further reduce water supply reliability throughout California. The potential effects of climate change, including the effects upon the alternatives, are discussed in Chapter 25 Climate Change and Greenhouse Gas Emissions.

The effects of implementation of Alternatives A, B, and C on water supply reliability are evaluated below.

6.5.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. For the purposes of this analysis, an alternative would result in a significant impact on water supply reliability if it would result in the following:

- A decrease in average annual CVP or SWP deliveries of greater than one percent with implementation of Alternatives A, B, and C, when compared to deliveries associated with the No Project/No Action Alternative.

A significance criterion value of one percent was selected to avoid consideration of minor fluctuations in model output due to simulation techniques.

No significance determination was made for the comparison of Alternatives A, B, and C CVP and SWP deliveries with Existing Conditions. Inherent in the differences in CVP and SWP deliveries between Alternatives A, B, and C and Existing Conditions are the differences in assumptions between the No Project/No Action Alternative and Existing Conditions. There are significant differences in key assumptions relating to increase in demands and build-out of facilities associated with CVP contracts (particularly M&I contract deliveries in the American River Basin), Level 2 supplies for wildlife refuges, increase in non-project water rights in the American River Basin, and new urban water intakes/Delta export facilities between the No Project/No Action Alternative and Existing Conditions, as described in Section 6.3.2.1. The differences in CVP and SWP deliveries between the No Project/No Action Alternative and Existing Conditions that are attributed to the differences in key assumptions are shown in Tables 6-37 and 6-38. Because the differences in CVP and SWP deliveries for Alternatives A, B, and C, when compared to Existing Conditions, are attributed to the differences in key assumptions between the

No Project/No Action Alternative and Existing Conditions and not the Project, it is not appropriate to make a significance determination for these comparisons.

6.5.2.1 Impact Assessment Methodology

CVP and SWP water supply allocations and the ability to divert from the south Delta intakes are determined in accordance with federal and State regulations. Factors that affect CVP and SWP water supply availability include CVP and SWP reservoir storage and Delta outflow requirements. CVP and SWP water supply allocations are calculated based upon current year hydrologic conditions and resultant reservoir storage. Overall, there are many factors that are considered in the determination of CVP and SWP deliveries and Delta exports.

For the purpose of this analysis, CVP and SWP water supply reliability was evaluated as a function of only CVP and SWP service area deliveries. The analysis of changes in CVP and SWP water service area deliveries compares simulated water supply conditions based upon CALSIM II results.

As discussed previously, there would be some changes between Existing Conditions and the No Project/No Action Alternative, such as a 2009 level of demand for Existing Conditions and a 2030 level of demand for the No Project/No Action Alternative. The level of demand change is one of several changes associated with implementation of the No Project/No Action Alternative. Refer to Section 6.3.2.1 for a more detailed discussion of key changes between Existing Conditions and the No Project/No Action Alternative, which are reflected in the modeling results.

Water supply reliability was evaluated based upon comparisons of CVP and SWP total annual water deliveries associated with Alternatives A, B, and C, when compared to the No Project/No Action Alternative, and is presented below. Water supply reliability is presented, but not evaluated, for Existing Conditions for total annual water deliveries and regional water deliveries. Regional water deliveries are also presented, but not evaluated, for the No Project/No Action Alternative.

6.5.2.2 Evaluation Results

CVP Contract Deliveries

Alternatives A, B, and C Compared to Existing Conditions

Table 6-118 shows the differences between Alternatives A, B, and C and Existing Conditions for annual CVP deliveries for the hydrologic regions within the Extended Study Area by water service type. It presents data for averages over the long-term and combined Dry and Critical water years averages.

Table 6-118

CVP = Central Valley Project
EXC = Existing Conditions
M&I = Municipal and Industrial
TAF = thousand acre-feet

Annual Long-Term Averages

Over the long-term averages, the total annual average CVP deliveries for all hydrologic regions show that increases of 288,000 to 319,000 acre-feet (six to seven percent) would occur for the three alternatives, when compared to Existing Conditions.

Over the long-term averages, the three alternatives show that increases in annual CVP M&I Service deliveries would occur in the Sacramento River and San Francisco Bay hydrologic regions.

Over the long-term averages, CVP M&I Service deliveries would increase substantially in the Sacramento River (by more than 125,000 acre-feet or 150 percent on average) and San Francisco Bay hydrologic regions (by 65,000 acre-feet or 29 percent on average) for the three alternatives, when compared to Existing Conditions. Average annual deliveries for CVP settlement contractors in the Sacramento River Hydrologic Region would increase from 31,000 to 35,000 acre-feet for the three alternatives, when compared to Existing Conditions.

Over the long-term averages, annual CVP Ag Service deliveries show that both positive and negative changes would occur in the four hydrologic regions for the three alternatives, when compared to Existing Conditions. The average annual deliveries for the CVP Exchange Contractors in the San Joaquin River Hydrologic Region would remain the same for the three alternatives, when compared to Existing Conditions.

If Alternative B is implemented, annual CVP Ag Service deliveries would decrease in the Sacramento River Hydrologic Region (by 7,000 acre-feet or three percent), in the San Joaquin River Hydrologic Region (by 1,000 acre-feet or less than one percent) and in the Tulare Lake Hydrologic Region (by 4,000 acre-feet or one percent).

If Alternatives A and C are implemented, annual CVP Ag Service deliveries would decrease in the Sacramento River Hydrologic Region (by 1,000 acre-feet) and San Joaquin River Hydrologic Region (by 7,000 and 4,000 acre-feet, or two and one percent, respectively).

Over the long-term averages, Wildlife Refuge Level 2 deliveries would increase (by 29,000 to 32,000 acre-feet or more than 20 percent) in the Sacramento River Hydrologic Region. However, Wildlife Refuge Level 2 deliveries would decrease in the San Joaquin River Hydrologic Region (by

20,000 acre-feet or seven percent) and in the Tulare Lake Hydrologic Region (by 3,000 acre-feet or 21 percent).

Over the long-term averages, Wildlife Refuge Level 4 supplies for Alternatives A, B, and C would increase, when compared to Existing Conditions. The Project would provide up to 2,000 acre-feet in the Sacramento River Hydrologic Region, up to 58,000 acre-feet in the San Joaquin River Hydrologic Region, and up to 14,000 acre-feet in the Tulare Lake Hydrologic Region. Water acquisitions to meet the Wildlife Refuge Level 4 supply goals would be reduced as the substitute supply from the Project becomes available, but total Wildlife Refuge Level 4 supplies would increase.

Annual Dry and Critical Years Averages

Over the Dry and Critical water years averages, the total annual average CVP deliveries for all hydrologic regions show that increases of 222,000 to 255,000 acre-feet (six to seven percent) would occur for the three alternatives, when compared to Existing Conditions.

Over the Dry and Critical water years averages, the three alternatives show that increases in annual CVP M&I Service deliveries would occur in the Sacramento River and San Francisco Bay hydrologic regions**.**

Over the Dry and Critical water years averages, CVP M&I Service deliveries would increase substantially in the Sacramento River (by more than 100,000 acre-feet or 135 percent on average) and San Francisco Bay hydrologic regions (by approximately 95,000 acre-feet or 42 percent on average) for the three alternatives. Over the Dry and Critical water years averages, annual CVP Ag Service deliveries show that positive and negative changes would occur in the four hydrologic regions for the three alternatives. CVP settlement contractors' deliveries in the Sacramento River Hydrologic Region would increase from 28,000 to 37,000 acre-feet for the three alternatives, when compared to Existing Conditions.

If Alternative B is implemented, annual Dry and Critical water years averages for CVP Ag Service deliveries would decrease in the San Francisco Bay Hydrologic Region (by 1,000 acre-feet or four percent) and in the Tulare Lake Hydrologic Region (by 17,000 acre-feet or six percent).

If Alternatives A, B, and C are implemented, annual Dry and Critical water years averages for CVP Ag Service deliveries would decrease in the Sacramento River Hydrologic Region (by 9,000 to 14,000 acre-feet or 8 to 13 percent) and San Joaquin River Hydrologic Region (by 1,000 to 9,000 acre-feet or one to six percent). Deliveries for the CVP Exchange Contractors in the San Joaquin River Hydrologic Region would remain the same for the three alternatives, when compared to Existing Conditions.

If Alternative C is implemented, annual Dry and Critical water years averages for CVP Ag Service deliveries would decrease in the Tulare Lake Hydrologic Region (by 8,000 acre-feet or three percent).

Over the Dry and Critical water years averages, Wildlife Refuge Level 2 deliveries would increase noticeably (by 25,000 to 27,000 acre-feet or more than 20 percent) in the Sacramento River Hydrologic Region. However, Wildlife Refuge Level 2 deliveries would decrease in the San Joaquin River Hydrologic Region (by 18,000 acre-feet or seven percent) and in the Tulare Lake Hydrologic Region (by 3,000 acre-feet or 21 percent).

Over the Dry and Critical water years averages, Wildlife Refuge Level 4 supplies for the Alternatives A, B, and C would increase, when compared to Existing Conditions. The Project would provide up to 1,000 acre-feet in the Sacramento River Hydrologic Region, up to 30,000 acre-feet in the San Joaquin

River Hydrologic Region, and up to 7,000 acre-feet in the Tulare Lake Hydrologic Region. Water acquisitions to meet the Wildlife Refuge Level 4 supply goals would be reduced as the substitute supply from the Project becomes available.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-119 shows total annual CVP deliveries for Alternatives A, B, and C, when compared to the No Project/No Action Alternative for averages over the long term as well as Dry and Critical water years averages.

Table 6-119

TAF = thousand acre-feet

Annual Long-Term Averages

Over the long-term averages, the total annual CVP deliveries for all hydrologic regions show that increases of 79,000 to 110,000 acre-feet (two percent) would occur for the three alternatives, when compared to the No Project/No Action Alternative. Thus, implementation of Alternative A, B or C would result in a **potentially beneficial effect** to total annual CVP deliveries, when compared to the No Project/No Action Alternative**.**

Over the long-term averages, annual CVP M&I Service deliveries show that either no change or minor increases (at most 1 percent) would occur in the four hydrologic regions, when compared to the No Project/No Action Alternative.

Over the long-term averages, annual CVP Ag Service deliveries show that positive and negative changes would occur in the four hydrologic regions for the three alternatives, when compared to the No Project/No Action Alternative. Annual deliveries for the CVP settlement contractors in the Sacramento River Hydrologic Region for the three alternatives would increase slightly from 5,000 to 9,000 acre-feet, and annual deliveries for the CVP Exchange Contractors in the San Joaquin River Hydrologic Region for the three alternatives would remain the same, when compared to the No Project/No Action Alternative.

Over the long-term averages, CVP Ag Service deliveries would increase in the Sacramento River Hydrologic Region (by 3,000 to 9,000 acre-feet or one to five percent) for the three alternatives.

If Alternative B is implemented, annual CVP Ag Service deliveries would decrease in the San Joaquin River Hydrologic Region (by 2,000 acre-feet or one percent) and in the Tulare Lake Hydrologic Region (by 3,000 acre-feet or one percent[2]).

If Alternatives A and C are implemented, annual CVP Ag Service deliveries would increase in San Joaquin River Hydrologic Region (by 3,000 to 6,000 acre-feet or one to two percent), San Francisco Bay Hydrologic Region (by 1,000 acre-feet or two percent), and the Tulare Lake Hydrologic Region (by 7,000 to 13,000 acre-feet or one to two percent).

Over the long-term averages, Wildlife Refuge Level 2 deliveries would increase in only the Sacramento River Hydrologic Region (by 3,000 to 6,000 acre-feet or two to four percent) for the three alternatives.

Over the long-term averages, Wildlife Refuge Level 4 supplies for the Alternatives A, B, and C would be the same, when compared to the No Project/No Action Alternative. The Project would provide up to 2,000 acre-feet in the Sacramento River Hydrologic Region, up to 58,000 acre-feet in the San Joaquin River Hydrologic Region, and up to 1,000 acre-feet in the Tulare Lake Hydrologic Region. Water acquisitions to meet the Wildlife Refuge Level 4 supply goals would be reduced as the substitute supply from the Project becomes available. The total Wildlife Refuge Level 4 supplies from both acquisitions and the Project would be the same as for the No Project/No Action Alternative.

Annual Dry and Critical Years Averages

Over the Dry and Critical water years averages, the total annual CVP deliveries for all hydrologic regions show that increases of 59,000 to 92,000 acre-feet (one to two percent) would occur for the three alternatives, when compared to the No Project/No Action Alternative. Thus, implementation of Alternative A, B, or C would result in a **potentially beneficial effect** to total annual CVP deliveries, when compared to the No Project/No Action Alternative.

Over the Dry and Critical water years averages, annual CVP M&I Service show either no change or minor increases (at most one percent) in the four hydrologic regions for the three alternatives, when compared to the No Project/No Action Alternative.

Over the Dry and Critical water years averages, annual CVP Ag Service deliveries show that either no change or noticeable increases would occur for the three alternatives, when compared to the No Project/No Action Alternative. Annual Dry and Critical water years averages for CVP settlement contractors deliveries in the Sacramento River Hydrologic Region for the three alternatives would increase slightly from 5,000 to 14,000 acre-feet, and annual Dry and Critical water years averages for the CVP Exchange Contractors deliveries in the San Joaquin River Hydrologic Region for the three alternatives would remain the same, when compared to the No Project/No Action Alternative.

If either Alternative A or C is implemented, annual Dry and Critical water years averages for CVP Ag Service deliveries would increase (by 45,000 acre-feet or nine percent for Alternative A and by 32,000 acre-feet or six percent for Alternative C) for the four hydrologic regions. If Alternative B is implemented, annual Ag Service deliveries would increase (by 14,000 acre-feet or three percent) in the Sacramento River, San Joaquin River, and Tulare Lake hydrologic regions.

[2] Table 6-119 shows a decrease of one percent due to rounding.

Over the Dry and Critical water years averages, annual Wildlife Refuge Level 2 deliveries would increase in only the Sacramento River Hydrologic Region (by 3,000 to 5,000 acre-feet or two to four percent) for the three alternatives, when compared to the No Project/No Action Alternative.

Over the Dry and Critical water years averages, Wildlife Refuge Level 4 supplies for the Alternatives A, B, and C would be the same, when compared to No Project/No Action Alternative. The Project would provide up to 1,000 acre-feet in the Sacramento River Hydrologic Region, up to 30,000 acre-feet in the San Joaquin River Hydrologic Region, and up to 7,000 acre-feet in the Tulare Lake Hydrologic Region. Water acquisitions to meet the Wildlife Refuge Level 4 supply goals would be reduced as the substitute supply from the Project becomes available. The total Wildlife Refuge Level 4 supplies from both acquisitions and the Project would be the same as for the No Project/No Action Alternative.

SWP Contract Deliveries

Alternatives A, B, and C Compared to Existing Conditions

Table 6-120 shows total annual SWP deliveries for Alternatives A, B, and C and Existing Conditions for averages over the long term as well as Dry and Critical water years averages.

[b]Long-Term is the average quantity for the period of October 1921 through September 2003.

[c]Dry and Critical Years Average is the average quantity for the combination of the SWRCB D-1641 40-30-30 Dry and Critical years for the period of October 1921 through September 2003.

Notes:

Ag = Agricultural
EXC = Existing Conditions
FRSA = Feather River Service Area
M&I = Municipal and Industrial
SWP = State Water Project
TAF = thousand acre-feet

Annual Long-Term Averages

Over the long-term averages, total annual deliveries to all hydrologic regions show that an increase of 144,000 to 156,000 acre-feet (four to five percent) would occur, when compared to Existing Conditions for the three alternatives. Alternatives B and C, with the larger 1.81-MAF reservoir size, would show annual delivery increases that are larger than those for Alternative A.

Over the long-term averages, substantial annual M&I Service delivery increases would be in the San Francisco Bay (by 18,000 to 19,000 acre-feet or 9 to 10 percent), South Lahontan (by 19,000 to 20,000 acre-feet or seven to eight percent), and South Coast hydrologic regions (by 110,000 to 116,000 acre-feet or eight to nine percent), when compared to Existing Conditions for the three alternatives.

Over the long-term averages, annual Ag Service deliveries show that no change would occur, except for decreases in the Tulare Lake Hydrologic Region with implementation of Alternative A (by 6,000 acre-feet or one percent) and Alternative B (by 4,000 acre-feet or one percent).

Annual Dry and Critical Years Averages

Over the Dry and Critical water years averages, total deliveries for all hydrologic regions show that an increase of 114,000 to 155,000 acre-feet (four to five percent) would occur, when compared to Existing Conditions for the three alternatives. Both Alternative A and C, which include the Delevan Pipeline Intake Facilities (diversion and release conveyance), have larger total annual delivery increases despite the reservoir size difference, when compared to Alternative B, which includes the release-only Delevan Pipeline Discharge Facility.

Over the Dry and Critical water years averages, substantial annual M&I Service delivery increases would be in the South Coast (by 74,000 to 98,000 acre-feet or seven to nine percent), Tulare Lake (by 6,000 to 8,000 acre-feet or 9 to 11 percent), and South Lahontan (by 5,000 to 10,000 acre-feet or two to five percent) hydrologic regions.

Over the Dry and Critical water years averages, the Tulare Lake Hydrologic Region shows that a large change in Ag Service deliveries would occur (by 23,000 to 34,000 acre-feet or five to seven percent), where current Ag Service deliveries are fairly substantial (492,000 acre-feet per year for Existing Conditions) in that region.

Alternatives A, B, and C Compared to the No Project/No Action Alternative

Table 6-121 shows total annual SWP deliveries for Alternatives A, B, and C and the No Project/No Action Alternative for averages over the long-term as well as Dry and Critical water years averages.

Notes:

Ag = Agricultural
FRSA = Feather River Service Area
M&I = Municipal and Industrial
NPA/NAA =No Project/ No Action Alternative
SWP = State Water Project
TAF = thousand acre-feet

Annual Long-Term Averages

Over the long-term averages, total annual SWP deliveries for all hydrologic regions show that an increase of 123,000 to 135,000 acre-feet (three to four percent) would occur, when compared to the No Project/No Action Alternative for the three alternatives. Because the three alternatives show that increases in total annual SWP deliveries over the long-term averages would occur, implementation of Alternative A, B, or C would result in a **potentially beneficial effect** to total annual SWP deliveries, when compared to the No Project/No Action Alternative.

Deliveries by hydrologic region show that uniform increases would occur, when compared to the No Project/No Action Alternative for the three alternatives.

Over the long-term averages, annual M&I Service deliveries would increase in the San Francisco Bay (by 9,000 to 10,000 acre-feet or five percent), South Lahontan (by 13,000 to 14,000 acre-feet or five percent), and South Coast hydrologic regions (by 62,000 to 68,000 acre-feet or five percent), for the three alternatives, when compared to the No Project/No Action Alternative.

Over the long-term averages, annual Ag Service deliveries show either no change or an increase would occur to all hydrologic regions for the three alternatives, when compared to the No Project/No Action Alternative. Tulare Lake Hydrologic Region shows the largest Ag Service increase (by 31,000 to 35,000 acre-feet or five percent).

Annual Dry and Critical Years Averages

Over the Dry and Critical water years averages, the total annual SWP deliveries to all hydrologic regions show that an increase of 248,000 to 289,000 acre-feet (9 to 10 percent) would occur, when compared to the No Project/No Action Alternative for the three alternatives.

Because the three alternatives show that increases in total annual SWP deliveries over the Dry and Critical water years averages would occur**,** implementation of Alternative A, B, or C would result in a **potentially beneficial effect** to total annual SWP deliveries, when compared to the No Project/No Action Alternative.

Over the Dry and Critical water years averages, annual deliveries by hydrologic region show that greater increases for M&I and Ag Service deliveries would occur, when compared to the No Project/No Action Alternative for the three alternatives.

Over the Dry and Critical water years averages, annual M&I Service deliveries would increase in all hydrologic regions, with an increase in the San Francisco Bay (by 17,000 to 21,000 acre-feet or 12 to 15 percent), South Lahontan (by 28,000 to 33,000 acre-feet or 14 to 17 percent), and South Coast hydrologic regions (by 131,000 to 155,000 acre-feet or 13 to 16 percent), when compared to the No Project/No Action Alternative for the three alternatives.

Over the Dry and Critical water years averages, annual Ag Service would increase, with the largest increase in the Tulare Lake Hydrologic Region (by 55,000 to 66,000 acre-feet or 12 to 14 percent), when compared to the No Project/No Action Alternative for the three alternatives.

If Alternative C is implemented, FRSA deliveries show that a 6,000 acre-feet decrease (one percent[3]) would occur.

7. Surface Water Quality

7.1 Introduction

This chapter describes the existing surface water quality of reservoirs and rivers for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Water quality can be affected by point and non-point discharges of contaminants, as well as physical and chemical changes within the water column caused by environmental and biological processes.

The regulatory setting for water quality is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary and Secondary study areas. Potential impacts in the Extended Study Area were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

7.2 Affected Environment

7.2.1 Extended Study Area

Water quality in the Extended Study Area varies regionally due to differences in land use practices, geology, source water, and climate. Agricultural water quality issues include the urban development of agricultural land due to the increasing human population in the State. Agricultural return flows to natural waters also affect water quality in terms of various contaminants, including pesticides, increased water temperatures and depressed dissolved oxygen levels, increased salinity and nutrient loads, and sedimentation and groundwater overdraft due to reductions in surface water deliveries. These agricultural return flows contribute to wildlife refuge water supply. Municipal and industrial water quality is directly related to population levels. Increased urban development arising from increasing populations also increases the need for infrastructure to treat drinking water supplies as well as wastewater. Most large wastewater treatment plants are required to perform tertiary treatment before recycling wastewater for urban landscape irrigation, as a means to increase limited drinking water supplies. Urban stormwater discharges have been shown to have an impact to receiving waters through increased nutrient loads, pesticides, and trash.

For planning purposes, California is divided into 10 hydrologic regions corresponding to the State's major water drainage basins (DWR, 2005a). The CVP and SWP service areas of the Extended Study Area are located within nine of California's 10 hydrologic regions. San Luis Reservoir is located within the San Joaquin River Hydrologic Region. The nine hydrologic regions are described below:

- **North Coast:** Klamath River and Lost River basins, and all basins draining into the Pacific Ocean from Oregon south through the Russian River Basin.
- **San Francisco Bay:** Basins draining into San Francisco, San Pablo, and Suisun bays, and into the Sacramento River downstream from Collinsville; western Contra Costa County; and basins directly

tributary to the Pacific Ocean downstream from the Russian River watershed to the southern boundary of the Pescadero Creek Basin.

- **Central Coast:** Basins draining into the Pacific Ocean downstream from the Pescadero Creek watershed to the southeastern boundary of Rincon Creek Basin in western Ventura County.
- **South Coast:** Basins draining into the Pacific Ocean from the southeastern boundary of Rincon Creek Basin to the international border with Mexico.
- **Sacramento River:** Basins draining into the Sacramento River system in the Central Valley (including the Pit River drainage), from the Oregon border south through the American River drainage basin.
- **San Joaquin River:** Basins draining into the San Joaquin River system, from the Cosumnes River basin on the north through the southern boundary of the San Joaquin River watershed.
- **Tulare Lake:** The closed drainage basin at the south end of the San Joaquin Valley, south of the San Joaquin River watershed, encompassing basins draining to Kern Lakebed, Tulare Lakebed, and Buena Vista Lakebed.
- **South Lahontan:** The interior drainage basins east of the Sierra Nevada crest, south of the Walker River watershed, northeast of the Transverse Ranges, and north of the Colorado River Region. The main basins are the Owens and the Mojave River basins.
- **Colorado River:** Basins south and east of the South Coast and South Lahontan regions; areas that drain into the Colorado River, Salton Sea, and other closed basins north of the border with Mexico.

The following discussions summarize surface water quality conditions for these hydrologic regions, and describe their relationships with the other hydrologic regions.

7.2.1.1 *North Coast Hydrologic Region*

The North Coast Hydrologic Region faces many water quality and water supply challenges. The North Coast Regional Water Quality Control Board's (North Coast RWQCB) water quality priorities highlight the need for control of nonpoint source runoff from logging, rural roads, agriculture, and urban areas (DWR, 2005b). Sediment, temperature, and nutrients are the primary focus of the RWQCB's 303(d) list of impaired water bodies. Along the coast, nonpoint-source pollution can cause microbial contamination of shellfish growing areas, especially oysters. Much of the region is characterized by rugged, steep, forested lands, with highly erodible, loosely consolidated soils; these conditions, combined with wildfires, extensive timber harvesting, and heavy precipitation primarily in the form of rain, make the watershed highly susceptible to erosion and landslides. Heavy runoff, in turn, causes stream sedimentation that adversely impacts habitat for spawning and rearing anadromous fish. Channel modifications and water diversions have radically changed water quality conditions in many waterbodies in the region by reducing natural flows that dilute contaminant concentrations and lessen their impacts. In the southern portion of the region, the development of new hillside vineyards is an increasing source of erosion and pesticides.

Fisheries can be adversely affected by a number of factors related to both water quality and water quantity. The Eel, Mad, Trinity, Klamath and Russian rivers, as well as many other streams, suffer from sedimentation, which can smother salmonid spawning areas. The *Water Quality Control Plan for the North Coast Region* (North Coast Basin Plan) sets turbidity (a measure of water clarity) restrictions to control erosion impacts from logging and related activities, such as road building (NCRWQCB, 2011).

Timber harvests can also decrease the canopy shading rivers and streams, thereby increasing water temperatures to levels that are detrimental to cold water fisheries.

The North Coast Basin Plan specifically establishes temperature objectives for the Trinity River, in which reduced flows have disrupted temperature and physical cues for anadromous fish runs. Because of water diversions, summer temperatures in the Trinity River as well as the Klamath River can be lethal to salmonids. Fisheries can be further affected by the lack of woody debris for pool habitat and sediment metering.

The North Coast Basin Plan requires tertiary, or three-phase, treatment of wastewater discharges to the Russian River, which is a major source of domestic water, and establishes limits on bacteriological contamination of shellfish-growing areas along the coast. The plan also prohibits or strictly limits waste discharges to the Klamath, Trinity, Smith, Mad, and Eel rivers, as well as estuaries and other coastal waters. Nonpoint source runoff, especially after heavy precipitation, has resulted in contamination and closure of shellfish harvesting beds in Humboldt Bay.

Other water quality concerns include the impacts of boating fuel constituents, such as methyl tertiary-butyl ether (MTBE) to recreational water use at Trinity, Lewiston, and Ruth lakes. Abandoned mines, forest herbicide application, and historical discharge of wood treatment chemicals at lumber mills, including from the Trinity River Lumber Company in Weaverville, also are regional issues of concern.

Relationship with Other Regions

The Klamath River Basin straddles the Oregon border, such that water from the upper basin flows into Oregon and eventually returns to California upstream from Iron Gate Reservoir. On the Oregon side of this interstate basin, two surface water diversions export an average of 29,600 acre-feet per year from Klamath River tributaries into the Rogue River system in Oregon. The Klamath River Basin also receives a small amount of imported water (approximately 2,000 acre-feet per year) from the upper reaches of the Sacramento River Hydrologic Region through a canal (the North Fork Ditch).

The North Coast Hydrologic Region exports a large volume of water from the upper reaches of the Trinity River into the Sacramento River Region through Reclamation's Lewiston Dam and the Clear Creek Tunnel. For 1998, 2000, and 2001, the Trinity River exports were 851,000 acre-feet per year, 1.11 million acre-feet per year, and 669,000 acre-feet per year, respectively (DWR, 2005b). In future years, these Trinity River exports are likely to be reduced due to the increased instream flows established for the Trinity River fishery.

7.2.1.2 *San Francisco Bay Hydrologic Region*

The San Francisco Bay Hydrologic Region is centered on the San Francisco Bay/Delta Estuary and its water quality (DWR, 2005c). The estuary's immediate watershed is highly urbanized, resulting in contaminant loads from point and nonpoint sources, as well as pollutants from the Napa, Petaluma, and Guadalupe rivers, the Sacramento-San Joaquin Delta, and the Central Valley. San Francisco Bay Area residents generally receive good quality drinking water that varies by source and treatment. Sources range from the Hetch Hetchy Reservoir and Mokelumne River, to local surface and groundwater and variable quality Delta water. Utilities that depend on the Delta for all or part of their domestic water supplies meet the current drinking water standards, although they remain concerned about issues, such as microbial contamination, salinity, and organic carbon.

Water and sediment in the estuary meet quality guidelines for most contaminants, with constituents in water meeting toxicity and chemical guidelines approximately 87 percent of the time. Sediment concentrations are more problematic due to legacy pollutants[1], with only approximately 60 percent of the sediment samples meeting chemical guidelines and passing toxicity tests. Estuary water quality has significantly improved since these chemicals have been prohibited, with fewer toxic episodes and decreased silver concentrations in the South Bay. Implementation of secondary, or two-phase, treatment of domestic wastewater has dramatically improved the quality of the San Francisco Estuary, especially the oxygen content, as has the reduction in the use of organophosphate pesticides.

Major water quality issues include control of stormwater, urban, and construction site runoff, as well as runoff and discharges from the vast Central Valley and Delta watershed. Legacy pollutants, such as PCBs and mercury, contaminate fish in the estuary. Other water quality concerns include copper and nickel in the South Bay, selenium from Contra Costa refineries, erosion from vineyards in Napa and Sonoma valleys, pesticides in urban creeks, and toxicity of water and sediment. Exotic and invasive species, such as the Chinese mitten crab and Asian clam, threaten to undermine the estuary's planktonic food web base, thus potentially altering its ecosystem (including native species). Because San Francisco Bay has several active seaports, discharge of ballast water and vessel wastes and maintenance dredging and disposal of contaminated sediments are water quality concerns. New contaminants are emerging that may be causing impacts to the aquatic ecosystem, including polybrominated diphenyl ethers (PBDEs), pyrethroid insecticides, and compounds from pharmaceuticals and personal care products.

The bay acts as a sediment repository, so persistent sediment-bound contaminants, such as mercury, dioxins, PCBs, and organochlorine pesticides have accumulated over time. These compounds also bioaccumulate[2] in the food chain, causing contamination of bay fish and endangering their consumers, including humans and wildlife. New inputs of the persistent sediment contaminants in the estuary are now controlled because the use of most organochlorine pesticides and PCBs are banned, and the concentrations in the sediments and in organisms appear to be declining. The San Francisco RWQCB is developing new regulatory requirements to address the mercury sources to the estuary, including the New Almaden mine, located in the vicinity of San Jose, and thousands of other abandoned mercury and gold mine tailings in the Central Valley watershed. Mercury contamination in estuary fish, such as the striped bass, has remained high for more than 30 years. Wetland restoration could increase mercury methylation[3] processes and cause higher contamination in fish. State and federal agencies, working through the CALFED Bay Delta Program and other organizations, have funded several studies to determine potential effects of restoration and explore management actions that would decrease methylmercury[4] production and bioaccumulation.

Relationship with Other Regions

The combined flows of the Sacramento and San Joaquin river watersheds flow through the Delta and into the San Francisco Bay. Delta outflow interacts with tides to determine how far salt water intrudes from the

---

[1] Legacy pollutants, which include certain heavy metals, dichloro-diphenyl-trichloroethane (DDT), and polychlorinated biphenyls (PCBs), are persistent organic pollutants that are now banned, but were used in the past and persist in the environment long after they were first introduced.

[2] The gradual build-up of toxins in an organism at levels higher than those that occur in the surrounding environment.

[3] The conversion of inorganic mercury by microorganisms in soil and sediments (in air or water) to organic methylmercury.

[4] An organic form of mercury. It is a neurotoxin that is especially dangerous to fetuses and infants, attacking the central nervous system and causing an array of developmental and other problems. Methylmercury contamination and exposure can also adversely affect reproductive success and health of fish and other species.

ocean into the San Francisco Bay Estuary. The resulting salinity gradients influence the distribution of many estuarine fishes and invertebrates as well as plants, birds, and animals in wetlands areas. Delta outflow varies with hydrology, reservoir releases, and diversions upstream. Some surface water supplies that originate in the San Joaquin Hydrologic Region are diverted across the valley to the San Francisco Bay Hydrologic Region via the Mokelumne Aqueduct, which is operated by the East Bay Municipal Utility District. Surface water is also diverted through the Hetch Hetchy Aqueduct, which is owned and operated by the City of San Francisco. The average annual diversions made by these two projects from the Mokelumne and Tuolumne rivers are approximately 245,000 acre-feet per year through the Mokelumne Aqueduct, and 267,000 acre-feet per year through the Hetch-Hetchy Aqueduct (DWR, 2005c).

7.2.1.3 *Central Coast Hydrologic Region*

The Central Coast's limited surface water supply and few large surface water storage facilities, combined with the growing demand for water, is resulting in more dependence on groundwater (DWR, 2005d). Unique coastal resources, such as Morro Bay and Monterey Bay, as well as the Salinas Valley, are the focus of water quality issues. Sedimentation poses the greatest water quality threat to Morro Bay, one of 28 estuaries in the National Estuary Program. The bay is also contaminated by pathogens from agriculture, boats, and urban runoff; nutrients from fertilizers, animal wastes, and urban runoff; heavy metals from abandoned mines in the upper watershed; and sediment from offshore boatyards. Elevated levels of bacteria have closed many of the shellfish-growing beds in Morro Bay, and have occasionally closed beaches in Santa Cruz County and southern Santa Barbara County. To protect special areas of biological significance, waste discharges are prohibited or limited in portions of Monterey Bay, a National Marine Sanctuary, and other specific coastal and ocean waters of the region. In its 2005 Triennial Review, the Central Coast RWQCB also identified the need to incorporate new microbiological standards for water-contact recreation in this region.

The Salinas River watershed has significant nitrate contamination related to agriculture, which is the valley's main land use. The nearby Pajaro River watershed faces a variety of water quality threats, such as erosion (primarily from agricultural practices), urban runoff, sand and gravel mining, flood control projects, off-road vehicles, and historical mercury mining in the Hernandez Lake area.

Relationship with Other Regions

Historically, the communities of the Central Coast Hydrologic Region have relied on local surface water and groundwater supplies to meet their needs. The northern part of the region first received imported water with completion of the San Felipe Unit of the CVP in 1987. This facility delivers water to San Benito County users primarily for agricultural purposes from San Luis Reservoir in the San Joaquin River Hydrologic Region. Ten years later, the Coastal Branch of the SWP was completed to import water to San Luis Obispo and Santa Barbara counties from the California Aqueduct in the Tulare Lake Hydrologic Region. There are no other water imports into the Central Coast region. Because there is seldom any excess surface water in this region's watersheds, there are no water exports from this region to other parts of the State.

7.2.1.4 *South Coast Hydrologic Region*

Similar to many regions in the State, water quality and water supply challenges are intertwined. The South Coast region must manage for uncertainties caused by population and economic growth (DWR, 2005e). Growth will not only affect demand, but it will add contamination challenges from increases in wastewater discharges and urban runoff, as well as increased demand for water-based recreation. Outside of the region, environmental and water quality needs in the Delta and Owens River/Mono Basin systems affect imported water supply reliability and quality. The region must also assess and plan for impacts of climate variations and global climate change, as well as the cost of replacing aging infrastructure.

Given the size of the region and the diverse sources of water supply, the challenges to the region's water quality are varied. Surface water quality issues in the South Coast are dominated by stormwater and urban runoff, which contribute contaminants (including trash) to local creeks and rivers. These pollutant sources, as well as sanitary sewer overflows, ocean outfalls, tidal input, and even wildlife, can degrade coastal water quality, closing beaches and increasing the health risks from swimming. These sources also specifically affect water quality in the major bays: Santa Monica, Newport, and San Diego. Newport Bay, for instance, suffers from algal blooms (due to excess nutrients), toxicity to aquatic life, high bacterial counts, and sedimentation. Shipping can also influence water quality, especially at the U.S. Navy base in San Diego Bay and the Long Beach and Los Angeles harbors, where there are toxic sediment hot spots. Harbors, marinas, and recreational boating threaten water quality via ballast water discharges, which can introduce petroleum and sewage discharges and spills, biocides from boat hulls, boat cleaning and fish wastes, trash, and reduced water circulation. Constructed wetland projects in Hemet/San Jacinto, San Diego Creek, and Prado Basin remove large loads of nitrogen from wastewater and urban runoff. Salinity, nitrogen, and microbes are the major contaminants in the Santa Ana River, affecting downstream beneficial uses such as swimming and groundwater recharge for domestic use. Because of upstream irrigation diversions, flows in the middle and lower Santa Ana River are composed mostly of recycled water, creating a year-round flow that is high in salinity.

Lake Elsinore, the largest natural freshwater lake in southern California, experiences nuisance algae blooms from excess nutrients, impairing its ecological and recreational beneficial uses. Local groups have implemented many wetland and river restoration projects to improve water quality, including at Bolsa Chica, in Ballona Creek, and along the Los Angeles and San Gabriel rivers. The United States and Mexico jointly built the International Wastewater Treatment Plant to treat a portion of the sewage from Tijuana, which flows across the international boundary into the San Diego Basin.

The Chino Basin hosts the highest concentration of dairy animals in the U.S. In a 40-square-mile area, over 300,000 animals are maintained on approximately 300 dairies (DWR, 2005e). Because of a lack of sufficient land for manure disposal, as well as flooding from expanding suburban development, dairy runoff contributes nitrate, salts, and microorganisms to groundwater as well as surface water. Since 1972, the Santa Ana RWQCB has issued waste discharge requirements to the dairies in this basin. In addition, pilot projects to develop sewer systems for dairies and for treating dairy wash water have also recently been completed.

Public health and environmental and economic concerns have grown with the expansion of water recycling programs in the South Coast region. Some concerns are related to the total dissolved solids (TDS) content of wastewater and the presence in treated wastewater of pharmaceuticals, household products, and other emerging contaminants. The high salinity of imported Colorado River water limits the number of times water can be reused before the salt content becomes too high, and wastewater can only be discharged to the ocean. Increased use of recycled water and marginal quality groundwater supplies during droughts can result in water quality problems for some local supplies that endanger future water management projects. For instance, groundwater recharge potential may be restricted because the RWQCB has established TDS requirements for recharge water in some groundwater basins to protect existing basin water quality.

The average TDS concentration of the Mohave Water District's Colorado River Aqueduct water is approximately 600 to 700 mg/L, and the average TDS content of SWP water supply is approximately 300 mg/L. The water supply from the Los Angeles Aqueduct has a significantly lower TDS concentration, typically approximately 160 mg/L (DWR, 2005e).

In addition to salinity, several established and emerging contaminants of concern to the region's drinking water supplies include disinfection byproducts (DBPs), perchlorate, arsenic, nitrosodimethylamine (NDMA), hexavalent chromium, and MTBE. Imported water from the Owens Valley is of excellent water quality, and imported Delta water quality is generally good. Nonetheless, arsenic is a concern in the Owens Valley supply, and Delta water can contain precursors (such as organic carbon and bromide) of potentially carcinogenic DBPs, if treated with certain disinfection processes necessary to inactivate pathogens in drinking water.

Relationship with Other Regions

The South Coast Hydrologic Region imports water from three primary regions including SWP deliveries from the Sacramento River and San Joaquin River hydrologic regions; Owens Valley Aqueduct deliveries from the South Lahontan Hydrologic Region; and deliveries from the Colorado River Hydrologic Region.

7.2.1.5 *Sacramento River Hydrologic Region*

Surface water quality in the Sacramento River watershed is relatively good, when compared with statewide data, making the Sacramento River one of the most desirable water sources in the State (DWR, 2005f).

Nonetheless, increased turbidity, rice pesticides, and organophosphate pesticides, such as diazinon, affect fisheries and drinking water supplies. The decline of fisheries in the Sacramento River is, in part, related to water quality problems on the river's mainstem. Those water quality problems include unsuitable water temperature, toxic heavy metals, such as mercury, copper, zinc, and cadmium from acid mine drainage; and pesticides and fertilizer in agricultural runoff. Holding of rice field drainage, which allows for degradation of rice herbicides by re-flooding after harvest, has effectively addressed this water quality concern among downstream water users. In the Cache Creek watershed, Clear Lake suffers from large mercury, sediment, and nutrient loadings, the latter leading to nuisance algal blooms. Along with a few select other waterbodies, the *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* (Central Valley Basin Plan) (CVRWQCB, 2011) specifically prohibits direct discharges of wastes into Folsom Lake and the lower American River downstream to its confluence with the Sacramento River; waste discharges from houseboats on Shasta, Clear Lake, and in the Delta are also banned. High density recreation use of Whiskeytown and Shasta lakes may be contributing to high bacteria levels in these two reservoirs.

An evaluation of the strength of relationships between human activity (as indicated by landcover) and pollutant concentrations in recently deposited (2008) stream sediment indicates that the majority of sample sites in the Sacramento River watershed are in the lowest quartile for the range of concentrations for the metals cadmium, copper, lead, and zinc, with sites near Redding and Woodland in the second quartile (SWRCB, 2012a). These second quartile site results are related to the major point sources for metals discharging from Iron Mountain Mine (Redding area) and Cache Creek (Woodland area). Quartile cutoffs are at 25 percent, 50 percent, and 75 percent of the maximum measured concentrations.

Adverse effects from these constituents on sediment-dwelling organisms are not expected to occur below a threshold effects concentration (TEC), while adverse effects are expected to occur frequently above a probable effects concentration (PEC) (MacDonald et al. 2000, as cited in SWRCB, 2008). At concentrations between a TEC and PEC, it is difficult to predict whether or not the sediments would be toxic to organisms. Total mercury in unsieved sediment samples were found to be below the threshold effects concentration (TEC) for the majority of sample sites in the watershed, with sites near Redding and Woodland falling between the TEC and PEC.

For the legacy pollutant PCB, results were below the laboratory detection limit for all but one site, which was below the TEC. Results for total DDT, another legacy pollutant, were mostly below the TEC, with two sites between the TEC and PEC (SWRCB, 2012a).

Pyrethroid pesticides were either ‘non-detect’ or in the lowest quartile in the watershed. The higher pyrethroid levels were associated with the larger urban areas within the watershed (SWRCB, 2012a).

Sediment toxicity observed in the watershed was determined to be not significantly toxic, with the exception of the sample site in the Redding area and the associated Iron Mountain Mine acid mine drainage (SWRCB, 2012a).

Mercury contamination is significant throughout the State. In its 2005 Triennial Review, the Central Valley RWQCB identified mercury loads, a legacy of California’s gold mining heritage, as one of the most significant water quality problems in the region (SWRCB, 2012a). The Sacramento River watershed is the major source of total mercury to the Delta, contributing approximately 90 percent of the total mercury loads (SRWP, 2004). In particular, the Cache Creek watershed is the major source of mercury to the Delta; to a lesser extent, mercury is also a concern in Lake Berryessa and Marsh Creek Reservoir. Major sources of total mercury loads to the Sacramento River watershed include runoff and erosion from historic gold mining sites, erosion of native soils, and natural mineral springs. Minor mercury sources include treated wastewater, urban runoff, historic mercury mines, and atmospheric mercury deposition from external sources (SRWP, 2004). Because of methylmercury’s bioaccumulative properties, several waterbodies in the Sacramento River region have fish consumption advisories. Pesticide management and agricultural water discharge have received increased attention by the Central Valley RWQCB, which made the decision to eliminate waivers associated with agricultural discharge in 2003. Coalitions in the region are forming partnerships to address this issue through a watershed approach, as provided for by the Central Valley RWQCB and affirmed by the State Water Resources Control Board in its 2005 review of the Irrigated Lands Conditional Waiver. Stakeholders in the region are working to find a solution that encompasses the protection of public health, meets current and future water quality regulations, and allows for a sustainable agricultural economy.

Relationship with Other Regions

The Sacramento River Hydrologic Region provides the majority of streamflow to the San Francisco Bay Hydrologic Region and is also the major contributor of fresh water to the CVP and SWP delivery systems, which supply portions of the water needs of the following hydrologic regions: San Joaquin River, Central Coast, South Coast, and Tulare Lake.

7.2.1.6 *San Joaquin River Hydrologic Region*

Historically, the surface water originating from Sierra Nevada rivers has proven to be a dependable supply of water, but it meets only half of the region’s total water requirements (DWR, 2005g). Water quality in this Region generally meets the standards for beneficial uses identified in the Central Valley Basin Plan. Imported surface water and groundwater pumping make up the difference. Because the region relies on imported surface water from other regions, there is growing concern over the long-term availability of external supplies.

The major water quality problems of the San Joaquin River Hydrologic Region are a result of many factors, including depleted freshwater flows. The San Joaquin River Restoration Program was formed in response to a 2006 settlement of an 18-year-old lawsuit between the U.S. Departments of the Interior and Commerce, the Natural Resources Defense Council, and the Friant Water Users Authority (SJRRP, 2010). The Settlement is based on two goals: the first goal is to restore flows to the San Joaquin River from Friant Dam to the confluence of the Merced River while reducing or avoiding adverse water supply impacts from restoration flows. The second goal is to restore and maintain fish populations in "good condition" in the mainstem of the San Joaquin River downstream from Friant Dam to the confluence of the Merced River, including naturally-reproducing and self-sustaining populations of salmon and other fish. Restoring flows to the San Joaquin River to meet these goals includes improving water quality conditions in the restoration reaches for the benefit of fish, wildlife, and other beneficial uses, including agricultural and municipal supply.

Other major water quality problems in the San Joaquin River Hydrologic Region include municipal and industrial wastewater discharges, salt loads from agricultural drainage and runoff, and other pollutants associated with long-term agricultural irrigation and production, including nutrients, selenium, boron, and organophosphate pesticides. The entire Central Valley, which includes the San Joaquin River, Sacramento River, and Tulare Lake basins, has 40 waterbodies that are impaired due to agricultural drainage and runoff, including 800 miles of waterways, and 40,000 acres of the Delta. In its 2005 Triennial Review of its basin plan, the Central Valley RWQCB identified high priority problems as salinity and boron discharges to the San Joaquin River, low dissolved oxygen problems in the lower San Joaquin River, control of organophosphorous pesticides, and the need for stronger policies to protect Delta drinking water quality.

High salinity is a problem in the San Joaquin River basin because of the greatly altered flows of the river, most of which is diverted from its natural course at Friant Dam. In addition, imported irrigation water from State and federal projects annually transport more than a half million tons of salts into the west side of the San Joaquin River region. Water released from New Melones Reservoir on the Stanislaus River is used to help meet the salinity and dissolved oxygen requirements at Vernalis on the lower San Joaquin River. Agricultural drainage and discharges from managed wetlands are already regulated in the 370,000-acre Grasslands watershed, which contributes high levels of salts, selenium, boron, and nutrients to Mud and Salt sloughs. These sloughs are some of the primary contributors of selenium to the San Joaquin River. Dairies, stockyards, and poultry ranches are also a concern in the region because they generate waste products including pathogens, nutrients, salts, and emerging contaminants[5] of concern that enter the waterways. Some dairies and other agricultural operations are already subject to regulatory review. Water releases from managed wetlands, a part of the State and federal wildlife refuge system, also

[5] Emerging contaminants are hazardous materials or mixtures (naturally occurring or humanmade chemical, microbial, or radiological substances) that are characterized by having: (1) a perceived or real threat to human health, public safety, or the environment; (2) no published health standards or guidelines; (3) insufficient or limited available toxicological information or toxicity information that is evolving or being re-evaluated; or (4) significant new source, pathway, or detection limit information.

can discharge salts and nutrients. The erosion of westside streams is the primary source of organochlorine pesticides in the San Joaquin River.

Migrating and spawning salmonids face high temperatures in the Stanislaus, Tuolumne, and Merced rivers downstream from dams during certain times of the year, depending on hydrologic and water supply conditions. Contamination of fish is also a concern in these three rivers, as well as in the mainstem of the San Joaquin River. For example, the Central Valley RWQCB cites one study that found a 43-mile reach of the San Joaquin River (between the confluences with the Merced and the Stanislaus rivers) to be toxic to fish approximately half the time. In the lower San Joaquin River, low dissolved oxygen levels in the Stockton Deepwater Ship Channel are attributable to warm temperatures, low flows, nutrients, and channel configuration. This portion of the river with low dissolved oxygen is potentially a barrier to fall-run Chinook salmon migrating upstream to the Merced, Tuolumne, and Stanislaus rivers to spawn.

In relation to other geographic regions of the State, water discharges from irrigated lands have their greatest impact to water quality in the Central Valley, which covers 40 percent of California's land area and contains seven million irrigated acres and more than 25,000 individual agricultural dischargers.

Although existing agricultural land use practices affect water quality now, the expanding urbanization of Central Valley cities will generate new and different water quality problems in the future. Since the late 1970s, landscape irrigation with recycled water is an increasingly used strategy to reduce potable water demand and reduces the volume of water wasted after a single use (SWRCB, 1977). The SWRCB prescribes general waste discharge permits for municipal wastewater discharge systems to construct and operate more costly tertiary wastewater treatment facilities to use recycled water and prevent water quality impacts to current and possible future beneficial uses (SWRCB, 2009).

Relationship with Other Regions

The San Joaquin River Hydrologic Region depends on receiving surface water from other regions of the State to meet a portion of its developed agricultural and urban water uses. For many years, the region has received imported CVP water from the Sacramento-San Joaquin Delta via the Delta Mendota Canal, and from CVP Friant Dam on the upper San Joaquin River. This region also receives some SWP water from the California Aqueduct.

Some surface water supplies that originate in the San Joaquin Hydrologic Region are also diverted across the valley to the San Francisco Bay Hydrologic Region via the Mokelumne Aqueduct and the Hetch Hetchy Aqueduct. The average annual diversions made by these two projects from the Mokelumne and Tuolumne rivers are approximately 245,000 acre-feet per year through the Mokelumne Aqueduct, and 267,000 acre-feet per year through the Hetch-Hetchy Aqueduct (DWR, 2005g).

7.2.1.7 *Tulare Lake Hydrologic Region*

The Tulare Lake Hydrologic Region is in the southern end of the San Joaquin Valley. This region includes all of Tulare and Kings counties and large portions of Fresno and Kern counties.

Agricultural runoff and drainage are the main sources of nitrate, pesticides, and selenium that endanger groundwater and surface water beneficial uses (DWR, 2005h). In locations where groundwater quality is marginal to unusable for agriculture, farmers use good quality surface water to irrigate crops or blend higher quality surface water with poor quality groundwater to create a larger supply. The basin also has a relatively large concentration of dairies that contribute microbes, salinity, and nutrients to both surface water and groundwater. In addition, oilfield waste has impacted water quality. According to the Central

Valley Basin Plan, there are more than 800 oilfield waste dischargers, of which 250 are regulated pursuant to waste discharge requirements.

The quality of local surface water from the Kings River and the San Joaquin River (diverted south through the Friant-Kern Canal) is generally considered excellent for irrigation, municipal, and industrial uses. However, the Central Valley RWQCB specifically identified salinity in the lower Kings River as a water quality priority in its 2007 Triennial Review. On the west side of the region, DWR has sought solutions to the flooding on the Arroyo Pasajero, which threatens the California Aqueduct. The aqueduct, which forms a barrier to arroyo floodwaters and sediment flow, is at risk of failure during major rainstorms in the watershed. Also, the naturally occurring asbestos in the arroyo sediments that enter the aqueduct during floods has raised questions of possible health risks. Both Panoche and Silver creeks contribute large sediment loads to the valley floor, and Panoche Creek also contains elevated levels of selenium.

In addition, drainage water is sometimes contaminated with naturally occurring, but elevated, levels of selenium, boron, and other toxic trace elements that threaten the water quality, environment, and fish and wildlife. Water planners had originally envisioned a master surface water drain to remove this poor quality water, but that proposal was never implemented. Reclamation has an obligation to provide agricultural drainage service to farm lands served by the CVP on the west side of the valley. To convey this sometimes contaminated drainwater more directly to the San Joaquin River and away from the sensitive San Luis National Wildlife Refuge Complex, a portion of the San Luis Drain was reopened in September 1996 as part of the Grassland Bypass Project. The San Luis Drain was modified to allow drainage through six miles of Mud Slough, a natural waterway that passes through the San Luis National Wildlife Refuge Complex and a section of the North Grassland Wildlife Area.

San Joaquin Valley agricultural drainage water quality monitoring began in 1959 as a cooperative agreement between DWR and the University of California. In 1984, the San Joaquin Valley Drainage Program was established as a joint federal and State effort to investigate drainage and drainage-related problems and identify possible solutions. In September 1990, the San Joaquin Valley Drainage Program summarized its findings and presented a plan to manage drainage problems in a report titled "A Management Plan for Agricultural Subsurface Drainage and Related Problems in the Westside San Joaquin Valley."

Relationship with Other Regions

The Tulare Lake Hydrologic Region receives CVP water from the San Joaquin River region via the Friant-Kern Canal and imported water from the Sacramento-San Joaquin Delta via the California Aqueduct and the San Luis and Delta-Mendota canals. The economic health of the region depends heavily on the availability of imported surface water to meet current and future needs.

7.2.1.8 *South Lahontan Hydrologic Region*

The quality of the limited surface water resources is excellent in the South Lahonton Hydrologic Region, and is influenced greatly by snowmelt from the eastern Sierra Nevada (DWR, 2005i). However, at lower elevations, groundwater and surface water quality can be degraded, both naturally from geothermal activity, and as a result of recreational uses and cattle grazing. Nutrients entering Crowley Reservoir, on the Owens River south of Mono Lake, have contributed to low dissolved oxygen levels in the reservoir. Water quality and quantity are inherently related in the Owens River watershed because of the large exports of surface and groundwater to the City of Los Angeles. Arsenic, a known human carcinogen, is a health concern in the basin, and therefore, in Los Angeles as well, especially with the recently proposed lower drinking water standard for this chemical. In its 2003 Triennial Review, the Lahontan RWQCB identified the need for site-specific ammonia objectives for Paiute Ponds and Amargosa Creek in Los Angeles County (LRWQCB, 2007). The monitoring and cleanup of chromium in groundwater and the cleanup of sites contaminated by mining wastes are additional water quality needs for this region.

Relationship with Other Regions

Although most of Mojave Water Agency's (MWA) service area is in the South Lahontan Hydrologic Region, a portion of its service area extends into the Colorado River Hydrologic Region (Lucerne and Johnson valleys and the Morongo Basin). The service area includes the community of Yucca Valley, which has an allocation for up to 7,200 acre-feet of MWA's surface water from the SWP. Imported SWP water is used to recharge groundwater supplies in the Mojave River Valley basins. Some of these surface water and groundwater supplies are also exported from the Owens and Mono portions of the South Lahontan Hydrologic Region to the South Coast Hydrologic Region by the Los Angeles Department of Water and Power via the Los Angeles Aqueduct.

7.2.1.9 *Colorado River Hydrologic Region*

The Salton Sea, with its increasing salinity, selenium contamination, and nutrient enrichment (i.e., eutrophication), is the primary focus of water quality issues within the Colorado River Hydrologic Region (DWR, 2005j). The largest sources of surface water inflow to the sea are the New and Alamo rivers and the Imperial Valley agriculture drains, all of which contribute pesticides, nutrients, selenium, and silt. The New River has been described as the most polluted river in the United States. Originating in Mexicali, Mexico, the New River flows across the border, through the City of Calexico, and continues north, where it empties into the Salton Sea. It conveys urban runoff, untreated and partially treated municipal and industrial wastes from the Mexicali Valley, and agricultural runoff from the Mexicali and Imperial valleys. These pollution sources contribute pesticides, pathogens, silt, nutrients, trash, and volatile organic compounds (the latter, primarily from Mexican industry) to the Salton Sea. The Alamo River, which originates two miles south of the border and also flows north to the Salton Sea, consists mainly of agricultural drainage from the Imperial Valley. The Coachella Valley Stormwater Channel, which also drains to the Salton Sea, is heavily contaminated at its north end with pathogens from municipal wastewater plants in the Coachella Valley and agricultural drainage.

A multiagency group, The Citizen's Congressional Task Force on the New River, was created in 1997. Its mission is to improve agricultural drain water quality that flows into the New River and, ultimately, to the Salton Sea. Participating agencies include the Imperial Irrigation District, Desert Wildlife Unlimited, County of Imperial, Reclamation, U.S. Geological Survey, USFS, DFG, California RWQCB, U.S. Environmental Protection Agency (USEPA), Ducks Unlimited, and U.C. Riverside. In 2000, the Task Force constructed two pilot wetland projects (a seven-acre site near Brawley and a 68-acre site near Imperial) to test the effectiveness of constructed wetlands in lowering non-point source pollutants. Due to the success of the pilot sites, up to 30 additional wetland sites are proposed on both the New and Alamo rivers.

Contamination in the Salton Sea presents threats to migrating birds on the Pacific Flyway. At certain times of the year, nutrient loading to the Salton Sea supports large algal blooms that contribute to odors, as well as low dissolved oxygen levels, which adversely affect fisheries. Selenium is a more recent constituent of concern, and has the potential to adversely affect fish and wildlife.

The relatively saline Colorado River provides irrigation and domestic water to much of southern California. USEPA first discovered low levels of perchlorate in the Lower Colorado River in 1997 from a Kerr-McGee chemical facility in the Las Vegas Wash, the nation's largest perchlorate contamination site. Cleanup of this site commenced in 2002 and has reduced perchlorate levels in the wash by 70 percent within the first two years (USEPA, 2004). Septic systems at recreational areas along the river are also a concern for domestic and recreational water uses.

Relationship with Other Regions

The Coachella Valley Water District and Desert Water Authority receive their annual allocations of SWP water through an exchange agreement with Metropolitan Water District of Southern California (MWD), the South Coast Hydrologic Region's largest water wholesale agency. These districts are also participants in another agreement that delivers and stores water from the Colorado River into the Coachella Valley's largest groundwater basin during periods of high flows.

7.2.2 Secondary Study Area

7.2.2.1 *Overview*

The water quality of the Sacramento River is affected by a variety of factors, including weather, geology, water storage projects (reservoirs), tributary streams, agricultural runoff, municipal and industrial discharges, and non-point sources, such as instream transport of stream-bottom sediments with elevated levels of heavy metals, and importation of water from other watersheds. Water quality in the mainstem of the Sacramento River is affected by releases from Shasta Dam, which forms Shasta Lake. Water quality in Shasta Lake is affected largely by three tributaries (McCloud, Pit, and Sacramento rivers) and the geochemical and biochemical processes occurring within the reservoir.

Many of the Sacramento River tributaries downstream from Shasta Dam are also regulated by reservoirs, which affects their water quality. Spring Creek Reservoir releases water to Spring Creek (contaminated with acid mine drainage), which is tributary to Keswick Reservoir. Clear Creek was impounded to form Whiskeytown Reservoir, through which water from the Trinity River is diverted into the Sacramento River drainage. Stony Creek has three reservoirs including East Park, Stony Gorge, and Black Butte. The mainstem of the Feather River is regulated by Oroville Dam. Upstream from Lake Oroville, the North Fork is regulated by Pacific Gas & Electric Company dams, and the South Fork is regulated by the South Feather Water and Power Agency. Further downstream, Englebright Narrows Dam controls releases to the Yuba River, and Rollins Reservoir controls releases to the Bear River. Releases to Cache Creek are controlled at Clear Lake, and the North Fork of Cache Creek is controlled by Indian Valley Reservoir. River flows in Putah Creek are controlled by the Solano Dam. Folsom and Nimbus dams control flows in the American River. All of these waterbodies flow into the Sacramento-San Joaquin Delta (Delta). The Delta includes rivers, islands and sloughs.

7.2.2.2 *Historic Water Quality of Reservoirs and Rivers*

The chemical quality of Sacramento River tributaries is directly related to the geology in the tributary drainage. Streams draining the igneous formations north and east of the Sacramento Valley are low in dissolved solids and electrical conductivity (EC)[6]. Streams from the coastal sedimentary formation are substantially higher in dissolved solids (salts), and therefore, exhibit higher EC values.

---

[6] Electrical conductivity (EC) is a measure of water's ability to conduct an electric current based on its dissolved salt content.

7.2.2.3 *Trinity River Basin Water Quality*

Trinity River water temperatures are influenced by Trinity and Lewiston reservoirs' release temperatures, flow rates, channel geometry, regional meteorology, and tributary flows and temperatures (the effect of Trinity and Lewiston reservoirs diminishes with distance downstream). Generally speaking, the greater the release volumes from the dams, the less susceptible the rivers temperature is to other factors. Trinity Reservoir releases tend to be cold (42°F to 47°F); whereas, Lewiston Reservoir, which is much shallower, tends to provide releases that are more affected by ambient temperatures.

During storm periods, turbidity in the Trinity River from Lewiston Dam to the South Fork is caused primarily by heavy inflows of suspended sediment from tributaries and the reservoirs. Highly erosive soils comprise approximately 17 percent of the Trinity River Basin, resulting in significant sediment loads entering the river. The reduced flows resulting from the construction and operation of the dams are partially responsible for sediment accumulation in the river. High flows, which historically flushed these sediments through the system, have become less frequent and of lower magnitude.

Elevated concentrations of mercury have been found in water, sediment, and biota (fish, frogs, and predatory aquatic insects) in the Trinity River Basin, similar to other river basins in California that have been subjected to historical gold mining operations (USGS, 2005). Sediment samples collected within and adjacent to some planned channel rehabilitation project sites of the Trinity River Restoration Plan contain mercury concentrations that are above what are considered naturally occurring levels.

Natural sources of mercury to the watershed may include wet and dry deposition of mercury from the atmosphere, and indigenous mercury that naturally occurs in rocks and soils. Some elemental mercury was likely introduced to the basin during gold mining operations. This elemental mercury was likely subject to chemical and biological processes that transform some of the elemental mercury into dissolved mercury phases that can become methylated. Sulfate-reducing bacteria in anaerobic environments are typically the source of methylation. The potential for methylation depends not only on solubility of mercury phases present, but also many other chemical variables, such as sulfate and organic carbon, and physical parameters such as temperature, pH, oxidation-reduction potential, and the bacterial community.

The primary source for gold in the Trinity River watershed is low sulfide quartz gold vein deposits. Gold in these deposits is commonly associated with pyrite and minor amounts of base metals. Weathering of these deposits may also cause locally elevated sulfate concentrations and enhance mercury methylation by exposure to sulfate-reducing bacteria. In the upper Trinity River Basin (upstream of Trinity Lake), the Altoona mercury mine in the East Fork Trinity River watershed releases mercury and sulfate that results in methylation of mercury and elevated levels of mercury in downstream plants and animals. Although natural mercury deposits are widespread in western California and are the source of mercury used in placer mining, the Altoona Mine is the only mercury mine in the Trinity Watershed. No information exists to indicate that methylmercury contamination from the Altoona Mine has migrated in significant amounts to areas downstream from Lewiston and Trinity dams, although some preliminary sampling efforts in the basin have been initiated.

Water quality in the lower Klamath River is regulated by the North Coast RWQCB. Standards for the Trinity River generally apply to the Klamath River because beneficial uses are similar, except that there are no time- and location-specific temperature objectives. Current water quality concerns in the Klamath River Basin are the result of agricultural practices, water management, timber harvesting activities, natural geologic instability, and mining operations. Water quality in the lower Klamath River can be influenced by dam releases from Iron Gate Dam on the Klamath River or dam releases from Lewiston

Dam on the Trinity River. Lower in the Klamath River, the effects of the high nutrient loads from the upper basin are typically diluted by tributary flow, including the Trinity River, the largest of its tributaries.

Lower Klamath River water temperatures may be influenced by releases from Iron Gate Dam. However, the Trinity River has a greater influence on water temperature of the Lower Klamath River than the releases from Iron Gate Dam. The two systems are different in that the coldwater storage of Trinity Reservoir is much greater than that of the upper Klamath River Basin reservoirs. Empirical data and a temperature model of the Trinity River has provided insight into the effects that variable Lewiston Dam releases may have on water temperatures at the confluence of the Klamath River at Weitchpec. Empirical data have shown the influence of a high Lewiston Dam release on Klamath River water temperatures. In June 1992, a 10-day Lewiston Dam release of 6,000 cubic feet per second (cfs) occurred and greatly influenced the temperature of the lower Klamath River. This release decreased temperature in the mainstem Klamath River (immediately downstream from the confluence) by nearly 4.5°F. Because 1992 was a Critically Dry water year, tributary accretion in both the Klamath and Trinity rivers was very small. As a consequence, the high release from Lewiston Dam resulted in the Trinity River becoming the dominant cold water source at the confluence. These interactions were confirmed during 2003 operations for late fall temperature maintenance.

Modeled dam releases from Lewiston Dam also provided assessments of the likely effects of releases on water temperatures at the confluence of the Klamath River during the spring and early summer. These evaluations focused on recommended flows identified in the analysis of alternatives, and the following generalities were identified from this evaluation. First, the model predicted that high-level releases can result in Trinity River water temperatures being colder than the Klamath River. Conversely, low-magnitude releases can result in Trinity River water temperatures becoming warmer than the Klamath River in the lower reaches. The main factor that can offset temperature differentials is likely the quantity of tributary accretion. When the Lewiston Dam release is large during Drought conditions (low tributary accretion) or small during Wet conditions, the temperature differentials become greatest. Marked temperature differentials may have a harmful effect on sensitive fishery resources. When dam release magnitudes are matched to emulate pre-TRD hydrologic conditions, the differences are lessened.

7.2.2.4 *Shasta Lake and Vicinity Water Quality*

Water quality in this portion of the Secondary Study Area generally meets the standards for beneficial uses identified in the Central Valley Basin Plan. The quality of surface waters in Shasta County is generally considered good. The following nonpoint pollution sources could affect surface water quality: high turbidity from controllable sediment discharge sources (e.g., land development and roads); high concentrations of nitrates and dissolved solids from range and agricultural runoff or septic tank failures; contaminated street and lawn runoff from urban areas, roads, and railroads; and warmwater discharges into coldwater streams.

The surface water quality of streams and lakes draining the Shasta-Trinity National Forest (STNF) and adjacent private lands generally meets standards for beneficial uses defined by the Central Valley Basin Plan. There are, however, some areas where the water quality does not meet the standards during periods of stormwater runoff because of past management activities. The cumulative impacts of successive activities, such as road construction and timber harvesting on private and National Forest lands, also contribute to the degradation of water quality in the STNF (USFS, 1995).

Approximately 6.2 million acre-feet of water flows annually into Shasta Lake from the Sacramento, McCloud, and Pit River drainages. A favorable inflow-outflow relationship of 1.4 to 1 results in good water quality, both in the lake and downstream (Reclamation, 2011).

Nutrient inputs and bacteria are not of concern in the Sacramento River and McCloud River arms (Reclamation, 2011); however, they could be an issue in the Pit River Arm as a result of runoff from agricultural and range lands in the upper Pit River watershed. Within Little Backbone Creek, Dry Creek, and the Squaw Creek Arm, the waters are locally limited by low pH and elevated concentrations of heavy metals caused by drainage from abandoned mines (Reclamation, 2011). In addition, data suggest that sediment and turbidity locally affect beneficial uses, mainly contact recreation.

7.2.2.5 *Sacramento River Water Quality – Upper Reach*

Shasta Lake is a major controlling factor of water quality in the upper reach (Keswick Dam to Red Bluff Diversion Dam [RBDD]) of the Sacramento River. The main source of water in the Sacramento River downstream from Keswick Dam is snowmelt that collects in upstream reservoirs and is released in response to water needs or flood control. The quality of surface water downstream from Keswick Dam is also influenced by other human activities along the Sacramento River downstream from the dam, including agricultural, historical mining, and municipal and industrial inputs (Reclamation, 2011).

Water quality in the Sacramento River is relatively good. Only during conditions of stormwater-driven runoff are water quality objectives typically not met. Water quality issues within the upper reach of the Sacramento River include the presence of mercury, organochlorine pesticides, trace metals, turbidity, and toxicity from unknown origin (CALFED as cited in Reclamation, 2011). Nutrients, such as nitrate, were found to be low throughout the Sacramento River basin. Water temperature is a principal water quality issue in the upper reach of the Sacramento River.

Significant tributaries flowing to the Sacramento River in this reach include Cow, Bear, Battle, and Paynes creeks from the east, and Spring, Clear, and Cottonwood creeks from the west. Since full operation of the TRD began in 1964, an average of 74 percent of the basin's inflow to the TRD (approximately 988,000 acre-feet) has been exported to the CVP annually. As of 2000, annual exports have decreased to an average of 732,400 acre-feet (Reclamation, 2000). Major discharges to the upper Sacramento River include treated sewage from the cities of Redding, Anderson, and Red Bluff. Industrial discharges are limited; the only significant potential discharge occurs from the Sierra Pacific Industries lumber mill located near Anderson. Previous significant industrial discharges had occurred from the Simpson Lee Paper Products mill located near Anderson, from which dioxin was discharged to the river.

Water temperatures in the upper reach during the summer are substantially cooler than prior to construction of Shasta Dam due to deep water releases from the reservoir made possible by the installation of a Temperature Control Device (TCD). The Shasta TCD was first operated in 1997. Winter temperatures are warmer than pre-Shasta Dam conditions due to heat stored in the reservoir. The combined effects of heat trapped during cool months and deep water releases during warm months have narrowed the seasonal range of temperatures in the upper reach of the Sacramento River Winter and spring river temperatures are relatively constant from Keswick Dam to Red Bluff, and summer and fall temperatures increase with distance downstream.

Settling of particulate matter in Shasta Lake results in low levels of suspended solids, turbidity, and discoloration (a narrative aesthetic criteria), in the river downstream from Keswick Dam (DWR, 1962, 1970). Lowest turbidity in this reach of the river occurs under low flow conditions during the summer and early fall, but increases slightly as the river flows from Keswick Dam to Red Bluff (DWR, 2012). Turbidity spikes occur during major storms, with the largest inputs coming from major tributaries (such as Cottonwood Creek) and bank erosion.

The pH in the upper reach generally ranges from approximately 6.6 to 8.0 (DWR, 2012). The pH remains relatively constant from Keswick Dam to Red Bluff, with no readily apparent seasonal trends.

EC in the tributaries to the upper reach of the Sacramento River is highest during low flow conditions of late summer and early fall due to dissolution of minerals in the substrate, and lowest during winter and spring due to dilution from higher flows. EC in the upper Sacramento River is controlled by water quality in Shasta Lake. It is lowest in the summer months and peaks occur during the winter (DWR, 2012). Highest EC occurs in the deeper waters during the winter, and lowest values occur in the summer (DWR, 2012). Higher EC in the winter in the reservoir is the result of increased mineralization from turbid tributary inflows, and lower EC during the summer occurs due to settling of materials from the water column.

Dissolved oxygen concentrations in the upper river are usually high, ranging from 9.5 to 12 milligrams per liter (mg/L) near Redding with greater than 95 percent saturations (DWR, 1962).

Nutrient levels are generally low in the upper reach of the river (DWR, 1970, 1973). Lowest levels of total phosphorus occur during the summer months, which may be due to uptake of nutrients by periphyton[7]. Total phosphorus was not found at levels exceeding 0.05 mg/L for this reach of the river.

One of the major sources of water quality degradation in this reach of the river stems from heavy metal contamination from acid mine drainage upstream from Keswick Dam. Heavy metals and acid are released by oxidation of massive fine-grained sulfide ores in abandoned surface mines, subsurface mines, and tailings. the resultant acidic solution causes further dissolution of heavy metals from the ores. Periodic fish kills investigated by the California Fish Commission since 1899 have been attributed to extremely acidic waters with high concentrations of iron, copper, zinc, cadmium, aluminum, and other heavy metals (USEPA, 2006).). Several tributaries to Shasta and Keswick reservoirs carry high concentrations of dissolved metals. As of 2006, acid mine drainage still escaped untreated from waste piles and seepage on the north side of Iron Mountain and flowed into Boulder Creek. USEPA continues to investigate and plan future actions to control acid mine drainage in the Boulder Creek catchment.

In 1983, USEPA placed the Iron Mountain Mine (IMM), which is the principal discharger of acid mine drainage in the Spring Creek watershed, on the National Priorities List (Superfund Site), and initiated actions to prevent formation of acid mine drainage. The acid mine drainage from IMM is among the most acidic and metal-laden anywhere on Earth. In 1989, USEPA removed tailings to a disposal cell near the top of Iron Mountain, and in 1994 a water treatment plant was built at Minnesota Flats. This facility, which has been expanded and upgraded since it was first constructed, uses lime (calcium oxide, CaO) to neutralize the acid. USEPA estimates that these cleanup actions control more than 99 percent of the copper, cadmium, zinc, and other metals that historically discharged to the Sacramento River. USEPA is now focusing actions on removing sediments contaminated by the previous acid mine discharges from the Spring Creek arm of Keswick Reservoir (USEPA, 2006).

[7] Periphyton are micro-organisms attached to, and living on, submerged solid surfaces and are useful indicators of water quality.

7.2.2.6 *Sacramento River Water Quality – Middle Reach*

The middle reach (RBDD to Colusa) of the Sacramento River flows mostly through recent alluvium and has formed a floodplain that ranges from one to five miles wide. The gradient decreases from approximately 2.5 feet per mile at Red Bluff to 1.3 feet per mile near Colusa. A regular riffle-pool sequence is evident in unaltered areas, but is less apparent in the river downstream from Princeton. The riverbed is essentially gravel and cobble in the upper portions of this reach, with gravel becoming less apparent downstream from the confluence of Stony Creek at river mile (RM) 190. Near Colusa, the riverbed is predominantly coarse sand with gravel occurring in crossover areas (DFG, 1982).

Tributary inflows of some significance in the middle reach of the Sacramento River include Antelope, Mill, Deer, and Big Chico creeks from the east, and Elder, Thomes, and Stony creeks from the west. Agricultural diversions are common in this reach of the river. Some of the major diversions include the Corning, Tehama-Colusa (T-C), Glenn-Colusa Irrigation District (GCID), Provident Irrigation District, and River Branch canals. In addition, several smaller diversions by private farming interests are present in this reach.

Winter water temperatures in the middle reach generally range from 45°F to 50°F (DWR, 2012) and decline in a downstream progression (DWR, 1962). Water temperatures in this reach during the rest of the year are higher than those in the upper reach and increase as the river flows from Red Bluff to Colusa. The most dramatic increases in temperatures predictably occur during warm periods with low flow (late summer and early fall). In addition, seasonal and diurnal fluctuations of water temperatures in this reach are greater than the upper reach, which is due largely to the river moving toward equilibrium with atmospheric conditions as it flows further from Shasta Reservoir.

Suspended solids, turbidity, and discoloration have been found to increase in a downstream progression (DWR, 1962, 1970, 1973). However, during late summer and early fall, when turbidities are lowest, the trend is far less evident. Turbidity levels are highest during the winter and early spring, due to tributary runoff and bank erosion from higher flows (DWR 1970, 1973). Some of the highest suspended solids levels observed were found early in the winter of 1978, with some levels showing a five-fold increase over historic data. This was due largely to heavy accumulations of sediments that occurred during the drought years of 1976 and 1977 (DWR, 1979).

The median pH of this reach of the river was found to be 7.3 (DWR, 1962); data collected from 1998 to 2012 show that pH ranges from 6.3 to 8.4 (DWR, 2012). The pH of the middle reach is slightly greater than the upper reach, particularly during late summer and early fall.

EC continues to increase in a downstream progression in this reach, with levels nearly always higher in this reach than in the upper reach (DWR, 2012). Data collected from 1998 to 2012 show EC in the upper reach ranging from 79 to 136 µmhos/cm, while ranging in the middle reach from 81 to 170 µmhos/cm. Typically, lowest EC in the river occurs during the summer, and highest levels occur in the winter. This seasonal difference in EC appears to be related to the limnology and operation of Shasta Reservoir. However, hydrologic factors operating in various years can alter this pattern. In 1960 to 1961, EC was lowest during the spring due to dilution from snowmelt runoff (DWR, 1962). In 1970, lowest EC levels in the river occurred during a series of January storms that caused excessive flooding, which resulted in dilution of mineral loads.

Nutrient levels tend to increase during the winter and in a downstream direction (DWR, 1970, 1973). Total phosphorus levels were nearly always higher in the middle reach than the upper reach of the Sacramento River.

7.2.2.7 *Sacramento River Water Quality – Lower Reach*

Water quality in the lower reach (Colusa to Verona) of the Sacramento River is affected by agricultural runoff, acid mine drainage, stormwater discharges, diversions, urban runoff, and water releases from dams. However, the flow volumes generally provide sufficient dilution to prevent excessive concentrations of contaminants in the river.

Several TMDLs are currently proposed for the lower reach of the Sacramento River. In addition, the Sacramento River downstream from RBDD to Knights Landing is listed as an impaired water body pursuant to Section 303(d) of the Clean Water Act (CWA) for mercury and unknown toxicity.

Elevated metals and pesticide levels have been found at some sites in the Sacramento River Valley downstream from Knights Landing. The parameters of concern in the Sacramento River from Knights Landing to the Delta include diazinon, mercury, and unknown sources of toxicity (SWRCB, 2007).

The Colusa Basin watershed covers approximately 1 million acres in Glenn, Colusa, and Yolo counties (WRA, 2007). The Colusa Basin Drain (CBD) is designed to convey drainage flows from agricultural lands and 32 ephemeral streams during the irrigation season to the Knights Landing outfall gates and stormwater flows during the winter. The Colusa Bain Drain drains approximately 1,620 square miles in the Sacramento Valley, and includes portions of Glenn, Colusa, and Yolo counties. The Canal starts in Glenn County northeast of the city of Willows and runs in a southerly direction for 70 miles to Knights Landing in Yolo County.

Water quality in this reach is influenced by agricultural drainage and the Feather River. Significant quantities of suspended sediments, turbidity, dissolved solids, minerals, and nutrients, as well as pesticides in some cases, are added to the Sacramento River via the CBD. The fifth Annual Monitoring Report for the Sacramento River Watershed Program (SRWP, 2004) reported monitoring results collected from 1997 to 2003. Drinking water parameters of potential concern included in the SRWP monitoring program include organic carbon, total dissolved solids, pathogens, turbidity, and nutrients. Organic carbon is of concern primarily due to its role in the creation of carcinogenic trihalomethanes (THMs) and other disinfection by-products during disinfection of source water.

Total dissolved solids (TDS) can have an important effect on the taste and palatability of drinking water, and at very high levels may cause health problems in sensitive individuals. The presence of high levels of TDS may also be objectionable to consumers owing to the resulting excessive scaling in water pipes and fixtures, heaters, boilers, and household appliances.

The highest concentrations of most drinking water parameters of concern were generally observed in agricultural drains (Sacramento Slough and CBD) and in urban drainages and creeks (Natomas East Main Drain, Arcade Creek) (SRWP, 2004). Concentrations of methylmercury in particulate matter (expressed as nanograms of particulate methylmercury per gram of suspended solids) in the mainstem exhibit no apparent spatial trend between Hamilton City and Greene's Landing (SRWP 2004). The CBD and Sacramento Slough exhibited methylmercury concentrations in particulates that were similar to the lower mainstem Sacramento River, but with much higher concentrations of suspended solids. Concentrations of methylmercury in particulates were dramatically higher in the major tributaries than in the mainstem.

The Feather River provides a substantial quantity of high quality water that generally meets the standards for beneficial uses identified in the Central Valley Basin Plan, to the Sacramento River. The Feather River originates in the volcanic formations of the Sierra Nevada Range and flows southwest to Oroville, where it is impounded behind Oroville Dam. The dam provides coldwater releases to the Feather River from deep within Lake Oroville, a thermally stratified lake. From Oroville, the Feather River flows south through the Sacramento Valley where it is joined by two major tributaries. The Yuba River joins the Feather River at Marysville; the Bear River has its confluence approximately 15 miles farther downstream. The Feather River then joins the Sacramento River at RM 80. The Feather River is generally lower in turbidity, suspended solids, dissolved solids, EC, and nutrients than the Sacramento River (DWR, 2004).

Water temperatures in this reach of the Sacramento River continue to increase in a downstream progression, except during the winter months when temperatures either decline slightly or hold fairly constant as the river flows downstream (DWR, 1962). During most of the year, water temperatures increase downstream from the CBD outfall (and then decline downstream from the Feather River confluence (USGS, 1978, as cited in DWR, 1986). The Feather River is warmer in August than the Sacramento River, resulting in continued warming downstream from their confluence (USGS, 1978, as cited in DWR, 1986).

Seasonal and diurnal temperature fluctuations are greater in this reach than in the upper two reaches (DWR, 2004). Temperatures in this reach have varied from 48°F in January 1984 to 71°F in August 1983.

Turbidity, as well as suspended solids and color, are also greater in this reach than in the upper reach, which is due largely to irrigation return flows, erosion, and algal production (DWR, 1962). However, the pattern is less evident during the late summer and early fall when flows and turbidities are lowest. Highest turbidity levels occur during periods of high rainfall and increased flows (DWR, 1970). The increase in turbidity as the Sacramento River flows downstream is interrupted at the confluence with the Feather River. The inflowing low turbidity water of the Feather River results in decreased turbidity in the Sacramento River downstream from their junction. Turbidity in this reach has been found to range from 2.5 FTUs8 in October to 46 FTUs during a storm in late November.

Monitoring results from the 2011 Annual Monitoring Report (AMR) of the Sacramento Valley Water Quality Coalition identified several herbicides and pesticides above laboratory detection levels including disulfoton from Sacramento Slough at Karnak, and Malathion, methomyl metolachlor, oxyfluorofen, simazine, and chlorpyrifos from the CBD at Highway 20 (SVWQC, 2012). However, these levels did not exceed Central Valley Basin Plan criteria or result in exceedences of sediment toxicity thresholds. The report identified three monitoring events when dissolved oxygen levels failed to meet objectives to protect the COLD beneficial use (7.0 mg/L), and one that failed to meet the WARM beneficial use goal (5.0 mg/L). On four monitoring events at the CBD at the Highway 20 location, measured EC levels failed to meet the Agricultural goal of 700 μmhos/cm, with two of these events also exceeding the California recommended 2° Maximum Contaminant Level of 900 μmhos/cm for drinking water. Monitoring results for E. coli, nutrients, pH, and trace metals met relevant Central Valley Basin Plan goals.

EC in this reach follows a pattern similar to the upper two reaches. Historical data indicate that EC is generally higher in the winter and lower in summer. However, hydrologic conditions interrupt this pattern from time to time. EC in 1970 was lowest during a January flood (DWR, 1970), but has been lowest at

---

8 The most widely used measurement unit for turbidity is the FTU (Formazin Turbidity Unit).

other times in the spring due to heavy runoff from snowmelt (DWR, 1962). In addition, agricultural practices in this reach may interrupt the seasonal pattern. EC was found to increase substantially during mid-September 1983, which corresponds to the period that rice fields were drained for harvest. EC during 1983 and 1984 ranged between 115 and 175 µmhos/cm.

EC in the lower reach of the river is greater than in the upper two reaches (DWR 1970, 1973). Substantial increases have been noted downstream from the CBD outfall.

DWR (1990) indicated that irrigation return waters increase EC in the river during most of the year, except during the spring.

The trend of increasing EC as the river moves downstream is interrupted at the confluence with the Feather River. The Feather River has lower EC than the Sacramento River, which results in lower EC in the Sacramento River downstream from the confluence with the Feather River (DWR, 1962, 1970, 1973). Nutrient concentrations in this reach tend to increase in a downstream progression, but decrease downstream from the confluence of the Feather River (DWR, 1970, 1973). Phosphorus and carbon concentrations are higher in the Sacramento River than in the Feather River. Nutrient concentrations are nearly always higher in the agricultural drains than the mainstem and result in increased concentrations in the river downstream from their outfalls.

Dissolved oxygen fluctuates more in this reach than in the upper reaches (DWR, 2004), which is due largely to seasonal temperature regimes. Concentrations of oxygen are highest in the winter when temperatures are lowest, and are lowest in the summer when temperatures are highest. Dissolved oxygen concentration decreases slightly downstream, due to increased temperatures and increased waste discharges (DWR, 1962). The Feather River, for the most part, has higher concentrations of oxygen than the Sacramento River. However, during low flow conditions, when the Feather River sometimes becomes warmer than the Sacramento River, dissolved oxygen may be higher in the Sacramento River. The diurnal dissolved oxygen cycle in this section of the river follows a predictable pattern. During August, oxygen concentrations increase in the afternoon due to photosynthetic activity and then decline at night (USGS,1978, as cited in DWR, 1986). Similar trends are seen in the Feather River during the same period. During November, however, no clear diurnal dissolved oxygen cycles were observed in the Feather River and Sacramento River downstream from the Feather River. Dissolved oxygen levels never declined significantly, indicating no waste assimilation problems in this reach.

7.2.2.8 *Lower Feather River Water Quality*

The quality of water in Lake Oroville is affected largely by upstream tributaries. Water released from Oroville Dam determines water quality downstream in the Feather River, which subsequently determines water quality in the Thermalito Forebay and Afterbay (DWR, 2004).

Thermal stratification during the summer in Lake Oroville occasionally leads to reduced dissolved oxygen conditions near the bottom of the water column. Nutrients and minerals in the reservoir were found at levels consistent with existing and proposed criteria, except for total phosphorus, which was occasionally at levels exceeding concentrations in the upstream tributaries and recommended water quality criteria. Metals exceeding various criteria in the reservoir included arsenic, aluminum, copper, iron, manganese, and lead. However, these and other metals are contributed to the reservoir in concentrations exceeding various criteria by the upper tributaries.

Water temperatures downstream from Oroville Dam are controlled by temperature requirements at the Feather River Fish Hatchery and Robinson Riffle. Releases are made from the reservoir to provide temperatures suitable for fish propagation at the hatchery, which also generally meets temperature requirements at Robinson Riffle. Water released from the reservoir to comply with fishery temperature needs conflicts with temperature requirements for other beneficial uses, such as irrigation.

Water quality in the Feather River downstream from Oroville Dam is affected by the reservoir. Dissolved oxygen levels in the Feather River are infrequently found at levels less than those suitable for beneficial uses. Turbidity levels in the river downstream from the dam are less than those measured in tributaries to Lake Oroville, indicating that the reservoir acts as a settling basin for the turbid inflows. Nutrients and minerals downstream from Oroville Dam are at levels suitable for all beneficial uses. Metals in the Diversion Pool at the base of the dam reflect the quality of water in the reservoir near the dam. Further downstream, accretions to the river from tributaries, storm drains, surface runoff, and other sources affect water quality in the river. Metals occasionally exceeding various criteria in the Feather River downstream from the Fish Barrier Dam include aluminum, arsenic, cadmium, copper, iron, and mercury.

Metals occasionally exceeding criteria in features of the Thermalito Complex include aluminum, arsenic, cadmium, iron, manganese, and lead. Some ponds in the Oroville Wildlife Area also occasionally were found with reduced oxygen levels, and elevated levels of aluminum, arsenic, iron, and manganese.

Pesticides are not found in the lower Feather River, though diuron was found upstream from Lake Oroville in the South Fork Feather River. MTBE was detected in the Diversion Pool.

Both total and fecal coliform bacteria are found from all water quality monitoring sites, but only fecal coliform bacteria exceed criteria. Total and fecal coliform and enterococcus bacteria are found at all swim areas and are present at some swim areas at densities greater than criteria. In addition to human contact with water, high wildlife use of the swim areas could contribute bacterial contamination.

The phytoplankton communities in Lake Oroville and the Thermalito Complex are dominated by diatoms; green algae are dominant in ponds in the Oroville Wildlife Area. Periphyton communities in the river are also generally dominated by diatoms, which are indicative of aquatic ecosystems that are not nutrient rich.

Aquatic macroinvertebrates in the Feather River are dominated by species that adapt readily to disturbed ecosystems. The species composition in the river near the dam is typical of that downstream of large reservoirs. Further downstream, habitat conditions allow additional species to colonize.

Sites both upstream and downstream from Lake Oroville produced toxic effects to test organisms in bioassays. Both survival and reproduction of *Ceriodaphnia* (a water flea) and survival and growth of fathead minnow are affected.

Total suspended and settleable solids are usually reported at very low levels in both upstream tributaries and the lower Feather River. Highest total suspended and settleable solids levels are usually found during winter months.

Water quality in the Feather River is potentially affected by treated sewage discharged through the Sewage Commission Oroville Region (SCOR) Outlet to the Feather River downstream from the Afterbay Outlet. Monitoring of gravels and water upstream and downstream from the SCOR Outlet produce variable results.

Periphyton and macroinvertebrate communities in the tributaries to Lake Oroville are indicative of healthy ecosystems. Both periphyton and macroinvertebrate communities are similar to those found in the Feather River downstream from Oroville Dam in the low-flow section, as well as other streams in which anadromous salmonids spawn. Comparisons of the periphyton and macroinvertebrate communities in the upper tributaries with communities in the low-flow channel and other streams do not indicate that the upstream tributaries suffer from nutrient deprivation due to purported blockage of salmonid spawning in the upper tributaries caused by Oroville Dam.

7.2.2.9 *Lower American River Water Quality*

Surface water quality in Folsom Reservoir, Lake Natoma, and the lower American River depends primarily on the mass balance of various water quality constituents from groundwater inputs, tributary inflow, permitted discharges from municipal and industrial sources, indirect watershed runoff (unchannelized flow), urban runoff, and stormwater discharges (Reclamation, 2009). Water quality varies somewhat among years and seasonally within a year, based primarily on these and related factors. The South Fork American River, which contributes to Folsom Reservoir and Lake Natoma, is listed as impaired for mercury; the American River segment from Nimbus Dam to the confluence with the Sacramento River is listed as impaired for both mercury and unknown toxicity.

Historically, water quality parameters for the lower American River have typically been well within acceptable limits to achieve water quality objectives and beneficial uses identified for this waterbody and remain so today. Principal water quality parameters of concern for the river (e.g., pathogens, nutrients, total dissolved solids (TDS), total organic carbon (TOC), priority pollutants, and turbidity) are primarily affected by urban land use practices and associated runoff and stormwater discharges. The stormwater discharges to the river temporarily elevate levels of turbidity and pathogens during and immediately after storm events. TOC and TDS levels in the lower American River are, however, relatively low compared to Sacramento River and Delta waters, and thus, are generally not of substantial concern.

Although urban land use practices, urban runoff, and stormwater discharges all contribute priority pollutants to the river, monitoring results conducted from 1998 to 2001 by the Sacramento River Watershed Program did not identify any priority pollutant at concentrations consistently above State water quality objectives (SRWP, 2004). However, water quality objectives for dissolved oxygen, temperature, and pH are not always met in the lower American River. Finally, taste and odor problems occasionally arise (generally during the late summer months) in the domestic water supplies taken from the lower American River at the Fairbairn Wastewater Treatment Plant.

Water released from Folsom Reservoir through Lake Natoma and into the lower American River can affect several water quality parameters in the river. In addition, operation of Folsom Dam and Reservoir directly affects lower American River temperatures throughout much of the year. Water temperatures in the lower American River are often unfavorably high for salmonids during the summer and fall months of the year. Elevated river temperatures can be particularly problematic to the river's salmonid resources during low-flow conditions, which occur during the drier years.

7.2.2.10 *Sacramento-San Joaquin Delta Water Quality*

Water quality in the Delta is highly variable temporally and spatially and is a function of complex circulation patterns that are affected by inflows, pumping for Delta agricultural operations and exports, operation of flow control structures, and tidal action. The existing water quality problems of the Delta system may be categorized as the presence of toxic materials, nutrient enrichment (eutrophication), and associated fluctuations in dissolved oxygen, the presence of suspended sediments and turbidity, salinity, and the presence of bacteria (Reclamation, 2011).

The Delta waterways within the area of Central Valley RWQCB's jurisdiction are listed as impaired on USEPA's 303(d) list for dissolved oxygen, EC, DDT, mercury, Group A pesticides, diazinon and chlorpyrifos, and unknown toxicity (SWRCB, 2007). The Delta, which is within the jurisdiction of the San Francisco Bay RWQCB, is listed as impaired for mercury, chlordane, selenium, DDT, dioxin compounds, PCB compounds, dieldrin, diazinon, exotic species, and furan compounds (SWRCB, 2007).

Organic carbon in the Delta originates from runoff from agricultural and urban land, drainage water pumped from Delta islands that have soils with high organic matter, runoff and drainage from wetlands, wastewater discharges, and primary production in Delta waters. Delta agricultural drainage can also contain high levels of nutrients, suspended solids, organic carbon, minerals (salinity), and trace chemicals, such as organophosphate, carbamate, and organochlorine pesticides.

Water temperatures and dissolved oxygen levels in the Delta and Lower San Joaquin River can act as a barrier to salmon migration and survival, and introduced aquatic invasive species and Delta pumping for export also affect native aquatic species survival.

Applicable California RWQCB impaired waters for the Secondary Study Area include SWRCB Regions 1 and 5 are listed in Appendix 7A. Applicable Central Valley Basin Plan water quality criteria (CVRWQCB, 2011) are listed in Appendix 7B.

7.2.3 Primary Study Area

7.2.3.1 *Overview and Methodology*

The proposed Project features are located in Glenn and Colusa counties west of the Sacramento River, and extend into the Coast Range foothills. Elevations within these counties range from approximately 35 feet along the Sacramento River to 3,000 feet in the foothills. This area is characterized by seasons of hot dry summers and moderately cold moist winters. Summer temperatures commonly exceed 100°F. Approximately 95 percent of the annual precipitation occurs during the winter months. Precipitation ranges from approximately 18 inches per year on the valley floor, 21 inches per year at Stony Gorge Reservoir, and 51 inches per year at the upper elevations of the Coast Range crest. Precipitation generally approaches the area from the west, is highest at the Coast Range crest, and diminishes as elevations drop toward the Sacramento Valley in a "rain-shadow" effect.

The proposed Sites Reservoir would impound Stone Corral and Funks creeks, as well as inundate Salt Lake. The chemical quality of waters in this area is directly related to the geology in the tributary drainage, as well as agricultural and cattle grazing land uses. Streams from the coastal sedimentary formation are substantially higher in dissolved solids and EC than the Sacramento River.

DWR began monthly sampling of streams in the Primary Study Area in 1997, including physical parameters, nutrients, minerals, and metals in the water column (DWR, 2012), as well as mercury analysis of sport fish tissues collected from nearby existing reservoirs, including East Park, Stony Gorge, and Black Butte (DWR, 2007). Routine water quality monitoring by DWR was periodically suspended due to funding limitations during portions of 2008 and 2009, and ended following the January 2010 monitoring run. Sampling results were then compared to Central Valley Basin Plan water quality criteria (CVRWQCB, 2011) (Appendix 7B) and USEPA ambient water quality criteria to prevent nuisance algal growth in streams (USEPA, 2001).

7.2.3.2 *Water Quality*

Existing Nearby Reservoirs

East Park and Stony Gorge reservoirs were sampled during the summer of 2000 to evaluate the extent of mercury contamination in fish because these reservoirs are representative of conditions that could be expected in the proposed Sites Reservoir. DWR analyses of total recoverable mercury indicate that levels in samples collected near the bottom of the water column at Stony Gorge and Black Butte reservoirs,exceeded the California Toxics Rules (CTR) for protection of human health. Methylmercury is assumed to be the form of mercury available for bioaccumulation in the food web. Most mercury in fish tissues is in the methylmercury fraction. Total mercury, however, is typically analyzed from fish tissue and is assumed to represent the methylmercury content of tissues.

Fish tissue samples were collected by DWR from East Park and Stony Gorge reservoirs during 2000 to 2001. Neither catfish nor bass composites collected from East Park Reservoir exceeded the OEHHA screening value or USEPA criterion, although mercury levels in the small-sized bass approached these values, and a very large channel catfish that was analyzed individually contained tissue mercury at over twice the level of the screening value and criterion limits. Mercury concentrations in tissues of channel catfish collected from Stony Gorge Reservoir contained levels less than the screening value and criterion (DWR, 2007).

Salt Lake

Salt Lake, located within the proposed Sites Reservoir inundation area, is a 28-acre area of impounded water and seasonal wetlands formed by warm salt springs that occur upslope Salt Lake was sampled on a few occasions during 1997 to 1998; therefore, it is difficult to make an assumption regarding the quality of water from this location. From these samples, it was found that waters from this location are extremely high in minerals. The EC value on one occasion reached 194,100 micromhos per centimeter. The TDS measurement at this time was 258,000 mg/L. EC, TDS, sodium, and boron exceeded all Central Valley Basin Plan criteria. A few metals also were noted at very high concentrations (aluminum, iron, and manganese) and exceeded all criteria, and a few others exceeded some criteria (arsenic, copper, lead and nickel). Levels of ammonia and orthophosphate also were noted at high levels and exceeded criteria. Temperatures from this site were variable, and probably depend on seasonal conditions. Concentrations present in water from this site likely depend on the season and flow.

Funks Creek

Funks Creek originates at approximately 850 feet elevation in the foothills west of Antelope Valley. The banks of this intermittent stream are heavily eroded and the gravel bed is highly disturbed and compacted by cattle. Along the north end of Antelope Valley, Funks Creek receives underground drainage from Salt Lake. Funks Creek widens as it cuts through Logan Ridge and enters the western side of the Sacramento Valley, although flows are still intermittent. Approximately one mile downstream from Logan Ridge, Funks Creek is impounded by Funks Reservoir. This reservoir is fed mainly from waters of the T-C Canal. Downstream from the reservoir, Funks Creek is bordered by agricultural lands, and much of this reach is channelized before emptying into Stone Corral Creek. This portion of Funks Creek likely has some flow year round, due to leakage from the dam at Funks Reservoir.

DWR identified total aluminum levels that exceed Central Valley Basin Plan criteria for protection of aquatic life at the Funks Creek at GCID Canal station. The highest levels of total aluminum were present during storm-related high flow events occurring in the winter months. Arsenic levels consistently met the final USEPA arsenic rule establishing a new MCL of 10 µg/L for total arsenic. However, all water samples analyzed for arsenic from this stream exceeded the much lower California Public Health Goal of 0.004 µg/L. Although copper levels did not exceed criteria in Funks Creek, due to high water hardness, the levels were elevated and would contribute to copper loads imported to the reservoir from Sacramento River diversions. Total recoverable iron levels in Funks Creek ranged as high as 25,200 µg/L during storm-related high flow events. Iron levels also exceeded drinking water, agricultural water, and aquatic life protection criteria. Dissolved iron concentrations were generally below the Central Valley Basin Plan objective. Total recoverable manganese levels occasionally exceeded drinking water standards in Funks Creek, and the Agricultural Goal was rarely exceeded. DWR analyses of total recoverable mercury in Funks Creek indicated levels approached, but did not exceed, the CTR of 50 nanograms per liter (ng/L) for protection of human health. Total recoverable nickel levels in Funks Creek occasionally exceeded the Public Health Goal; total phosphorus levels were at or above the recommended criteria range of 10 to 20 µg/L to prevent excess algal growth.

Stone Corral Creek

Stone Corral Creek originates at approximately 700 feet elevation in the foothills west of Antelope Valley. As the intermittent stream flows into the grasslands of Antelope Valley, the channel is narrow and the banks eroded. The much larger Antelope Creek flows into Stone Corral Creek from the south near the town of Sites. Stone Corral Creek flows through the gap in the foothills and into the western Sacramento Valley.

DWR identified total aluminum levels that exceeded criteria for protection of aquatic life at the Stone Corral Creek near Sites station. As was described above for Funks Creek, samples from Stone Corral Creek also consistently met the final USEPA arsenic rule, and all samples were found at levels that exceeded the Public Health Goal. Stone Corral Creek had hardness levels much higher than found in Funks Creek. Copper levels analyzed from Stone Corral Creek exceeded the hardness-dependent criteria twice. The Central Valley Basin Plan level for dissolved copper was not exceeded in Stone Corral Creek samples.Total recoverable iron levels in Stone Corral Creek ranged as high as 7,420 µg/L during storm-related high-flow events, and occasionally exceeded drinking water and aquatic life criteria, as well as agricultural goals. Dissolved iron concentrations were generally below the Central Valley Basin Plan objective. Total manganese levels occasionally exceeded drinking water standards and very rarely exceeded the Agricultural Goal.

As described for Funks Creek, total recoverable mercury measured in Stone Corral Creek did not exceed any criteria. Nickel levels rarely exceeded the Public Health Goal, and nearly half of the samples collected exceeded the aquatic life criterion for total selenium. Total phosphorus levels measured in Stone Corral Creek ranged as high as 450 µg/L during a sampled high flow event. All samples contained total phosphorus at levels at or above the recommended criteria range to prevent nuisance algal growth in streams.

Tehama-Colusa Canal

The intake for the T-C Canal occurs at the southeast end of the City of Red Bluff at RM 243. The intake occurs downstream from the mouth of Red Bank Creek at the RBDD. The T-C Canal is approximately 111 miles long and extends from Red Bluff in Tehama County to downstream from Dunnigan in Yolo County. Funks Reservoir is approximately 66 canal miles downstream from RBDD.

DWR sampled the T-C Canal downstream from the siphon under Stony Creek. Aluminum levels rarely exceeded criteria for drinking water, aquatic life protection, and the agricultural goal. Arsenic levels exceeded human toxicity criteria during all sampling events, and cadmium levels rarely exceeded human toxicity criteria. Iron levels in the canal occasionally exceeded drinking water standards. All samples contained total phosphorus at levels at or above the recommended criteria range to prevent nuisance algal growth in streams.

Glenn-Colusa Irrigation District Canal

The intake for the GCID Canal is on a side channel off the Sacramento River at RM 205.5, north of the town of Hamilton City. GCID's Hamilton City pump station, located at the intake, diverts water into the GCID Canal from the Sacramento River for distribution within the GCID service area. The canal is an unlined earthen channel that stretches approximately 65 miles from the system diversion point near Hamilton City to its downstream southern terminus at the CBD near Williams, in Colusa County.

Total aluminum levels in the GCID Canal (GCID Canal at Intake station) frequently exceeded aquatic life criteria during associated high flow conditions in the Sacramento River, and rarely exceeded drinking water criteria and the agricultural goal. Arsenic levels exceeded human toxicity thresholds in all samples collected, and the criterion for protection of aquatic life for cadmium was exceeded in fifty percent of samples collected. Copper levels frequently exceeded hardness-dependent aquatic life protection criteria during high flow conditions in the Sacramento River at the intake to the canal, and iron levels frequently exceeded drinking water and aquatic life protection criteria, as well as the agricultural goal during the same river conditions. Dissolved iron levels exceeded the Central Valley Basin Plan objective occasionally. Mercury levels approached, but did not exceed, the CTR criterion during the highest flow conditions in the river. Manganese levels in the GCID canal occasionally exceeded drinking water standards and the agricultural goal, and lead levels rarely exceeded drinking water criteria. All samples contained total phosphorus at levels at or above the recommended criteria range to prevent nuisance algal growth in streams.

Colusa Basin Drain

The CBD is a human-made channel located in Glenn, Colusa, and Yolo counties, and was designed to convey agricultural return flows and storm runoff from the Colusa Basin to the Sacramento River at the Knights Landing Outfall Gates at Sacramento RM 34.15. The Colusa Basin includes 32 intermittent streams in the Coast Range Foothills including Funks and Stone Corral creeks.

Aluminum levels in the CBD at Gunners Field station frequently exceeded criteria for the protection of aquatic life, but usually met drinking water and agricultural goals. Similar to all currently monitored sampling sites, arsenic exceeded human toxicity criteria in all samples analyzed from the CBD, and cadmium levels rarely exceeded human toxicity standards. Total iron levels in the CBD frequently exceeded aquatic life and drinking water criteria, with less frequent exceedances of the agricultural goal. Dissolved iron levels occasionally exceeded the level established in the Central Valley Basin Plan during high flows caused by storm runoff. Manganese levels frequently exceeded aquatic life and agricultural goals, as well as drinking water standards to a lesser extent. Total recoverable lead levels analyzed by DWR were found to rarely exceed criteria except for the Public Health Goal, which was exceeded in the CBD. All samples contained total phosphorus at levels at or above the recommended criteria range to prevent nuisance algal growth in streams.

Sacramento River Opposite Moulton Weir

DWR monitored water quality at the Sacramento River Opposite Moulton Weir station from 2000 to 2010. Total aluminum levels in the Sacramento River at this location frequently exceeded aquatic life criteria during associated high flow conditions in the river, but rarely exceeded drinking water criteria and the agricultural goal. Arsenic levels exceeded human toxicity thresholds in all samples collected, and the criterion for protection of aquatic life for cadmium was occasionally exceeded. Copper levels frequently exceeded hardness-dependent aquatic life protection criteria during high flow conditions in the river, and iron levels frequently exceeded drinking water and aquatic life protection criteria, as well as the agricultural goal during the same river conditions. Dissolved iron levels exceeded the Central Valley Basin Plan level occasionally. Mercury levels approached, but did not exceed, the CTR criterion during the highest flows in the river. Manganese levels occasionally exceeded drinking water standards and the agricultural goal, and lead levels rarely exceeded drinking water criteria. All samples contained total phosphorus at levels at or above the recommended criteria range to prevent nuisance algal growth in streams.

7.3 Environmental Consequences

7.3.1 Regulatory Setting

Water quality is regulated at the federal and State levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

7.3.1.1 *Federal Plans, Policies, and Regulations*

- Clean Water Act
  - Section 303(d) – Total Maximum Daily Load
  - Section 402 – National Pollutant Discharge Elimination System (NPDES) Permit Compliance
  - Section 404 – Discharge of Dredged or Fill Material
- Rivers and Harbors Act Section 10
- Federal Antidegradation Policy
- Federal Safe Drinking Water Act
- Federal Surface Water Treatment Rule
- National Toxics Rule
- Long-Term Management Strategy for the placement of Dredged Material in the San Francisco Bay Region
- Disinfectant and Disinfection Byproducts Rule
- Comprehensive Environmental Response, Compensation and Liability ActFederal Insecticide, Fungicide, and Rodenticide Act and Federal Environmental Pesticide Control Act
- Federal Environmental Protection Agency Ambient Water Quality Criteria Recommendations for Rivers and Streams in Nutrient Ecoregion I

7.3.1.2 *State Plans, Policies, and Regulations*

- Porter-Cologne Water Quality Act
- State Water Resources Control Board Decision 1641 (D-1641)
- Water Quality Control Plan for the Sacramento/San Joaquin River Basins
- San Francisco Bay Basin Water Quality Control Plan
- California Water Code Section 13160
- State Water Resources Control Board Water Rights Decisions, Water Quality Control Plans, and Water Quality Objectives
- California Antidegradation Policy
- Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary
- Water Quality Control Plan for the North Coast
- Water Quality Control Plan for the Tulare Basin
- Central Valley RWQCB Drinking Water Policy
- California Toxics Rule
- California Safe Drinking Water Act

7.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* suggests the following evaluation criteria for water quality:

Would the Project:

- Violate any water quality standards or waste discharge requirements?
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?
- Otherwise substantially degrade water quality?

The evaluation criteria used for this impact analysis represent a combination of the Appendix G criteria and professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- A violation of any water quality standard or waste discharge requirement, a change in water quality resulting in adverse effects to designated beneficial uses, or otherwise substantially degrade water quality
- A violation of any regulatory temperature criteria or temperature targets

Specifically, the following thresholds were used in the impact evaluation based on the requirements specified in the fourth edition of the water quality control plan (Central Valley Basin Plan) for the Sacramento River and San Joaquin River basins (CVRWQCB, 2011):

- EC threshold of 700 µmhos/cm for agricultural water quality and 900 µmhos/cm for drinking water quality for Extended Study Area service area deliveries
- EC threshold of 230 micromhos/cm (50 percentile) or 235 micromhos/cm (90 percentile) for the Sacramento River upstream of Knights Landing
- EC threshold of 240 micromhos/cm (50 percentile) or 340 micromhos/cm (90 percentile) for the Sacramento River upstream of the I Street Bridge
- Temperature threshold of 56°F in the Sacramento River reach from Keswick Dam to Hamilton City, during periods when temperature increases would be detrimental to the fishery. For the purpose of this analysis, this period was assumed to be from July 1st through November 30th, which is the period of salmonid upstream migration and spawning.
- Temperature threshold of 68°F in the Sacramento River reach from Hamilton City to the I Street Bridge.
- The CVP Operations Criteria and Plan (CVP OCAP) maximum temperature target, as measured at Watt Avenue, of 65°F from July 1st through September 30th (Reclamation 2009).
- A temperature increase of COLD or WARM intrastate waters more than 5°F above natural receiving waters.
- Specific Feather River temperature targets established in a 1983 DFG Agreement to protect the different lifestages of salmonids as measured at the Feather River Fish Hatchery (Fish Barrier Dam):
  - September 1 to September 30 56°F
  - October 1 to May 31 55°F
  - June 1 to August 31 60°F

Impacts to water quality in the Delta are considered significant or potentially significant if they increase salinity, when compared to Existing Conditions to a point that levels would violate D-1641 standards. D-1641 standards specify that salinity shall be controlled on the San Joaquin River at Vernalis to a 30-day mean EC mmhos/cm of 0.7 (700 µmhos/cm) for the irrigation season of April to August and 1.0 EC mmhos/cm (1,000 µmhos/cm) for the non-irrigation season of September to March. D-1641 standards also address the application of the salinity standard to additional downstream compliance locations beginning in April 2005 (Reclamation 2009). These standards are presented in Table 7-1.

Table 7-1
D-1641 EC Standards for the Delta

Water Year Type	Western Delta			
	Sacramento River @ Emmaton		San Joaquin River @ Jersey Point	
	EC 450 µmhos/cm from April 1st to Date Shown 14-Day Mean	EC Value from Date Shown to Aug 15th (µmhos/cm) 14-Day Mean	EC 450 µmhos/cm from April 1st to Date Shown* 14-Day Mean	EC Value from Date Shown to Aug 15th (µmhos/cm) 14-Day Mean
Wet	Aug 15	*	Aug 15	*
Above Normal	Jul 1	630	Aug 15	*
Below Normal	Jun 20	1,140	Jun 20	740
Dry	Jun15	1,670	Jun15	1,350
Critical	*	2,780	*	2,200

*When no date is shown, EC limit continues from April 1st.

If the monthly average X2[9] from implementation of an alternative would increase (i.e., X2 moves east/upstream from the Golden Gate Bridge) relative to the baseline, and would increase the frequency of a violation of the X2 water quality standard, it was considered to be a potentially significant impact. In this analysis, the changes in the monthly average X2 from implementation of an alternative are complex, and often result in improved X2 position and increased estuarine habitat. The potential impact of X2 on aquatic biological resources is addressed in Chapter 12 Aquatic Biological Resources.

Detailed evaluation of the implementation of an alternative was limited in the Suisun Bay, San Pablo Bay, and San Francisco Bay region. Therefore, as a conservative assumption, if the monthly average Delta outflow from implementation of an alternative would decrease by greater than five percent, it was considered to be a potentially significant impact.

7.3.3 Impact Assessment Assumptions and Methodology

7.3.3.1 *Assumptions*

The following assumptions were made regarding Project-related impacts (construction, operation, and maintenance impacts) to water quality:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).

[9] Pursuant to D-1641, X2 is the location of the two parts per thousand salinity contour (isohaline), one meter off the bottom of the estuary, as measured in kilometers upstream from the Golden Gate Bridge. In the 1995 Bay-Delta Plan, an EC value of 2.64 mmhos/cm is used to represent the X2 location.

- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation, increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.
- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake or Discharge facilities would be required.
- All construction activities along the Sacramento River would be conducted during months when instream flows are managed outside of the flood season (e.g., June 15th to September 15th).
- The beneficial uses of the North Coast and Central Valley water bodies included in the Project are as follows: municipal and domestic supply (MUN), agricultural supply (AGR), industrial service supply (IND), industrial process supply (PRO), navigation (NAV), hydropower generation (POW), water contact recreation (REC-1), non-contact water recreation (REC-2), commercial and sport fishing (COMM), aquaculture (AQUA), warm freshwater habitat (WARM), cold freshwater habitat (COLD), estuarine habitat (EST), wildlife habitat (WILD), preservation of biological habitats of special significance (BIOL), migration of aquatic organisms (MIGR), spawning, reproduction, and/or early development (SPWN), and shellfish harvesting (SHELL). The Basin Plans also state that waterbodies within the basins that do not have beneficial uses designated are assigned MUN designations in accordance with the provisions of State Water Board Resolution No. 88-63.

7.3.3.2 *Methodology*

This section describes the approach used to evaluate the surface water quality impacts of the alternatives. Surface water quality was evaluated for the Extended, Secondary, and Primary study areas. Modeling was used to estimate the changes in surface water EC and temperature that would result from implementation of each alternative. EC was used as a surrogate for evaluating other water quality constituents that were not modeled. For the waterbodies where explicit EC or temperature estimates were unavailable, surface water quality impacts were assessed based on modeled changes in flow or storage conditions.

Impact Evaluation Approach

The Extended Study Area represents the regions south of the Delta where Delta exports are used for agricultural, municipal, industrial, and wildlife refuge water supply. The EC values for the Extended Study Area were determined based on the EC and volume of the exports at the Banks and Jones pumping plants. These EC values were estimated using the results from the DSM2 Delta Simulation Model (DSM2 QUAL). The monthly EC summary results at the Banks and Jones pumping plants for an alternative were compared with the appropriate baseline to determine the resulting change. If the monthly average EC was higher from an alternative, when compared to Existing Conditions, the increased level was evaluated against an applicable water quality standard to determine whether the increase in EC exceeded the standard.

The Secondary Study Area is comprised of the waterbodies that could be affected by Project operations. It includes the CVP and SWP storage and conveyance features, reaches of the rivers downstream of the CVP and SWP storage features, the Sacramento-San Joaquin Delta, and the bays. For the Sacramento River at the three potential intakes for Sites Reservoir, worst-case EC values were estimated based on the composition of the water present at the intakes. The origin of the water at each intake was traced to various contributing sources, and the worst-case EC at each intake was estimated based on the worst-case EC estimate of each of the sources, as explained in the EC Mass Balance approach. For the Sacramento-San Joaquin River Delta, the EC values were estimated using the results from the DSM2 QUAL model.

For the locations where EC results are available, monthly EC summary results for each alternative were compared with the appropriate baseline. EC results for the Secondary Study Area are available for the three intake locations along the Sacramento River and the various compliance locations in the Delta. If monthly average EC was found to be higher from an alternative, when compared to the baseline, it was evaluated against an available water quality standard to determine whether the increase in EC exceeded the standard. Impacts to the X2 position in the Delta were determined by comparing the monthly X2 position summary results from the CALSIM II model for each alternative with the appropriate baseline. Impacts to water temperature were determined using USRWQM and Reclamation Temperature Model results for the Trinity, Sacramento, Feather, and American rivers. Initially, the monthly average temperatures were compared for each alternative with the appropriate baseline. If the temperature was found to be higher from an alternative, when compared to the baseline, it was evaluated against an appropriate temperature threshold to determine whether the increase in temperature exceeded that threshold.

The Primary Study Area represents the area within which the Project storage and conveyance facilities would be constructed. The EC values within the Primary Study Area were determined based on the worst-case EC mass balance estimates (described below) at the three potential Sacramento River intakes. For impacts to Sacramento River temperatures downstream of the Delevan Pipeline Intake/Discharge Facilities that would result from Sites Reservoir releases, results from the preliminary Sites Reservoir temperature model were used.

Model results are presented by Water Year Type as defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB, 2006) for the full 82-year simulation period (water years 1922 through 2003). The different Water Year Types and the percentage of the 82-year simulation period that each type of water year occurred are listed below:

- Wet: 32 percent
- Above Normal: 15 percent
- Below Normal: 17 percent
- Dry: 22 percent
- Critical: 15 percent

EC Mass Balance Approach

Worst-case EC conditions were simulated to assess the maximum potential impact of Project implementation on Sacramento River EC. The analysis included estimation of the worst-case concentrations for various sources along the Sacramento River, as well as the estimation of source water contribution and worst-case concentrations at locations of interest along the Sacramento River. The analysis calculated a simple mass balance using the source concentrations and the percent of source volumes estimated, based on the daily results from USRDOM modeling. The analysis was limited to the three Project proposed intake locations along the Sacramento River (T-C Canal Intake, GCID Canal Intake, and the proposed Delevan Pipeline Intake). The Primary and Secondary study area analyses were formulated using the limited EC field measurements available for various tributaries (sources) and locations along the Sacramento River and assume worst-case EC conditions. The USRDOM model description and results are included in Appendix 6C. The EC Mass Balance Approach description and results are included in Appendix 7C.

DSM2 Delta Simulation Model and CALSIM II CVP and SWP Operations Model

DSM2 is a one-dimensional hydrodynamic and water quality simulation model used to simulate hydrodynamics and water quality in the Sacramento-San Joaquin Delta. DSM2 represents the best available planning model for Delta tidal hydrodynamics and salinity modeling. It is appropriate for describing the existing conditions in the Delta, as well as performing simulations for the assessment of incremental environmental impacts caused by changes in the facilities and operations. The DSM2 model has two separate components: HYDRO and QUAL. The HYDRO module is a one-dimensional, implicit, unsteady, open channel flow model that simulates flows, velocities, and water surface elevations. HYDRO provides the flow input for QUAL. The QUAL module is a one-dimensional water quality transport model that simulates fate and transport of water quality constituents, such as EC, given a flow field simulated by HYDRO. DSM2 QUAL provides EC estimates at various locations in the Sacramento-San Joaquin Delta, including at key salinity control points such as Emmaton, Jersey Point, and at the two export locations at the Banks Pumping Plant and the Jones Pumping Plant. The DSM2 model description and results are included in the Appendix 7D.

DSM2 does not provide all of the water quality information needed for this assessment. The CALSIM II model provides results for the X2 position. Figure 7-1 shows the locations of selected SWRCB D-1641 water compliance stations located in the Delta that were used in this evaluation, including the three stations for defining the X2 standard. Figure 7-1 also includes lines showing the potential range of the X2 location, from 66 km to 95 km from the Golden Gate Bridge, in increments of 5 km.

The X2 position is used along with DSM2 EC results for the assessment of changes in the Sacramento-San Joaquin Delta. The CALSIM II model description and results are included in Appendix 6B. The model results for the X2 position are included in Appendix 6B.

USRWQM and Reclamation Temperature Model

Water temperatures were modeled for major rivers in the Secondary Study Areas to evaluate the thermal impacts of Project operations using the Upper Sacramento River Water Quality Model (USRWQM) and the Reclamation Temperature Model.

USRWQM was developed using the HEC-5Q model to simulate mean daily (using six-hour meteorology) reservoir and river temperatures at Shasta, Trinity, Lewiston, Whiskeytown, Keswick, and Black Butte reservoirs, and the Trinity River, Clear Creek, the upper Sacramento River from Shasta to Knights Landing, and Stony Creek. USRWQM is designed for long-term planning simulations of temperature variability in these the reservoirs and streams, given CVP/SWP Project operations, and allows comparison between existing and assumed future scenarios. Daily flows, simulated in the USRDOM model for an 82-year period (water years 1922 to 2003), are used as input to the USRWQM.

The Reclamation Temperature Model is a reservoir and stream temperature model, which simulates monthly reservoir and stream temperatures used for evaluating the effects of CVP/SWP Project operations on mean monthly water temperatures in the basin. The model simulates temperatures in five major reservoirs (Trinity, Whiskeytown, Shasta, Oroville, and Folsom), four downstream regulating reservoirs (Lewiston, Keswick, Thermalito, and Natoma), and four main river systems (Trinity, Sacramento, lower Feather, and lower American). The reservoir component of the Reclamation Temperature Model calculates temperature changes in main and regulating reservoirs. Using regulating reservoir release temperature as the initial river temperature, the river model computes temperatures at several locations along the rivers. The calculation points for river temperatures generally coincide with tributary inflow locations.

The modeled temperatures used to represent waters in the Secondary Study Area include temperatures from three locations on both the Trinity River and Clear Creek, eight locations on the Sacramento River from Keswick to Freeport, and three locations in both the Feather and Lower American rivers. Sacramento River locations modeled for the Primary Study Area include at Red Bluff, downstream of Red Bluff, downstream of Hamilton City, at Delevan, and downstream of Delevan.

For the Trinity River and Upper Sacramento River locations, where results were available from both the USRWQM and the Reclamation Temperature Model, the results from the USRWQM model were used.

The USRDOM model description and results are included in Appendix 6C. The USRWQM and the Reclamation Temperature Model descriptions and results are included in Appendix 7E.

Sites Reservoir Discharge Temperature Model

- A preliminary Sites Reservoir Discharge Temperature Model was drafted for the temperature analysis of the proposed Sites Reservoir. Only Alternative C was evaluated, based on the assumption that it is the alternative that would result in the worst-case impact to the Sacramento River temperature conditions downstream of the proposed Delevan Pipeline Intake/ Discharge facilities. Therefore, the results from the analysis of Alternative C were assumed to be applicable to the other two action alternatives.
- The physical characteristics and the daily operations of Sites Reservoir, as proposed for Alternative C, were derived from the Alternative C USRDOM simulation. Sites Reservoir inflow temperatures and the Sacramento River temperature targets were derived using the results from the Alternative C USRWQM simulation. Inflow to Sites Reservoir was assumed to be the daily flow from the Holthouse Reservoir Complex to Sites Reservoir, and outflow from Sites Reservoir was specified using daily flow from Sites Reservoir to the Holthouse Reservoir Complex, as simulated in the USRDOM model. Using the information from the USRDOM model ensured that the daily Sites Reservoir operations in the preliminary Sites Reservoir Temperature Model were consistent with the resulting operations from USRDOM and CALSIM II models for Alternative C. Sacramento River temperatures for the location upstream from the proposed Delevan Pipeline Intake/ Discharge facilities were blended with simulated Sites Reservoir release temperatures. The blended temperature was then used to determine whether Sacramento River temperatures would be affected by Sites Reservoir releases. A limitation to this model output is that the potential warming effects from the Project conveyance facilities were not taken into account while computing inflow or release temperatures. However, significant warming is not expected within an underground pipeline.

- The USRDOM model description and results are included in Appendix 6C. The USRWQM and the Reclamation Temperature Model descriptions and results are included in Appendix 7E. The Sites Reservoir Discharge Temperature Model description and results are included in Appendix 7F.

7.3.4 Topics Eliminated from Further Analytical Consideration

Water temperature impacts (Impact SW Qual-2) were not specifically evaluated for agricultural, municipal, industrial, or wildlife refuge water supply within the Extended Study Area, or for San Luis Reservoir and its service areas, because there are no applicable temperature criteria for these beneficial uses.

The following facilities within the Primary Study Area would not store or release water and do not have waterbodies located within their facility footprints; their construction, operation, and maintenance activities would, therefore, have no impact on water temperature (**Impact SW Qual-2**) and are not discussed further: Recreation Areas, Road Relocations and South Bridge, Sites Electrical Switchyard, Field Office Maintenance Yard, Delevan Pipeline Electrical Switchyard, TRR Electrical Switchyard, TRR Pipeline Road, Holthouse Reservoir Electrical Switchyard, Delevan Transmission Line, and the Project Buffer.

7.3.5 Impacts Associated with the No Project/No Action Alternative

7.3.5.1 *Extended Study Area – No Project/No Action Alternative*

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge *Water Use*

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. A comparison of the modeled long-term average EC levels for the No Project/No Action Alternative and Existing Conditions at Clifton Court Forebay indicates that EC levels are expected to decrease (improve) or remain similar in all months. A negligible increase of 0.2 percent in long-term average EC levels is expected to occur in September. Comparing water year type averages, EC levels for the No Project/No Action Alternative are expected to decrease or remain similar to Existing Conditions in most months. Average EC levels for the No Project/No Action Alternative are expected to increase slightly in September during Wet and Above Normal water years (2.6 percent and 1.4 percent, respectively); in September and October during Below Normal water years (1.2 percent and 1.7 percent, respectively); and in July, August, and October in Critical water years (negligible increases). However, these modeled average EC levels are well below the Agricultural Water Quality Goal (Ag Goal) of 700 µmhos/cm, which is protective of various agricultural water uses, including crop irrigation and stock watering (CVRWQCB, 2011). As such, the drinking water goal of 900 µmhos/cm to protect human health would not be exceeded.

Similarly, long-term average EC levels for the No Project/No Action Alternative, when compared to Existing Conditions at the Jones Pumping Plant, are expected to decrease during all months. Water year type averages are expected to decrease or remain similar, with negligible increases expected during a few months of some water year types. Implementation of the No Project/No Action Alternative is expected to reduce the long-term average export-weighted EC, TDS, chloride, and bromide concentrations, when compared to Existing Conditions. Similarly, the Dry and Critical water year type average export-weighted concentrations for the No Project/No Action Alternative would be reduced.

During November, December, and January of Critical water years at Clifton Court Forebay, and during November through March of Critical water years at the Jones Pumping Plant, average EC levels are expected to exceed the Ag Goal. However, the average EC levels associated with Existing Conditions already exceed the goal, and implementation of the No Project/No Action Alternative would decrease those levels. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on EC levels, TDS, bromide, and chloride concentrations associated with agricultural, municipal, industrial, and wildlife refuge water supply.

Central Valley Basin Plan EC criteria only apply to agricultural and drinking water supplies. Other water quality parameters, such as metals and nutrients, were not modeled as part of this analysis. The potential changes to the concentrations of these constituents are unknown at this time. However, the improvements in EC levels for the No Project/No Action Alternative, when compared to Existing Conditions, are expected to translate into improvements of the concentrations of these constituents. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on the concentrations of nutrients, metals, and other water quality constituents (including mercury) associated with agricultural, municipal, industrial, and wildlife refuge water supply.

Regardless of the predicted changes in surface water quality within the Extended Study Area as a result of implementing the No Project/No Action Alternative, the impacts of the projects included in the No Project/No Action Alternative have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to surface water quality have been addressed in those environmental documents.

Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. A larger population could be expected to adversely impact surface water quality. However, plans for population growth in General Plans would be subject to their own environmental reviews. Therefore, population growth associated with implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on surface water quality.

San Luis Reservoir

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Reservoir surface water level fluctuations can exacerbate nuisance algae blooms when reservoir levels are low due to increased nutrient concentration, reduced reservoir mixing, and higher water temperatures during low storage conditions. With implementation of the No Project/No Action Alternative, San Luis Reservoir would continue to experience water level fluctuations as in the past. Modeled end-of-month long-term average surface water elevations for the No Project/No Action Alternative, when compared to Existing Conditions, indicate slight decreases in elevation during all months. These decreases in surface water elevation fall within the historic range of operation for San Luis Reservoir.

A comparison of water year type averages indicates an increase in elevation of up to 16 feet during April through December in Critical water years and up to 12 feet during April through June in Dry water years resulting from a reduction in South of Delta allocations. Elevations would, therefore, be improved during periods in which algae blooms are a concern. San Luis Reservoir typically experiences dissolved oxygen and algae concerns when storage levels falls below 250,000 acre-feet. End-of-month storage exceedance plots indicate that San Luis Reservoir would have storage levels greater than 250,000 acre-feet during December through May 100 percent of the time for both the No Project/No Action Alternative and Existing Conditions. During June through November, the No Project/No Action Alternative would perform similarly to Existing Conditions. The greatest difference would occur in August, when Existing Conditions would exceed a storage level of 250,000 acre-feet approximately 80.2 percent of the water years, and the No Project/No Action Alternative would exceed the low level approximately 84 percent of the water years. Therefore, water level and storage fluctuations associated with the No Project/No Action Alternative **would not have a substantial adverse effect** on nuisance algae blooms in San Luis Reservoir, when compared to Existing Conditions.

Water quality conditions in San Luis Reservoir depend on Delta exports from the Banks and Jones pumping plants. Refer to the **Impact SW Qual-1** discussion for Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use; it is directly applicable to San Luis Reservoir. Implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on EC levels, TDS, bromide and chloride concentrations, metals, nutrients, and other water quality constituents in the San Luis Reservoir.

7.3.5.2 *Secondary Study Area – No Project/No Action Alternative*

<u>Construction, Operation, and Maintenance Impacts</u>

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream from Trinity River, Whiskeytown Lake, Spring Creek, Keswick Reservoir, and Clear Creek -

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Changes in water quality within the Trinity River Basin associated with implementation of the No Project/No Action Alternative, when compared to Existing Conditions, are expected to be negligible and entirely consistent with flow requirements in the Trinity Record of Decision (refer to Section 6.2.2.3 in Chapter 6 Surface Water Resources). Implementation of the No Project/No Action Alternative would result in similar storage conditions in Trinity Lake. Similar storage conditions would not be expected to adversely affect water quality. Consequently, releases from Trinity Lake to the Trinity River would not be expected to adversely impact water quality, and flows from the Trinity River into the Klamath River would not be expected to adversely impact water quality.

With implementation of the No Project/No Action Alternative, Lewiston Lake and Whiskeytown Lake would continue to operate as regulating reservoirs within their historical operational range and would not be expected to adversely impact water quality. Consequently, Whiskeytown Lake releases to Clear Creek would not be expected to adversely impact water quality in Clear Creek. Spring Creek and Keswick Reservoir would also continue to operate within their historical operational range.

Continued operations within the historical range of operation associated with implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would, therefore, not have a substantial adverse effect** on water quality in these waterbodies.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Trinity Lake and Lewiston Lake control releases to the Trinity River. Modeling results indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in either negligible changes or no change to average monthly Trinity River water temperatures at the Trinity River at North Fork, Trinity River at Douglas City, and Trinity River downstream of Lewiston Dam locations. Consequently, flows from the Trinity River into the Klamath River would be expected to result in negligible changes or no change to Klamath River average monthly water temperatures.

Whiskeytown Lake regulates releases into Clear Creek. Modeling results indicate similar negligible changes to average monthly Clear Creek water temperatures for the Clear Creek at Igo, Clear Creek at Mouth, and Clear Creek downstream of Whiskeytown locations, when compared to Existing Conditions. In addition, Keswick Reservoir would continue to operate as a regulating reservoir. Consequently, flows from Clear Creek and Keswick Reservoir into Spring Creek would be expected to result in negligible changes or no change to Spring Creek average monthly water temperatures.

Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on water temperatures in Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream from Trinity River, Whiskeytown Lake, Spring Creek, and Clear Creek.

Shasta Lake

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Water quality conditions within the Shasta Lake basin associated with the No Project/No Action Alternative are expected to be similar to Existing Conditions. Sediment and heavy metal runoff during rain events would continue to impact water quality due to local geology, mining history, and timber harvest land uses. In addition, sediment and nutrient impacts from the Pit River input to the reservoir due to agricultural runoff would continue to occur.

Modeling results indicate that implementation of the No Project/No Action Alternative would result in negligible changes to average end-of-month surface water elevation at Shasta Lake during all months of all water year types, when compared to Existing Conditions. These negligible changes to surface water elevations would not be expected to adversely impact water quality.

Other water quality constituents of concern, including mercury and unknown toxicity on the 303(d) list of impaired waters, were not evaluated explicitly. However, modeling results indicate that implementation of the No Project/No Action Alternative would also result in negligible changes to Shasta Lake average end-of-month storage conditions during all months of all water year types. These negligible changes would not be expected to adversely impact these water quality constituents.

Keswick Reservoir water quality is determined by releases from Shasta Lake. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on Shasta Lake and Keswick Reservoir water quality.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-1** discussion related to storage conditions. Slight changes to average end-of-month storage would not be expected to result in adverse impacts to water temperature. In addition, modeling results for releases to the Sacramento River downstream of Keswick indicate negligible changes to long-term average monthly temperatures in all months, and negligible changes to average monthly temperature during all months of all water year types.The greatest average change would occur during September of Critical water years, in which temperatures are expected to decrease by 0.6 degree. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on Shasta Lake and Keswick Reservoir water temperature.

Sacramento River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Looking at worst-case EC for the Keswick to Red Bluff reach of the Sacramento River, modeling results for the T-C Canal Intake for the No Project/No Action Alternative indicate that long-term monthly average EC levels are expected to increase slightly during all months, when compared to Existing Conditions, with the greatest increase of 0.8 percent occurring in November. Modeling results indicate that monthly average EC levels by water year type would increase in all months of all water year types, with the exception of negligible decreases in February of Below Normal water years and March of Dry water years. The largest increases of 1.2 percent would occur in November of Dry water years.

Worst-case EC modeling results for the Red Bluff to Hamilton City reach of the Sacramento River, estimated at the GCID Canal Intake, indicate similar results for the No Project/No Action Alternative because slight increases are expected in all months for the long-term average monthly EC, when compared to Existing Conditions, and the greatest increase (0.8 percent) would occur in November. Modeling results for monthly average EC by water year type are also similar, with the greatest increase (1.1 percent) expected to occur in November of Dry water years.

For the GCID Canal Intake to the Delevan Pipeline Intake reach of the Sacramento River, estimated at the Delevan Pipeline, worst-case EC modeling results for the No Project/No Action Alternative show similar trends to the upstream reaches because slight increases in long-term monthly average EC levels are expected during most months, and negligible decreases are expected during February, July, and August, when compared to Existing Conditions. The greatest increase (0.9 percent) is expected to occur in November. Modeling indicates results for monthly average EC by water year type that would be similar, with the greatest increase of 1.2 percent expected to occur in November. Modeling results for worst-case EC levels for the Sacramento River downstream of the Delevan Pipeline are expected to be similar.

Worst-case EC levels for the CBD to the entrance of the Delta at the I Street Bridge reach of the Sacramento River were not estimated explicitly. However, the changes in the EC levels in this reach are expected to trend consistently with the changes described for the upper Sacramento River reaches.

The water year type averages of the worst-case EC values for the No Project/No Action Alternative, in all months, are expected to be below the Central Valley Basin Plan requirement of 230 µmhos/cm for the Sacramento River reach upstream of the CBD. Therefore, these negligible to minor increases in worst-case EC levels on the Sacramento River resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect**, when compared to Existing Conditions.

Other water quality constituents of concern, including mercury and unknown toxicity on the 303(d) list of impaired waters, were not evaluated explicitly. Water quality in the upper reach of the Sacramento River would continue to be generally good. Stormwater-driven runoff would continue to cause occasional elevated levels of mercury, other trace metals, pesticides, and turbidity that would adversely affect water quality in this reach. Water quality in the lower reach of the Sacramento River is expected to be similar to Existing Conditions. Elevated levels of metals and pesticides, turbidity, and pesticide and metal bioaccumulation in fish caused primarily by agriculture return flows from CBD releases near Knights Landing are expected to continue to adversely affect water quality in this reach. However, the changes in the concentrations of the other water quality constituents are expected to be proportional to the changes in the worst-case EC levels for the No Project/No Action Alternative. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on water quality constituents in the Sacramento River, when compared to the Existing Conditions.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Modeling results for the No Project/No Action Alternative indicate negligible changes to long-term average monthly temperatures in all months, and to monthly average temperature during all months of all water year types, for each of the following Sacramento River locations, when compared to Existing Conditions: downstream of Keswick, at Balls Ferry, at Jellys Ferry, at Bend Bridge, at Red Bluff, downstream of Red Bluff, downstream of Hamilton City, at Delevan, downstream of Delevan, and at Knights Landing.

Modeled average monthly temperatures by water year type for the No Project/No Action Alternative indicate that the 56°F criterion for July through October would be exceeded at the following locations on the Sacramento River: downstream of Keswick from August through October in Critical water years; at Balls Ferry from July through October in Critical water years and September in Dry water years; at Jellys Ferry in September in Above Normal, Below Normal, and Dry water years, as well as from July through October in Critical water years; and at Bend Bridge from July through August in Wet water years, August and September in Above Normal, Below Normal, and Dry water years, and July through October in Critical water years.

Modeled average monthly temperatures by water year type for the No Project/No Action Alternative also indicate that the 68°F criterion for July through November would be exceeded at the following Sacramento River locations: at Knights Landing during July and August of all water year types; at Feather River and at American River during July and August in Wet water years, and July through September in Below Normal, Dry, and Critical water years.

Although these criteria temperatures would be exceeded, it is important to note that the criteria temperatures are already exceeded during Existing Conditions at these locations, and implementation of the No Project/No Action Alternative would result in either the same or decreased (improved) temperatures. In some locations during some months, modeling results indicate that the No Project/No Action Alternative could result in increased temperatures, but the expected increase of less than one percent falls within the "noise" of the model and is not considered significant. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on Sacramento River water temperatures.

Lake Oroville, Thermalito Complex, and the Feather River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeling results indicate that implementation of the No Project/No Action Alternative would result in decreased long-term average end-of-month storage conditions at Lake Oroville during all months, when compared to Existing Conditions, with the greatest decrease of 2.8 percent expected to occur in September. Modeling results for average end-of-month storage by water year type indicate decreases in all months of all water year types, with the exception of negligible increases of up to 0.4 percent expected in October and November of Dry water years, and July of Critical water years. These slight decreases in storage conditions would not be expected to have a substantial adverse effect on the water quality of Lake Oroville. The Thermalito Complex would continue to operate as a regulating reservoir system within the historical operational range. Consequently, releases from Lake Oroville and the Thermalito Complex would not be expected to have a substantial adverse effect on the water quality of the Feather River.

Therefore, with implementation of the No Project/No Action Alternative, water quality in the Feather River is expected to continue to be generally good. Some metals and turbidity levels are expected to continue to occasionally exceed Central Valley Basin Plan criteria, mainly during periods of stormwater-driven runoff. Elevated pathogen levels are expected to continue, primarily during the contact recreation season at developed recreation areas. Therefore, water quality impacts to Lake Oroville, the Thermalito Complex, and the Feather River resulting from implementation of the No Project/No Action Alternative **would not have a substantial adverse effect**, when compared to Existing Conditions**.**

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-1** discussion. Slight decreases in storage conditions at Lake Oroville, and continued operation of the Thermalito Complex as a regulating reservoir system, would not be expected to result in a substantial adverse effect to their water temperatures. In addition, modeling results for long-term average monthly water temperatures and monthly average temperatures by water year type for the Feather River downstream of the Fish Barrier Dam, downstream of Thermalito Afterbay, and at the mouth indicate that implementation of the No Project/No Action Alternative would result in negligible changes, when compared to Existing Conditions. In addition, models indicate that water temperatures at all three Feather River locations would meet the basic Central Valley Basin Plan temperature criteria.

Specific Oroville Facilities temperature targets for the Feather River Fish Hatchery would be exceeded during one or more months in all but Above Normal water year types. Although these criteria temperatures would be exceeded, it is important to note that the criteria are already exceeded during Existing Conditions during these months, and implementation of the No Project/No Action Alternative would result in either the same or decreased temperatures. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on Lake Oroville, Thermalito Complex, and Feather River water temperatures.

Sutter Bypass and Yolo Bypass

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The changes in water quality in the Sutter Bypass and Yolo Bypass were not modeled. However, the changes in the flow spills and flows into these bypasses, respectively, were modeled.

Spills into the Sutter Bypass were modeled at Ord Ferry, Moulton Weir, Colusa Weir, and Tisdale Weir. The modeling of spills was performed at a daily timestep using the USRDOM model. Monthly average exceedance probability plots indicate that spills for the No Project/No Action Alternative would be the same or similar in magnitude and frequency to spills for Existing Conditions at Ord Ferry, Moulton Weir, Colusa Weir and Tisdale Weir.

Spills into the Sutter Bypass from the Sacramento River represent only some of the hydrologic inputs to the lower Sutter Bypass. Large reductions in spill flows can potentially affect the available dilution flows for various water quality constituents. The relationships and interactions of the various hydrologic inputs into the Sutter Bypass and the resulting flow and flooded area in the Sutter Bypass were not modeled. It is not anticipated that the changes in spill exceedance probabilities discussed above would have a substantial impact on surface water quality in the Sutter Bypass. Therefore, it is concluded that the implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on surface water quality, when compared to Existing Conditions.

Spills into the Yolo Bypass at Fremont Weir and Sacramento Weir and resultant flows from the Yolo Bypass into the Sacramento-San Joaquin Delta were modeled at a daily timestep using a specialized module built into the CALSIM II model. Monthly average exceedance probability plots indicate that Yolo Bypass flows for the No Project/No Action Alternative would be the same or similar in magnitude and frequency to flows for Existing Conditions.

It is not anticipated that the described changes in Yolo Bypass flows and outflow would have a substantial impact on surface water quality. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on Yolo Bypass water quality, when compared to Existing Conditions.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperature modeling was not performed for the Sutter Bypass and the Yolo Bypass. However, as described above, the expected changes in spills to the Sutter Bypass represent only a portion of the input to the bypass, and flows into and out of the Yolo Bypass are expected to remain similar. Therefore, it is expected that implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on water temperature in the Sutter Bypass and Yolo Bypass, when compared to Existing Conditions.

Folsom Lake, Lake Natoma, and the American River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeled end-of-month storage conditions for the No Project/No Action Alternative for Folsom Lake indicate minor decreases to long-term averages in all months, with the exception of a negligible increase in March, when compared to Existing Conditions. Modeling results for average end-of-month storage by water year type indicate similar minor changes, with the exception of a 6.2 percent decrease in August of Below Normal water years. These slight decreases in storage conditions would not be expected to have a substantial adverse effect on the water quality of Folsom Lake. Lake Natoma would continue to operate as a regulating reservoir system within the historical operational range. Consequently, releases from Folsom Lake and Lake Natoma would not be expected to have a substantial adverse effect on the water quality of the American River.

Therefore, with implementation of the No Project/No Action Alternative, water quality in the American River is expected to continue to be generally good. Elevated levels of pathogens and nutrients would still occur during periods of stormwater-driven urban runoff. Depressed dissolved oxygen levels, pH, and taste and odor issues would continue to occur occasionally during the warm summer months. Permitted municipal and industrial discharges could also affect water quality in the river. Therefore, water quality impacts to Folsom Lake, Lake Natoma, and the American River resulting from implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect.**

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-1** discussion. Minor decreases to average end-of-month storage conditions at Folsom Lake, and continued operation of Lake Natoma as a regulating reservoir system, associated with implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on their water temperatures.

Modeling results for average monthly water temperatures by water year type for the American River downstream of Nimbus Dam, at Watt Avenue, and at the mouth indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in negligible decreases in some months, and minor increases of one degree or less in most months of all water year types.

However, modeling results also indicate that the OCAP temperature target at Watt Avenue would be exceeded during July through September in all but Above Normal water year types. This temperature target is already exceeded during Existing Conditions, but implementation of the No Project/No Action Alternative would increase temperatures by up to 0.9 degree, when compared to Existing Conditions. Exceedance plots indicated that the temperature criteria would be exceeded 100 percent of the years in July and August for both the No Project/No Action Alternative and Existing Conditions, but in September would be exceeded in approximately 91.3 percent of the years during Existing Conditions, and approximately 97.5 percent of the years if the No Project/No Action Alternative is implemented. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would have a potentially substantial adverse effect** on American River water temperatures.

Sacramento-San Joaquin Delta

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in minor changes in average monthly EC during March through November, and moderate decreases during January and February. Modeled average monthly EC results indicate minor changes during all months of Wet and Above Normal water years. Below Normal, Dry, and Critical water years would also experience minor changes in average monthly EC during most months, with the exception of moderate decreases in January and July of Below Normal water years, and January and February of Critical water years. A moderate increase (7.5 percent) is expected to occur in August of Dry water years. Based on these expected monthly averages, D-1641 salinity targets may not be met at this compliance location during August in Wet and Above Normal water years, and during June and August in Dry water years. These salinity targets would already be exceeded during Existing Conditions, and during two of these months, implementation of the No Project/No Action Alternative would reduce the average EC levels. However, average EC levels may be increased above Existing Conditions levels during August in Wet and Dry water years.

To further determine if the increases in average EC levels associated with implementation of the No Project/No Action Alternative during August in Wet and Dry water years would impact compliance with D-1641 salinity standards, exceedance probabilities were examined and compared to those of Existing Conditions. The exceedance plots show that the No Project/No Action Alternative and Existing Conditions would perform similarly because results for both indicate that monthly average EC in August would exceed the 450 µmhos/cm Wet water year standard approximately 96 percent of the years. However, monthly Average EC in August would exceed the 1,670 µmhos/cm Dry water year standard approximately 17 percent of the years with implementation of the No Project/No Action Alternative, and the 1,670 µmhos/cm standard would be exceeded approximately 13 percent of the years during Existing Conditions. Therefore, implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on average monthly EC levels in the Delta due to changes at the Sacramento River at Emmaton compliance location.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in decreases of up to 6.2 percent in average monthly EC levels during all months. Modeled average monthly EC results indicate minor increases from August through December in Wet and Above Normal water years, in September and October in Below Normal water years, and in April through June in Critical water years. Based on these expected monthly averages, D-1641 salinity targets may not be met at this compliance location during August in Wet, Above Normal, and Dry water years; and during July and August in Below Normal water years. These salinity targets are also exceeded during Existing Conditions, and during several of these months, implementation of the No Project/No Action Alternative would reduce EC levels. However, EC levels would be increased above Existing Conditions levels during August in Wet and Above Normal water years.

To further determine if the increases in average EC levels associated with implementation of the No Project/No Action Alternative during August in Wet and Above Normal water years would impact compliance with D-1641 salinity standards, exceedance probabilities were examined and compared to those of Existing Conditions. The exceedance plots show that the No Project/No Action Alternative and Existing Conditions would perform similarly because results for both indicate that monthly average EC in August would exceed the 450 µmhos/cm Wet and Above Normal water year standard in approximately 96 percent of the years. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on average monthly EC levels in the Delta due to changes at the San Joaquin River at Jersey Point compliance location.

EC is a good indicator of other water quality constituents in the Delta. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on the other water quality constituents in the Delta.

Modeling results for long-term average monthly X2 position indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in an eastward movement of X2 by up to 0.2 kilometer (km) in April through June, and either no change or a westward movement of up to 0.1 km in July through March. Modeling results for average monthly X2 position indicate that, in Wet water years, X2 would move eastward by up to 0.2 km in all months, with the exception of March when X2 would move westward by 0.1 km. During Above Normal water years, X2 would move eastward by up to 0.3 km in April and May, and would experience either no change or move westward up to 0.2 km in June through March. During Below Normal water years, X2 would move eastward by up to 0.3 km in April and May, as well as in October through December, and would experience either no change or move westward by up to 0.5 km in the remaining months. During Dry water years, X2 would move eastward up to 0.2 km in March through May, and would experience either no change or move westward up to 0.3 km June through February. During Critical water years, X2 would move eastward in April and May by 0.2 km, and would experience either no change or move westward by up to 0.5 km.

The small eastward movements indicated during the February through June and September through November D-1641 compliance periods for the No Project/No Action Alternative, when compared to Existing Conditions, have the potential to move the X2 position out of compliance. However, a comparison of exceedance probabilities for all years indicates that the No Project/No Action Alternative would perform similarly to Existing Conditions during February through June, and would perform the same as Existing Conditions during September through November. Therefore, these slight changes in X2 position associated with implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on X2 position compliance.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for the Delta, and there are no specific water temperature criteria in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (SWRCB, 2006). However, water temperatures in the Delta approach equilibrium temperatures where the meteorological conditions primarily influence the water temperatures. Thus, the differences between the No Project/No Action Alternative and Existing Conditions would be minimized. Therefore, implementation of No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on water temperature in the Delta.

Suisun Bay, San Pablo Bay, San Francisco Bay

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Model simulations for Delta outflow indicate that implementation of the No Project/No Action Alternative would result in minor decreases in average monthly outflow during most months of Wet, Above Normal, and Below Normal water year types, when compared to Existing Conditions. Delta outflow would experience minor increases and decreases during Dry and Critical water years. The largest decreases are expected to occur in August of Wet water years (-5.3 percent) and October of Below Normal water years (-5.0 percent). The decrease in outflow of 5 percent during Below Normal water years could have an adverse effect on water quality in the bays. Therefore, implementation of the No Project/No Action Alternative **would have a potentially substantial adverse effect** on water quality in the bays, when compared to Existing Conditions.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for Suisun Bay, San Pablo Bay, or San Francisco Bay, and there are no specific water temperature criteria in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (SWRCB, 2006). Based on the seasonal flow changes described above with implementation of the No Project/No Action Alternative, when compared to Existing Conditions, and because the temperatures in the Suisun Bay, San Pablo Bay, and San Francisco Bay are primarily controlled by the meteorological conditions, **there would not be a substantial adverse effect** on water temperature.

7.3.5.3 *Primary Study Area – No Project/No Action Alternative*

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

With implementation of the No Project/No Action Alternative, the proposed Project would not be constructed; additionally, none of the 14 projects included in the No Project/No Action Alternative would occur within the Primary Study Area. Therefore, surface water quality conditions in local creeks within the Primary Study Area are expected to remain similar to Existing Conditions.

Modeling results indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in changes of up to 0.8 percent in long-term average monthly EC levels during all months at Funks Reservoir. Modeling indicates results for average monthly EC levels that would be similar during all months of all water year types, with the greatest increase of 1.2 percent occurring in November of Dry water years. No specific EC threshold exists for Funks Reservoir; these modeling results are presented to provide a base of comparison for the with-Project alternative evaluations.

Similarly, modeling results indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in changes of up to 0.8 percent in long-term average monthly EC levels during all months at the T-C Canal intake location. Modeling indicates that results for average monthly EC levels would be similar during all months of all water year types, with the greatest increase of 1.2 percent occurring in November of Dry water years. Modeling indicates that results would be similar for long-term average and average monthly EC levels at the GCID Canal intake location, as well as at and downstream of the proposed Delevan Pipeline intake location, which is discussed for the No Project/No Action Alternative to provide a base of comparison for the with-Project alternative evaluations. The modeled average monthly EC values would not exceed the EC threshold of 230 micromhos/cm for the Sacramento River upstream of Knights Landing. Therefore, implementation of the No Project/No Action Alternative, when compared to Existing Conditions, **would not have a substantial adverse effect** on EC levels within the Primary Study Area.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Funks Reservoir water temperature was not modeled. However, because this facility would continue to act as a regulating reservoir within its historical operational range, implementation of the No Project/No Action Alternative **would not have a a substantial adverse effect** on Funks Reservoir water temperature, when compared to Existing Conditions.

Modeled Sacramento River water temperatures for the existing T-C Canal intake (Sacramento River at and downstream of Red Bluff) and GCID Canal intake (Sacramento River downstream of Hamilton City) indicate that implementation of the No Project/No Action Alternative, when compared to Existing Conditions, would result in either no change or negligible changes in average monthly temperature during all months of all water year types at these locations. Modeling indicates that results would be similar at and downstream of the location of the Delevan Pipeline Intake Facilities.

Although the specific temperature criteria of 56°F would be exceeded during several months in most water year types, the criteria is already exceeded during Existing Conditions, and implementation of the No Project/No Action Alternative would not make conditions worse. Therefore, implementation of the No Project/No Action Alternative **would not have a substantial adverse effect** on water temperatures within the Primary Study Area, when compared to Existing Conditions.

7.3.6 Impacts Associated with Alternative A

7.3.6.1 *Extended Study Area – Alternative A*

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Comparison of the modeled long-term average EC levels for Alternative A and Existing Conditions at Clifton Court Forebay indicates that EC levels are expected to decrease or remain similar in all months. Comparing water year type averages, EC levels for Alternative A are expected to decrease or remain similar in nearly all months of all water year types. Negligible increases of up to 2.6 percent are expected primarily in September of Wet, Above Normal, and Below Normal water years, and October of Below Normal water years. The modeled long-term average and water year type average EC levels at the Jones Pumping Plant if Alternative A is implemented are also expected to be lower or similar to Existing Conditions in all months.

Comparison of the modeled long-term average EC levels for Alternative A and the No Project/No Action Alternative at Clifton Court Forebay indicates that EC levels are expected to decrease or remain similar in all months. Negligible increases of up to 0.8 percent in the long-term average EC are expected to occur in December, April, and May. Comparing water year type averages, EC levels with implementation of Alternative A are again expected to be lower than or similar to the No Project/No Action Alternative in most months. In July and November of Above Normal water years, the average EC with Alternative A would increase by 6.5 percent and 6.1 percent, respectively. Further, negligible increases are expected in the winter, spring, and summer months of all water year types. The modeled long-term average and water year type average EC levels at the Jones Pumping Plant with implementation of Alternative A are also expected to be lower or similar to the No Project/No Action Alternative in most months. Negligible increases of up to 4.5 percent in EC levels are expected at the Jones Pumping Plant in a few months with implementation of Alternative A, when compared to the No Project/No Action Alternative.

Alternative A is expected to reduce the long-term average export-weighted EC, TDS, chloride, and bromide concentrations, when compared to Existing Conditions and the No Project/No Action Alternative. Similarly, the Dry and Critical water year average export-weighted concentrations are expected to decrease with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

Although minor increases in EC levels are expected with implementation of Alternative A, the largest of all the increases are expected to occur in July and November during Above Normal water years, which have relatively wetter conditions. The resulting EC levels for Above Normal water years are expected to remain below water quality standards. Other increases in EC levels are indicated in other water year types, but the modeled EC levels are expected to remain below the Ag Goal of 700 µmhos/cm during April through August, and 1,000 µmhos/cm during September through March, which is protective of various agricultural water uses, including crop irrigation and stock watering (CVRWQCB, 2011). Consequently, EC levels are also expected to remain below the drinking water goal of 900 µmhos/cm to protect human health. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on EC levels, TDS, bromide, and chloride concentrations associated with agricultural, municipal, industrial, and wildlife refuge water supply.

Central Valley Basin Plan EC criteria apply only to agricultural and drinking water supplies. Other water quality parameters, such as metals and nutrients, were not modeled as part of this analysis. The potential changes to the concentrations of these constituents are unknown at this time. However, the improvements in EC levels with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, are expected to translate into improvements in the concentrations of these constituents. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the concentrations of nutrients, metals, and other water quality constituents, including mercury, associated with the deliveries for agricultural, municipal, industrial, and wildlife refuge use.

San Luis Reservoir

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

With implementation of Alternative A, San Luis Reservoir would continue to experience water level fluctuations as it currently does. Modeled end-of-month long-term average surface water elevations for

Alternative A, when compared to Existing Conditions, indicate minor decreases of up to six feet in elevation in June through October. These decreases in surface water elevation fall within the historic range of operation for San Luis Reservoir. A comparison of water year type averages indicates an increase in elevation of up to seven feet during all months of Below Normal water years, and up to twelve feet during all months in Critical water years. During Dry water years, increases of up to eight feet are expected in January through June. Elevations would, therefore, be improved during periods in which algae blooms are a concern, with the exception of decreases of up to twelve feet in July through December of Dry water years.

Modeled end-of-month long-term average surface water elevations for Alternative A, when compared to the No Project/No Action Alternative, indicate minor decreases of up to three feet during June through August. These decreases in surface water elevation also fall within the historic range of operation for San Luis Reservoir. A comparison of water year type averages indicates an increase of up to eleven feet in all months of Below Normal water years. Elevations are expected to decrease up to 13 feet in all months in Dry and Critical water years.

End-of-month storage exceedance plots indicate that San Luis Reservoir would exceed 250,000 acre-feet 100 percent of the years in December through May with both Alternative A and the No Project/No Action Alternative, and that Alternative A would perform similarly to the No Project/No Action Alternative in June through November.

End-of-month storage exceedance plots indicate that San Luis Reservoir would exceed 250,000 acre-feet 100 percent of the years in December through May with both Alternative A and Existing Conditions. Alternative A would perform similarly to Existing Conditions in August through November. In June, Existing Conditions would exceed 250,000 acre-feet approximately 87 percent of the years, and Alternative A would exceed 250,000 acre-feet approximately 91 percent of the years. In July, Existing Conditions would exceed 250,000 acre-feet approximately 80 percent of the years, and Alternative A would exceed 250,000 acre-feet approximately 85 percent of the years.

Even with the expected decreases in surface water elevations associated with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, the end-of-month storage exceedances of 250,000 acre-feet would be similar or improved with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, operational changes at San Luis Reservoir would be expected to have a less-than-significant impact on nuisance algae blooms, when compared to Existing Conditions and the No Project/No Action Alternative.

Water quality conditions in the San Luis Reservoir depend on the Delta exports from the Banks and Jones pumping plants. Refer to **Impact SW Qual-1** for the Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use, which are directly applicable to San Luis Reservoir. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on EC levels, TDS, bromide, and chloride concentrations, metals, nutrients, and other water quality constituents in the San Luis Reservoir.

7.3.6.2 *Secondary Study Area – Alternative A*

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River downstream from Trinity River, Whiskeytown Lake, Spring Creek, Keswick Reservoir and Clear Creek

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would result in improved long-term average end-of-month storage conditions in Trinity Lake during all months. Average end-of-month storage by water year types is also expected to increase, with the largest increases of up to 16.1 percent expected to occur in Critical water years. Improved storage conditions would not be expected to adversely affect water quality, and would, therefore, have a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative. Consequently, releases from Trinity Lake to the Trinity River would not be expected to adversely impact water quality, nor would flows from the Trinity River into the Klamath River. Impacts to water quality would, therefore, be **less than significant,** when compared to Existing Conditions and the No Project/No Action Alternative.

With implementation of Alternative A, Lewiston Lake and Whiskeytown Lake would continue to operate as regulating reservoirs within their historical operational range, and would not be expected to adversely impact water quality. They would, therefore, have a **less-than-significant impact,** when compared to Existing Conditions and the No Project/No Action Alternative. Consequently, Whiskeytown Lake releases to Clear Creek would not be expected to adversely impact water quality in Clear Creek, and would, therefore, be **less than significant,** when compared to Existing Conditions and the No Project/No Action Alternative.

Spring Creek and Keswick Reservoir would also continue to operate within their historical operational ranges; therefore, water quality conditions in these waters from implementation of Alternative A would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Modeled water temperature results indicate that implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would result in negligible changes to average monthly water temperature on the Trinity River at North Fork, Trinity River at Douglas City, and Trinity River downstream of Lewiston Dam locations. Consequently, flows from the Trinity River into the Klamath River would be expected to result in negligible changes or no change to Klamath River average monthly water temperatures.

Modeling results for Alternative A also indicate negligible changes to the average monthly water temperatures for the Clear Creek at Igo, Clear Creek at Mouth, and Clear Creek downstream of Whiskeytown locations, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, Keswick Reservoir would continue to operate as a regulating reservoir. Consequently, flows from Clear Creek into Spring Creek would be expected to result in negligible changes or no change to Spring Creek average monthly water temperatures.

Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on water temperatures in Trinity Lake, Lewiston Lake, the Trinity River, Klamath River downstream from Trinity River, Whiskeytown Lake, Spring Creek, Keswick Reservoir, and Clear Creek.

Shasta Lake

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeling results indicate that implementation of Alternative A, when compared to Existing Conditions, would result in increased long-term average end-of-month storage at Shasta Lake during all months, with the exception of a negligible decrease expected during February. Modeling indicates that results for average end-of-month storage by water year type would be similar, with increased storage of up to 14.3 percent expected in all months of Critical water years. Modeling indicates that results would be similar for Alternative A, when compared to the No Project/No Action Alternative. Increased end-of-month storage would not be expected to adversely impact water quality.

Other water quality constituents of concern, including mercury and unknown toxicity, were not evaluated explicitly. However, because the Shasta Lake storage conditions are expected to improve with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, it is expected that the water quality would not be adversely impacted.

Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on Shasta Lake water quality.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-1** discussion. Improved storage conditions in Shasta Lake, with implementation of Alternative A, are expected to result in improved temperature conditions. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on water temperatures in Shasta Lake.

Sacramento River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

For the Keswick to Red Bluff reach of the Sacramento River, worst-case EC modeling results estimated at the T-C Canal Intake with implementation of Alternative A are expected to remain similar in most months of all water year types, when compared to Existing Conditions and the No Project/No Action Alternative. There is an expected increase of up to 0.4 percent in Wet water years to 2.7 percent in Critical water years in the April EC levels at the Red Bluff location, due to the reduction in the flow released from Shasta Lake to meet downstream requirements.

Similarly, for the Red Bluff to Hamilton City reach of the Sacramento River, worst-case EC modeling results estimated at the GCID Canal Intake are expected to decrease in most months if Alternative A is implemented, when compared to Existing Conditions and the No Project/No Action Alternative. A small increase of 0.6 percent in Wet water years to 3.4 percent in Critical water years is expected to occur in

March and April, and up to 1.4 percent in some of the fall months if Alternative A is implemented, when compared to Existing Conditions and No Project/No Action Alternative, due to the reduction in the Shasta release and the increased diversions at the T-C Canal Intake. For the Sacramento River reach between the GCID Canal Intake and the Delevan Pipeline Intake, worst-case EC modeling results indicate similar trends to the upstream reaches, when Alternative A is compared to Existing Conditions and the No Project/No Action Alternative. The worst-case EC levels with Alternative A upstream of the Delevan Pipeline Intake show minor increases in March of up to 1.8 percent and April of up to 5.6 percent, and up to 2.7 percent in some fall months. These increased EC levels would result from the reduction in Shasta releases and increased diversions at both the T-C Canal and GCID Canal intakes to fill Sites Reservoir.

Downstream of the Delevan Pipeline, worst-case EC levels in the Sacramento River are expected to increase in most months of all water year types with implementation of Alternative A when compared to Existing Conditions and the No Project/No Action Alternative. The largest of the increases are expected in April (up to 5.3 percent) and in the fall months (up to 5.9 percent). Small increases are also expected in some winter, spring, and summer months in all water year types.

The EC levels for the Sacramento River reach from the CBD to the entrance of the Delta at the I Street Bridge were not estimated explicitly. However, the changes in the EC levels in this reach are expected to trend consistently with the changes found in the upper Sacramento River reaches.

Increased EC levels with implementation of Alternative A would result from reductions in the flows released from Shasta Lake. Further, in the winter and spring months, increased diversions at the three intakes to fill Sites Reservoir would contribute to increased EC levels in the Sacramento River. In the summer and fall months, releases from Sites Reservoir would also cause EC levels to increase in the Sacramento River reach downstream of the Delevan Pipeline. Despite these increases, the water year type averages of the worst-case EC values with Alternative A, in all months, are expected to be below the Central Valley Basin Plan requirement of 230 μmhos/cm for the Sacramento River reach upstream of the CBD.

Therefore, the minor increases in the worst-case EC levels are considered negligible, and the impacts to Sacramento River EC levels due to the implementation of Alternative A would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Other water quality constituents of concern, including mercury and unknown toxicity on the 303(d) list of impaired waters, were not evaluated explicitly. However, the changes in the concentrations of the other water quality constituents are expected to be proportional to the changes in the worst-case EC levels with Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, the impact on other water quality constituents in the Sacramento River due to the implementation of Alternative A would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Implementation of Alternative A would allow Shasta Dam water releases with temperatures within an acceptable range, and subsequently from Keswick Dam, to maintain mean daily water temperatures year-round at levels suitable for all species and life stages of anadromous salmonids in the Sacramento River between Keswick Dam and RBDD, with particular emphasis on the months of the highest potential water temperature-related impacts (i.e., July through October) during Below Normal, Dry, and Critical water year types.

For the Sacramento River reach between Keswick and Bend Bridge, comparison of temperature results for Alternative A with Existing Conditions and the No Project/No Action Alternative indicates similar or decreased water temperatures in summer and fall months of Below Normal, Dry, and Critical water years when the ambient temperatures are higher. In the winter and spring months (December through May) when the ambient temperatures are lower, Alternative A results indicate similar or slightly elevated water temperatures of up to 1.7 percent in all water years, and in the summer months of Wet and Above Normal water years. Modeled average monthly temperatures by water year type for Alternative A indicate that the 56°F criterion for July through October would be exceeded in this Sacramento River reach during some months of Below Normal, Dry, and/or Critical water years. Although this criterion temperature would be exceeded, it is important to note that the criterion is already exceeded with Existing Conditions and the No Project/No Action Alternative at these locations, and implementation of Alternative A would result in decreased temperatures relative to Existing Conditions and the No Project/No Action Alternative.

For the Sacramento River downstream of the GCID Canal Intake near Hamilton City, water temperatures with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, are expected to be similar or lower in summer and fall months of Dry and Critical water years and in fall months of Below Normal water years when the ambient temperatures are higher. Similar or slightly elevated water temperatures are expected in winter and spring months (December through May) of up to 1.7 percent in all water years, and in the summer months of Wet, Above Normal, and Below Normal water years, when the ambient temperatures are low.

For the reach upstream of the Delevan Pipeline, the changes in water temperatures would be consistent with Hamilton City. Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, indicates similar or lower water temperatures in summer and fall months of Below Normal, Dry, and Critical water years when the ambient temperatures are higher. Similar or slightly elevated water temperatures are expected in winter and spring months (December through May) of up to 1.4 percent in all water years, and in the summer months of Wet and Above Normal water years, when the ambient temperatures are low.

Downstream of Delevan Pipeline, water temperatures in the Sacramento River may be affected by releases from Sites Reservoir. The results from preliminary temperature modeling of Sites Reservoir performed for Alternative C (Alternative C was assumed to show the worst-case conditions) indicate that in approximately 98 percent of the months, Sites Reservoir releases would be within 0.5°F of the receiving Sacramento River water temperatures. Even though the model indicates a small number of months (less than five percent) with a likely cooling impact of 0.2°F or more, the Sites Reservoir temperature results showed that it is possible to avoid such impacts by releasing from appropriate outlets. Only one month showed a cooling of more than 1°F in the 82-year simulation period. In a few years, mainly in an extended drought period when both Sites Reservoir storage and Sacramento River flow upstream of Delevan Pipeline would be low, releases from Sites Reservoir are likely to cause warming of the receiving Sacramento River waters. In less than one percent of the months, the temperatures in the Sacramento River downstream of the Delevan Pipeline are expected to increase by 1°F or more due to releases from Sites Reservoir. There are approximately five percent of the months with a likely warming impact of 0.2°F or more, although most of the months are within the same year. The warming impact is mainly found during September and October. Therefore, changes in water temperature in the Sacramento River downstream of Delevan Pipeline with implementation of Alternative A would remain consistent with the changes observed upstream of Delevan Pipeline, when compared to Existing Conditions and the No Project/No Action Alternative.

Water temperatures in the Sacramento River reach from the Feather River confluence to the I Street Bridge near the Delta approach equilibrium temperatures where the meteorological conditions primarily influence the water temperatures. Thus, the differences between Alternative A and Existing Conditions and the No Project/No Action Alternative would be minimized. Comparison of the average water temperatures for Alternative A to Existing Conditions and the No Project/No Action Alternative at the Freeport location indicates that the temperatures are expected to be similar or lower in summer and fall months of all water years. Typically, this is when the ambient temperatures are higher.

For the winter and spring months (December through May) when the ambient temperatures are low, the resulting average temperatures with implementation of Alternative A are expected to be slightly elevated by up to 0.5 percent in all water years, when compared to Existing Conditions and the No Project/No Action Alternative. Modeled average monthly temperatures by water year type for Alternative A indicate that the 68°F criterion for July through November from Hamilton City to the I Street Bridge would be exceeded at Knights Landing during some months of all water years, and at the Feather River and American River during some months of Below Normal, Dry, and Critical water years. However, it is important to note that the criterion is already exceeded with Existing Conditions and the No Project/No Action Alternative at these locations, and implementation of Alternative A would result in decreased temperatures, when compared to Existing Conditions and the No Project/No Action Alternative.

Based on the above model observations, implementation of Alternative A would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative for Sacramento River temperatures in the reach between Keswick and the I Street Bridge.

Pump Installation at the Red Bluff Pumping Plant

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Alternative A includes the installation of one pump into an existing concrete bay at the Red Bluff Pumping Plant. Operations and maintenance of this facility would include occasional dredging of the forebay to maintain design flow capacity. Pump installation and associated maintenance would occur during the annual maintenance period for the T-C Canal and would not result in sediment discharge. These activities are, therefore, expected to have a **less-than-significant impact** to EC levels and other water quality constituents in the Sacramento River, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Installation of the pump would not affect the water temperatures in the Sacramento River. Modeling results indicate that operation of this pump, as part of Alternative A, would result in similar or lower temperatures in summer and fall months of Below Normal, Dry, and Critical water years when the ambient temperatures are higher. In the winter and spring months (December through May) water temperatures would be similar or slightly elevated by up to 1.7 percent in all water years, and in the summer months of Wet and Above Normal water years, when the ambient temperatures are low. Therefore, installation of a pump at the Red Bluff Pumping Plant would have a **less-than-significant impact** on Sacramento River water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative.

Lake Oroville, Thermalito Complex, and Feather River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeling results indicate that implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would result in increased long-term average end-of-month storage at Lake Oroville in December through July, and decreased storage by up to 2.1 percent in September through November. Modeling results for average end-of-month storage indicate increases during all months of Below Normal and Critical water years, and increases in all months with the exception of minor decreases in January, February, and September in Dry water years. These overall improved storage conditions at Lake Oroville resulting from implementation of Alternative A, when compared to Existing Conditions and the No Project/no Action Alternative, would not adversely affect water quality conditions. The Thermalito Complex would continue to operate as a regulating reservoir system within its historical operational range. Consequently, releases from Lake Oroville and the Thermalito Complex would not be expected to have an adverse affect on Feather River water quality. Therefore, water quality impacts to these waters resulting from implementation of Alternative A would be **less than significant,** when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-1** discussion. Improved storage conditions in Lake Oroville would result in similar or lower temperatures, when compared to Existing Conditions and the No Project/No Action Alternative, and would therefore have a **less-than-significant impact** on water temperature in Lake Oroville.

The Thermalito Complex would continue to operate as a regulating reservoir within the historical operational range; implementation of Alternative A would, therefore, have a **less-than-significant impact** on its water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative. Modeled water temperatures for the Feather River for Alternative A indicate overall decreases, with some negligible increases in water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative. Alternative A would result in similar or lower average water temperatures at the fish barrier in the low flow channel and in the high flow channel from Thermalito to the confluence of the Sacramento River in September of all water years, when compared to Existing Conditions and the No Project/No Action Alternative. In other months, there would be minor fluctuations in average water temperatures with Alternative A, with the elevated temperatures representing less than 0.8 percent in all water years. Specific Oroville Facilities temperature targets for the Feather River Fish Hatchery would be exceeded during one or more months in Below Normal, Dry, and Critical water years. Although these criteria temperatures would be exceeded, it is important to note that the criteria are already exceeded for Existing Conditions during these months, and implementation of the Alternative A would result in either the same or decreased temperatures. These slight changes in water temperatures on the Feather River resulting from implementation of Alternative A would, therefore, result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Sutter Bypass and Yolo Bypass

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Alternative A would be operated to divert excess Sacramento River flows from November through March to fill Sites Reservoir. During these months, this operational scenario would potentially reduce flows by up to 5,900 cfs (the total maximum diversion possible at the three intakes for Sites Reservoir) in the Sutter and Yolo bypasses. Changes in operations associated with integrated operations of Sites Reservoir with Shasta Lake may also influence the frequency and magnitude of flows in the Sutter and Yolo bypasses.

Spills into the Sutter Bypass were modeled at Ord Ferry, Moulton Weir, Colusa Weir, and Tisdale Weir. The modeling of spills was performed at a daily time-step using the USRDOM model. Monthly average exceedance probability plots indicate that spills for Alternative A would be the same or similar in frequency of spills for Existing Conditions at Ord Ferry, Moulton Weir, and Colusa Weir. Exceedance probability plots for Alternative A, when compared to the No Project/No Action Alternative would be similar in frequency of spills.

Of the four weirs, Tisdale Weir spills at the lowest flow rate, when flow in the Sacramento River exceeds approximately 23,500 cfs. Colusa Weir spills when flow in the Sacramento River exceeds approximately 30,000 cfs. Ord Ferry and Moulton Weir do not spill until flow in the Sacramento River is 70,000 cfs or higher. The changes in spills for Alternative A, when compared to Existing Conditions, vary from minor increases to decreases during high flow months when the weirs are spilling. Though the overall frequency of spills is similar, the long-term average volume of spill for Alternative A, when compared to Existing Conditions, decreases by approximately five percent at Tisdale Weir and three percent at Colusa Weir, generally in the period of December through March. Exceedance probability plots for Alternative A, when compared to the No Project/No Action Alternative, show similar decreases in the volume of spills.

Spills into the Sutter Bypass from the Sacramento River represent only some of the hydrologic inputs to the lower Sutter Bypass. Large reductions in spill flows can potentially affect the available dilution flows for various water quality constituents. The relationships and interactions of the various hydrologic inputs into the Sutter Bypass and the resulting flow and flooded area in the Sutter Bypass were not modeled. It is not anticipated that the changes in spill exceedance probabilities discussed above would have a substantial impact on surface water quality in the Sutter Bypass. Therefore, it is concluded that implementation of Alternative A would result in a **less-than-significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Spills into the Yolo Bypass at Fremont Weir and Sacramento Weir and resultant flows from the Yolo Bypass into the Sacramento-San Joaquin Delta were modeled at a daily time-step using a specialized module built into the CALSIM II model. Monthly average exceedance probability plots of Yolo Bypass flows with Alternative A, when compared to Existing Conditions, indicate lower or similar exceedance probabilities, and lower long-term average flows by approximately five percent, generally in the period of December through March. It is not anticipated that the described changes in Yolo Bypass flows and outflow would have a substantial impact on surface water quality. Therefore, water quality impacts to the Yolo Bypass resulting from implementation of Alternative A would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperature modeling was not performed for the Sutter Bypass and the Yolo Bypass. However, as described above, the expected changes in spills to the Sutter Bypass represent only a portion of the input to the bypass, and flows into and out of the Yolo Bypass are expected to decrease slightly. Therefore, it is anticipated that implementation of Alternative A would have a **less-than-significant impact** on water temperature in the Sutter Bypass and Yolo Bypass, when compared to Existing Conditions and the No Project/No Action Alternative.

Folsom Lake, Lake Natoma, and American River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeled long-term average end-of-month storage for Alternative A for Folsom Lake, when compared to Existing Conditions and the No Project/No Action Alternative, indicate increased storage during all months, with the exception of a negligible decrease expected to occur in June. Average end-of-month storage results indicate similar conditions in Wet, Above Normal, and Dry water years. Negligible decreases are expected in September through January and April through June of Below Normal water years, and in August through October in Critical water years. Overall improved storage conditions in Folsom Reservoir associated with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would not be expected to adversely affect water quality. Lake Natoma would continue to operate as a regulating reservoir within its historical operational range. Thus, the changes in water quality in the two reservoirs would be negligible. Consequently, releases from Folsom Lake and Lake Natoma would not be expected to have a substantial adverse effect the water quality of the American River. Therefore, water quality impacts to these waters resulting from implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would be **less than significant.**

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-1** discussion. Increased Folsom Reservoir storage conditions and continued operation of Lake Natoma as a regulating reservoir system with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would not result in adverse impacts to their water temperatures. Therefore, the impact to water temperature at Folsom Lake and Lake Natoma would be **less than significant.**

Modeled water temperatures for the American River downstream of Nimbus Dam, at Watt Avenue, and at the mouth for Alternative A indicate that the average monthly temperatures are expected to increase in June through November in all water years, with the exception of Critical water years, by up to 1.9 percent, when compared to Existing Conditions. These months typically have warmer water temperatures and any increase can cause an adverse effect. The indicated increases would exceed the July through September temperature target at Watt Avenue during all water years except Above Normal. However, this apparent increase in temperature is actually a result of increased American River demands and the change in operations occurring with the No Project/No Action Alternative; these adverse changes are carried forward into Alternative A, but are not associated with implementation of Alternative A.

In addition, implementation of Alternative A would result in slightly decreased temperatures in July through September during Critical water years. Therefore, the impact to American River water temperatures resulting from implementation of Alternative A is considered to be **less than significant,** when compared to Existing Conditions. When the modeled water temperatures for the American River downstream of Nimbus Dam, at Watt Avenue, and at the mouth with implementation of Alternative A are compared to the No Project/No Action Alternative, the average monthly water temperatures are found to be similar in all months during all water year types. One exception is that the average monthly temperatures with implementation of Alternative A are expected to increase in July in Above Normal water years by 0.6 percent and in Below Normal water years by 1.8 percent. The increase would not exceed the July through September temperature target at Watt Avenue during Above Normal water years, but would exceed it during Below Normal water years. To verify if the expected minor increases in temperature with implementation of Alternative A would impact compliance with the Watt Avenue temperature target, exceedance probability plots were evaluated and compared to those of the No Project/No Action Alternative. In all three months, Alternative A would perform the same as the No Project/No Action Alternative. Overall, implementation of Alternative A would result in negligible changes to American River water temperatures, and therefore, would result in a **less-than-significant impact**, when compared to the No Project/No Action Alternative.

Sacramento-San Joaquin Delta

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location indicates that implementation of Alternative A, when compared to Existing Conditions, would result in similar or lower EC levels during June through January, and a slightly elevated EC levels during February through May (up to 1.3 percent). Modeled water year type average monthly EC values indicate similar trends, with increased EC during February through May, and decreased EC in other months.

The largest average EC increase is expected to occur in February in Critical water years when EC is expected to increase by 10.7 percent from approximately 459 µmhos/cm with Existing Conditions to approximately 508 µmhos/cm with Alternative A. February through May months typically have lower EC levels in the Delta because of the high natural runoff from the upstream watersheds and less salinity intrusion from the San Francisco Bay.

To verify if the minor increases in average EC levels expected in the April and May months with implementation of Alternative A would impact compliance with D-1641 salinity standards at Emmaton, exceedance probability plots of the monthly average EC values were evaluated and compared to those of Existing Conditions. The EC exceedance plots indicate that monthly average EC in April would exceed the 450 µmhos/cm Wet water year standard less than five percent of the years with Alternative A and Existing Conditions. Similarly, the monthly average EC in April with Existing Conditions and Alternative A would exceed the 630 µmhos/cm Above Normal water year standard approximately one percent of the years, and all of the years would be well under the 1,140 µmhos/cm Below Normal water year standard. During May, Alternative A and Existing Conditions would exceed 450 µmhos/cm in approximately 15 percent of the years, exceed 630 µmhos/cm in seven percent of the years, and exceed 1,140 µmhos/cm in approximately four percent of the years. In all of the years, the May monthly average EC would be less than the 1,670 µmhos/cm Dry water year standard. Therefore, in terms of compliance with D-1641 salinity standards at Emmaton, Alternative A is expected to perform, similar to Existing Conditions.

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location also indicate that Alternative A, when compared to the No Project/No Action Alternative, would result in similar or lower EC levels during June through December and elevated EC levels during January through May (up to 6.4 percent). Modeled water year type monthly average EC values indicate similar trends, with increased EC during January through May and decreased EC in other months. The largest increase in average EC is expected to occur in February in Critical water years, where the EC would increase by 25.8 percent from approximately 404 µmhos/cm with the No Project/No Action Alternative to approximately 508 µmhos/cm with Alternative A. January through May months typically have lower EC levels in the Delta because of the high natural runoff from the upstream watersheds and less salinity intrusion from the San Francisco Bay.

To verify if the minor increases in average EC levels expected in April and May with implementation of Alternative A would impact compliance with D-1641 salinity standards at Emmaton, exceedance probability plots of the monthly average EC values were evaluated and compared to the No Project/No Action Alternative. The EC exceedance plots indicate that the monthly average EC in April would exceed 450 µmhos/cm less than five percent of the years with Alternative A and the No Project/No Action Alternative. Similarly, the monthly average EC in April with the No Project/No Action Alternative and Alternative A would exceed 630 µmhos/cm in one percent of the years, and all of the years would be well under 1,140 µmhos/cm. For May, Alternative A and the No Project/No Action Alternative would exceed 450 µmhos/cm in approximately 15 percent of the years, exceed 630 µmhos/cm in eight percent of the years, and exceed 1,140 µmhos/cm in approximately four percent of the years. In all of the years, the May monthly average EC would be less than 1,670 µmhos/cm. Therefore, in terms of compliance with D-1641 salinity standards at Emmaton, Alternative A is expected to perform similar to the No Project/No Action Alternative.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location indicate that Alternative A, when compared to Existing Conditions, would result in similar or lower EC levels during all months except November, when EC levels are expected to increase by 2.4 percent. Modeled water year type average monthly EC values for Alternative A indicate lower or similar EC values, when compared to Existing Conditions during January through August months, and higher EC values during September through December by up to 28.5 percent in the Wet and Above Normal water years. In Below Normal and Dry water year types, the average EC values with implementation of Alternative A would be lower or similar to Existing Conditions in all months. In the Critical water year types, the average EC with implementation of Alternative A would be lower or similar to Existing Conditions in June through August, October, December, and January, and higher in September, November, and February through May months by up to 5.5 percent.

To verify if the minor increases in average EC levels associated with implementation of Alternative A would impact compliance with D-1641 salinity standards at Jersey Point, exceedance probability plots of the monthly average EC values for Alternative A were evaluated and compared to those of Existing Conditions. The EC exceedance plots indicate that the monthly average EC in April would exceed 450 µmhos/cm less than 0.5 percent of the years with Alternative A and Existing Conditions, and all of the years would be well under 740 µmhos/cm. Similarly, the monthly average EC in May with Existing Conditions and Alternative A would exceed 450 µmhos/cm in approximately six percent of the years, would exceed 740 µmhos/cm in approximately three percent of the years, and all of the years would be well under 1,350 µmhos/cm. For June, July, and August, the number of years that Alternative A would exceed the compliance standards at Jersey Point would be similar to or lower than Existing Conditions. Therefore, in terms of compliance with D-1641 salinity standards at Jersey Point, Alternative A would perform similar to Existing Conditions.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location with implementation of Alternative A, when compared to the No Project/No Action Alternative, indicate similar or lower EC levels during June through October and December, and higher EC levels during November, and January through May, where EC is expected to increase by up to 4.9 percent. Modeled water year type average monthly EC values for Alternative A indicate lower or similar EC values, when compared to the No Project/No Action Alternative during January through August months, and higher EC values during September through December by up to 17.6 percent in the Wet water years. In Above Normal water years, Alternative A EC levels are expected to be lower or similar in March through June months and in August and September, with increased EC levels in other months by up to 26 percent, when compared to the No Project/No Action Alternative. In Below Normal and Dry water years, the average EC values with implementation of Alternative A are expected to be lower or similar to the No Project/No Action Alternative in the most months. January, February, and March are expected to have slightly elevated EC levels of up to 3.5 percent with Alternative A, when compared to the No Project/No Action Alternative in the Below Normal water years. In Dry water years, the average EC levels with Alternative A are expected to increase by up to 2.7 percent, when compared to the No Project/No Action Alternative, in April, November, and December. In Critical water years, the average EC with Alternative A is expected to be lower or similar to the No Project/No Action Alternative in June, July, October, and December, and higher in August, September, November, and January through May by up to 10.2 percent.

To verify if the minor increases in the average EC levels expected in April and May with implementation of Alternative A would impact compliance with D-1641 standards at Jersey Point, exceedance probability plots of the monthly average EC values were evaluated and compared to the No Project/No Action Alternative. As indicated in the EC exceedance plots, the monthly average EC in April would exceed 450 µmhos/cm in approximately 0.5 percent of the years with Alternative A and the No Project/No Action Alternative, and all of the years are expected to be well under 740 µmhos/cm. For May, both Alternative A and the No Project/No Action Alternative would exceed 450 µmhos/cm in approximately five percent of the years, exceed 740 µmhos/cm in three percent of the years, and in all of the years, the May monthly average EC would be less than 1,350 µmhos/cm. For June, July, and August, the number of years that Alternative A would exceed the compliance standards at Jersey Point is similar to or lower than those of the No Project/No Action Alternative. Therefore, in terms of the compliance with D-1641 salinity standards at Jersey Point, Alternative A would perform similar to the No Project/No Action Alternative.

Implementation of Alternative A would provide supplemental Delta outflow during summer and fall months (May through December) to improve X2 position and increase estuarine habitat. Modeling results indicate that implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would result in eastward movement of X2 by up to 0.9 km in December through May, and a westward movement of X2 by up to 1.4 km in June through November on a long-term average basis. In Wet water years, the average X2 position with Alternative A would move eastward in October through May by up to 0.7 km, and would move up to 1.2 km westward in June through September, when compared to Existing Conditions and the No Project/No Action Alternative. In Above Normal water years, the average X2 position with Alternative A would move eastward in

November through May by up to 0.9 km, and would move up to 1.6 km westward in June through October, when compared to Existing Conditions and the No Project/No Action Alternative. In Below Normal and Dry water years, the average X2 position with Alternative A would move eastward in January through May by up to 1.7 km, and would move up to 1.9 km westward in June through December, when compared to Existing Conditions and the No Project/No Action Alternative. In Critical water years, the average X2 position with implementation of Alternative A would move eastward in February through May and November by up to two km, and would move up to 1.2 km westward in June through January, when compared to Existing Conditions and the No Project/No Action Alternative.

Even though modeling results for the average X2 position in the February through June D-1641compliance period indicate slight eastward movement, Alternative A would comply with the D-1641 spring X2 position requirements. During the September through November compliance period, the monthly average X2 position with implementation of Alternative A would be at or westward of the X2 position for Existing Conditions and the No Project/No Action Alternative.

Implementation of Alternative A would generally improve Delta salinity conditions in the summer and fall months, which are the peak salinity intrusion periods, with minor increased EC levels in the winter and spring months Alternative A complies with the X2 standards for both spring and fall. Salinity conditions at the Emmaton and Jersey Point compliance locations and X2 location are good indicators of the salinity conditions in the Delta. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the salinity conditions in the Delta. EC is a good indicator of other water quality constituents in the Delta. Therefore, implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the other water quality constituents in the Delta.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for the Delta, and there are no specific water temperature criteria in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (SWRCB, 2006). However, water temperatures in the Delta approach equilibrium temperatures where the meteorological conditions primarily influence the water temperatures. Thus, the differences between Alternative A and Existing Conditions and the No Project/No Action Alternative are minimized. Therefore, implementation of Alternative A would results in a **less-than-significant impact** on water temperature in the Delta**,** when compared to Existing Conditions and the No Project/No Action Alternative.

Suisun Bay, San Pablo Bay, San Francisco Bay

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Model simulations for Delta outflow indicate that implementation of Alternative A would result in increased average monthly outflow in the summer and fall months, when conditions are relatively Dry, and small reductions in Delta outflow in the winter and spring months, when the conditions are Wet, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, these changes would result in a **less-than-significant impact** to the water quality conditions in Suisun Bay, San

Pablo Bay, and San Francisco Bay with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for Suisun Bay, San Pablo Bay, or San Francisco Bay, and there are no specific water temperature criteria in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (SWRCB, 2006). Based on the seasonal flow changes described above with the implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative, and because temperatures in Suisun Bay, San Pablo Bay, and San Francisco Bay are primarily controlled by the meteorological conditions, the impacts to water temperature would be **less than significant**.

7.3.6.3 *Primary Study Area – Alternative A*

Construction, Operation, and Maintenance Impacts

Impacts to surface water quality could result from the following Project construction activities:

- Soil disturbing activities such as clearing, grubbing, and earthwork that may affect drainage patterns and contribute to erosion and increased turbidity in receiving waters.
- Stockpiles of construction material that have the potential to contribute to increased deposition of sediment to receiving waters through stormwater and wind erosion.
- New unpaved construction access roads that may contribute to increased sediment deposition through wind erosion.
- Construction-related hazardous material spills.
- Temporary diversion of surface waters around construction sites.
- Dewatering of shallow groundwater.
- Disposal of concrete waste.
- Vehicle and equipment cleaning, fueling, and maintenance.
- Pile driving activities.

These activities and their potential effects on surface water quality are discussed below for the Project facilities that are proposed as part of Alternative A.

Sites Reservoir Inundation Area

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The proposed 1.27-MAF Sites Reservoir would inundate Stone Corral, Funks, Grapevine, and Antelope creeks. It would also inundate Salt Lake. Construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around construction sites, and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills.

These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Salt Lake is a 28-acre area of impounded water and seasonal wetlands located within the Sites Reservoir Inundation Area. Salt Lake is formed by warm salt springs that occur upslope. Measured EC, hardness, total dissolved solids, dissolved sodium, chloride, magnesium, and boron exceeded all applicable Central Valley Basin Plan criteria (DWR, 2012) at Salt Lake. In addition, a few metals were noted at very high concentrations (aluminum, iron, and manganese) and exceeded all criteria; and a few others exceeded some criteria (arsenic, copper, lead, and nickel). Levels of some nutrients (ammonia and orthophosphate) were noted at high levels and exceeded Central Valley Basin Plan criteria (CVRWQCB, 2011). The impact to Sites Reservoir water quality that would result from Salt Lake impoundment within the reservoir footprint would be **potentially significant.**

Refer to the **Impact SW Qual-1** discussion for the Sacramento River (Secondary Study Area discussion) for the effects of Sites Reservoir diversions and releases. Implementation of Alternative A is expected to result in a worst-case long-term average EC of 190 to 192 µmhos/cm in Sites Reservoir. The EC levels would not vary significantly among various months. Fall months show slightly lower EC levels, when compared to spring months, when Sites Reservoir is filled with water from the Sacramento River. Modeled water year type averages indicate that average worst-case EC levels would range from approximately 187 µmhos/cm in fall months of Above Normal water years to 195 µmhos/cm in spring months of Critical water years. The worst-case EC calculations include only EC from the river; they do not include EC from the inundated soils and do not consider evaporation. Based on the above model observations, releases from the reservoir into Funks and Stone Corral creeks, as well as releases into the T-C and GCID canals, would have average worst-case EC levels that fall well below the Ag Goal that is protective of agricultural water uses. Therefore, implementation of Alternative A would result in a **less-than-significant impact** in the receiving waters affected by releases from Sites Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

Although Project impacts to EC levels as an indicator of expected general water quality conditions suggest municipal and agricultural beneficial uses would be affected at a less-than-significant level, Project effects for numerous other water quality constituents of concern are not well understood. In newly constructed reservoirs, water quality issues commonly include eutrophication (nutrient enrichment leading to nuisance algal production), sedimentation, stratification, oxygen depletion, and chemical changes in the deeper layers. The extent to which these occur depends largely upon the morphometric (i.e., size and depth) and limnological (water biology) characteristics of the reservoir, such as mixing (wind and seasonal factors), light penetration, and biological productivity, all of which are affected to some extent by the source of water, richness of the soils being flooded, and operation of the dam (URS, 2002). These water quality issues, including sedimentation, eutrophication, oxygen depletion, methylmercury levels, and chemical transformations within the water column, were not modeled, and are, therefore, considered to be **potentially significant** with implementation of Alternative A.

Maintenance activities would include debris and vegetation removal from the embankments. In addition, ongoing movement and seepage monitoring would be necessary. Impacts associated with these maintenance activities are expected to be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-2** Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on surface water temperatures. That discussion of Sites Reservoir release temperatures is applicable to release temperatures in Funks and Stone Corral creeks, as well as to the T-C and GCID canals.

Sites Reservoir Dams

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Construction of Golden Gate Dam would result in an obstruction of flows to Funks Creek, and the construction of Sites Dam would result in an obstruction of Stone Corral Creek. Some boring would occur during grout injection of damsites during which drilling mud would be used. Drilling mud is typically a betonite (clay)-based material containing various chemical additives that may have deleterious effects if discharged into receiving waters. Some blasting may be necessary during the preparation of the dam foundations. Construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around construction sites, dewatering, and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative. Once the dams are constructed and Sites Reservoir is filled, there are few dam operations required, other than the release of water from the reservoir during normal operations using the multi-level intake to optimize water quality and temperatures, or emergency operational releases. Releases could affect water quality within Sites Reservoir or downstream in receiving waters. However, these impacts are discussed for the appropriate receiving bodies of water. Typical ongoing dam maintenance would consist of equipment, foundation, and embankment inspections and repairs. Debris and vegetation removal from the embankments would be required. In addition, ongoing movement and seepage monitoring would be necessary. Water quality impacts associated with these maintenance activities would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

The saddle dams surrounding Sites Reservoir are not located near a stream, and therefore, would have **no impact** on water temperatures during construction. During construction of Sites and Golden Gate dams, the ephemeral Funks and Stone Corral creeks would be diverted. Funks Creek would be diverted away from the Golden Gate Dam construction site and routed to Stone Corral Creek; however, flows would continue to be released downstream of Funks Reservoir to maintain aquatic life. Stone Corral Creek and flows from Funks Creek would then be diverted around the Sites Dam construction site to continue downstream in the Stone Corral Creek channel. Cofferdams would be used to impound water at both sites before waters are diverted. Flow patterns would not be altered substantially from existing ephemeral conditions, and there are no downstream coldwater beneficial uses. Dam construction would, therefore, result in a **less-than-significant impact** on water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation, the saddle dams would not release water and would, therefore, have **no impact** on water temperatures. Sites and Golden Gate dams would release maintenance flows into Stone Corral and

Funks creeks, respectively. Refer to the **Impact SW Qual-2** Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on water temperatures. That discussion of Sites Reservoir release temperatures is applicable to release temperatures in Funks and Stone Corral creeks.

Typical ongoing dam maintenance would consist of equipment, foundation, and embankment inspections and repairs. Debris and vegetation removal from the embankments would be required. In addition, ongoing movement and seepage monitoring would be necessary. These maintenance activities would occur outside of the proposed reservoir, and would have a **less-than-significant impact** on water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative.

Recreation Areas

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

It is anticipated that all construction activities associated with the five proposed recreation areas would occur within the footprints of the recreation areas, associated boat ramps, and the temporary and permanent access road/utility areas. Construction activities would result in ground-disturbing activities, and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills. These construction activities would, therefore, have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Operations of these recreational facilities would include recreation use such as hiking, camping, picnicking, and swimming. These activities could result in increased erosion, accidental hazardous or other types of materials spills, or the introduction of detergents, sewage, or solid wastes to the proposed reservoir. The provision of designated roads, trails, parking lots, campsites, beaches, day use areas, restrooms, and garbage containers would reduce the potential impacts of these activities to **less than significant**.

Recreation use would also include boating. Accidental hazardous spills from motorboats primarily occur while fueling at marina facilities. No marina or fueling facilities would be constructed at Sites Reservoir. Therefore, motorboat operation associated with recreation activities would be expected to have a **less-than-significant impact** on surface water quality.

Maintenance activities would include periodic inspection and repair of wells and water systems; vegetation trimming and management; restroom/vault toilet cleaning, stocking of supplies, pumpout, inspection, and repair; and road grading. During peak recreation use periods, these activities would likely occur on a daily basis, except for road grading, which is expected to occur once per year prior to the start of the recreation season, and repairs, which would occur when needed. During the non-peak period, the activities other than road grading would likely occur on a weekly basis and repairs would occur when needed. Water quality impacts associated with most of the described maintenance activities are, therefore, expected to be **less than significant**. However, road grading activities could result in a **potentially significant impact** due to increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills, when compared to Existing Conditions and the No Project/No Action Alternative.

Road Relocations and South Bridge

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The construction disturbance area for the road relocations would include the footprint of the proposed roads and stream crossings, the materials and equipment staging areas, the area needed to construct the facilities, and construction access roads. Given the miles of new asphalt roads being constructed for the Project and the remote site location, an asphalt batch plant would be built on-site adjacent to the Field Office Maintenance Yard. Construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around construction sites, dewatering, and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills. These construction activities would, therefore, have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

During Project operation, vehicles associated with recreational users, operations staff, and local traffic have the potential to leak fluids, resulting in accidental hazardous or other types of materials spills while traveling on the roads and the bridge. Potential pollutant sources from the Project roads and bridge include motor vehicles; highway surface materials, such as fine particles of asphalt and concrete; erodible shoulder materials; eroding cut and filled slopes; abrasive sand and deicing salts used in winter operations; abraded tire rubber; illegal dumping; and fluids from accidents and spills (SWRCB, 2012b). Pollutant categories include, but are not limited to, metals (such as copper, lead, and zinc); synthetic organic compounds (pesticides); Polycyclic Aromatic Hydrocarbons (PAHs) from vehicle emissions, oil, and grease; Total Petroleum Hydrocarbons (TPH); sediment; nutrients (nitrogen and phosphorus fertilizers); debris (trash and litter); pathogens; and oxygen demanding substances (decaying vegetation, animal waste, and other organic matter (SWRCB, 2012b).These pollutants are at risk of entering natural receiving waters during precipitation events and would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Typical paved road maintenance would include chip sealing, patching, crack filling, asphalt overlays, embankment erosion repair, and vegetation control and maintenance. Typical culvert and minor bridge maintenance would include debris removal. Gravel road maintenance could include periodic grading. Typical bridge maintenance would include debris clearing from bridge deck and deck drainage outlets and abutment erosion maintenance and repair. Bridge maintenance could also include the periodic repair of guard rails, or the replacement of light fixtures. These maintenance activities could result in the accidental spill of hazardous materials or concrete waste, and therefore, would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Pumping/Generating Plant, Sites Reservoir Inlet/Outlet Structure and Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Construction activities associated with these facilities would result in ground-disturbing activities, the temporary diversion of surface waters around construction sites, dewatering, and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills. These construction activities would, therefore, have a **potentially significant impact** on surface water quality when compared to Existing Conditions and the No Project/No Action Alternative.

These facilities would only convey water to and from Sites Reservoir; therefore, their operation would have **no impact** on surface water quality.

Routine maintenance and monitoring would likely be required on a daily basis. Regular maintenance and inspection would be done for each pump unit and the related equipment, such as gates, valves, and electrical equipment. It is possible that accidental spills of lubricants or other fluids could occur during maintenance of the pumping/generating plant. However, the plant design includes a spill containment system and a hazardous materials storage sump. Therefore, these maintenance activities would have a **less-than-significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

The pumping plant, inlet structure, and tunnel are not located near a stream, and therefore, would have **no impact** on water temperatures during construction. The footprint of the outlet structure would overlap with a portion of Funks Creek, upstream of Funks Reservoir. During construction of this facility, Funks Creek would be diverted away from the construction site, and releases would be made into Funks Creek downstream of Funks Reservoir to maintain aquatic life. Flows from Funks Creek would be diverted around the Sites Dam construction site to continue downstream in the Stone Corral Creek channel. Flow patterns would not be substantially altered from existing ephemeral conditions, and there are no downstream coldwater beneficial uses. Outlet structure construction would therefore result in a **less-than-significant impact** on water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative.

During operation, these Project facilities would convey water to and from Sites Reservoir. Refer to the **Impact SW Qual-2** Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on water temperatures.

Routine maintenance, including the inspection of equipment, would not be expected to interfere with facilities operations and would, therefore, have **no impact** on water temperatures, when compared to Existing Conditions and the No Project/No Action Alternative.

Sites Electrical Switchyard, Delevan Pipeline Electrical Switchyard, and Delevan Transmission Line

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The construction disturbance area for the Delevan Pipeline Electrical Switchyard and Delevan Transmission Line would be completely contained within the construction disturbance area of the Delevan Pipeline. The existing agricultural fields where the transmission line alignment would cross would be fallowed and not watered. Anticipated major construction activities include clearing and grading the construction workspace; placing necessary construction materials at staging areas; preparing the substation pads, and excavating and constructing tower footings. The construction disturbance area for the switchyards would include the footprint of the proposed facilities, the materials and equipment staging area, the area needed to construct the facilities, electrical transformer area, and temporary access roads. Construction activities would result in ground-disturbing activities and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of the switchyards and transmission lines is an unmanned activity. Because these facilities would not store or release water, their operation would have **no impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

The transmission line would require only periodic inspection and maintenance (once or twice a year), using few vehicles and personnel. The maintenance activities would, therefore, result in **no impact** to water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance of the electrical switchyards may include annual washing and cleaning of insulating equipment, and landscape maintenance. These maintenance activities could result in ground disturbance and accidental hazardous or other types of materials spills. Therefore, the maintenance of these facilities would be a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Field Office Maintenance Yard

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Construction of the Field Office Maintenance Yard would include transportation and placement of materials to the Project site, clearing and grading, construction of the buildings and ancillary facilities (e.g., leach field, water treatment, incinerator), and site restoration after construction is complete. Construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around the Project construction site, and could result in increased erosion, sediment deposition, and/or accidental hazardous or other types of materials spills. These construction activities would have a **potentially significant** impact on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Spare parts for mechanical and electrical equipment would be stored in the warehouse along with lubricants, oils, and greases to maintain equipment. Daily operations could include personnel traveling from the Field Office Maintenance Yard to Project facilities and performing scheduled repairs and maintenance of Project equipment, observing canals and Project facilities, fueling and washing vehicles and equipment, gathering technical data on water quality and Project facilities, and as-needed repairs. Equipment repair and overhaul (e.g., pumps, turbines) may take place at this facility.

Operational activities related to the storage of hazardous materials and repair of equipment and vehicles could result in accidental spills, and could, therefore, have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Periodic maintenance would be performed on an as-needed basis including road, vegetation, and fence maintenance, as well as debris removal. These maintenance activities could result in increased erosion, sediment deposition, or accidental hazardous or other types of materials spills, and would, therefore, have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Holthouse Reservoir Complex and Holthouse Reservoir Electrical Switchyard

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The existing Funks Reservoir would be dredged to remove accumulated sediment. Funks Creek would be diverted around the Project construction site, and Funks Reservoir would be dewatered. Installation of a T-C Canal construction bypass pipeline would also be required to divert T-C Canal flows before starting modifications to the existing Funks Reservoir or constructing the new facilities. Construction activities associated with Funks Reservoir dredging, the Holthouse Reservoir Complex, and the Holthouse Reservoir Electrical Switchyard would result in ground-disturbing activities, the temporary diversion of surface waters around the Project construction site, and dewatering, and could result in increased erosion or sediment deposition. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Comparison between Alternative A modeled EC levels for Funks Reservoir versus Existing Conditions and the No Project/No Action Alternative indicate that these levels would increase by up to 37 percent during all months of all water year types. These increases in EC are expected to be greatest during the summer and fall months when flow is generally released from Sites Reservoir for agricultural use. The elevated EC values in November can be attributed to the initial Sites Reservoir inundation period following the previous release period when Sites Reservoir is at the lowest storage level for the year. Funks Reservoir and the Holthouse Reservoir Complex would be hydrologically connected, so EC levels for Holthouse Reservoir would be the same as described for Funks Reservoir. Despite these large increases, EC levels would fall below the Ag Goal that is protective of agricultural water uses. Implementation of Alternative A would, therefore, result in a **less-than-significant impact** on water quality (based on modeled EC conditions as an indicator of general water quality conditions), when compared to Existing Conditions and the No Project/No Action Alternative.

Other water quality issues, including sedimentation, eutrophication, oxygen depletion, methylmercury levels, and chemical transformations within the water column, were not modeled, and are, therefore, considered to be **potentially significant** with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

Current periodic maintenance required for the existing Funks Reservoir includes road, vegetation, and fence maintenance, as well as debris removal, on an as-needed basis. The reservoir is also drained annually. These maintenance activities are expected to continue after Funks Reservoir dredging and connection to Holthouse Reservoir. Maintenance of the electrical switchyard may include annual washing and cleaning of insulating equipment, and landscape maintenance. These maintenance activities could result in ground disturbance, the temporary diversion of surface waters around the Project construction site, accidental hazardous or other types of materials spills, and increased erosion or sediment deposition. Therefore, there would be a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Dredging activities would require the draining of Funks Reservoir; currently (i.e., Existing Conditions), the reservoir is drained annually for maintenance. A T-C Canal bypass would be constructed prior to draining the reservoir so that canal flows would not be disrupted. Construction of Holthouse Reservoir would not affect the T-C Canal, but would affect a portion of Funks Creek immediately downstream of Funks Reservoir. However, flows would be maintained in Funks Creek downstream of Funks Reservoir to maintain aquatic life. Funks Reservoir dredging and the construction of the Holthouse Reservoir Complex would, therefore, have **no impact** on water temperatures in the T-C Canal or Funks Creek, when compared to Existing Conditions and the No Project/No Action Alternative.

The Holthouse Reservoir Complex would act as a regulating reservoir for Sites Reservoir. Refer to the **Impact SW Qual-2** Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on water temperatures.

The existing Funks Reservoir is drained annually for maintenance. T-C Canal operations accommodate this maintenance period. This maintenance activity is expected to continue after Funks Reservoir dredging and connection to Holthouse Reservoir. T-C Canal operations would be expected to continue as they do during maintenance of the existing Funks Reservoir, and flows would be maintained downstream in Funks Creek during maintenance. Therefore, maintenance activities associated with the Holthouse Reservoir Complex would have **a less-than significant impact** on water temperatures in the T-C Canal and Funks Creek, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Facilities Modifications

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Construction activities associated with the new GCID Canal headgate structure, lining a portion of the canal, and replacing a railroad siphon would occur during the annual maintenance period when the canal is dry, but hazardous materials, sediment, and Portland cement wastes could be mobilized when the canal is re-watered. These activities would, therefore, be expected to have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Operation of the GCID Canal Intake following completion of Project construction would be similar to Existing Conditions, although an increase in wintertime operation could occur. Refer to the Secondary Study Area discussion for Sacramento River water quality impacts associated with increased diversions.

Required maintenance activities would be very similar to current maintenance. However, additional sediment removal activities may be required due to increased wintertime operation. The new headgate structure would require annual inspection and maintenance, including painting and motor control unit inspections, similar to typical check structures along the canal. Increased sediment removal activities could result in increased erosion, sediment deposition, or accidental hazardous or other types of materials spills, and would, therefore, have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

There would be no impact to water temperatures resulting from modification of the GCID Canal because construction would be performed while the canal is dewatered. Following completion of the modification, operation of the canal would be similar to Existing Conditions, and annual maintenance activities would continue to be performed when the canal is dry. These activities would, therefore, be expected to have **no impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Glenn-Colusa Irrigation District Canal Connection to the Terminal Regulating Reservoir, Terminal Regulating Reservoir, Terminal Regulating Reservoir Pumping/Generating Plant, Terminal Regulating Reservoir Pipeline, Terminal Regulating Reservoir Electrical Switchyard, and Terminal Regulating Reservoir Pipeline Road

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

It is anticipated that the reservoir inlet/connection from the GCID Canal to the TRR would be constructed by first building a temporary bypass channel to the west of the existing canal alignment. The temporary bypass channel would connect into the GCID Canal upstream and downstream of the construction zone to supply water to the reach of the Canal downstream of the TRR facilities area. The temporary bypass channel would be constructed using a combination of excavation, earth embankment, and sheet pile walls to isolate the Project construction site from the diversion canal. Anticipated major construction activities associated with the remaining TRR facilities include transportation of materials to the Project site, clearing and grading the construction work space, staging of construction materials, dewatering, and excavation and embankment construction. Construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around Project construction sites, and could result in increased erosion or sediment deposition. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Operational impacts to water quality for the TRR and for potential releases from the TRR to the Funks Creek Pipeline into Funks Creek are expected to be the same as described for the GCID Canal intake structure. These impacts would be **less than significant** for EC as a general water quality indicator. However, sedimentation, eutrophication, oxygen depletion, and chemical transformations within the water column have not been evaluated, and would, therefore, have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Maintenance activities would include removing debris that could collect upstream of check structures, maintaining gate operators to provide adequate control of gates, periodically repairing and re-painting the connection, road maintenance, and dredging the dissipation bay and inlet channel for sediment concurrently with the TRR dredging. Maintenance of the electrical switchyard may include annual washing and cleaning of insulating equipment, and landscape maintenance. Typical maintenance of the reservoir would include dredging to remove sediment when the reservoir is drained, clearing vegetation from the slopes of the embankments, and maintaining the gravel service road atop the embankment. Maintenance activities could result in ground-disturbing activities accidental hazardous or other types of materials spills, and increased erosion or sediment deposition. These maintenance activities would have a

potentially significant impact on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Prior to the start of construction of these facilities, a temporary bypass channel would be constructed to connect into the GCID Canal upstream and downstream of the construction disturbance area. During construction of these facilities, water deliveries within the canal would not be interrupted. Construction activities would, therefore, have **no impact** on water temperatures within the canal, when compared to Existing Conditions and the No Project/No Action Alternative.

For the impacts of the integrated operation of these facilities with Sites Reservoir releases on water temperatures, refer to the Alternative A Secondary Study Area **Impact SW Qual-2** discussion for the Sacramento River.

Maintenance activities that could affect the GCID Canal would be performed during the annual maintenance period of the canal, and would, therefore, have **no impact** on water temperatures within the canal, when compared to Existing Conditions and the No Project/No Action Alternative.

Delevan Pipeline

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Construction of the Delevan Pipeline would likely be performed in independent and concurrent sections. Construction of two of the sections would likely begin from the same point and move in opposite directions. As pipelines are installed and tested, the trench would be backfilled to minimize the amount of trench that is left open. Approximately 6.3 million cubic yards of material would be excavated for the pipeline trench. Excavated material would be stockpiled within the construction disturbance area and managed with standard stormwater pollution prevention practices. Trench side slopes would be approximately 1:1.5. No shoring would be installed under normal excavation conditions. Dewatering of the trench would be necessary in many locations and could be permitted to discharge into local irrigation ditches and drainage canals and/or the CBD after settling of silt. One foot of bedding material would be installed in the trench before installation of the pipeline. Bedding material would likely be sand, consolidated backfill, or cemented controlled density fill (CDF).

Excavated material would be reused to backfill the pipeline trench or would be moved to other Project locations for use, to the extent possible, after placement of the pipes. Excess spoils from the excavation (estimated at 1.3 cubic yards) would be spread on adjacent agricultural lands of willing landowners within the 800-yard-wide corridor along the pipeline alignment, used as backfill at the Sacramento River Pumping/Generating Plant, or placed in the Sites Reservoir footprint. These construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around the Project construction site, dewatering, and could result in increased erosion or sediment deposition. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

The Delevan Pipeline would convey water to and from Sites Reservoir and its associated regulating reservoirs, and therefore, the pipeline’s operation would have **no impact** on surface water quality.

Periodic pipeline inspection and maintenance would likely occur once per year, typically in the months of April and May, with possible additional inspections and maintenance needed after earthquakes or storm, flood, or other emergency events. Permanent rights-of-way for the land overlying the pipeline would be maintained to guarantee future access. These routine maintenance activities are expected to have a **less-than-significant impact** to water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Because the Delevan Pipeline would convey water underground between Sites Reservoir and its associated regulating reservoirs and the Sacramento River, it is expected to have **no impact** to water temperatures.

Delevan Pipeline Intake Facilities

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The Delevan Pipeline Intake Facilities are a system of structures designed to divert water from the Sacramento River, to safely release water from Sites Reservoir to the Sacramento River, and to generate electricity when water is released from Holthouse Reservoir through the Delevan Pipeline to the Sacramento River.

To isolate the construction area from the Sacramento River, a cellular sheet pile cofferdam would be installed in the Sacramento River near the location of the proposed fish screen. Approximately 1,200 feet of sheet piles would be required. The cofferdam would likely remain in place throughout the duration of Project facility construction. The area behind the cofferdam would be dewatered prior to construction by pumping water out from behind the cofferdam. After construction of the Project pump station is complete, the cofferdam would be removed by pulling the sheet piles out of the river and restoring the river to its previous condition. These construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around the Project construction site, dewatering, and could result in increased erosion or sediment deposition. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Diversion operations would be such that a minimum of 4,000 cfs would remain in the river channel immediately downstream of the diversion point. The expected associated minimum water surface elevation at this design condition is 51 feet. The invert of the screen structure would be set at 38 feet (four feet above the invert of the river) to reduce sediment deposition in front of the screen panels.

Intake mode would occur when the diversion is pumping water from the Sacramento River to Sites Reservoir. The Intake Facility would have the largest flows and velocities during intake mode. Water would flow through the fish screen into the forebay, through the levee tubes, into the afterbay, and then would be pumped to Sites Reservoir. During this operation, the screen cleaning mechanism would be working continuously to prevent buildup on the screen panels, and the sediment removal system would operate.

Discharge mode would occur when water from Sites Reservoir would flow back through the pumping plant to generate electricity, and the water would be discharged into the afterbay, through the levee tubes, into the forebay, and then through the fish screen and into the Sacramento River. During this activity, the sediment removal system would operate.

The diversions and the discharge at the Delevan Pipeline Intake Facilities would contribute to the worst-case EC levels in the Sacramento River. Refer to the Secondary Study Area discussion for Sacramento River water quality impacts associated with these diversions and discharges.

A jetted-piping sediment removal system would be installed behind the fish screens, moving sediment that collects behind the fish screens back into the river channel, or into the forebay. Sediment that settles in the forebay would be removed, as needed, with mechanical dredging equipment to maintain optimal operational hydraulics. Depending on sediment load in the river, the forebay may need to be cleaned annually. Operation of the sediment removal system has the potential to adversely affect turbidity in the Sacramento River if excess sediment is moved back into the river channel. This impact would be **potentially significant,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the Alternative A **Impact SW Qual-2** Secondary Study Area discussion for the Sacramento River regarding water temperature impacts associated with diversions and releases from the Delevan Pipeline Intake Facilities.

Project Buffer

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Construction activities within the Project Buffer include the demolition and removal of existing structures, installation of fencing, and the creation of a fuelbreak. These ground-disturbing activities may cause erosion that could result in a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Agricultural lands within the Project Buffer would be converted to annual vegetative cover to prevent wind and water erosion of soil. This conversion would minimize the potential for erosion, and would therefore, be expected to have a **less than significant impact** on surface water quality, when compared to Existing Conditions and the No Project/ No Action Alternative.

No activities are planned or expected to occur within the Project Buffer during Project operation. Operation of the buffer would, therefore, have **no impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative. Project maintenance activities would include fence repair and fuelbreak maintenance.

Fence repair, such as the replacement of a post or barbed wire, would require little to no ground disturbance, and would, therefore, have a **less-than significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Fuelbreak maintenance, which could include additional disking or grading activities that would result in ground disturbance, may cause erosion that could result in a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

7.3.7 Impacts Associated with Alternative B

7.3.7.1 *Extended Study Area – Alternative B*

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Comparison of the modeled long-term average EC levels for Alternative B and Existing Conditions at Clifton Court Forebay indicates that EC levels are expected to decrease by up to 8.3 percent in all months. Comparing the water year type averages, EC levels for Alternative B would be reduced in nearly all months of all water year types. Minor increases of up to 4.3 percent are expected primarily in November and December of Above Normal water years, and October of Critical water years. The modeled long-term average and water year type average EC levels at the Jones Pumping Plant with implementation of Alternative B, when compared to Existing Conditions would be similarly reduced, with the exception of negligible increases of up to 1.9 percent in November of Above Normal water years and October of Critical water years.

Comparison of the modeled long-term average EC levels for Alternative B and the No Project/No Action Alternative at Clifton Court Forebay indicates that EC levels are expected to decrease or remain similar in all months. Negligible increases of up to 0.8 percent in the long-term average EC are expected to occur in December. Comparing the water year type averages, EC levels with implementation of Alternative B are expected to increase by up to 2.5 percent in December, March through May, and July in Wet water years. EC levels are also expected to increase by up to 5.8 percent in November through July in Above Normal water years; by up to 1.3 percent in April, May, and July of Below Normal water years; by up to 2.5 percent in December, May, and June in Dry water years; and by up to 3.4 percent in October and December of Critical water years. The modeled long-term average EC levels at the Jones Pumping Plant with implementation of Alternative B are also expected to be lower or similar to the No Project/No Action Alternative in most months, with negligible increases of up to 0.7 percent expected in December and March through June. Comparing the water year type averages, EC levels with implementation of Alternative B at the Jones Pumping Plant are expected to increase similarly to those described for Clifton Court Forebay, but would experience negligible increases in EC levels during more months in Below Normal, Dry, and Critical water years.

Similar to Alternative A, modeling results indicate that Alternative B is expected to reduce the long-term average export-weighted EC, TDS, chloride, and bromide concentrations, when compared to Existing Conditions and the No Project/No Action Alternative. Similarly, the Dry and Critical water year average export-weighted concentrations are expected to decrease with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative.

Although minor increases in EC levels are expected with implementation of Alternative B, the largest of all of the increases are expected to occur in July, November, and December during Above Normal water years, which have relatively wetter conditions. The resulting increased EC levels for Above Normal water years for these months would be highest in December (up to 517 µmhos/cm). These modeled increases in EC levels are, therefore, expected to be below the Ag Goal and drinking water goal.

During the Below Normal, Dry, and Critical water year types, the expected negligible increases would result in higher EC levels than those described for Above Normal water years. The highest EC levels resulting from an increase would occur during the time of year when the Ag Goal is 1,000 µmhos/cm (September through March), and the drinking water goal is 900 µmhos/cm. The highest EC level resulting from an increase (772 µmhos/cm) is expected to occur during December of Critical water years at the Jones Pumping Plant. These modeled increases in EC levels are, therefore, expected to be below the Ag Goal and drinking water goal.

Therefore, implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on EC levels, TDS, bromide, and chloride concentrations associated with agricultural, municipal, industrial, and wildlife refuge water supply.

Other water quality parameters, such as metals and nutrients, were not modeled as part of this analysis. The potential changes to the concentrations of these constituents are unknown at this time. However, the overall improvements in EC levels with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, are expected to translate into improvements in the concentrations of these constituents. Therefore, implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the concentrations of nutrients, metals, and other water quality constituents, including mercury, associated with the deliveries for agricultural, municipal, industrial, and wildlife refuge use.

San Luis Reservoir

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Similar to Alternative A, implementation of Alternative B would result in continued water level fluctuations at San Luis Reservoir and minor decreases in end-of-month long-term average surface water elevations of up to six feet in June through October, when compared to Existing Conditions. A comparison of water year type averages indicates an increase in elevation of up to nineteen feet during all months in Critical water years. During Below Normal and Dry water years, increases of up to seven feet are expected in January through August. Elevations would, therefore, be improved during periods in which algae blooms are a concern, except for during September and October in Above Normal water years and July through October in Dry water years when there would be decreases of up to 10 feet.

Similar to Alternative A, modeled end-of-month long-term average surface water elevations for Alternative B, when compared to the No Project/No Action Alternative, indicate minor decreases of up to three feet during June through August. These decreases in surface water elevation fall within the historic range of operation for San Luis Reservoir. A comparison of water year type averages indicates an increase of up to eight feet in all months of Below Normal water years. Elevations are expected to decrease up to 14 feet in April through November in Dry water years, and in May through August, October, and December in Critical water years.

End-of-month storage exceedance plots indicate that San Luis Reservoir would exceed 250,000 acre-feet 100 percent of the years in December through May with both Alternative B and Existing Conditions. In June, Existing Conditions would exceed 250,000 acre-feet approximately 87 percent of the years, and Alternative B would exceed 250,000 acre-feet approximately 92 percent of the years. In July and August, Existing Conditions would exceed 250,000 acre-feet approximately 80 percent of the years, and Alternative B would exceed 250,000 acre-feet approximately 82 percent of the years. In September, Existing Conditions would exceed 250,000 acre-feet approximately 94 percent of the years, and Alternative B would exceed 250,000 acre-feet approximately 98 percent of the years. Alternative B would perform similarly to Existing Conditions in October.

End-of-month storage exceedance plots indicate that San Luis Reservoir would exceed 250,000 acre-feet 100 percent of the years in December through May with both Alternative B and the No Project/No Action Alternative. Alternative B and the No Project/No Action Alternative would perform within a two percent difference of each other during June and September through November, and would perform similarly to each other in July and August.

Even with the expected decreases in surface water elevations associated with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, the end-of-month storage exceedances of 250,000 acre-feet would be similar or improved with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, operational changes at San Luis Reservoir would be expected to have a **less-than-significant impact** on nuisance algae blooms, when compared to Existing Conditions and the No Project/No Action Alternative.

The impact findings for the Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use water quality conditions are directly applicable to San Luis Reservoir. Therefore, implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on EC levels; TDS, bromide, and chloride concentrations; metals, nutrients, and other water quality constituents in the San Luis Reservoir.

7.3.7.2 *Secondary Study Area – Alternative B*

Construction, Operation, and Maintenance Impacts

Implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would result in improved storage conditions similar to those described for Alternative A at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. In addition, Whiskeytown Lake, Lewiston Lake, Keswick Reservoir, the Thermalito Complex, and Lake Natoma would continue to operate as regulating reservoirs within their historical operational range, as described for Alternative A. Therefore, the impact of Alternative B on surface water quality (**Impact SW Qual-1**) and water temperature (**Impact SW Qual-2**) within these reservoirs would be the same as described for Alternative A. Consequently, modeling results show that releases from these reservoirs into the Trinity River, Klamath River downstream of the Trinity River, Clear Creek, Spring Creek, the Feather River, and the American River would also have the same impacts on surface water quality (**Impact SW Qual-1**) and water temperature (**Impact SW Qual-2)** as was described for Alternative A.

Construction, operation, and maintenance activities at the Red Bluff Pumping Plant would be the same with implementation of Alternative B as was described for Alternative A, and would, therefore, have the same impacts on surface water quality (**Impact SW Qual-1**) and water temperature(**Impact SW Qual-2)**.

Alternative B would include a 1.81-MAF Sites Reservoir, and would replace the Delevan Pipeline Intake Facilities with the Delevan Pipeline Discharge Facility. These changes in storage and diversion capacity would result in operational effects to downstream Project facilities that differ slightly from those described for Alternative A. Therefore, the operational impacts of Alternative B on surface water quality and water temperatures for the remaining Project facilities in the Secondary Study Area are described below.

Sacramento River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Implementation of Alternative B would have effects on Sacramento River EC levels upstream of the Delevan Pipeline Discharge Facility location similar to those described for Alternative A, because the long-term average worst-case EC estimated at the T-C Canal Intake with implementation of Alternative B for the Sacramento River reach between Keswick and Red Bluff is expected to decrease or remain similar in all months, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, the worst-case EC estimated at the GCID Canal Intake for the reach between Red Bluff and Hamilton City is expected to remain similar in most of the months with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative. The worst-case EC levels for the Sacramento River reach between the GCID Canal Intake and the Delevan Pipeline Discharge Facility location indicate similar trends as the upstream reaches, when Alternative B is compared to the Existing Conditions and No Project/No Action Alternative. However, downstream of the Delevan Pipeline Discharge Facility, worst-case EC levels in the Sacramento River associated with Alternative B would differ from Alternative A, because Alternative B includes a discharge-only facility, rather than the intake facility included with Alternative A. Similar to Alternative A, long-term average worst-case EC levels in the Sacramento River are expected to increase in all months with Alternative B, and increase in most months in all water year types, when compared to Existing Conditions and the No Project/No Action Alternative. However, the increases associated with Alternative B are not expected to be as great as those described for Alternative A, with the largest of the increases expected to occur in April (up to 4.2 percent) and to a lesser extent in fall months (up to 3.8 percent).

The EC levels for the Sacramento River reach from the CBD to the entrance of the Delta at the I Street Bridge were not estimated explicitly. However, the changes in the EC levels in this reach are expected to trend consistently with the changes found in the upper Sacramento River reaches.

The increased EC levels with Alternative B are a result of reduction in the flows released from the Shasta Reservoir. Further, in the winter and spring months, the increased diversions at the two intakes to fill the Sites Reservoir would contribute to increased EC levels in the Sacramento River. In the summer and fall months, releases from Sites Reservoir would also cause EC levels to increase in the Sacramento River reach downstream of the Delevan Pipeline Discharge Facility. However, the water year type averages for the worst-case EC levels with Alternative B, in all months, are expected to be below the Central Valley Basin Plan requirement of 230 µmhos/cm for the Sacramento River reach upstream of the CBD.

Therefore, the minor increases in the worst-case EC levels are considered negligible, and the impact to Sacramento River EC levels due to the implementation of Alternative B would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Other water quality constituents of concern, including mercury and unknown toxicity on the 303(d) list of impaired waters, were not evaluated explicitly. However, the changes in the concentrations of the other water quality constituents are expected to be proportional to the changes in the worst-case EC levels with implementation of Alternative B from Existing Conditions and the No Project/No Action Alternative. Therefore, the impact on the water quality constituents in the Sacramento River due to the implementation of Alternative B would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Similar to Alternative A for the Sacramento River reach from Keswick to downstream of the Delevan Pipeline Discharge Facility, modeling results indicate that Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would result in similar or decreased water temperatures in summer and fall months of Below Normal, Dry, and Critical water year types when the ambient temperatures are higher. In April, Alternative B would result in slightly elevated water temperatures of up to 1.8 percent in all water year types.

Downstream of the Delevan Pipeline Discharge Facility, results based on preliminary temperature modeling of Sites Reservoir releases performed for Alternative C (Alternative C was assumed to show the worst-case conditions) would be similar with implementation of Alternative B, as was described for Alternative A.

Modeling results for water temperatures in the Sacramento River at Knights Landing indicate that implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would result in negligible changes in all months of all water year types, with the greatest increase of up to 0.6 percent expected in April in all water years. Similar to Alternative A, comparison of the average water temperatures for Alternative B to Existing Conditions and the No Project/No Action Alternative at the Freeport location indicates that the temperatures would be similar or lower in summer and fall months of all water years. For the winter and spring months (December through May), the resulting average temperatures with implementation Alternative B would be slightly elevated by up to 0.5 percent in all water years, when compared to Existing Conditions and the No Project/No Action Alternative.

Modeled average monthly temperatures by water year type for Alternative B indicate that the 68°F criterion for July through November from Hamilton City to the I Street Bridge would be exceeded at Knights Landing during all water year types, and at the Feather River and American River during all water years but Above Normal. However, it is important to note that the criterion is already exceeded with Existing Conditions and the No Project/No Action Alternative at these locations, and implementation of Alternative B would result in decreased temperatures.

Based on the above model observations, implementation of Alternative B would results in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative, for the Sacramento River temperature for the reach between Keswick and the I street bridge.

Sutter Bypass and Yolo Bypass

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

As described for Alternative A, Alternative B would be operated to divert excess Sacramento River flows from November through March to fill Sites Reservoir. However, this operational scenario for the two intakes associated with Alternative B would potentially reduce flows by up to 3,900 cfs in the Sutter and

Yolo bypasses (as compared to the maximum of 5,900 cfs with the three intakes associated with Alternative A). Changes in operations associated with integrated operations of Sites Reservoir with Shasta Lake may also influence the frequency and magnitude of flows in the Sutter and Yolo bypasses. Because of the reduced rate of diversion, it is expected that the duration of diversion of excess flows to fill Sites Reservoir would be greater for Alternative B, when compared to Alternative A.

Similar to Alternative A, monthly average exceedance probability plots indicate that spills for Alternative B would be the same or similar in frequency of spills for Existing Conditions at Ord Ferry, Moulton Weir, and Colusa Weir. Exceedance probability plots for Alternative B, when compared to the No Project/No Action Alternative, indicate a similarity in frequency of spills.

Similar to Alternative A, the changes in spills for Alternative B, when compared to Existing Conditions, would vary from minor increases to decreases during high flow months when the weirs are spilling. Although the overall frequency of spills would be similar, the long-term average volume of spill for Alternative B, when compared to Existing Conditions, would decrease by approximately 5 percent at Tisdale Weir and 3 percent at Colusa Weir. Because it is expected that the duration of diversion of excess flows to fill Sites Reservoir would be greater for Alternative B, when compared to Alternative A, the period over which reductions in spills would occur would be longer, generally in the period of December through April. Exceedance probability plots for Alternative B, when compared to the No Project/No Action Alternative, show that similar decreases in the volume of spills are expected.

Spills into the Sutter Bypass from the Sacramento River represent only some of the hydrologic inputs to the lower Sutter Bypass. Similar to Alternative A, it is anticipated that the changes in spill exceedance probabilities discussed above would not have a substantial impact on surface water quality in the Sutter Bypass. Therefore, implementation of Alternative B would result in a **less-than-significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Similar to Alternative A, monthly average exceedance probability plots of Yolo Bypass flows with implementation of Alternative B, when compared to Existing Conditions, indicate lower similar exceedance probabilities, and lower long-term average flows, by approximately 5 percent. Because it is expected that the duration of diversion of excess flows to fill Sites Reservoir would be greater for Alternative B, when compared to Alternative A, the period over which reductions in spills would occur would be longer, generally in the period of December through April. It is anticipated that the described changes in Yolo Bypass flows and outflow would not have a substantial impact on surface water quality. Therefore, water quality impacts to the Yolo Bypass resulting from implementation of Alternative B are considered to be **less than significant,** when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperature modeling was not performed for the Sutter Bypass and the Yolo Bypass. However, as described above, the expected changes in spills to the Sutter Bypass represent only a portion of the input to the bypass, and flows into and out of the Yolo Bypass are expected to decrease slightly. Therefore, it is anticipated that implementation of Alternative B would have a **less-than-significant impact** on water temperature in the Sutter Bypass and Yolo Bypass, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento-San Joaquin Delta

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location indicates that implementation of Alternative B, when compared to Existing Conditions, would result in slightly elevated EC levels during March through May of up to 1.1 percent. Modeled water year type average monthly EC values indicate similar trends, with the greatest expected increase (3.7 percent) occurring in March of Below Normal water years.

During May in Critical water years, an increase of 2.8 percent is expected to occur from approximately 828 µmhos/cm with Existing Conditions to approximately 851 µmhos/cm with Alternative B.

To verify if the minor increases in average EC levels expected in April and May with implementation of Alternative B would impact compliance with D-1641 salinity standards at Emmaton, exceedance probability plots of the monthly average EC values were evaluated and compared to those of Existing Conditions. The EC exceedance plots indicate that monthly average EC in April would exceed the 450 µmhos/cm Wet water year standard less than four percent of the years with both Alternative B and Existing Conditions. Similarly, the monthly average EC in April with both Existing Conditions and Alternative B would exceed the 630 µmhos/cm Above Normal water year standard approximately one percent of the years, and all of the years would be well under the 1,140 µmhos/cm Below Normal water year standard. During May, both Alternative B and Existing Conditions would exceed 450 µmhos/cm in approximately 14 percent of the years, exceed 630 µmhos/cm in six percent of the years, and exceed 1,140 µmhos/cm in approximately four percent of the years. In all of the years, the May monthly average EC would be less than the 1,670 µmhos/cm Dry water year standard. Therefore, in terms of compliance with D-1641 salinity standards at Emmaton, Alternative B is expected to perform similar to Existing Conditions.

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location indicate that Alternative B, when compared to the No Project/No Action Alternative, would result in decreased EC levels during June through January and elevated EC levels during February through May (up to 3.4 percent). Modeled water year type monthly average EC values indicate similar trends. The largest increase in average EC is expected to occur in February in Critical water years, where the EC would increase by 15.8 percent from approximately 404 µmhos/cm with the No Project/No Action Alternative to approximately 467 µmhos/cm with Alternative B.

To verify if the minor increases in average EC levels expected in the April and May months with implementation of Alternative B would impact compliance with D-1641 salinity standards at Emmaton, exceedance probability plots of the monthly average EC values were evaluated and compared to the No Project/No Action Alternative. The EC exceedance plots indicate that the monthly average EC in April would exceed 450 µmhos/cm less than four percent of the years with both Alternative B and the No Project/No Action Alternative. Similarly, the monthly average EC in April with both the No Project/No Action Alternative and Alternative B would exceed 630 µmhos/cm in one percent of the years, and all of the years would be well under 1,140 µmhos/cm. For May, both Alternative B and the No Project/No Action Alternative would exceed 450 µmhos/cm in approximately 15 percent of the years, exceed 630 µmhos/cm in eight percent of the years, and exceed 1,140 µmhos/cm in approximately four percent of the years. In all of the years, the May monthly average EC would be less than 1,670 µmhos/cm.

Therefore, in terms of compliance with D-1641 salinity standards at Emmaton, Alternative B is expected to perform similar to the No Project/No Action Alternative.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location indicate that Alternative B, when compared to Existing Conditions, would result in lower EC levels during all months except November, where EC is expected to increase by two percent. Modeled water year type average monthly EC values for Alternative B indicate lower EC values, when compared to Existing Conditions, during January through August months in all but Critical water years, and higher EC values during September through December by up to 33.2 percent in Wet and Above Normal water years. In Below Normal and Dry water years, the average EC values with implementation of Alternative B would be lower or similar to Existing Conditions in all months. In Critical water years, the average EC with implementation of Alternative B would be lower or similar to Existing Conditions in June through August, October, December, and January, and higher in September, November, and February through May months by up to 3.8 percent.

To verify if the minor increases in average EC levels associated with implementation of Alternative B would impact compliance with D-1641 salinity standards at Jersey Point, exceedance probability plots of the monthly average EC values for Alternative B were evaluated and compared to those of Existing Conditions. The EC exceedance plots indicate that the monthly average EC in April would exceed 450 µmhos/cm less than one percent of the years with both Alternative B and Existing Conditions, and all of the years would be well under 740 µmhos/cm. Similarly, the monthly average EC in May with both Existing Conditions and Alternative B would exceed 450 µmhos/cm in approximately five percent of the years, would exceed 740 µmhos/cm in approximately three percent of the years, and all of the years would be well under 1,350 µmhos/cm. For June, July, and August, the number of years that Alternative B would exceed the compliance standards at Jersey Point would be similar to or lower than Existing Conditions. Therefore, in terms of compliance with D-1641 salinity standards at Jersey Point, Alternative B would perform similar to Existing Conditions.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location with implementation of Alternative B, when compared to the No Project/No Action Alternative, indicate similar or lower EC levels during June through October, December, and January, and higher EC levels during November and February through May, where EC is expected to increase by up to 4.2 percent. Modeled water year type average monthly EC values for Alternative B indicate similar or decreased EC values, when compared to the No Project/No Action Alternative, during most months of all water year types, with increased EC values during September through December by up to 24.1 percent in Wet years. In Above Normal years, EC levels with Alternative B are expected to be lower or similar in March through September, with increased EC levels in other months by up to 30.6 percent, when compared to the No Project/No Action Alternative. In Below Normal and Dry years, the average EC values with implementation of Alternative B are expected to be lower or similar to the No Project/No Action Alternative in the most months. February through April are expected to have slightly elevated EC levels of up to 1.9 percent with implementation of Alternative B, when compared to the No Project/No Action Alternative in Below Normal years. In Dry years, the average EC levels with Alternative B are expected to increase by up to 3.3 percent, when compared to the No Project/No Action Alternative, in April, November, and December. In Critical years, the average EC with Alternative B is expected to be lower than the No Project/No Action Alternative in June, July, October, and December and higher in the remaining months by up to 17.6 percent.

To verify if the minor increases in the average EC levels expected in April and May with implementation of Alternative B would impact compliance with D-1641 standards at Jersey Point, exceedance probability plots of the monthly average EC values were evaluated and compared to the No Project/No Action Alternative. As indicated in the EC exceedance plots, the monthly average EC in April would exceed 450 µmhos/cm in approximately 0.5 percent of the years with both Alternative B and the No Project/No Action Alternative, and all of the years are expected to be well under 740 µmhos/cm. For May, both Alternative B and the No Project/No Action Alternative would exceed 450 µmhos/cm in approximately 4 percent of the years, exceed 740 µmhos/cm in 3 percent of the years, and in all of the years, the May monthly average EC would be less than 1,350 µmhos/cm. For June, July, and August, the number of years that Alternative B would exceed the compliance standards at Jersey Point would be similar to or lower than those of the No Project/No Action Alternative. Therefore, in terms of the compliance with D-1641 salinity standards at Jersey Point, Alternative B would perform similar to the No Project/No Action Alternative.

As described for Alternative A, implementation of Alternative B would provide supplemental Delta outflow during summer and fall months (May through December) to improve X2 position and increase estuarine habitat. Similar to Alternative A, modeling results indicate that implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would result in eastward movement of X2 by up to 0.9 km in January through May, and a westward movement of X2 by up to 1.4 km in June through November, on a long-term average basis. In Wet years, the average X2 position with implementation of Alternative B would move eastward in October through May by up to 0.5 km, and would move up to 1.2 km westward in June through September, when compared to Existing Conditions and the No Project/No Action Alternative. In Above Normal years, the average X2 position with Alternative B would move eastward in December through May by up to 0.9 km, and would move up to 1.8 km westward in June through October, when compared to Existing Conditions and the No Project/No Action Alternative. In Below Normal and Dry years, the average X2 position with Alternative B would move eastward in January through May by up to 1.7 km, and would move up to 1.8 km westward in June through December, when compared to Existing Conditions and the No Project/No Action Alternative. In Critical years, the average X2 position with Alternative B would move eastward in February through May and November by up to 0.4 km, and would move up to 1.6 km westward in June through January, when compared to Existing Conditions and the No Project/No Action Alternative.

Even though modeling results for the average X2 position in the February through June D-1641compliance period indicate slight eastward movement, Alternative B would comply with the D-1641 spring X2 position requirements. During the September through November compliance period, the monthly average X2 position with implementation of Alternative B would be at or westward of the X2 position for Existing Conditions and the No Project/No Action Alternative.

Similar to Alternative A, implementation of Alternative B would generally improve Delta salinity conditions in the summer and fall months, which are the peak salinity intrusion periods, with minor increased EC levels in the winter and spring months. Compliance with Delta salinity standards with implementation of Alternative B would be consistent with Existing Conditions and the No Project/No Action Alternative. Alternative B would comply with the X2 standards for both spring and fall. Salinity conditions at the Emmaton and Jersey Point compliance locations, and X2 location, are good indicators of the salinity conditions in the Delta. Therefore, implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the salinity conditions in the Delta. EC is a good indicator of other water quality constituents in the Delta. Therefore, implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the other water quality constituents in the Delta.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for the Delta, and there are no specific water temperature criteria in the *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (SWRCB, 2006). However, as described for Alternative A, water temperatures in the Delta approach equilibrium temperatures where the meteorological conditions primarily influence the water temperatures. Thus, the differences between Alternative B and Existing Conditions and the No Project/No Action Alternative would be minimized. Therefore, implementation of Alternative B would results in a **less-than-significant impact** on water temperatures in the Delta, when compared to Existing Conditions and the No Project/No Action Alternative.

Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Similar to Alternative A, model simulations for Delta outflow indicate that implementation of Alternative B would result in increased average monthly outflow in the summer and fall months, when conditions are relatively Dry, and small reductions in Delta outflow in the winter and spring months when the conditions are Wet, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, these changes would result in a **less-than-significant impact** to the water quality conditions in Suisun Bay, San Pablo Bay, and San Francisco Bay with the implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for Suisun Bay, San Pablo Bay, or San Francisco Bay, and there are no specific water temperature criteria in the Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (SWRCB, 2006). However, based on the seasonal flow changes described above with the implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative, and because temperatures in Suisun Bay, San Pablo Bay, and San Francisco Bay are primarily controlled by the meteorological conditions, the impacts to water temperature would be **less than significant**.

7.3.7.3 *Primary Study Area – Alternative B*

Construction, Operation, and Maintenance Impacts

The following Project facilities are included in both Alternatives A and B. These facilities would require the same construction methods and operation and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to surface water quality and water temperature:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard

- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard
- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

If Alternative B is implemented, the footprints or construction disturbance areas of Sites Reservoir Dams, the Road Relocations and South Bridge, the Delevan Transmission Line, and the Project Buffer would differ from Alternative A. However, these differences in the size of the facility footprint, alignment, or construction disturbance area would not change the type of construction, operation, and maintenance activities that were described for Alternative A. They would, therefore, have the same impact on surface water quality (**Impact SW Qual-1**) and water temperature (**Impact SW Qual-2**) as described for Alternative A.

Alternative B would include a 1.81-MAF Sites Reservoir. The larger size of the facility footprint would not change the type of construction and maintenance activities that were described for Alternative A, but would result in changes in operation. The Holthouse Reservoir Complex footprint would not change between alternatives, and would, therefore, require the same type of construction and maintenance activities that were described for Alternative A. However, changes in the operation of Sites Reservoir would affect operation of Holthouse Reservoir. The Delevan Pipeline Intake Facilities (that are included in Alternative A) would be replaced by the release-only Delevan Pipeline Discharge Facility in Alternative B. Potential differences in operational impacts to Sites Reservoir and Holthouse Reservoir water quality resulting from the operation of a 1.81-MAF Sites Reservoir, as well as potential differences in impacts from the construction, operation, and maintenance of the Delevan Pipeline Discharge Facility, are discussed below.

Sites Reservoir Inundation Area

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Refer to the **Impact SW Qual-1** Alternative B Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on surface water quality. Implementation of Alternative B is expected to result in a worst-case long-term average EC of 180 to 183 µmhos/cm in Sites Reservoir, which is lower than the expected long-term average associated with implementation of Alternative A. Fall months would have slightly lower EC levels, when compared to spring months, when Sites Reservoir would be filled with water from the Sacramento River. Modeled water year type averages indicate that average worst-case EC levels would range from approximately 179 µmhos/cm in fall months of Above Normal years to 186 µmhos/cm in spring months of Critical years. Based on the above model observations, releases from the reservoir into Funks and Stone Corral creeks, as well as releases into the T-C and GCID canals, would have average worst-case EC levels that fall well below the Ag Goal that is protective of agricultural water uses. Therefore, implementation of Alternative B would result in a **less-than-significant impact** in the receiving waters affected by releases from Sites Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

Other water quality issues, including sedimentation, eutrophication, oxygen depletion, and chemical transformations within the water column were not modeled, and are, therefore, considered to be **potentially significant** with implementation of Alternative B.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-2** Alternative B Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on water temperature. That discussion of Sites Reservoir release temperatures is applicable to release temperatures in Funks and Stone Corral creeks, as well as to the T-C and GCID canals.

Holthouse Reservoir Complex

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Similar to Alternative A, a comparison between Alternative B modeled EC levels for Funks Reservoir with Existing Conditions and the No Project/No Action Alternative indicate that these levels would increase by up to 34.3 percent during all months of all water year types. These increases in EC are expected to be greatest during the summer and fall months when flow is generally released from Sites Reservoir for agricultural use. Funks Reservoir and the Holthouse Reservoir Complex would be hydrologically connected, so EC levels for Holthouse Reservoir would be the same as described for Funks Reservoir.

Despite these large increases, EC levels would fall below the Ag Goal that is protective of agricultural water uses. Water quality impacts, based on modeled EC conditions with implementation of Alternative B, would therefore, be **less than significant**, when compared to Existing Conditions and No Project/No Action Alternative.

Based on EC modeling results as an indicator of general water quality conditions, impacts associated with operation of this facility would be **less than significant**, when compared to Existing Conditions and No Project/No Action Alternative.

The following water quality issues have not been estimated for this analysis: sedimentation, eutrophication, oxygen depletion, and chemical transformations within the water column. These water quality issues would, therefore, have a **potentially significant impact** with implementation of Alternative B, when compared to Existing Conditions and No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

These facilities would act as regulating reservoirs for Sites Reservoir. Refer to the **Impact SW Qual-2** Alternative B Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on surface water temperatures.

Delevan Pipeline Discharge Facilities

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

The Delevan Pipeline Discharge Facility would be capable of releases to only the Sacramento River. The discharge facility would not extend into the river channel as described for the Delevan Pipeline Intake Facilities, but would still require the installation of a cellular sheet pile cofferdam extending approximately eight feet into the river. The cofferdam would likely remain in place throughout the duration of facility construction. The area behind the cofferdam would be dewatered prior to construction by pumping water out from behind the cofferdam. After construction of the pump station is complete, the cofferdam would be removed by pulling the sheet piles out of the river and restoring the river to its previous condition. These construction activities would result in ground-disturbing activities, the temporary diversion of surface waters around construction sites, and could result in increased erosion or sediment deposition. These construction activities would have a **potentially significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

The discharges from this facility would contribute to the worst-case EC levels in the Sacramento River. Refer to the **Impact SW Qual-1** Alternative B Secondary Study Area discussion for Sacramento River water quality impacts associated with these discharges. The discharge-only facility would not require sediment removal, as was described for the Alternative A Delevan Pipeline Intake Facilities. Routine maintenance activities for this facility would, therefore, have a **less-than-significant impact** to water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-2** Alternative B Secondary Study Area discussion for Sacramento River temperature impacts associated with releases from this facility.

7.3.8 Impacts Associated with Alternative C

7.3.8.1 *Extended Study Area – Alternative C*

<u>Construction, Operation, and Maintenance Impacts</u>

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Comparison of the modeled long-term average EC levels for Alternative C and Existing Conditions at Clifton Court Forebay indicates that EC levels are expected to decrease by up to 10.1 percent in all months. Comparing the water year type averages, EC levels for Alternative C would be reduced in nearly all months of all water year types. Increases of up to 5.8 percent are expected in November and December of Above Normal years. The modeled long-term average and water year type average EC levels at the Jones Pumping Plant with implementation of Alternative C, when compared to Existing Conditions would be similarly reduced, with the exception of negligible increases of up to 2.5 percent in November of Above Normal years.

Comparison of the modeled long-term average EC levels for Alternative C and the No Project/No Action Alternative at Clifton Court Forebay indicates that EC levels are expected to decrease or remain similar in all months. Comparing the water year type averages, EC levels with implementation of Alternative C are expected to increase by up to 2.5 percent in December, February through May, and July in Wet years.

EC levels are also expected to increase by up to 7.3 percent in November through July in Above Normal years; by up to 0.8 percent in February, April, and May of Below Normal years; by up to 0.6 percent in April through June in Dry years; and by up to 0.6 percent in December of Critical years. The modeled long-term average EC levels at the Jones Pumping Plant with implementation of Alternative B are also expected to be lower or similar to the No Project/No Action Alternative in most months, with negligible increases of up to 0.5 percent expected in March through June. Comparing the water year type averages, EC levels with implementation of Alternative C at the Jones Pumping Plant are expected to increase similarly to those described for Clifton Court Forebay, but would experience negligible increases in EC levels during more months in Below Normal, Dry, and Critical years.

Similar to Alternatives A and B, modeling results indicate that Alternative C is expected to reduce the long-term average export-weighted EC, TDS, chloride, and bromide concentrations, when compared to Existing Conditions and the No Project/no Action Alternative. Similarly, the Dry and Critical year average export-weighted concentrations are expected to decrease with Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative.

Although minor increases in EC levels are expected with implementation of Alternative C, the largest of all the increases are expected to occur in November, and December during Above Normal years, which have relatively wetter conditions. The resulting increased EC levels for Above Normal years for these months are highest in December (up to 414 µmhos/cm). These modeled increases in EC levels are, therefore, expected to be below the Ag Goal and drinking water goal.

Therefore, implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative would have a **less-than-significant impact** on EC levels, TDS, bromide, and chloride concentrations associated with agricultural, municipal, industrial, and wildlife refuge water supply.

Other water quality parameters, such as metals and nutrients, were not modeled as part of this analysis. The potential changes to the concentrations of these constituents are unknown at this time. However, the overall improvements in EC levels with Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, are expected to translate into improvements in the concentrations of these constituents. Therefore, implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the concentrations of nutrients, metals, and other water quality constituents, including mercury, associated with the deliveries for agricultural, municipal, industrial, and wildlife refuge use.

San Luis Reservoir

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Implementation of Alternative C would result in continued water level fluctuations at San Luis Reservoir and minor decreases in end-of-month long-term average surface water elevations of up to eight feet in May through October, when compared to Existing Conditions. A comparison of water year type averages indicates an increase in elevation of up to eight feet during all months in Below Normal and Critical years. During Dry years, increases of up to three feet are expected in January through April. Elevations would, therefore, be improved during periods in which algae blooms are a concern, with the exception of decreases of up to 14 feet during May through December in Dry years.

Modeled end-of-month long-term average surface water elevations for Alternative C, when compared to the No Project/No Action Alternative, indicate decreases of up to five feet during May through September. These decreases in surface water elevation fall within the historic range of operation for San Luis Reservoir. A comparison of water year type averages indicates an increase of up to nine feet in all months of Below Normal years. Elevations are expected to decrease up to 20 feet in all months in Dry and Critical years.

End-of-month storage exceedance plots indicate that San Luis Reservoir would exceed 250,000 acre-feet in 100 percent of the years in December through May with both Alternative C and Existing Conditions. Alternative C would perform similarly to Existing Conditions in June through August, and would perform within an approximate three percent difference in September through November.

End-of-month storage exceedance plots indicate that San Luis Reservoir would exceed 250,000 acre-feet in 100 percent of the years in December through May with both Alternative C and the No Project/No Action Alternative. Alternative C would perform similarly to the No Project/No Action Alternative in June and July. And Alternative C and the No Project/No Action Alternative would perform within an approximate three percent difference in August through November.

Even with the expected decreases in surface water elevations associated with implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, the end-of-month storage exceedances of 250,000 acre-feet would be similar or improved with Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, operational changes at San Luis Reservoir would be expected to have a **less-than-significant impact** on nuisance algae blooms, when compared to Existing Conditions and the No Project/No Action Alternative.

The impact findings for the Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use water quality conditions are directly applicable to San Luis Reservoir. Therefore, implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on EC levels, TDS, bromide and chloride concentrations, metals, nutrients, and other water quality constituents in the San Luis Reservoir.

7.3.8.2 *Secondary Study Area – Alternative C*

Construction, Operation, and Maintenance Impacts

Implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would result in improved storage conditions similar to those described for Alternative A at Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. In addition, Whiskeytown Lake, Lewiston Lake, Keswick Reservoir, the Thermalito Complex, and Lake Natoma would continue to operate as regulating reservoirs within their historical operational range, as described for Alternative A. Therefore, the impact of Alternative C on surface water quality (**Impact SW Qual-1**) and water temperature (**Impact SW Qual-2**) within these reservoirs would be the same as described for Alternative A. Modeling results show that releases from these reservoirs into the Trinity River, Klamath River downstream of the Trinity River, Clear Creek, Spring Creek, the Feather River, and the American River would also have similar impacts on surface water quality (**Impact SW Qual-1**) and water temperature (**Impact SW Qual-2**) as described for Alternative A.

Construction, operation, and maintenance activities at the Red Bluff Pumping Plant would be the same with implementation of Alternative C as described for Alternative A, and would, therefore, have the same impacts on surface water quality (**Impact SW Qual-1**) and water temperature (**Impact SW Qual-2**) as described for Alternative A.

Alternative C would include a 1.81-MAF Sites Reservoir (as was described for Alternative B) and the Delevan Pipeline Intake Facilities (as was described for Alternative A). This combination of storage and diversion capacity would result in operational effects to downstream Project facilities that differ slightly from those described for Alternative A. Therefore, the operational impacts of Alternative C on surface water quality and water temperatures for the remaining Project facilities in the Secondary Study Area are described below.

Sacramento River

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Implementation of Alternative C would have effects on Sacramento River EC levels upstream of the Delevan Pipeline location similar to those described for Alternatives A and B because the long-term average worst-case EC estimated at the T-C Canal Intake with implementation of Alternative C for the Sacramento River reach between Keswick and Red Bluff is expected to decrease or remain similar in all months, when compared to Existing Conditions and the No Project/No Action Alternative. In addition, the worst-case EC estimated at the GCID Canal Intake for the reach between Red Bluff and Hamilton City is expected to remain similar in most of the months with Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative. The worst-case EC levels for the Sacramento River reach between the GCID Canal Intake and the Delevan Pipeline Intake location indicate similar trends as the upstream reaches, when comparing Alternative C to Existing Conditions and the No Project/No Action Alternative.

However, downstream of the Delevan Pipeline Intake location, worst-case EC levels in the Sacramento River would differ slightly with implementation of Alternative C, when compared to Alternatives A and B, because Alternative C includes a 1.81-MAF Sites Reservoir and three intakes. Similar to Alternative A, long-term average worst-case EC levels in the Sacramento River are expected to increase in all months with implementation of Alternative C, and increase in most months in all water year types, when compared to Existing Conditions and the No Project/No Action Alternative. However, the increases associated with Alternative C are expected to be greater than those described for the other alternatives, with the largest of the increases expected to occur in April (up to 5.4 percent) and October (up to 8.2 percent).

The EC levels for the Sacramento River reach from the CBD to the entrance of the Delta at the I Street Bridge were not estimated explicitly. However, the changes in the EC levels in this reach are expected to trend consistently with the changes found in the upper Sacramento River reaches.

The increased EC levels with implementation of Alternative C are a result of reduction in the flows released from the Shasta Reservoir. Further, in the winter and spring months, the increased diversions at the three intakes to fill the Sites Reservoir would contribute to increased EC levels in the Sacramento River. In the summer and fall months, releases from Sites Reservoir would also cause EC levels to increase in the Sacramento River reach downstream of the Delevan Pipeline Intake Facilities. However, the water year type averages for the worst-case EC levels with implementation of Alternative C, in all months, are expected to be below the Central Valley Basin Plan requirement of 230 µmhos/cm for the Sacramento River reach upstream of the CBD.

Therefore, the minor increases in the worst-case EC levels can be considered negligible, and the impacts to Sacramento River EC levels due to the implementation of the Alternative C would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Other water quality constituents of concern, including mercury and unknown toxicity on the 303(d) list of impaired waters, were not evaluated explicitly. However, the changes in the concentrations of the other water quality constituents are expected to be proportional to the changes in the worst-case EC levels with implementation of Alternative C from Existing Conditions and the No Project/No Action Alternative. Therefore, the impact on the water quality constituents in the Sacramento River due to the implementation of Alternative C would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Similar to Alternative A for the Sacramento River reach from Keswick to downstream of the Delevan Pipeline Intake Facilities, modeling results indicate that Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would result in similar or decreased water temperatures in summer and fall months of Below Normal, Dry, and Critical water year types when the ambient temperatures are higher. In April, Alternative C would result in slightly elevated water temperatures of up to 1.9 percent in all water year types.

Downstream of the Delevan Pipeline Intake Facilities, results based on preliminary temperature modeling of the Alternative C Sites Reservoir would be similar to Alternative A.

Modeling results for water temperatures in the Sacramento River at Knights Landing indicate that implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would result in negligible changes in all months of all water year types, with the greatest increase of up to 0.6 percent expected in April in all water year types. Similar to Alternative A, comparison of the average water temperatures for Alternative C to Existing Conditions and the No Project/No Action Alternative at the Freeport location indicates that the temperatures would be similar or lower in summer and fall months of all water year types. For the winter and spring months (December through May), the resulting average temperatures with implementation of Alternative C would be slightly elevated by up to 0.6 percent in all water year types, when compared to Existing Conditions and the No Project/No Action Alternative.

Modeled average monthly temperatures by water year type for Alternative C indicate that the 68°F criterion for July through November from Hamilton City to the I Street Bridge would be exceeded at Knights Landing during all water year types, and at the Feather River and American River during all but Above Normal years. However, it is important to note that the criterion is already exceeded with Existing Conditions and the No Project/ No Action Alternative at these locations, and implementation of Alternative C would result in decreased temperatures.

Based on the above model observations, implementation of Alternative C would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative, for the Sacramento River temperature for the reach between Keswick and the I Street Bridge.

Sutter Bypass and Yolo Bypass

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

As described for Alternative A, Alternative C would be operated to divert excess Sacramento River flows from November through March to fill Sites Reservoir and would potentially reduce flows by up to 5,900 cfs in the Sutter and Yolo bypasses. Changes in operations associated with integrated operations of Sites Reservoir with Shasta Lake may also influence the frequency and magnitude of flows in the Sutter and Yolo bypasses. Because of the increased capacity of Sites Reservoir with Alternative C, when compared to Alternative A, it is expected that the frequency of diversion of excess flows to fill Sites Reservoir would be greater for Alternative C than with Alternative A.

Similar to Alternative A, monthly average exceedance probability plots indicate that spills for Alternative C would be the same or similar in frequency of spills for Existing Conditions at Ord Ferry, Moulton Weir, and Colusa Weir. Exceedance probability plots for Alternative C, when compared to the No Project/No Action Alternative, would be similar in frequency of spills.

Similar to Alternative A, the spills for Alternative C, when compared to Existing Conditions, would vary from minor increases to decreases during high flow months when the weirs are spilling. Although the overall frequency of spills would be similar to those of Existing Conditions, the long-term average volume of spill for Alternative C when compared to Existing Conditions would decrease by approximately 8 percent at Tisdale Weir and 5 percent at Colusa Weir, generally in the period of December through March. Exceedance probability plots for Alternative C, when compared to the No Project/No Action Alternative, show similar expected decreases in the volume of spills.

Spills into the Sutter Bypass from the Sacramento River represent only some of the hydrologic inputs to the lower Sutter Bypass. Similar to Alternative A, it is anticipated that the changes in spill exceedance probabilities discussed above would not have a substantial impact on surface water quality in the Sutter Bypass. Therefore, it is concluded that implementation of Alternative C would result in a **less-than-significant impact** on surface water quality, when compared to Existing Conditions and the No Project/No Action Alternative.

Similar to Alternative A, monthly average exceedance probability plots of Yolo Bypass flows with implementation of Alternative C, when compared to Existing Conditions, indicate lower similar exceedance probabilities and lower long-term average flows by approximately 7 percent, generally in the period of December through March. It is anticipated that the described changes in Yolo Bypass flows and outflow would not have a substantial impact on surface water quality. Therefore, water quality impacts to the Yolo Bypass resulting from implementation of Alternative C are considered **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperature modeling was not performed for the Sutter Bypass and the Yolo Bypass. However, as described above, the expected changes in spills to the Sutter Bypass represent only a portion of the input to the bypass, and flows into and out of the Yolo Bypass are expected to decrease slightly. Therefore, it is anticipated that implementation of Alternative C would have a **less-than-significant impact** on water temperature in the Sutter Bypass and Yolo Bypass, when compared to Existing Conditions and the No Project/No Action Alternative.

Sacramento-San Joaquin Delta

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location indicates that implementation of Alternative C, when compared to Existing Conditions, would result in slightly elevated EC levels during March through May of up to 1.2 percent. Modeled water year type average monthly EC values indicate similar trends, with the greatest expected increase (3.3 percent) occurring in March of Below Normal water years.

During May in Critical years, an increase of 3.4 percent is expected to occur from approximately 828 µmhos/cm with Existing Conditions to approximately 856 µmhos/cm with Alternative C.

To verify if the minor increases in average EC levels expected in April and May with implementation of Alternative C would impact compliance with D-1641 salinity standards at Emmaton, exceedance probability plots of the monthly average EC values were evaluated and compared to those of Existing Conditions. The EC exceedance plots indicate that monthly average EC in April would exceed the 450 µmhos/cm Wet year standard less than 4 percent of the years with both Alternative C and Existing Conditions. Similarly, the monthly average EC in April with both Existing Conditions and Alternative C would exceed the 630 µmhos/cm Above Normal water year standard approximately 1 percent of the years, and all of the years would be well under the 1,140 µmhos/cm Below Normal water year standard. During May, both Alternative C and Existing Conditions would exceed 450 µmhos/cm in approximately 14 percent of the years, exceed 630 µmhos/cm in 7 percent of the years, and exceed 1,140 µmhos/cm in approximately 4 percent of the years. In all of the years, the May monthly average EC would be less than the 1,670 µmhos/cm Dry water year standard. Therefore, in terms of compliance with D-1641 salinity standards at Emmaton, Alternative C is expected to perform similar to Existing Conditions.

Modeled long-term average monthly EC results for the Sacramento River at Emmaton compliance location indicate that Alternative C, when compared to the No Project/No Action Alternative, would result in decreased EC levels during June through December and elevated EC levels during January through May (up to 4.8 percent). Modeled water year type monthly average EC values indicate similar trends. The largest increase in average EC is expected to occur in February in Critical water years, where the EC would increase by 20.5 percent, from approximately 404 µmhos/cm with the No Project/No Action Alternative to approximately 486 µmhos/cm with Alternative C.

To verify if the minor increases in average EC levels expected in the April and May months with implementation of Alternative C would impact compliance with D-1641 salinity standards at Emmaton, exceedance probability plots of the monthly average EC values were evaluated and compared to the No Project/No Action Alternative. The EC exceedance plots indicate that the monthly average EC in April would exceed 450 µmhos/cm less than four percent of the years with both Alternative C and the No Project/No Action Alternative. Similarly, the monthly average EC in April with both Alternative C and the No Project/No Action Alternative would exceed 630 µmhos/cm in one percent of the years, and all of the years would be well under 1,140 µmhos/cm. For May, both Alternative C and the No Project/No Action Alternative would exceed 450 µmhos/cm in approximately 15 percent of the years, exceed 630 µmhos/cm in eight percent of the years, and exceed 1,140 µmhos/cm in approximately four percent of the years. In all of the years, the May monthly average EC would be less than 1,670 µmhos/cm.

Therefore, in terms of compliance with D-1,641 salinity standards at Emmaton, Alternative C is expected to perform similar to the No Project/No Action Alternative.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location indicate that Alternative C, when compared to Existing Conditions, would result in lower EC levels during all months except March, where EC is expected to increase by 0.4 percent. Modeled water year type average monthly EC values for Alternative C indicate lower EC values, when compared to Existing Conditions, during January through August in all but Critical water years, and higher EC values during September through December by up to 36.7 percent in Wet and Above Normal water years. In Below Normal and Dry water years, the average EC values with implementation of Alternative C would be lower or similar to Existing Conditions in all months. In Critical water years, the average EC with Alternative C would be lower or similar to Existing Conditions in June through January and higher in February through May by up to 3.5 percent.

To verify if the minor increases in average EC levels associated with implementation of Alternative C would impact compliance with D-1641 salinity standards at Jersey Point, exceedance probability plots of the monthly average EC values for Alternative C were evaluated and compared to those of Existing Conditions. The EC exceedance plots indicate that the monthly average EC in April would exceed 450 µmhos/cm less than one percent of the years with both Existing Conditions and Alternative C, and all of the years would be well under 740 µmhos/cm. Similarly, the monthly average EC in May with Existing Conditions and Alternative C would exceed 450 µmhos/cm in approximately six percent of the years, would exceed 740 µmhos/cm in approximately three percent of the years, and all of the years would be well under 1,350 µmhos/cm. For June, July and August, the number of years that Alternative C would exceed the compliance standards at Jersey Point would be similar to or lower than Existing Conditions. Therefore, in terms of compliance with D-1641 salinity standards at Jersey Point, Alternative C would perform similar to Existing Conditions.

Modeled long-term average monthly EC results for the San Joaquin River at Jersey Point compliance location with implementation of Alternative C, when compared to the No Project/No Action Alternative, indicate lower EC levels during June through October and December, and higher EC levels during November and January through May, where EC is expected to increase by up to 4.8 percent. Modeled water year type average monthly EC values for Alternative C indicate similar or decreased EC values, when compared to the No Project/No Action Alternative, during most months of all water year types, with increased EC values during September through December by up to 27.7 percent in Wet water years. In Above Normal water years, Alternative C EC levels are expected to be lower or similar in February through September, with increased EC levels in other months by up to 34.1 percent, when compared to the No Project/No Action Alternative. In Below Normal and Dry water years, the average EC values with implementation of Alternative C are expected to be lower or similar to the No Project/No Action Alternative in the most months. February through April are expected to have slightly elevated EC levels of up to 1.7 percent with Alternative C, when compared to the No Project/No Action Alternative in Below Normal water years. In Critical water years, the average EC with Alternative C is expected to be lower than the No Project/No Action Alternative in June, July, October, and December and higher in the remaining months by up to 21.5 percent.

To verify if the minor increases in the average EC levels expected in April and May with implementation of Alternative C would impact compliance with D-1641 standards at Jersey Point, exceedance probability plots of the monthly average EC values were evaluated and compared to the No Project/No Action Alternative. As indicated in the EC exceedance plots, the monthly average EC in April would exceed

450 µmhos/cm in approximately 0.5 percent of the years with both Alternative C and the No Project/No Action Alternative, and all of the years are expected to be well under 740 µmhos/cm. For May, both Alternative C and the No Project/No Action Alternative would exceed 450 µmhos/cm in approximately five percent of the years, exceed 740 µmhos/cm in three percent of the years, and in all of the years, the May monthly average EC would be less than 1,350 µmhos/cm. For June, July and August, the number of years that Alternative C would exceed the compliance standards at Jersey Point would be similar to or lower than those of the No Project/No Action Alternative. Therefore, in terms of the compliance with D-1641 salinity standards at Jersey Point, Alternative C would perform similar to the No Project/No Action Alternative.

As described for Alternative A, implementation of Alternative C would provide supplemental Delta outflow during summer and fall months (May through December) to improve the X2 position and increase estuarine habitat. Similar to Alternative A, modeling results indicate that implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would result in eastward movement of X2 by up to 0.6 km in December through May, and a westward movement of X2 by up to 1.5 km in June through November, on a long-term average basis. In Wet water years, the average X2 position with implementation of Alternative C would move eastward in October through May by up to 0.9 km, and would move up to 1.2 km westward in June through September, when compared to Existing Conditions and the No Project/No Action Alternative. In Above Normal water years, the average X2 position with Alternative C would move eastward in December through May by up to 0.9 km, and would move up to 1.8 km westward in June through October, when compared to Existing Conditions and the No Project/No Action Alternative. In Below Normal and Dry water years, the average X2 position with Alternative C would move eastward in January through May by up to 1.9 km, and would move up to 1.9 km westward in June through December, when compared to Existing Conditions and the No Project/No Action Alternative. In Critical water years, the average X2 position with Alternative C would move eastward in February through May by up to 0.8 km, and would move up to 1.4 km westward in June through January, when compared to Existing Conditions and the No Project/No Action Alternative.

Even though modeling results for the average X2 position in the February through June D-1641compliance period indicate slight eastward movement, Alternative C would comply with the D-1641 spring X2 position requirements. During the September through November compliance period, the monthly average X2 position with implementation of Alternative C would be at or westward of the X2 position for Existing Conditions and the No Project/No Action Alternative.

Similar to Alternative A, implementation of Alternative C would generally improve Delta salinity conditions in the summer and fall months, which are the peak salinity intrusion periods, with minor increased EC levels in the winter and spring months. Alternative C would comply with the X2 standards for both spring and fall. Salinity conditions at the Emmaton and Jersey Point compliance locations and the X2 location are good indicators of the salinity conditions in the Delta. Therefore, implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the salinity conditions in the Delta. EC is a good indicator of other water quality constituents in the Delta. Therefore, implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, would have a **less-than-significant impact** on the other water quality constituents in the Delta.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for the Delta, and there are no specific water temperature criteria in the *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (SWRCB, 2006). However, as described for Alternative A, water temperatures in the Delta approach equilibrium temperatures where the meteorological conditions primarily influence the water temperatures. Thus the differences between Alternative C and Existing Conditions and the No Project/No Action Alternative would be minimized. Therefore, implementation of Alternative C would results in a **less-than-significant impact** on water temperatures in the Delta, when compared to Existing Conditions and the No Project/No Action Alternative.

Suisun Bay, San Pablo Bay, San Francisco Bay

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Similar to Alternative A, model simulations for Delta outflow indicate that implementation of Alternative C would result in increased average monthly outflow in the summer and fall months, in relatively Dry water year conditions, and small reductions in Delta outflow in the winter and spring months, in Wet water year conditions, when compared to Existing Conditions and the No Project/No Action Alternative. Therefore, Alternative C would result in a **less-than-significant impact** to the water quality conditions in Suisun Bay, San Pablo Bay, and San Francisco Bay, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Water temperatures were not modeled or evaluated for Suisun Bay, San Pablo Bay, or San Francisco Bay, and there are no specific water temperature criteria in the *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (SWRCB, 2006). However, based on the seasonal flow changes described above with implementation of Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative, and because temperatures in Suisun Bay, San Pablo Bay, and San Francisco Bay are primarily controlled by the meteorological conditions, the impacts to water temperature would be **less than significant**.

7.3.8.3 *Primary Study Area – Alternative C*

<u>Construction, Operation, and Maintenance Impacts</u>

The following Primary Study Area Project facilities are included in Alternatives A, B, and C. These facilities would require the same construction, operation, and maintenance activities regardless of alternative, and would, therefore, result in the same construction, operation, and maintenance impacts to surface water quality and water temperature:

- Recreation Areas
- Sites Pumping/Generating Plant
- Sites Electrical Switchyard
- Tunnel from Sites Pumping/Generating Plant to Sites Reservoir Inlet/Outlet Structure
- Sites Reservoir Inlet/Outlet Structure
- Field Office Maintenance Yard

- Holthouse Reservoir Electrical Switchyard
- GCID Canal Facilities Modifications
- GCID Canal Connection to the TRR
- TRR
- TRR Pumping/Generating Plant
- TRR Electrical Switchyard
- TRR Pipeline
- TRR Pipeline Road
- Delevan Pipeline
- Delevan Pipeline Electrical Switchyard

The Alternative C Sites Reservoir would be the same size as that described for Alternative B, and the Delevan Pipeline Intake Facilities included with Alternative C would be the same as described for Alternative A. These facilities would, therefore, require the same type of construction and maintenance activities that were described for those alternatives. However, the combination of the 1.81-MAF Sites Reservoir and the Delevan Pipeline Intake Facilities would change Project operation of Sites and Holthouse reservoirs. Therefore, although construction and maintenance impacts associated with the Holthouse Reservoir Complex would be the same as described for Alternative A, operational impacts could differ. The potential differences in impacts to water quality resulting from changes in operations in Sites Reservoir and the Holthouse Reservoir Complex are described below.

Sites Reservoir Inundation Area

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Refer to the **Impact SW Qual-1** Alternative C Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on surface water quality. Implementation of Alternative C is expected to result in a worst-case long-term average EC of 190 to 193 µmhos/cm in Sites Reservoir, which is similar to the expected long-term average associated with implementation of Alternative A, and higher than expected levels with implementation of Alternative B. Fall months show slightly lower EC levels, when compared to spring months, when Sites Reservoir is filled with water from the Sacramento River. Modeled water year type averages indicate that average worst-case EC levels would range from approximately 187 µmhos/cm in fall months of Above Normal water years to 195 µmhos/cm in spring months of Critical water years. Based on the above model observations, releases from the reservoir into Funks and Stone Corral creeks, as well as releases into the T-C and GCID canals, would have average worst-case EC levels that fall well below the Ag Goal that is protective of agricultural water uses. Therefore, implementation of Alternative C would result in a **less-than-significant impact** in the receiving waters affected by releases from Sites Reservoir, when compared to Existing Conditions and the No Project/No Action Alternative.

Other water quality issues, including sedimentation, eutrophication, oxygen depletion, and chemical transformations within the water column were not modeled, and are, therefore, considered to be **potentially significant** with implementation of Alternative C.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

Refer to the **Impact SW Qual-2** Alternative C Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on water temperature. That discussion of Sites Reservoir release temperatures is applicable to release temperatures in Funks and Stone Corral creeks, as well as to the T-C and GCID canals.

Holthouse Reservoir Complex

Impact SW Qual-1: A Violation of any Water Quality Standard or Waste Discharge Requirement, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality

Similar to Alternative A, a comparison between Alternative C modeled EC levels for Funks Reservoir and Existing Conditions and the No Project/No Action Alternative indicates that these levels would increase by up to 39.5 percent during all months of all water years. These increases in EC are expected to be greatest during the summer and fall months. Funks Reservoir and the Holthouse Reservoir Complex would be hydrologically connected, so EC levels for Holthouse Reservoir would be the same as described for Funks Reservoir. Despite these large increases, EC levels would fall below the Ag Goal that is protective of agricultural water uses. Water quality impacts based on modeled EC conditions with implementation of Alternative C would, therefore, be **less than significant**, when compared to Existing Conditions and No Project/No Action Alternative.

Additionally, the following water quality issues have not been estimated for this analysis: sedimentation, eutrophication, oxygen depletion, and chemical transformations within the water column. These water quality issues would have a **potentially significant impact** with implementation of Alternative C, when compared to Existing Conditions and No Project/No Action Alternative.

Impact SW Qual-2: A Violation of any Regulatory Temperature Criteria or Temperature Targets

These facilities would act as regulating reservoirs for Sites Reservoir. Refer to the **Impact SW Qual-2** Alternative C Secondary Study Area discussion for the Sacramento River for the effects of Sites Reservoir diversions and releases on water temperatures.

7.4 Mitigation Measures

Mitigation measures are provided below and summarized in Table 7-2 for the impacts that have been identified as significant or potentially significant.

Table 7-2
Summary of Mitigation Measures for
NODOS Project Impacts to Surface Water Quality

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact SW Qual-1: A Violation of any Water Quality Standards or Waste Discharge Requirements, a Change in Surface Water Quality Resulting in Adverse Effects to Designated Beneficial Uses of Surface Water, or Otherwise Substantially Degrade Surface Water Quality				
Impact SW Qual-1a: Reservoir sedimentation, eutrophication, oxygen depletion, and chemical transformation	Sites Reservoir, Funks Reservoir, Holthouse Reservoir, TRR	Potentially Significant	Mitigation Measure SW Qual-1a: Implement a Water Quality Monitoring, Modeling, and Operations coordination Program to Protect Beneficial Uses	Less than Significant
Impact SW Qual-1b: Contamination from inundation of Salt Lake	Sites Reservoir	Potentially Significant	Mitigation Measure SW Qual-1b: Excavate and remove or consolidate and cap Salt Lake	Less than Significant
Impact SW Qual-1c: Soil disturbing activities contributing to erosion and increased turbidity to receiving waters	All Primary Study Area Project facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1c (1): Implement soil stabilization and sediment control BMPs Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant
Impact SW Qual-1d: Material stockpile management that could adversely affect surface water quality	All Primary Study Area Project Facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1c (1): Implement soil stabilization and sediment control BMPs Mitigation Measure SW Qual-1c (2) Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant
Impact SW Qual-1e: Hazardous material spills that could adversely affect surface water quality	All Primary Study Area Project Facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan	Less than Significant

Table 7-2
Summary of Mitigation Measures for
NODOS Project Impacts to Surface Water Quality

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact SW Qual-1f: Temporary diversion of surface waters that could adversely affect surface water quality	All Primary Study Area Project Facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1f: Implement BMPs including diversion ditches, berms, pipelines, sheet piles, and coffer dams	Less than Significant
			Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	
Impact SW Qual-1g: Temporary dewatering of shallow groundwater	Sites Reservoir Dams, Road Relocations, Sites Pumping/Generating Plant, Sites Electrical Switchyard, Tunnel, Sites Reservoir Inlet/Outlet Structure, Field Office Maintenance Yard, Holthouse Reservoir Complex, TRR, TRR Pipeline, TRR Pumping/Generating Plant, TRR to Funks Creek Pipeline, GCID Connection to TRR, Delevan Pipeline, Delevan Pipeline Intake/Discharge Facilities	Potentially Significant	Mitigation Measure SW Qual-1g: Implement Caltrans Field Guide to Construction Site Dewatering	Less than Significant
			Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	
Impact SW Qual-1h: Concrete waste that could adversely affect surface water quality	All Primary Study Area Project facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1h: Implement concrete waste management BMPs	Less than Significant
			Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	
Impact SW Qual-1i: Vehicle and equipment cleaning activities that could adversely affect surface water quality	All Primary Study Area Project facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1i: Implement vehicle and equipment cleaning procedures and practices	Less than Significant
			Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	

Table 7-2
Summary of Mitigation Measures for
NODOS Project Impacts to Surface Water Quality

Impact	Associated Project Facility	LOS Before Mitigation	Mitigation Measure	LOS After Mitigation
Impact SW Qual-1j: Vehicle and equipment fueling activities that could adversely affect surface water quality	All Primary Study Area Project facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1j: Implement vehicle and equipment fueling procedures and practices	Less than Significant
			Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	
Impact SW Qual-1k: Vehicle and equipment maintenance activities that could adversely affect surface water quality	All Primary Study Area Project facilities except the GCID Canal Facilities Modifications	Potentially Significant	Mitigation Measure SW Qual-1k: Implement appropriate vehicle and equipment maintenance procedures and practices	Less than Significant
			Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	
Impact SW Qual-1l: Pile driving activities that could adversely affect surface water quality	Sites Reservoir and Dams, Road Relocations, Sites Pumping/Generating Plant, Sites Tunnel, Sites Reservoir Inlet/Outlet Structure, Holthouse Reservoir Complex, Terminal Regulating Reservoir, TRR Pipeline, TRR Pumping/Generating Plant, TRR to Funks Creek Pipeline, GCID Connection to TRR, Delevan Pipeline, Delevan Pipeline Intake/Discharge Facilities	Potentially Significant	Mitigation Measure SW Qual-1l: Implement appropriate pile driving procedures and practices	Less than Significant
			Mitigation Measure SW-Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan	

Note:
LOS = Level of Significance

Mitigation Measure SW Qual-1a: Implement a Water Quality Monitoring, Modeling, and Operations Coordination Program to Protect Beneficial Uses

A comprehensive water monitoring program, including analysis of water quality conditions at the Project intake/discharge locations on the Sacramento River, as well as major Project conveyance and impoundment features, shall be implemented. This monitoring program shall include a network of automated real-time water monitoring locations at these locations, with data available to operators on the SCADA control system to allow real-time adaptive alteration in diversion amounts based on these conditions. This would allow operators to select the best quality waters to fill Sites Reservoir and potentially avoid importation of poor quality water that may affect the quality of Project water deliveries. This strategy could require additional modeling of Project water quality conditions to better understand the complex chemical interactions and physical and biological processes that affect contaminant levels. In addition, fish in Sites Reservoir shall be sampled and analyzed for mercury and other potential contaminants that may have deleterious effects to human and wildlife consumers. Results from these analyses shall be submitted to the Office of Environmental Health Hazard Assessment (OEHHA) for determination of the threats to consumers of fish in Sites Reservoir. Determination of adverse health effects to consumers would lead to educational postings at access points and public media to reduce exposure to contaminated fish.

Mitigation Measure SW Qual-1b: Excavate and Remove or Consolidate and Cap Salt Lake

The Salt Lake site within the footprint of Sites Reservoir for Alternatives A, B, and C would be either excavated and removed or consolidated and capped by an impermeable cover to avoid dissolution of the salt deposit into the reservoir waters. Salt Lake is fed by upslope salt springs, is many decades old, and the salt pan has accumulated to an unknown thickness over this time by evaporation. After removal/capping of the salt pan, the salt spring inputs to a completed Sites Reservoir would be diluted by high quality Sacramento River imports to a level that would be less than significant to water quality.

Mitigation Measure SW Qual-1c (1): Implement Soil Stabilization and Sediment Control BMPs

During construction activities, onsite monitoring shall be performed to identify runoff impacts. Appropriate soil stabilization BMPs; such as hydroseeding and application of other soil binders; installation of culverts, pipelines, and lined ditches to divert stormwater around disturbed soil areas; dust suppression through application of water to unpaved access roads; and placing cover material over material stockpiles; shall be implemented to reduce potentially significant construction impacts from erosion to a less-than-significant level. Sediment control BMPs, such as installation of fiber rolls and straw bales, settling/desilting basins, and other control measures, shall be implemented to reduce potentially significant construction impacts to surface water quality (suspended sediment and turbidity) and drainage to a less-than-significant level. Details of these BMPs are described in Section WM-3 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1c (2): Prepare and Implement a Stormwater Pollution Prevention Plan

The Project is subject to construction-related stormwater permit requirements of the Clean Water Act National Pollutant Discharge Elimination System (NPDES) Permit Program. DWR and Reclamation shall obtain any required permits through the CVRWQCB before any ground-disturbing construction activities occur. DWR and Reclamation shall prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) that identifies BMPs to prevent or minimize the introduction of contaminants into surface waters. BMPs for the Project could include, but are not limited to, silt fencing, straw bale barriers, diversion ditches, fiber rolls, storm drain inlet protection, hydraulic mulch, and stabilized construction entrance. The SWPPP shall include development of site-specific structural and operational BMPs to prevent and control impacts on runoff quality, measures to be implemented before each storm event, inspection and maintenance of BMPs, and monitoring of runoff quality by visual and/or analytical means.

Mitigation Measure SW Qual-1e: Prepare and Implement a Stormwater Pollution Prevention Plan

DWR and Reclamation shall prepare and implement a SWPPP that emphasizes proper hazardous materials storage and handling procedures; shall outline spill containment, cleanup, and reporting procedures; and shall limit refueling and other hazardous activities to designated upland areas. Signs prohibiting refueling shall be posted in sensitive areas. Equipment shall be inspected prior to use each day to ensure that hydraulic hoses are tight and in good condition. Other appropriate BMPs, such as use of concrete washout basins and proper waste management, combined with visual observation and water sample collection and analysis, shall be used to prevent discharge of drilling mud and other chemicals associated with construction activities and into receiving waters. Details of these BMPs are described in Section WM-4 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1f: Implement BMPs including Diversion Ditches, Berms, Pipelines, Sheet Piles, and Cofferdams

Clear water diversion consists of a system of structures and measures that intercept clear surface water runoff upstream from a Project site, transport it around the work area, and discharge it downstream from the work area with minimal water quality degradation. Clear water diversions shall be used during construction at all Primary Study Area Project Facilities except the GCID Canal Facilities Modifications, and shall be included in the SWPPP. Structures used as part of this system shall include some or all of the following: diversion ditches, berms, dikes, slope drains, pipelines, rock, gravel bags, wood, sheet piles, aqua barriers, cofferdams, filter fabric or turbidity curtains, drainage and interceptor swales, pipes, or flumes. Details of these BMPs are described in Section NS-5 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1g: Implement Caltrans Field Guide to Construction Site Dewatering

Effluent from dewatering activities shall be properly stored and disposed of to prevent contamination of surface water. This measure is intended to prevent the discharge of pollutants from construction site dewatering operations associated with stormwater (accumulated rain) and non-stormwater (e.g., groundwater or water from a diversion or cofferdam). Dewatering effluent that is discharged from a construction site to a storm drain or receiving water is subject to the requirements of the applicable NPDES Permit. Detailed guidance for management of dewatering operations is included in the *Caltrans Field Guide to Construction Site Dewatering* (Caltrans, 2001). The dewatering effluent shall be managed according to Central Valley RWQCB requirements and California Stormwater Quality Association BMPs.

Mitigation Measure SW Qual-1h: Implement Concrete Waste Management BMPs

Concrete waste management procedures and practices shall be implemented during construction of all Project facilities except the GCID Canal Facilities Modifications, where the following conditions exist: where concrete is used as a construction material or where concrete dust and debris would result from demolition activities; where slurries containing Portland cement concrete (PCC) or asphalt concrete (AC) are generated, such as from sawcutting, coring, grinding, grooving, and hydro-concrete demolition; and where concrete trucks and other concrete-coated equipment are washed on-site. Concrete waste management procedures and practices shall include some or all of the following: placing temporary berms or sandbags to contain concrete slurry wastes; constructing temporary concrete washout facilities, consisting of pits or berms with sufficient volume to contain all concrete waste from concrete truck washout procedures; regular inspection and maintenance of these BMPs; and proper disposal of hardened concrete wastes and backfill of removed concrete waste facilities after construction activities are complete. Details of these BMPs are described in Section WM-8 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1i: Implement Vehicle and Equipment Cleaning Procedures and Practices

Vehicle and equipment cleaning procedures and practices shall be used to minimize or eliminate the discharge of pollutants from vehicle and equipment cleaning operations to storm drain systems or to watercourses. On-site vehicle and equipment washing shall be discouraged. The use of solvents shall be minimized and the use of diesel for vehicle and equipment cleaning shall be prohibited. Details of these BMPs are described in Section NS-8 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1j: Implement Vehicle and Equipment Fueling Procedures and Practices

Vehicle and equipment fueling procedures and practices, including off-site fueling of all vehicles and equipment that regularly enter and leave a worksite, on-site designated fueling areas appropriately designed to prevent spilled fuel from entering storm drains or receiving waters, access to absorbent spill clean-up materials and proper disposal of used material, drip pans if equipment is fueled in an area other than designated fueling areas, and fuel nozzles equipped with automatic shut-off to control drips, shall be implemented to minimize or eliminate the discharge of fuel spills and leaks into storm drain systems or to watercourses at all Project facility sites. Fueling BMPs and spill response procedures shall also be described in the SWPPP. Details of these BMPs are described in Section NS-9 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1k: Implement Vehicle and Equipment Maintenance Procedures and Practices

Vehicle and equipment maintenance procedures and practices shall be performed to minimize or eliminate the discharge of pollutants from vehicle and equipment maintenance operations to storm drain system or to watercourses. Details of these BMPs are described in Section NS-10 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Mitigation Measure SW Qual-1l: Implement Pile Driving Procedures and Practices

The construction and retrofit of bridges and retaining walls often include driving piles for foundation support and shoring operations. Driven piles are typically constructed of concrete, steel, or timber. Driven sheet piles are used for shoring and cofferdam construction. Proper control and use of equipment, materials, and waste products from pile driving operations shall be implemented to reduce the discharge of potential pollutants to the storm drain system or watercourses. Details of these BMPs are described in Section NS-11 of the *Construction Site Best Management Practices Manual* (Caltrans, 2003).

Implementation of **Mitigation Measures SW Qual-1a, SW Qual-1b, SW Qual-1c (1), SW Qual-1c (2), SW Qual-1e, SW Qual-1f, SW Qual-1g, SW Qual-1h, SW Qual-1i, SW-Qual-1j, SW-Qual-1k,** and **SW Qual-1l** would reduce the level of significance of Project impacts to surface water quality to **less than significant**.

8. Fluvial Geomorphology and Riparian Habitat

8.1 Introduction

This chapter describes the fluvial geomorphological setting for the Extended, Secondary, and Primary study areas. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction. Fluvial geomorphology describes the origin and development of a river's shape, form, and function as a result of streamflow, sediment, underlying geology, the regional climate, river hydrology, and human-induced changes. These physical relationships affect the associated riparian habitat and wildlife that live there. The fish, wildlife, and riparian vegetation have adapted to the cycle of erosion, deposition, and changing channel pattern. The health and productivity of the fluvial system depend on the periodic rejuvenation associated with large storm events and channel movements.

The regulatory setting for geomorphology is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Sacramento River between Keswick Dam and the Pacific Ocean (a portion of the Secondary Study Area). Impacts in the remainder of the Secondary Study Area, as well as the Primary and Extended study areas, were evaluated and discussed qualitatively. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided in this EIR/EIS for identified significant or potentially significant impacts, where appropriate. Because none were identified for this resource, no mitigation is included in this chapter.

8.2 Environmental Setting/Affected Environment

8.2.1 Extended Study Area

The Extended Study Area includes the State and federal service areas. It includes the west side of the San Joaquin Valley, the Los Angeles Basin, and the California coast south of the San Francisco Bay Area. These three service areas have no large river systems or catchments, limited groundwater resources, generally have less precipitation than other parts of the State, and depend on water imports to meet water demands. The creeks and rivers are typically short, with little flow during summer months. Intense winter storms can cause flooding and large amounts of sediment and debris to rush down local drainages.

The Feather River watershed upstream of Lake Oroville is also part of the Extended Study Area. It is entrenched in older metamorphic and igneous rocks for the most part, except for the upper reaches where the river flows across several down-dropped fault basins filled with sedimentary deposits.

8.2.2 Secondary Study Area

The Secondary Study Area includes the Trinity, Klamath, and Sacramento rivers. The Trinity River portion extends from downstream of Lewiston Dam to its confluence with the Klamath River. The Klamath River portion includes the reach downstream of the confluence to the Pacific Ocean. The Sacramento River portion begins downstream of Keswick Dam and extends to the Pacific Ocean. It is divided into four reaches, with each reach differing substantially from the adjacent upstream and downstream reaches. These river systems and their major tributaries that comprise the Secondary Study Area are described in more detail below.

8.2.2.1 Trinity and Klamath Rivers

The Trinity River is linked to the Sacramento River by diversions from Lewiston Lake through the Clear Creek Tunnel to Whiskeytown Lake on Clear Creek. Trinity River and Clear Creek water is then diverted to Keswick Reservoir on the Sacramento River. Water from Whiskeytown Lake is also diverted through the Spring Creek Tunnel to Spring Creek and then the Sacramento River. These diversions affect streamflow in the Trinity River, in Clear Creek, and in the Sacramento River. An average of approximately 1,100 cfs of streamflow is diverted from the Trinity River basin into the Sacramento River.

The Trinity and Klamath rivers are both bedrock streams, incised into older metamorphic rocks that generally constrain the channel into narrow gorges. Riparian vegetation generally occurs in a narrow band on both banks of the river. Valley reaches also occur, such as near Weaverville and Hoopa Valley. In these areas where the narrow gorge widens, sand, gravel, and silt deposit on gravel bars to provide a wider riparian corridor.

The existing dams and diversions have affected the geomorphology primarily through the interaction with the riparian vegetation and the altered streamflow. Prior to the development of the Trinity Dam and diversions into the Sacramento River system, floodwaters would periodically remove the established riparian vegetation on stream banks and gravel bars. Large amounts of sediment would move downstream from the watershed and deposit on riffles and bars, providing new spawning habitat, and a new seed bed for vegetation. These infrequent storm events removed the older vegetation and rejuvenated the forest.

The operation of Trinity Dam has removed most of the flood peaks from the hydrograph. As a result, riparian vegetation has constricted the channel and invaded channel bars and riffles. The riparian vegetation has reduced fish habitat, significantly narrowed the channel, and isolated the gravel bars from the channel. Most of the vegetation is old, dating back to the time when Trinity Dam was being constructed. Some old vegetation is currently being removed mechanically, and high scouring flows are being released periodically. Spawning gravel is also being added periodically to riffles downstream of the dam. These flows and the added gravel should assist in returning the Trinity River to a more natural state.

Trinity Dam and Reservoir, their afterbay, and Lewiston Reservoir also affect the movement of sediment by trapping all of the bedload material and most of the suspended material. The river downstream of the dam is starved of sediment, resulting in the washing away of finer material and riffles too coarse for salmon to spawn on. Farther downstream, the removal of high flushing flows has resulted in the deposition of fine sediment from tributaries. The deposition constricts the channel and encourages riparian growth. The sand also deposits on riffles, suffocating salmon eggs and young salmon. Large woody debris is important fish habitat but is also captured by the two reservoirs, resulting in a lack of this type of habitat downstream of the dams. These effects continue to the confluence of the Trinity and the Klamath, and then to the Pacific Ocean, but decrease downstream because tributary inflow of both sediment and water reduce the influence of the dams.

8.2.2.2 Sacramento River

The Sacramento River is the largest and most important river system in California. It drains 17 percent of California’s land area, yet yields 18.4 million acre-feet, (approximately 35 percent of the water supply) annually. The river and its tributaries are the State’s most important watershed for salmon.

The Sacramento River headwaters originate on the east slope of Mt. Eddy in the vicinity of Mt. Shasta. Mt. Shasta provides much of the snowmelt that feeds the upper part of the Sacramento River during early spring months.

From Mt. Shasta, the river is cradled between the Cascade Range on the east and the Klamath Mountains on the west. The river flows into the 4.5 million acre-feet Shasta Lake, and its afterbay, Keswick Reservoir, a few miles upstream of Redding. The river then enters the Redding Basin of the Sacramento Valley, the northern half of the Great Central Valley. The river flows through the center of the approximately 150-mile-long, and 30- to 60-mile-wide, Sacramento Valley. Joining the Sacramento River are numerous smaller tributaries, including Clear, Cottonwood, Thomes, Stony, and Cache creeks on the west side, and Stillwater, Bear, Battle, Mill, Deer, Big Chico and Butte creeks on the east side. The Feather, American, Cosumnes, and Mokelumne rivers are larger tributaries draining the Sierra Nevadas on the east side of the Sacramento Valley. The Sacramento River joins the San Joaquin River in the Sacramento-San Joaquin Delta, and then empties into Suisun, then San Pablo, and finally San Francisco bays. Land elevations vary from 40 feet below sea level in the Sacramento-San Joaquin Delta region, to approximately 500 feet at the valley edge, to over 14,000 feet at Mt. Shasta. The Sacramento Valley is bordered on the east by the Sierra Nevada and Cascade ranges, and on the west by the California Coast Ranges.

The Sacramento River geomorphology from Shasta and Keswick dams to the Pacific Ocean is influenced by existing facilities causing changes in flow, temperature, sediment transport, and other factors. The four reaches of the Sacramento River are: Keswick Dam to Red Bluff, Red Bluff to Colusa, Colusa to Clarksburg, and Clarksburg to the Pacific (Figure 8-1).

Keswick Dam to Red Bluff

The Sacramento River drains approximately 6,500 square miles upstream of Shasta and Keswick dams. This includes the upper Sacramento, Pit, and McCloud rivers. An additional 2,400 square miles occur between Redding and Red Bluff, for a total drainage area of 8,900 square miles at Red Bluff.

Between Keswick Dam (at River Mile [RM] 302) and Redding (RM 298), the river flows across highly erosion-resistant Copley Formation metamorphic rocks. The river is stable, meaning that the river will remain in the current channel and retain about the same geomorphologic characteristics for the foreseeable future. The river is referred to as a bedrock stream because it flows across, and is incised into, older stable geologic formations. Boulders and cobbles are the most common bed material, because finer material has been eroded from the bed, and replacement material is being trapped by the dams. Salmon spawning gravel is being trucked in and injected into the river downstream of Keswick Dam to mitigate for this, providing some spawning gravel in the reach between Keswick and Redding.

Downstream of Redding, the river cuts through Plio-Pleistocene sedimentary deposits of the Tehama Formation, and volcanic-sedimentary deposits of the Tuscan Formation. These two formations are erosion resistant, with only minor river movement expected. The river is still considered mostly a bedrock stream. Bedrock streams are generally not affected to a large degree by changes in streamflow or sediment.

In places along this reach, the Tehama and Tuscan formations form vertical banks several hundred feet or more high. Volcanic basalts and andesites, flowing down from the Cascade Ranges to the east, show evidence of damming the river for short periods of time in the past. One such flow occurs at Table Mountain near Jellys Ferry, and another at Paynes Creek.

Bright red gravelly deposits of the Pleistocene Red Bluff Formation are exposed on top of the older Tehama-Tuscan formations. The sources of these gravels were glacial streams from the surrounding mountains to the east, west, and north.

Terrace deposits occur in places. These are typically flat benches inset into the older deposits. Four terrace levels are generally present, with the older terraces being higher than the younger terraces.

A few places in this reach are mostly alluvium, resulting in erodible unstable banks. In these places, the river may move its channel several thousand feet before encountering more resistant deposits.

For the most part, the river is stable, with only minor bank erosion occurring in alluvial reaches. The river is entrenched, having cut down through hundreds of feet of older rocks and deposits. Iron Canyon, north of the City of Red Bluff, is a dramatic example. Several large bends occur in the lower section of this reach, with one near Jellys Ferry and another in the Bend area.

Three larger and several smaller tributaries join the Sacramento River in this reach. Clear Creek drains the metamorphic and igneous rocks west of Redding. Whiskeytown Dam controls the flows in Clear Creek, and also receives Trinity River water. The creek downstream of the dam is entrenched in a canyon consisting of erosion-resistant metamorphic rocks. The downstream end of the creek is underlain by Tehama Formation and is flanked by terrace deposits. Extensive terrace deposits on the north side of the creek were dredged for gold, leaving dredger tailings that are subsequently being mined for sand and gravel. Gravel mining was also done in the channel, and coupled with the capture of bedload by the reservoir, have resulted in channel incision and loss of salmon spawning riffles. Several gravel bars and riffles have been re-constructed to mitigate for this loss. Gravel injection has also been done by placing spawning gravel along banks, and allowing the deposit to erode during high flows.

Cottonwood Creek also drains the west side of the valley, but the underlying rocks are mostly sedimentary shale, siltstone, sandstone, and conglomerate of the Great Valley Sequence. Upstream, the North Fork, Middle Fork, and South Fork originate in the Klamath Mountains and Coast Ranges. The lower ten miles of the creek is alluvial, with sediment deposition, bank erosion, and meandering creating a broad riparian corridor.

The construction of Shasta, Keswick, and Whiskeytown dams in the watershed has resulted in the capturing of bedload sediment that would normally supply the downstream reaches. The dams capture all the bedload moving in from the upstream watershed, and release clear water. The tributaries in the upper part of this reach are too small to provide sufficient bedload sediment. Cottonwood Creek is the first creek to provide a substantial amount of sediment.

Battle Creek drains the volcanic rocks of the Cascade Range on the valley's east side. Battle Creek does not produce much sediment, but cool clear springs in the upper part of the watershed provide a year-round flow. Hydroelectric project dams and diversions occur, blocking upstream migration of salmonids, but some of these are planned for removal. The Battle Creek Fish Hatchery, built to mitigate for Shasta Dam, can attract tens of thousands of returning Chinook salmon and steelhead into Battle Creek each year.

The Sacramento River in this reach has a boulder, cobble, and gravel bed for the most part. The channel upstream of the confluence with Cottonwood Creek has mostly an armored stream bed, a condition where finer particles have been eroded, leaving a much coarser surface deposit. Most of the salmon spawning riffles between Redding and the Cottonwood Creek confluence are too coarse for the salmon to spawn in, despite efforts to mitigate for this with salmon spawning gravel injections.

Red Bluff to Colusa

The riparian corridor between Red Bluff and Colusa is one of the richest and most diverse wildlife habitats remaining in California. The river reach from Red Bluff to Colusa is substantially different from the Keswick Dam to Red Bluff reach. At Red Bluff (RM 243), the Sacramento River exits from the canyon and flows onto the broad alluvial plains of the Sacramento Valley. At that location, the river flows across its own deposits of sand, silt, and gravel. Both the bed and the banks consist of erodible alluvium resulting in a river whose form and function vary greatly with changes in streamflow, sediment, underlying geology, bank composition, climate, and human activities. The watershed increases in size by 3,190 square miles, for a total watershed area of 12,090 square miles at Colusa (RM 144).

In this reach, bank erosion is a normal, natural, and essential element of the landscape. The fish, wildlife, and riparian vegetation have adapted to the cycle of erosion, deposition, and changing channel pattern in which the river meanders slowly back and forth across a broad meander belt. The health and productivity of the system at any one point depends on the periodic rejuvenation associated with these channel movements.

Streamflow is a major determinant of the amount of erosion that occurs. Therefore, this more erodible reach of the river will be affected by dams and diversions that reduce streamflow.

In meandering river systems, erosion is generally associated with the outside (concave side) of the bends (Figure 8-2). Point bars form on the inside (convex side) of channel bends where lower flow velocities cause sediment to deposit. The combination of erosion of outside bends and deposition on point-bars results in channel migration. Over the long term, the river width and profile does not significantly change because erosion and deposition are generally in balance.

Over time, this process of erosion and deposition creates a broad alluvial floodplain. Channel movement is often incremental and the bends in the river gradually move downstream. The channel will move back and forth, re-working much of the same area. This area is referred to as a meander belt. On each side of the meander belt, there are older deposits that are generally more erosion resistant. These older deposits are generally referred to as geologic control in that they tend to constrain the meander belt.

Erosion rates and meander rates vary widely, depending on a number of different variables. Bank composition is a major factor, with the more clay-rich banks and gravelly banks less erodible, and the sandy banks being more erodible. In some places, the river impinges on geologic control at the edge of the meander belt, reducing the erosion rate.

Stream discharge is another factor. Changes in flow resulting from Shasta, Keswick, Whiskeytown, and Black Butte reservoirs have affected bank erosion rates to some degree. By comparing pre-Shasta to post Shasta meander lines, estimates of bank erosion can be calculated. The pre-Shasta 1896 to 1946 bank erosion rate, as calculated by the U.S. Army Corps of Engineers (USACE), is 1.94 acres per mile per year (16 feet per year) between Red Bluff and Colusa (USGS, 1977). The rate between Chico Landing and Colusa was significantly lower after Shasta Dam was constructed (USGS, 1977). The bank erosion rate was 14 feet per year between Red Bluff and Ord Ferry for the period 1977 to 1987. The calculated post-Shasta rate was 16.2 feet per year from 1976 to 1997 for the Red Bluff to Colusa reach, but this short time includes the 1997 flood event, which skews the data (DWR, 2010). Note that the calculated rates depend to a large degree on the period selected and the inclusion of major storm events.

Bank curvature is also a major factor controlling meandering. Generally, the erosion rate is higher, the more that a river curves. However, with higher curvature, there is an increasing tendency for chute cutoffs to occur. Chute cutoffs create a new channel across the bend, straightening the channel. This can occur in a single high flow event. The old channel may fill with sediment or may form an oxbow lake (formed when bends are cut off) separated from the new channel.

The Red Bluff to Colusa reach may be divided into a number of sub-reaches based on fluvial geomorphology. In general, short straight reaches with lower gradient are separated by longer more winding, or sinuous reaches with higher gradient. The sinuosity of a river channel refers to the tightness of its meander loops. A straight reach has a low sinuosity, while a curved reach has a higher sinuosity. The straight reaches generally have some geologic control providing bank stability. Meander migration in the short straight reaches tend to be at a rate of a few hundred feet per 100 years, while in the longer more sinuous reaches, the rate can be as high as 5,000 feet per 100 years.

Bank protection has been installed along the outside of river bends in many places to protect existing land uses, including agriculture, as well as buildings, pumping plants, bridges, and levees. This bank protection stops bank erosion locally, and reduces the average reach-length erosion rate.

These “hard points” will change the rate and pattern of channel movement both upstream and downstream. For example, if the downstream bank of a bend is protected, and the upper bank is left unprotected, then upper bank migration will cause the bend to collapse and be cut off. In other places, bank protection can actually increase bank erosion and meandering, generally by concentrating flows toward an erodible bank downstream, or by inducing a channel bend cutoff. There are also many locations where bank protection was not maintained and the river eventually either eroded around or through the bank protection.

Levees have also been constructed along the river, mostly in the lower half of the reach downstream of Chico Landing near Hamilton City. Levees affect both the river channel and the floodplain. Levees affect the channel by concentrating the flow, increasing velocities and sediment transport. Leveed river sections tend to become deeper, particularly where the levees are close together, because flow velocities are concentrated in one place. Levees generally prevent overbank flow and the deposition of fine sediment over the floodplain. This can cause problems farther downstream when the sediment deposits in weirs, floodways, and bypasses. Levees in these areas are typically set back to the edge of the meander belt and generally founded on geologic control. In most places, at least part of the Sacramento River floodplain is between the levees.

Flood relief structures were built along with the levees to control the amount of flow in the leveed section of the river. Excess flow spills over into the Butte Basin at three of these weirs: the M&T, 3Bs, and Goose Lake flood relief structures. These structures are located at natural depressions in private levees between Chico Landing and Colusa.

Between Chico Landing and Colusa, broad natural levees and wide overflow basins have developed on both sides of the river. Manmade levees have been built on the crest of the natural levees in many places. The Colusa basin drain is on the west side of the river, and the Butte basin on the east. The basins serve as natural flood overflow areas during the winter and as agricultural drains during the irrigation season. The Colusa, Sutter, and Yolo bypasses are broad marshy areas underlain by clayey soils rich in organic deposits. The bypasses convey floodwaters safely out of the basin and into the Sacramento-San Joaquin Delta. They may be flooded for months at a time, but a large percentage of this land is being farmed during the summer.

Agriculture primarily affects the river by the removal of floodplain vegetation. The vegetation acts as a filter, causing the finer sediment to deposit. Vegetation removal on meander bends increases floodflow velocities and increases the likelihood that a chute cutoff will occur. These cutoffs are new channels that straighten the river and may reduce the available habitat. Land leveling along the banks of the river generally removes soil from the upstream end and moves it to the downstream end, a process that lowers the upstream bank, thereby increasing the incidence of flooding.

Meander migration rates are important to the species that depend on the habitat variability, riparian forest continuity, and transient features such as oxbow lakes, islands, and point bars. The meandering process creates a wide corridor with a variety of riparian forest ages and stages. Habitat complexity is high, a result of the different soil types, depths to groundwater, and wetland areas.

There is a wide variety of riparian forest species that develop in the meander belt, resulting partially from the different soil types. The clay-rich soils that developed on old oxbow lake deposits support many species. Because of the richness and water-holding capacity, the trees on these soils grow much taller than the surrounding forests. Willow scrub forests develop on the water-side edge of a point bar. Cottonwoods also germinate here, and the survivors develop deeper root systems as deposition continues and the river migrates farther away. Other species include sycamore, alder, box elder, black walnut, Oregon grape, and poison oak.

Over time, the river migrates away, the soils become deeper, and the depth to the groundwater table increases to a point where it becomes too far down for the riparian species to survive. Gradually, valley oak and live oak replace the cottonwoods. Savannahs and seasonal grasslands exist until the river returns to begin the process anew.

Bank swallows depend on bank erosion to create new vertical bank habitat, clean of parasites, and protected from predators. Riparian tree species depend on deposition on the inside of bends to create new seed beds close to the groundwater table. Birds depend on habitat variability caused by bend migration to provide nesting, feeding, and breeding habitats. Fish depend on shade and insect food from streamside riparian vegetation, on large woody debris and tree roots washed into the river for cover, and on fresh gravel washed from eroding banks for spawning.

Bank erosion and meandering also creates complexity in the river channel. Multiple channels, islands, point bars, and pools are formed as a result of the meandering process. Mature trees on the eroding bank are undercut and fall into the river. This large woody debris provides insect food, cover, shade, and holding areas for feeding fish. The large woody debris also creates hydraulic diversity, creating a more complex channel bottom.

Fall-run Chinook salmon spawn in this reach, particularly later in the spawning season when temperatures drop. The spawning gravel is generally appropriately sized and clean—a result of the active meandering which re-works the gravel deposits. Bank erosion supplies new fresh gravel on a yearly basis to the riffle surface. Green sturgeon also use this area.

There are existing diversions in this reach, the larger of which are the T-C Canal at Red Bluff, the GCID Canal upstream of Hamilton City, the M&T Ranch pumps downstream of Hamilton City, the Provident-Princeton-Codora-Glenn pumps downstream of Ord Ferry, the Reclamation District 1004 pumps in Princeton, and the Maxwell Irrigation District pumps downstream of Princeton. The T-C Canal and the GCID Canal are potential sources of water for the Project.

The RBDD, at the upstream end of this reach, historically diverted both water and sediment into the T-C Canal at RM 243. The RBDD will cease operation in September 2011, and will be replaced by the Red Bluff Pumping Plant's turbine pumps and a new set of fish screens. The Red Bluff Pumping Plant is the first of the three diversion points proposed for the Project. The gaging station that best defines hydraulic conditions in this reach of the river is located above Bend Bridge, about ten miles north of Red Bluff

The existing GCID Canal diversion is located approximately five miles upstream of Hamilton City at RM 206. Bank erosion and meander rates have traditionally been high in this area. However, bank protection at the upstream Snaden Island, geologic control exposed on the west bank directly upstream, and a grade control structure (with riprap on both banks) decrease bank erosion susceptibility. Sediment is also diverted at this location. Suspended sediment deposits in the GCID Canal facilities, and bedload depositing in the meander loop is removed periodically. The stream gage that best defines the hydraulic conditions in this reach is at Hamilton City.

Beginning downstream of Hamilton City is a series of flood relief structures, weirs, and bypasses that move excess flood flows out of the Sacramento River and into the adjacent basins. There are three weirs (flood relief structures with a controlled elevation) adjusting the flow remaining in the river: Moulton, Colusa, and Tisdale (Figures 9-2A and 9-2B in Chapter 9 Flood Control and Management). Moulton and Colusa weirs are located a few miles upstream of Colusa. These weirs divert all but 45,000 cfs of flood flows into the Colusa Bypass. The Colusa Bypass then moves the overflow into the Butte Basin, the Sutter Bypass, the Yolo Bypass, and the Sacramento-San Joaquin Delta. The stream gages that best define the hydraulic conditions in this reach are at Butte City and Colusa.

The flood structures are part of the Sacramento River Flood Control Project, authorized by Congress in 1917 and built by USACE. Downstream, Tisdale Weir moves flood water into the Sutter Bypass and then into the Yolo Bypass. Most of the bypass areas are farmed during the agricultural season. However, during floods, much of the weir and bypass areas become spawning and rearing habitat for splittail, and rearing areas for salmonids and other fish species. Some riparian vegetation, sloughs, and wetlands occur in the bypasses, providing habitat for numerous species.

Colusa to Clarksburg

The Sacramento River at Colusa (RM 144) has a watershed area of 12,090 square miles. At the City of Sacramento, the watershed area has increased substantially to 23,502 square miles, the result of the addition of the drainages of the Feather, Yuba, Bear, and American rivers.

Downstream of Colusa to the Sacramento-San Joaquin Delta (beginning at Clarksburg), the river is completely different from the two reaches upstream. Levees built to contain the flow line both banks. The channel capacity is low, approximately 45,000 cfs, with most of the floodwaters diverted out of the channel at Moulton Weir, Colusa Bypass, and Tisdale Weir into the Sutter Bypass. The gradient is also low, and the banks contain cohesive clay, resulting in little erosion and meandering. Riprap has been installed in many areas to protect the banks and levees. The river has also been straightened for navigation in places by cutting a new channel across a bend.

Riparian habitat is generally sparse, with some vegetation along banks. However, in many places, the bank protection is being maintained by the removal of vegetation. Most of the surrounding land has been converted to farms and urban areas, with only a few isolated remnants of riparian forests and oxbow lakes. Riparian habitat is patchy and does not have the complexity and variety typical of the Red Bluff to Colusa reach.

The river channel is also uniform, a single channel with no islands, point bars, or riffles. The bed consists mostly of sand with some gravel. There is very little sediment transport, evidenced by the presence of only a few sand bars. Flood flows are diverted into the bypasses, where most of the fine sediment is deposited.

The river is a migration corridor for Chinook salmon, steelhead, and green and white sturgeon to spawn in the upper two reaches and for fry heading for the Pacific Ocean. The temperatures are too high, and the gravel too small for salmon spawning downstream of Hamilton City. Numerous warm water species live in this area or migrate through it, including the introduced striped bass and American shad.

Numerous irrigation diversions exist, from small turbine pumps set on the bank, to large reclamation district or municipal pumping plants placed directly on the river.

The Feather River joins the Sacramento River near Verona. The Feather River drainage also includes the Yuba and Bear rivers, for a total watershed area of nearly 6,000 square miles. Hydraulic gold mining in the late 1800s was responsible for huge amounts of sediment being introduced into the lower Feather River. Since then, the channel has been cutting down through these deposits, seeking its pre-mining elevation. The lower ten miles of the Feather River still has abundant and large sand bars slowly moving down the river. Lake Oroville on the Feather River, Englebright Reservoir on the Yuba River, and New Camp Far West Reservoir on the Bear River, impound and control flows and sediment in their respective watersheds. To a lesser extent, the afterbay of the Thermalito Complex, located downstream of Lake Oroville, also affects Feather River flows.

Downstream of the Feather River, the Sacramento River widens substantially. Enormous amounts of fine sediment poured out of the Feather River drainage during the latter part of the 1800s, the result of hydraulic mining for gold. Wood piles were installed in the Sacramento River on both banks in an attempt to concentrate the flow in the center of the channel and keep it free of sand bars. Remnants of these structures are still visible. Dredging to remove sediment was done on a periodic basis during the 1900s to keep the channel open for navigation.

The American River, with an additional 2,000 square miles of watershed, joins the Sacramento River at Sacramento. Hydraulic mining also occurred in this watershed, but the mining activity was not nearly as extensive as on the Feather River. Folsom Reservoir, and its afterbay Lake Natoma, control the flows in this river. The two reservoirs also stop the movement of bedload into the downstream reach of the river, which has resulted in some of the riffles becoming gravel starved with a surface layer containing substrates too coarse for salmon spawning.

Most of the length of the American River from Lake Natoma to its mouth in Sacramento is leveed on both sides of the river. Rock riprap and more biologically friendly forms of bank protection have been installed to protect the levees. Only minimal bank erosion and few channel changes occur.

In some places, tall compacted clay-silt banks of the Laguna Formation (correlated to the Tehama Formation) provide protection from erosion. Tailings, remaining from floating gold dredges, occur in places. Clayey gravels of the Victor Formation (correlated to the Red Bluff Formation) cap some of the ridges.

Clarksburg to the Pacific Ocean

The total watershed area of the Sacramento River, where it joins the San Joaquin River near Collinsville, is 26,332 square miles.

The Sacramento-San Joaquin Delta is a low lying region of the Great Central Valley formed by the confluence of two great river systems, the Sacramento and San Joaquin rivers. The Delta region consists of several islands surrounded by channels. Most of the islands are surrounded by levees protected with rock riprap. Subsidence, caused by farming, wind erosion, and oxidation and burning of peat, has been a problem on many of the islands, with elevations now as low as 40 feet below sea level.

The upstream end of the Delta region begins near the town of Clarksburg (RM 42). Sloughs include Elk, Sutter, Georgiana, Steamboat, Snodgrass, and many others. The sloughs, and the Sacramento River upstream to Sacramento, are affected by tidal influences and salt water intrusion. These sloughs and the river have a surface elevation higher than the interiors of most of the islands. The current geomorphology depends on the levees constructed to prevent flooding. If a levee breaks, an island would be flooded to depths of several tens of feet.

Most of the Delta channels are sand bedded. Velocities tend to be low, even during major floods. During most of the year, tidal flows predominate. Bank erosion is minimal. Most of the levees are protected by rock riprap. Boat wakes and wind-driven waves are the largest causes of bank erosion.

Streamflow in the Delta channels is maintained artificially high during the summer months by releasing additional water from reservoirs. This is done to flush pollutants, reduce salt water intrusion, increase water quality, and to provide fresh water to irrigation pumps and municipal uses in the western part of the Delta.

8.2.3 Primary Study Area

The only location along the Sacramento River within the Primary Study Area where Project construction, operation, and maintenance activities would occur is at the proposed Delevan Pipeline Intake and Discharge Facilities location, on the west side of the Sacramento River at RM 158.5. This location is within the Red Bluff to Colusa Reach of the Sacramento River, approximately five miles south of the Town of Princeton and immediately downstream of the Maxwell Irrigation District pumps.

The Sacramento River, at RM 158.5, is located on erosion resistant deposits (referred to as geologic control) of the Modesto Formation. The Tehama Formation, an older erosion resistant unit, underlies the Modesto Formation at a depth of a few tens of feet. Although the river is currently near the edge of geologic control, it has historically moved back and forth over a thousand feet or more within its narrow meander belt. The river's meander belt at this location is narrow compared to the upstream and downstream areas. Levees occur on both banks, with the levees 2,000 to 2,500 feet apart. Upstream and downstream, the levees are farther apart; in some locations, more than one mile apart. Bank protection occurs along the east bank in the bend directly upstream.

Bank erosion and deposition are active processes in this area. Figure 8-3 shows the Sacramento River channel meander locations since 1896. A meander is a bend that is moving because of bank erosion. As the bend moves sideways and downstream, the location of deposition also moves downstream. It is expected that the channel will move away from its current location over a period of time.

A point bar that is located on the west bank upstream of the proposed intake facility location has been quite active, moving generally south toward the diversion point. As of 2012, the point bar is located approximately 1,400 feet north of the proposed intake facility location. A second point bar is located directly across the river on the east bank.

The upstream point bar moved downstream approximately 400 feet between 1958 and 1976, or the equivalent of 22 feet per year. In 1981, USACE installed bank protection along the bank across from the point bar, and then extended the bank protection both upstream and downstream in 1987. Between 1976 and 1990, the point bar moved an additional 150 feet, but has not moved in the last 22 years since then. This is a typical point bar reaction to the placement of bank protection, and it is expected that the point bar will not move in the future if the bank protection continues to function.

The downstream point bar, across from the diversion point on the east bank, also moved downstream for a distance of approximately 1,000 feet between 1958 and 1990, or the equivalent of 31 feet per year. During this time, the river was meandering westward at the same rate as the point bar. Around 1990, the river encountered geologic control (older and more erosion resistant geologic deposits) along the west bank, essentially stopping the migration. Since then, the point bar has not moved.

Sediment movement in the Sacramento River may be high in this location. Suspended sediment levels, consisting mostly of silt and sand, are high during large discharges. High suspended sediment levels are mostly a result of bank erosion occurring upstream, although tributary inflow is also a factor.

River banks in this area generally consist of an upper layer of silt and sand that averages approximately 10 feet thick, and a lower layer of sand and gravel that averages approximately 16 feet thick. When eroded, the upper layer becomes mostly suspended sediment, and the lower layer becomes mostly bedload (sand and gravel). The bedload moves by bouncing along the bottom until it reaches an area with lower velocities, which is generally the next point bar or island downstream. Figure 8-4 shows an abundance of gravel bars and mid-channel islands, suggesting that bedload sediment is abundant in this area.

Moulton Weir is located across and on the opposite side of the river from RM 158.5. This overflow weir, which is part of the Sacramento River Flood Control Project, spills excess water into the Butte Basin during floods. Moulton Weir may affect the movement of bedload sediment. The weir removes water and suspended sediment from the river during high flow events. However, bedload sediment moves along the bottom and does not transport into the weir. The reduced flows in the Sacramento River downstream of the weir have less stream power to move the sediment transported in from upstream, resulting in deposition in this general area.

8.3 Environmental Impacts/Environmental Consequences

8.3.1 Regulatory Setting

The Sacramento River's natural resources that comprise the geomorphology are regulated at the federal and State levels. Provided below is a list of the applicable regulations. These regulations are discussed in detail in Chapter 4 Environmental Compliance and Permit Summary of this EIR/EIS.

8.3.1.1 Federal Plans, Policies, and Regulations

- Coordinated Operations Agreement
- 2009 National Marine Fisheries Service Biological Opinion
- Federal Endangered Species Act
- U.S. Fish and Wildlife Service Operations Criteria and Plan Biological Opinion

8.3.1.2 State Plans, Policies, and Regulations

- Senate Bill 1086
- California Endangered Species Act (CESA) of 1982

8.3.2 Evaluation Criteria and Significance Thresholds

Significance criteria represent the thresholds that were used to identify whether an impact would be significant. Appendix G of the *CEQA Guidelines* does not include criteria that are specific to fluvial geomorphology. The evaluation criteria used for this impact analysis were based on professional judgment that considers current regulations, standards, and/or consultation with agencies, knowledge of the area, and the context and intensity of the environmental effects, as required pursuant to NEPA. For the purposes of this analysis, an alternative would result in a significant impact if it would result in any of the following:

- Substantial alteration of natural river processes and characteristics such as bank erosion, sinuosity, gradient, flow velocity, sediment transport, bed coarseness, depth, and width.
- Substantial alteration of natural river meandering, bank erosion, and deposition, with consequent substantial alteration of riparian vegetation regeneration and habitat complexity.
- Substantial alteration of the amount of large woody debris, boulders, shaded riverine aquatic habitat, or spawning gravel in rivers, resulting in substantial loss of fish rearing, holding, spawning, and feeding habitat.

Significance of the impacts on the above-listed geomorphologic parameters was determined by comparing the results from computer models that modeled different scenarios of the proposed operation of the alternatives, checking the parameters for changes that are larger than normal and natural variations over a long study period. The modeled changes that were predictable, consistent, and larger than the observable natural variations in the above-listed parameters would be considered to be significant impacts.

8.3.3 Impact Assessment Assumptions and Methodology

8.3.3.1 Assumptions

The following assumptions were made regarding Project-related construction, operation, and maintenance impacts to river geomorphology:

- Direct Project-related construction, operation, and maintenance activities would occur in the Primary Study Area.
- Direct Project-related operational effects would occur in the Secondary Study Area.
- The only direct Project-related construction activity that would occur in the Secondary Study Area is the installation of an additional pump into an existing bay at the Red Bluff Pumping Plant.
- The only direct Project-related maintenance activity that would occur in the Secondary Study Area is the sediment removal and disposal at the two intake locations (i.e., GCID Canal Intake and Red Bluff Pumping Plant).
- No direct Project-related construction or maintenance activities would occur in the Extended Study Area.
- Direct Project-related operational effects that would occur in the Extended Study Area are related to San Luis Reservoir operation; increased reliability of water supply to agricultural, municipal, and industrial water users; and the provision of an alternate Level 4 wildlife refuge water supply. Indirect effects to the operation of certain facilities that are located in the Extended Study Area, and indirect effects to the consequent water deliveries made by those facilities, would occur as a result of implementing the alternatives.
- The existing bank protection located upstream of the proposed Delevan Pipeline Intake/Discharge facilities would continue to be maintained and remain functional.

- No additional channel stabilization, grade control measures, or dredging in the Sacramento River at or upstream of the Delevan Pipeline Intake/Discharge facilities would be required.

8.3.3.2 Methodology

For this analysis, the Sedimentation and River Hydraulics Group of the U.S. Bureau of Reclamation conducted computer river hydraulic, sediment, and meander modeling that compared the effects of the four alternatives on natural river processes and characteristics. The USRDOM hydraulic model simulated 82 years of Sacramento River flow (from 1921 to 2003) for each of the alternatives.

Sediment transport models, in conjunction with the USRDOM model, were used to predict sediment transport and changes in bed coarseness, depth, and width. Two sediment transport models were used: one to predict variations in bedload movement, and one for suspended sediment movement.

The USRDOM model simulates daily river flows in the Sacramento River based on the operations specified by the CALSIM II model for each alternative. The monthly CALSIM II results are used to simulate daily reservoir operations and river flows over the period of simulation extending from water year 1922 through 2003 (82-year simulation period). The USRDOM model description and results are included in Appendix 6C. Detailed discussion of the CALSIM II model is provided in Appendix 6B.

The bedload analysis (Appendix 8A) investigated the sediment transport capacity of the Sacramento River from Keswick to Colusa Weir. The river was divided into 15 reaches based on geomorphology and hydrology. The USRDOM model daily flows were used to develop flow duration curves. Bedload transport was calculated using several available equations, with one selected that best described the available observational data. The transport of material greater in size than 2 millimeters was calculated in tons per year for each reach. Using this approach, the aggrading and degrading reaches could be identified, as well as changes in streambed composition predicted over the 82-year simulation period.

The suspended sediment transport model (Appendix 8A) investigated the movement of sediment in the Sacramento River and estimated the amount of sediment that would be diverted at the proposed Project diversions for each alternative. The USRDOM model simulated daily flows were used in conjunction with actual U.S. Geological Survey gaging station sediment sampling results to develop a flow versus suspended sediment rating curve. The rating curve was then used to calculate the sediment transport in the Sacramento River and the amount of sediment entrained in the diversion for each alternative.

The effects on natural river meandering, bank erosion, and deposition in the Sacramento River channel between Red Bluff and Colusa, with consequent effects on riparian vegetation, was modeled using the SRH-Meander model (Appendix 8A). Inputs to the model included USRDOM model daily flows, streambank erodibility, and channel hydraulic characteristics.

The SRH-Meander model simulated the bed topography, flow field, and bank erosion rate in a curved channel with an erodible bank and bed. At the end of each time step, it computed the amount of bank erosion and updated the channel centerline alignment. The amount of bank erosion was calculated using the near-bank depth-averaged flow velocity and a method that incorporated a multiple-size sediment transport equation (Appendix 8A). The model was run with all of the existing riprap in place. The model was calibrated by running the model between 1976 and 1999 using existing conditions and comparing the actual channel changes with the results of modeling. The model was tuned by adjusting the bank erodibility factors until a best-fit between actual and calculated meandering occurred.

The calibrated SRH-Meander model was run using the USRDOM daily flows from 1980 to 2010 to predict channel meandering from 2010 to 2030. The outputs of the model were a series of maps showing the channel centerline alignment in 2030 for each of the alternatives and graphs showing the accumulated migration distance.

Further, in assessing the impacts to the riparian vegetation along the Sacramento River in the Secondary Study Area, modeling specific to riparian vegetation, including results from the SRH-1DV and SacEFT models, were used. The SacEFT results were also used to analyze impacts to the large woody debris recruitment on the Sacramento River.

The SRH-1DV model simulates the establishment, growth, and mortality of vegetation, in addition to computing hydraulics and groundwater surface in the riparian zone near the river. The simulation tracks daily vegetation changes through 82 years of simulated flow, within the 107 river miles of Sacramento River from upstream of Red Bluff to Colusa. The SRH-1DV analysis focuses on four key valley foothill riparian vegetation types that are representative of the range of riparian communities of the Sacramento River: cottonwood, mixed forest, Gooding’s black willow, and narrow leaf willow. The detailed description of the SRH-1DV model and the associated alternatives evaluation is provided in Appendix 8A.

The SacEFT decision support tool provides key performance measures for various focal aquatic and terrestrial species, and riparian habitat in the Sacramento River. It specifically includes performance measures for evaluating the effects of various flow scenarios on the initiation success and post-initiation scour risk of the Fremont Cottonwood seedlings, and the amount of large woody debris recruited to the mainstem Sacramento River. These performance measures are used as a general indicator for assessing the impacts on riparian vegetation and potential habitat quality in the mainstem Sacramento River in Secondary Study Area. The detailed description of the SacEFT model and the associated alternatives evaluation is provided in Appendix 8B.

8.3.4 Topics Eliminated from Further Analytical Consideration

Because reservoir level fluctuations at San Luis Reservoir would have no effect on geomorphologic processes, only the operational impacts associated with water supply reliability are discussed in the impacts analysis for the Extended Study Area.

Because the existing Red Bluff Pumping Plant and GCID intakes would be the only locations along the Sacramento River where Project construction and/or operation and maintenance activities would occur (and where potential impacts to/from geomorphologic processes as a result of those activities may occur), the remainder of the Secondary Study Area is not discussed.

Because the only location along the Sacramento River where Project construction, operation, and maintenance activities would occur (and where potential impacts to/from geomorphologic processes as a result of those activities may occur) would be at the proposed Delevan Pipeline Intake/Discharge facilities location, potential impacts related to geomorphology are not discussed for the remaining Primary Study Area Project facilities. Similarly, because the proposed Delevan Pipeline Intake/Discharge facilities would not be constructed with implementation of the No Project/No Action Alternative, the Primary Study Area is not discussed for that Alternative.

8.3.5 Impacts Associated with the No Project/No Action Alternative

8.3.5.1 Extended Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Agricultural, Municipal, Industrial, and Wildlife Refuge Water Use

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

The No Project/No Action Alternative includes implementation of projects and programs being constructed, or those that have gained approval, as of June 2009. The impacts of these projects have already been evaluated on a project-by-project basis, pursuant to CEQA and/or NEPA, and their potential for impacts to geomorphological processes has been addressed in those environmental documents. Therefore, **there would not be a substantial adverse effect** on natural river processes and characteristics, when compared to Existing Conditions.

Most geomorphologic changes occur as a result of flood flows. Modeling of water supply reliability for the Extended Study Area indicates that changes in flow resulting from changes in water deliveries would be generally small and would occur during summer months when flows are too low to cause significant hydraulic changes. Therefore, **there would not be a substantial adverse effect** on geomorphological processes, when compared to Existing Conditions.

Modeling of water supply reliability for the Extended Study Area indicates that changes in flow resulting from changes in water deliveries would be generally small and would occur during summer months when flows are too low to cause significant hydraulic changes. Population growth is expected to occur in California throughout the period of Project analysis (i.e., 100 years), and is included in the assumptions for the No Project/No Action Alternative. Changes in water deliveries could occur in response to population growth. However, most geomorphologic changes occur as a result of flood flows, and changes in water deliveries would not be expected to result in flood flows. Therefore, **there would not be a substantial adverse effect** on geomorphological processes, when compared to Existing Conditions.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

Refer to the **Impact Geom-1** discussion. That discussion is also applicable to alterations to the river, erosion and deposition, and riparian vegetation and habitat complexity.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

Refer to the **Impact Geom-1** discussion. That discussion is also applicable to effects on fish habitat from alterations to the amount of large woody debris, boulders, shaded riverine aquatic habitat, or spawning gravel.

8.3.5.2 Secondary Study Area – No Project/No Action Alternative

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and

Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

Impacts to the geomorphology of the Klamath, Trinity, and Sacramento River tributaries; the San Joaquin river system; and other elements of the Secondary Study Area depend on the degree of hydraulic alteration associated with the No Project/No Action Alternative. These hydraulic changes and consequent geomorphologic changes as a result of the projects included in the No Project/No Action Alternative would be evaluated pursuant to CEQA and/or NEPA during individual project environmental review, and mitigation would be required for significant geomorphologic impacts during those reviews.

Most of the geomorphologic impacts of this alternative would occur in the Sacramento River between Keswick Dam and the Pacific Ocean, as explained below. Reclamation's computer modeling for the Sacramento River showed minor changes in river flow and flow duration (Appendix 8A).

Modeling results indicate that the Sacramento River annual flow volumes would be comparable between Existing Conditions and the No Project/No Action Alternative (Appendix 8A). There would be a slight decrease in annual flow upstream of the Red Bluff Pumping Plant and a slight increase in flow downstream of the Red Bluff Pumping Plant with the No Project/ No Action Alternative. However, high flows are more geomorphologically significant than lower flows. The changes in high flow events would also be minor and have a low exceedance probability (Appendix 8A).

Modeling results indicate that suspended sediment would continue to be entrained at the Red Bluff Pumping Plant and GCID Canal Intake if the No Project/No Action Alternative were implemented. The existing suspended sediment entrainment rate at the Red Bluff Pumping Plant is estimated to be approximately 4,000 tons[1] per year. Modeling results indicate that this rate would not change if the No Project/No Action Alternative is implemented (Appendix 8A).

Therefore, the amount of suspended sediment that would be entrained at the Red Bluff Pumping Plant with implementation of the No Project/No Action Alternative **would not have substantial adverse effect**, when compared to Existing Conditions**.**

The estimated average amount of suspended sediment currently moving in the river past the Hamilton City stream gage is approximately 3.92 million tons (USACE, 1983).The existing GCID Canal Intake sediment entrainment rate is estimated to be 44,000 tons, representing 1.1 percent of the amount of suspended sediment in the Sacramento River at that location. Modeling results indicate that the amount of suspended sediment that would be entrained at the existing GCID Canal Intake as a result of implementing the No Project/No Action Alternative would be 47,000 tons, representing 1.2 percent of the amount of suspended sediment in the Sacramento River at that location. The slight increase in the amount of sediment diverted, when comparing Existing Conditions to the No Project/No Action Alternative, is less than one-tenth of one percent and is well within natural annual variation. Therefore, implementation of the No Project/No Action Alternative **would not result in a substantial adverse effect** on Sacramento River geomorphology, when compared to Existing Conditions.

---

[1] In general, 1.5 tons of sediment is equal to one cubic yard.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

Modeling results indicate that impacts to meandering between Existing Conditions and the No Project/No Action Alternative would be minor (Appendix 8A), which **would not result in a substantial adverse effect**.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

The effects on the amount of instream woody material, boulders, shaded riverine aquatic habitat, and spawning gravel are primarily functions of bank erosion. Bank erosion undercuts the banks, and trees fall in the water. The banks are composed of silt, sand, and gravel. The gravel deposits on riffles to form spawning habitat. Because there would be no significant difference in bank erosion between Existing Conditions and the No Project/No Action Alternative, **there would be no substantial adverse effect**.

8.3.6 Impacts Associated with Alternative A

8.3.6.1 Extended Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Agricultural Water Use, Municipal and Industrial Water Use, and Wildlife Refuge Water Use

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

When compared to Existing Conditions and/or the No Project/No Action Alternative, the amount of alteration to natural river processes and characteristics within the Extended Study Area associated with implementation of Alternative A would be minor. Most geomorphologic changes occur during flood flows. Reservoir releases may increase or decrease as a result of Alternative A operations for water deliveries, but the hydraulic changes would not increase or significantly change flood flows. Therefore, geomorphologic impacts are expected to be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative**.**

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

Refer to the **Impact Geom-1** discussion. That discussion is also applicable to alterations to the river, erosion and deposition, and riparian vegetation and habitat complexity.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

Refer to the **Impact Geom-1** discussion. That discussion is also applicable to effects on fish habitat from alterations to the amount of large woody debris, boulders, shaded riverine aquatic habitat, or spawning gravel.

8.3.6.2 Secondary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Sacramento River, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex (Thermalito Diversion Pool, Thermalito Forebay, and Thermalito Afterbay), Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

The Sacramento River from Keswick Dam to the Pacific Ocean is considered to be the main area where Project-related fluvial geomorphology impacts could occur[2]. Compared to Existing Conditions and/or the No Project/No Action Alternative, implementation of Alternative A would result in the Sacramento River experiencing the largest changes in flow and sediment due to hydraulic changes.

The remainder of the Secondary Study Area, including Trinity Lake, Lewiston Lake, Trinity River, the Klamath River, Whiskeytown Lake, Spring Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Folsom Lake, Lake Natomas, or the American River would experience only minor changes in peak flow, and would, therefore, not be expected to substantially alter natural river processes. More noticeable flow changes would occur during the summer, but low summer flows do not substantially alter natural river processes. Also, no Project construction or maintenance activities would occur at any of the above-listed locations. Operational changes resulting in alteration of streamflow would be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative, because it would not significantly affect fluvial geomorphology in these areas.

Construction activities associated with the addition of a pump at the Red Bluff Pumping Plant would not occur within the Sacramento River and would not require changes in pumping plant operations. Sediment removal at the Red Bluff Pumping Plant and GCID Canal Intake would occur during the regularly scheduled maintenance period for these intakes and would require the same maintenance activities conducted for Existing Conditions. Therefore, construction activities at the Red Bluff Pumping Plant, and maintenance activities at the Red Bluff Pumping Plant and GCID Canal Intake, are expected to be **less than significant** to Sacramento River geomorphology, when compared to Existing Conditions and the No Project/No Action Alternative.

Implementation of Alternative A would result in alterations to natural river processes and characteristics, such as bank erosion, sinuosity, gradient, flow velocity, sediment transport, bed coarseness, depth, and width by changing the timing, distribution, and amount of flow in the Sacramento River between Shasta Dam and the Pacific Ocean. There would be operational impacts to the Sacramento River downstream of Keswick Dam, and extending into overflow areas, such as the Yolo Bypass, and the Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and the San Francisco Bay to the Pacific Ocean, as a result of these hydraulic changes. The three Project intakes would also affect the amount of sediment and water in the river downstream of each diversion.

---

[2] Other river systems within the Secondary and Extended study areas would experience impacts, but the impacts to the other river systems are considered to be less than significant because impacts to the Sacramento River are considered less than significant.

Modeling results indicate that the effects of Alternative A on the Sacramento River would include a slight decrease in suspended sediment load and bed load (because of reduced flow and bed mobility) in the Sacramento River downstream of the Red Bluff Pumping Plant, GCID Canal, and the Delevan Pipeline intakes, mostly during winter months. The expected amount of sediment that would be entrained in these proposed intakes would be less than one percent of the existing changes in sediment deposition into the Delta.

The estimated average amount of suspended sediment currently moving in the river past the Bend Bridge gage is approximately 2.01 million tons (USACE, 1983). The average amount of suspended sediment that would be entrained at the Red Bluff Pumping Plant annually if Alternative A is implemented is estimated to be approximately 46,000 tons per year, as compared to 4,000 tons estimated for Existing Conditions and the No Project/No Action Alternative (Appendix 8A). Therefore, implementation of Alternative A would decrease the amount of suspended sediment in the Sacramento River downstream of the Red Bluff Pumping Plant by approximately 2.3 percent, as compared to the 0.2 percent decrease associated with Existing Conditions and the No Project/No Action Alternative at this location.

The amount of sediment that would be entrained at the GCID Canal Intake if Alternative A is implemented is estimated to be approximately 53,000 tons per year (Appendix 8A), as compared to 44,000 tons estimated for Existing Conditions and 47,000 tons estimated for the No Project/No Action Alternative. Therefore, implementation of Alternative A would decrease the amount of sediment in the Sacramento River downstream of Hamilton City by approximately 1.4 percent, as compared to the 1.1 percent decrease associated with Existing Conditions and the 1.2 percent decrease associated with the No Project/No Action Alternative at this location. At Hamilton City, there is a large component of flow and sediment that goes overbank during large flood events, so the actual percentage would be less.

The estimated annual amount of suspended sediment moving in the Sacramento River past the Butte City gage, which is approximately 10 miles upstream of the proposed Delevan Pipeline Intake location, is estimated at 4.32 million tons (USACE, 1983).Modeling results indicate that the amount of suspended sediment that would be entrained at the Delevan Pipeline Intake would be approximately 47,000 tons (Appendix 8A), representing approximately 1.1 percent of the amount of suspended sediment in the Sacramento River at that location. This intake is considered part of the Primary Study Area, but the downstream effects would occur in the Secondary Study Area.

The diverted suspended sediment at the three intake locations would be less than two percent of the total suspended sediment moving in this reach of the river. However, because the water and sediment would both be diverted, the concentration of the sediment in the water would remain unchanged, so there would be a **less-than-significant impact** on sediment concentration, turbidity or water clarity, when compared to Existing Conditions and the No Project/No Action Alternative.

The loss of suspended sediment would affect the river, floodplain, overflow areas, weirs, bypasses, the Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and the Pacific Ocean by reducing the amount of deposition in these areas. The impacts of the loss of suspended sediment at the existing Red Bluff Pumping Plant would occur in the Sacramento River from Red Bluff and downstream. The loss of suspended sediment at the existing GCID Canal Intake would occur in the Sacramento River from Hamilton City and downstream, and the loss of suspended sediment at the proposed Delevan Pipeline Intake would occur in the Sacramento River from the vicinity of Princeton and downstream. The effects would be considered **beneficia**l in some places, when compared to Existing Conditions and the No

Project/No Action Alternative, by reducing suspended sediment that could deposit in spawning gravel, agricultural fields, navigable waters, and in weirs and bypasses.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

Compared to Existing Conditions and/or the No Project/No Action Alternative, implementation of Alternative A is expected to affect natural Sacramento River meandering, bank erosion, and deposition, with consequent effects on riparian vegetation.

The installation of the fish screen at the proposed Delevan Pipeline Intake would be functionally equivalent to bank protection, and may affect meandering downstream of the diversion. However, the bank at this location consists of geologic control (erosion resistant unit). In addition, the existing Maxwell ID Pumping Plant, located immediately upstream of the proposed Delevan Pipeline Intake location, is located in a narrow section of the river and consequently acts as a local flow control point (Reclamation, 2012). Therefore, a **less-than-significant impact** is expected, when compared to Existing Conditions and the No Project/No Action Alternative.

Bank protection installed in the mid-1980s exists on the right bank in the bend upstream of the diversion, stabilizing the bend. This riprap does not protect the entire bend, and the potential for a partial cutoff exists.

The changes in streamflow downstream of Keswick Dam and the three Project intakes would also have effects on bank erosion. Decreased flows would potentially reduce the amount of sediment delivered to the Sacramento River from this source, at least directly downstream of the intakes. The largest effect would be associated with the existing Red Bluff Pumping Plant because of the 100 miles of meandering river occurring between the intake to the end of the meandering reach at the town of Colusa. The GCID Canal Intake would affect approximately 50 miles of meandering river, and the Delevan Pipeline Intake would have the least operational effect, affecting only approximately 10 miles of the Sacramento River, located downstream of the proposed intake.

The Reclamation meander study produced flow duration curves that indicate only minor differences in flow would occur between Existing Conditions, the No Project/No Action Alternative, and Alternative A. Most of the flow differences would occur below the threshold flow of 30,000 cfs, which is the flow above which significant geomorphologic river changes typically begin to occur.

The differences in channel migration between the Existing Conditions, the No Project/No Action Alternative, and Alternative A would be small. There would be a slight increase in bank erosion and meander rates with Alternative A (Appendix 8A). This is considered a **beneficial effect**, when compared to Existing Conditions and the No Project/No Action Alternative, because it would result in more benefits to riparian vegetation, fish, and wildlife because of a slight increase in floodplain rejuvenation.

Meandering is beneficial because it maintains forest health, complexity, and diversity by removing late stage older riparian vegetation, such as cottonwood forests on one side of the river, and replacing them with younger stages such as willow shrub on the other side. Trees, rootwads, and gravel (used by salmonids for habitat and spawning) would be introduced into the river and would also provide habitat for a variety of other fish and wildlife.

Modeling performed using SRH-1DV and SacEFT indicates that the coverage of the riparian vegetation along the Sacramento River would increase or remain similar with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

It would typically be expected for the meander rates to decrease locally downstream of the Sacramento River winter diversions as a result of implementing Alternative A because the water diverted would reduce streamflow. However, this does not appear to be the case. The hydraulic modeling showed that the coordinated operation of the proposed Sites Reservoir and Shasta Lake would generally result in higher Shasta Lake storage in the late summer and early fall, and higher Keswick Dam releases in the fall and winter. Therefore, there would be a slight increase in the incidence of high flow events upstream of the intakes. The expected increase in flows upstream of the intakes, combined with the expected decrease in flows downstream of the intakes (due to diversion of excess flows primarily from tributaries), generally do not coincide. Therefore, it is expected that flow levels that are effective at increasing meander rates would increase slightly.

Alternative A would slightly increase erosion and slightly reduce sediment deposition. The change in the erosion-deposition balance with implementation of Alternative A would be small and is considered to be **less than significant** when considering the large natural fluctuations in these two parameters, and when compared to Existing Conditions and the No Project/No Action Alternative.

Downstream of Colusa, meandering would not occur to any significant degree because the river is confined by levees. Reduction of suspended sediment resulting from Alternative A downstream of Colusa is considered to be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative, because the river is isolated by levees from its floodplain, and sediment deposition in the overflow areas is not considered environmentally beneficial. The weirs, bypasses, and overflow areas would benefit from the reduced deposition associated with operation of Alternative A because periodic removal of sediment is required to maintain their proper function.

Reduced suspended sediment supply has the potential to affect the replenishment of sand on ocean beaches south of San Francisco. However, the Sacramento and San Joaquin rivers are not significant suppliers of sand to the beaches, partly because of the many dams on those rivers, and also because of the low gradient through the Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, and San Francisco Bay to the Pacific Ocean. All but the very fine sediment drops out before reaching the ocean. Other streams that feed directly into the ocean, such as the Klamath, Mad, Van Duzen, Eel, Russian, and other smaller rivers, provide the majority of the sand to beaches. **No impact** would occur to sand deposition on beaches depending on these rivers, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

Compared to Existing Conditions and/or the No Project/No Action Alternative, Alternative A would result in impacts on fish and wildlife habitat by affecting the amount of large woody debris, shaded riverine aquatic habitat, and spawning gravel in the river. The slight increase in bank erosion would increase the number of trees in the river used by fish as cover and holding habitat, and the amount of gravel used for spawning. The gravel would become part of the sediment supply in the river, and would move as bedload. The bedload would deposit on riffles where salmon build their nests and deposit their eggs.

Modeling performed using SacEFT indicates that the large woody debris recruitment to the Sacramento River would remain similar with implementation of Alternative A, when compared to Existing Conditions and the No Project/No Action Alternative.

It is not certain how Alternative A would affect the shaded riverine aquatic habitat that occurs along the banks of a stream; however, it is expected that the increased bank erosion would result in improved riparian forest health.

No bedload is expected to be entrained in the three Project intakes, but the reduced flow downstream of those intakes would reduce the mobility of the bedload in the channel. This may have a slight aggradational effect to the channel downstream of each intake because bedload derived from bank erosion and tributaries would continue to move into the area. This would be a **beneficial effect** to salmon spawning gravel riffle habitat, when compared to Existing Conditions and the No Project/No Action Alternative.

Bedload is the main source of spawning gravel for salmonids. The salmon depend on fresh gravel, free from fine sediment, to deposit their eggs. Bedload movement on a periodic basis is important in maintaining high spawning gravel quality. Bedload deposition is also important in maintaining hydraulic diversity. Islands, point bars, and multiple channels provide a variety of habitat elements for the fish and wildlife.

Reclamation modeling of the movement of bedload sediment for Alternative A indicates that the bedload transport capacity upstream of the Red Bluff Pumping Plant intake would increase by two to six percent, and would decrease by approximately two percent downstream (Appendix 8A). Alternative A would affect the movement of gravel and the overall bedload budget by less than five percent, which is considered to not significantly affect the bedload sediment balance in the Sacramento River. Some aggradation and degradation would occur in the different reaches; the amounts are small, less than 0.1 inch per year (Appendix 8A).

The GCID Canal Intake has an existing bedload deposition problem at the mouth of the river intake channel. Dredging to remove these deposits currently occurs infrequently, every five years or so. Implementation of Alternative A may slightly increase the frequency and amount of dredging that would need to occur. Similar maintenance activities may be required at the Red Bluff Pumping Plant and the Delevan Pipeline Intake. If the gravel is removed from the river permanently, it is a negative impact. However, the gravel may be spread on point bars downstream of the intakes, essentially re-introducing the gravel and minimizing the effects of this activity. Modeling results (Appendix 8A) indicate that the change in hydrology that would be associated with the operation of Alternative A would result in a **less-than-significant impact** on bedload movement, when compared to Existing Conditions and the No Project/No Action Alternative.

The slight increase in bank erosion rates mentioned previously (Appendix 8A) is expected to have a slightly **beneficial effect** on riparian vegetation over the long-term, when compared to Existing Conditions and the No Project/No Action Alternative. Increased erosion would result in more of the floodplain being converted back to riparian vegetation. Shaded riverine aquatic habitat would also increase because more of the floodplain would be occupied by riparian forests, and more woody material and spawning gravel would be introduced to the river.

8.3.6.3 Primary Study Area – Alternative A

Construction, Operation, and Maintenance Impacts

Delevan Pipeline Intake Facilities

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

The only location along the Sacramento River where Alternative A construction, operation, and maintenance activities would occur, and where impacts from/to Sacramento River fluvial geomorphology would occur, is at the proposed Delevan Pipeline Intake Facilities location.

The proposed pump station and afterbay would be located on erosion resistant deposits (referred to as geologic control) of the Modesto Formation. The proposed fish screen, floodgates, and pipes leading to the afterbay, would be located on river deposits in the 1896 to 1937 channel alignment (Figure 8-3).

When compared to Existing Conditions and/or the No Project/No Action Alternative, the proposed fish screens, as part of Alternative A, would stabilize a short section of bank, and are expected to be the only feature that could affect Sacramento River geomorphology directly. However, the bank where the fish screens would be constructed is considered to be geologic control and not part of the meander belt. The construction of the screens would result in a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Refer to the **Impact Geom-1** discussion for the Sacramento River within the Secondary Study Area for a discussion of the operation and maintenance impacts associated with the two existing intakes (Red Bluff Pumping Plant and GCID Canal) and the proposed Delevan Pipeline intake. There may be some minor changes in sediment levels and local flow around the proposed Delevan Pipeline Intake construction area, when compared to Existing Conditions and/or the No Project/No Action Alternative. These changes in sediment and flow would not affect the local geomorphology in the Sacramento River and would, therefore, have **no impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

The proposed fish screens would result in the local removal of riparian vegetation along this short length of bank, reducing habitat complexity, when compared to Existing Conditions and/or the No Project/No Action Alternative. The impact would be slight and is considered to be **less than significant**.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

The bank where the proposed Delevan Pipeline Intake fish screens would be located consists of geologically stable units that do not erode significantly. The reduction in spawning gravel and fish habitat would be slight, when compared to Existing Conditions and/or the No Project/No Action Alternative, and is considered to be a **less-than-significant impact**.

8.3.7 Impacts Associated with Alternative B

8.3.7.1 Extended Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B, as they relate to natural river processes and characteristics (**Impact Geom-1**), riparian vegetation and habitat complexity (**Impact Geom-2**), and fish habitat (**Impact Geom-3**), would be the same as described for Alternative A for the Extended Study Area.

8.3.7.2 Secondary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative B operations, as they relate to natural river processes and characteristics (**Impact Geom-1**), riparian vegetation and habitat complexity (**Impact Geom-2**), and fish habitat (**Impact Geom-3**), would be the same as described for Alternative A for Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction impacts associated with the pump installation at the Red Bluff Pumping Plant.

Operational impacts associated with implementation of Alternative B to the Sacramento River downstream of Shasta Dam to the Pacific Ocean are discussed below.

Sacramento River

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

Suspended sediment entrained into the existing Red Bluff Pumping Plant would be somewhat higher for Alternative B than that described for Alternative A (approximately 58,000 tons per year instead of 46,000 tons) (Appendix 8A) because of the larger diversion amounts that would be needed to fill the larger 1.8 MAF Sites Reservoir, and because the Delevan Pipeline Intake would be replaced by the release-only Delevan Pipeline Discharge Facility.

The amount of suspended sediment entrained at the existing GCID Canal Intake, as a result of Alternative B, also would be a little higher than for Alternative A (64,000 instead of 53,000 tons per year), but no sediment would be entrained at the proposed Delevan Pipeline Discharge Facility because there would be no intake there. These impacts would extend downstream in the Secondary Study Area, primarily in the Sacramento River downstream of Hamilton City through the Delta and to the Pacific Ocean. Although Alternative B impacts would be slightly larger to the meandering reach of the river than Alternative A because the water is removed farther upstream in the system, Alternative B operation would still result in a **less-than-significant impact** on the amount of suspended sediment when compared to the large amount of sediment moving in the river (as described in the Alternative A analysis), when compared to Existing Conditions and the No Project/No Action Alternative.

The movement of bedload downstream of the two existing intakes would decrease slightly, when comparing Alternative B to Alternative A because of the reduced flow in the channel. The impact of the reduced bedload movement is considered to be **less than significant** for Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

Because of the slight differences in the hydrology between Alternative A and Alternative B, the differences in meandering, bank erosion and deposition are also slight. Alternative B would result in less natural river meandering than Alternative A, which would result in less bank erosion and deposition, with less consequent alteration of riparian vegetation regeneration and habitat complexity. The meandering is only slightly more for Alternative B than for Existing Conditions and the No Project/No Action Alternative. As discussed for Alternative A, these differences are considered to be small, when compared to the natural variation in these parameters. Therefore, the consequent alteration of riparian vegetation regeneration and habitat complexity is considered to be **beneficial, but less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Modeling performed using SRH-1DV and SacEFT indicates that the coverage of the riparian vegetation along Sacramento River would increase or remain similar with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative. The only exception is that the SacEFT indicates that there would be a slightly higher number of years with post-initiation scour risk for Fremont Cottonwood seedlings with implementation of Alternative B, when compared to the No Project/No Action Alternative.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

Alternative B would affect large woody debris, shaded riverine aquatic habitat, and spawning gravel in the Sacramento River, which could result in a loss of fish rearing, holding, spawning, and feeding habitat. However, modeling performed using SacEFT indicates that the large woody debris recruitment to the Sacramento River would remain similar with implementation of Alternative B, when compared to Existing Conditions and the No Project/No Action Alternative. As discussed for Alternative A, implementation of either of these action alternatives would result in a slight increase in bank erosion and meandering (Appendix 8A), when compared to Existing Conditions and the No Project/No Action Alternative, resulting in a **less-than-significant, but beneficial, impact** due to the increase in large woody debris, shaded riverine aquatic habitat, and spawning gravel in the river.

8.3.7.3 Primary Study Area – Alternative B

Construction, Operation, and Maintenance Impacts

Delevan Pipeline Discharge Facility

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

As described for the Delevan Pipeline Intake Facilities, the Delevan Pipeline Discharge Facility would also be located on geologic control outside of the Sacramento River meander belt. The discharge facility would have no associated fish screens, and therefore, would not extend into the river, but would require a cofferdam that would extend into the river during Project construction. However, the construction area would also be located on geologic control. The discharge facility would be operated as a release-only facility, and would, therefore, not entrain sediment during operation or require the maintenance activity of sediment removal that was described for the intake facility associated with Alternative A. Construction, operation, and maintenance of the Delevan Pipeline Discharge Facility would, therefore, result in a

less-than-significant impact to Sacramento River geomorphology in the Primary Study Area, when compared to Existing Conditions and/or the No Project/No Action Alternative.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

The proposed discharge facility would result in less riparian vegetation being removed along this length of bank when compared to Alternative A. Because of the short length of bank affected, the impact would be slight and is considered to be **less than significant**, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

The bank where the proposed Delevan Pipeline Discharge Facility would be located consists of geologically stable units that do not erode significantly. The reduction in fish habitat resulting from the loss of a small amount of shaded riverine aquatic habitat would be slight, when compared to Existing Conditions and/or the No Project/No Action Alternative, and is considered to be a **less-than-significant impact**, when compared to Existing Conditions and the No Project/No Action Alternative.

8.3.8 Impacts Associated with Alternative C

8.3.8.1 Extended Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C, as they relate to natural river processes and characteristics (**Impact Geom-1**), riparian vegetation and habitat complexity (**Impact Geom-2**), and fish habitat (**Impact Geom-3**), would be the same as described for Alternative A for the Extended Study Area.

8.3.8.2 Secondary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

The impacts associated with Alternative C operations, as they relate to natural river processes and characteristics (**Impact Geom-1**), riparian vegetation and habitat complexity (**Impact Geom-2**), and fish habitat (**Impact Geom-3**), would be the same as described for Alternative A for Trinity Lake, Lewiston Lake, Trinity River, Klamath River Downstream of the Trinity River, Whiskeytown Lake, Spring Creek, Shasta Lake, Keswick Reservoir, Clear Creek, Lake Oroville, Thermalito Complex, Feather River, Sutter Bypass, Yolo Bypass, Folsom Lake, Lake Natoma, American River, Sacramento-San Joaquin Delta, Suisun Bay, San Pablo Bay, San Francisco Bay, and for the Sacramento River as it pertains to the construction, operation, and maintenance impacts associated with the pump installation at the Red Bluff Pumping Plant.

Operational impacts associated with implementation of Alternative B for the Sacramento River downstream of Shasta Dam to the Pacific Ocean are discussed below.

Sacramento River

Impact Geom-1: Substantial Alteration of Natural River Processes and Characteristics

The implementation of Alternative C would alter hydraulic conditions in the Sacramento River and result in changes to natural river processes and characteristics such as bank erosion, sinuosity, gradient, flow velocity, sediment transport, bed coarseness, depth, and width.

The impacts to hydrology from operation of Alternative C would be slightly larger than for Alternative A because the larger reservoir associated with Alternative C would allow more diversions to occur, which could increase the amount of diverted sediment. However, as discussed for Alternative A, the diverted suspended sediment at the three Project intake locations would represent a small percentage of the total suspended sediment in this reach of the river, and because the water and sediment would both be diverted, the concentration of the sediment in the water would remain unchanged. There would, therefore, be a **less-than-significant impact** to the Sacramento River natural river processes, such as bank erosion, sinuosity, gradient, flow velocity, sediment transport, bed coarseness, depth, and width, when compared to Existing Conditions and the No Project/No Action Alternative.

The movement of bedload downstream of the two existing intakes would be similar, when comparing Alternative C to Alternative A, because of similar flow in the channel, and is considered to be **less than significant** for Alternative C, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geom-2: Substantial Alteration of Natural River Meandering, Bank Erosion, and Deposition, and Substantial Alteration of Riparian Vegetation and Habitat Complexity

Alternative C would result in a slight increase in natural meandering, bank erosion, and deposition, with a consequent slight increase in riparian vegetation regeneration and habitat complexity, when compared to the No Project/No Action Alternative. The accumulated channel migration distance (Appendix 8A) showed the results of the meander modeling for Alternative A. Alternative C would result in less channel migration distance than Alternative A, but more than Alternative B. All three action alternatives would differ by less than 10 feet of channel migration for the 30-year model period. The average meander distance would be approximately 175 feet for all three alternatives, with an associated potential increase of approximately a maximum of six percent. This is considered a beneficial effect to the environment, when compared to Existing Conditions and the No Project/No Action Alternative.

Impact Geom-3: Substantial Alteration of the Amount of Large Woody Debris, Boulders, Shaded Riverine Aquatic Habitat, or Spawning Gravel in Rivers, with Effects on Fish Habitat

Modeling performed using SacEFT indicates that the large woody debris recruitment to the Sacramento River with implementation of Alternative C would be the same as described for Alternative A. As discussed for Alternative A, implementation of either of these action alternatives would result in a slight increase in bank erosion and meandering (Appendix 8A), when compared to Existing Conditions and the No Project/No Action Alternative, resulting in a **less-than-significant, but beneficial, impact** due to the increase in large woody debris, shaded riverine aquatic habitat, and spawning gravel in the river.

8.3.8.3 Primary Study Area – Alternative C

Construction, Operation, and Maintenance Impacts

Similar to Alternative A, Alternative C would include the Delevan Pipeline Intake Facilities within the Primary Study Area. The impacts associated with Alternative C, as they relate to natural river processes and characteristics (**Impact Geom-1**), riparian vegetation and habitat complexity (**Impact Geom-2**), and fish habitat (**Impact Geom-3**), would, therefore, be the same as described for Alternative A for the Primary Study Area.

8.4 Mitigation Measures

Because no significant or potentially significant impacts were identified, no mitigation is required or recommended.

9. Flood Control and Management

9.1 Introduction

This chapter describes the flood hydrology, control, and management system in the Primary, Secondary, and Extended study areas, with particular focus on the Primary Study Area and Sacramento River Basin. Descriptions and maps of these three study areas are provided in Chapter 1 Introduction.

The regulatory setting for flood hydrology, control, and management is discussed briefly in this chapter, and is presented in greater detail in Chapter 4 Environmental Compliance and Permit Summary.

This chapter focuses primarily on the Primary Study Area. Potential impacts in the Secondary Study Area, particularly related to the Sacramento River Flood Management System, were evaluated and discussed qualitatively. The portions of the Extended Study Area that are located outside of the Project flood control and management impacted areas were not evaluated or discussed. Potential local and regional impacts from constructing, operating, and maintaining the alternatives were described and compared to applicable significance thresholds. Mitigation measures are provided for identified significant or potentially significant impacts, where appropriate.

9.2 Affected Environment

This section describes flood control and management facilities in the three study areas, with particular focus on the Primary Study Area (including local flood management facilities) and the Secondary Study Area (including the Sacramento River flood management system).

9.2.1 Extended Study Area

The Extended Study Area includes the entire statewide CVP and SWP service areas. This study area is extensive and includes hundreds, if not thousands, of federal, State, regional and local flood control and management facilities. This study area encompasses the CVP and SWP service areas outside of the greater Sacramento River Basin and south of the Sacramento-San Joaquin Delta. The only Extended Study Area reservoir included in Project operations modeling is San Luis Reservoir. However, San Luis Reservoir is operated entirely as a joint CVP and SWP supply storage reservoir and is not operated for flood control purposes. The portions of the Extended Study Area that are outside of the greater Sacramento River Basin, and south of the Sacramento-San Joaquin Delta, would also be outside of the affected environment for Project flood impacts, and are, therefore, not discussed.

9.2.2 Secondary Study Area

9.2.2.1 Sacramento River Flood Control and Management

The Sacramento River flood control and management system is a complex network of dams and reservoirs, levees, weirs, bypasses and other flood control features. A portion of this complex flood protection system includes State- and federally-authorized projects for which the Central Valley Flood Protection Board (CVFPB) or DWR has provided assurances of cooperation to the federal government. This portion of the flood protection system is known as the State Plan of Flood Control (SPFC). A summary of features of the SPFC is provided in Figure 9-1.

The CVFPB or DWR has not provided assurances of cooperation for all parts of the flood protection system. Projects without CVFPB or DWR assurances are not part of the SPFC (i.e., they are non-SPFC facilities). Although these facilities are not part of the SPFC, their operation may influence operation of the SPFC, especially in reducing peak flood flows through the SPFC levee system. Non-SPFC facilities include multipurpose reservoir projects (with the exception of Lake Oroville, which is the only major multipurpose project discussed in this chapter that is part of the SPFC), local and regional projects, non-project levees, local pumping plants, and State-designated floodways (DWR, 2010).

Multipurpose flood management reservoirs in the greater Sacramento River Basin are listed in Table 9-1 in chronological order of construction.

Table 9-1
Sacramento River Basin Multi-Purpose Flood Management Reservoirs

Reservoir	Total Reservoir Capacity (acre-feet)	Maximum Flood Storage Capacity (acre-feet)	Operator
Shasta	4,550,000	1,300,000	Reclamation
Black Butte	160,000	137,000	USACE
Folsom	1,010,000	650,000	Reclamation
Oroville	3,540,000	750,000	DWR
New Bullards Bar	960,000	170,000	Yuba County Water Agency
Indian Valley	300,000	40,000	Yolo County Flood Control and Water Conservation District

Notes:

USACE = U.S. Army Corps of Engineers
DWR = California Department of Water Resources
Reclamation = U.S. Bureau of Reclamation

Other major SPFC facilities in the Sacramento River flood control and management system include project levees and flood control weirs, as shown on Figures 9-2A and 9-2B. These figures also indicate system capacities and flood flow routing.

The 100-year floodplain delineations for the Sacramento River Valley north of the Sacramento-San Joaquin Delta are illustrated on Figure 9-3. Major federal, State and local non-SPFC projects impacting flood hydrology or providing flood management for the Sacramento Valley are located on the Trinity River, Sacramento River, Feather River, American River and within the Delta. These areas are discussed below.

9.2.2.2 Trinity River (Including Trinity Lake, Lewiston Lake, Whiskeytown Lake, Clear Creek and Spring Creek)

The Trinity River is the largest tributary to the Klamath River. The Trinity River Diversion includes Trinity Dam, Lewiston Dam, and facilities to transfer water from the Trinity River Basin to the Sacramento River Basin. Trinity Dam was completed in 1962. The dam forms Trinity Lake, which has a capacity of approximately 2.4 MAF. Releases from Trinity Dam are regulated downstream at Lewiston Lake for downstream flow requirements and diversions through the Clear Creek Tunnel to Whiskeytown Lake on Clear Creek. From Whiskeytown Lake, water is delivered through the Spring Creek tunnel to Keswick Reservoir. The outflow from Trinity and Lewiston reservoirs provides water to meet temperature objectives for special-status fish species in the Trinity and upper Sacramento rivers (Reclamation, 2009).

Flood control was not an original project purpose of the two dams. However, because of its large storage and spillway surcharge capacities, Trinity Lake has the potential to provide flood control storage, and Reclamation’s Safety of Dams criteria stipulate flood control releases November through March if the overall storage is forecasted to exceed 2.0 MAF (Reclamation, 2004). In addition, Trinity Lake is operated in conjunction with Shasta Lake, when necessary, as part of Shasta's Sacramento River flood control operations.

9.2.2.3 Sacramento River (Including Shasta Lake and Keswick Reservoir)

A complex system of dams and associated reservoirs, levees, weirs, bypasses and other features have been constructed over the last 150 years to help manage flooding along the Sacramento River. The primary flood control features on the Sacramento River system are Shasta Lake and the federally authorized Sacramento River Flood Control Project.

Regulating inflows from the Sacramento, McCloud, and Pit rivers, Shasta Lake provides flood control to the upper Sacramento River through Shasta Lake's 1.3-MAF of flood control storage. The reservoir is managed for flood control from October 1 through March 30. In non-emergency flood conditions, Shasta Dam releases are restricted to 79,000 cfs at the tailwater of Keswick Dam (79,000 cfs is the estimated safe channel carrying capacity of the Sacramento River downstream of Keswick through Redding) and by a flood stage of 27.0 feet at the Sacramento River at Bend Bridge gage (flood stage of 27.0 ft equates to approximately 100,000 cfs). The Sacramento River at Bend Bridge is a key Sacramento River flood forecasting point. The Sacramento River Flood Control Project area spans from Red Bluff to Verona (north of Sacramento on the Sacramento River) and includes levees, cleared channels, bypasses, and overflow flood control facilities (Figures 9-2A and 9-2B).

The Chico Landing to Red Bluff reach of the Sacramento River (RM 194 to RM 244) is relatively unaffected by flood control facilities. The river naturally meanders through alluvial deposits, and tributaries contribute unregulated flood inflows. This reach of the Sacramento River Flood Control Project was authorized in 1958 for bank protection and incidental channel modification. Floodway designation and floodplain planning and zoning are used to prevent encroachment into the natural floodplain. Most of the floodplain along this reach is used primarily for either agricultural production or riparian habitat. The 100-year floodplain can range up to four miles wide. Some rural residential development has occurred along the river, with concentrated urban development around the City of Tehama and Hamilton City. The design flow of the river upstream of Chico Landing is 260,000 cfs.

The Colusa to Chico Landing reach of the Sacramento River (RM 143 to RM 194) consists of levees and overflow areas. Black Butte Reservoir regulates Stony Creek flood flows, which enter the Sacramento River downstream of Hamilton City. Right bank levees extend south from Ord Ferry through Colusa to prevent Sacramento River flood water from entering the Colusa Basin, except when flows exceed 300,000 cfs near Ord Ferry (USACE, 1999). Three flood relief weirs, downstream of Chico Landing, spill flood flows to the Butte Basin Overflow Area, which consists of lands that have historically flooded prior to flood control development. The left bank levee begins midway between Ord Ferry and Butte City and extends south through Verona. The leveed capacity of the Sacramento River near Butte City is 160,000 cfs. Moulton and Colusa weirs divert flood flows to the Butte Basin Overflow Area at RM 158 and 146, respectively. The capacity of Moulton and Colusa weirs is 25,000 and 70,000 cfs, respectively. These weirs provide relief to meet the downstream river capacity of 65,000 cfs at Colusa.

The natural Sutter Basin overflow to the east of the Sacramento River and downstream of the Sutter Buttes was included in the Sacramento River Flood Control Project by confining the extent of overflow through a leveed bypass. The Sutter Bypass conveys floodwaters from the Butte Basin Overflow Area, Butte Creek, Wadsworth Canal, Reclamation Districts 1660 and 1500 drainage plants, State drainage plants 1, 2 and 3, and Tisdale Weir to the juncture of the Sacramento and Feather rivers. The capacity of the Sutter Bypass is 216,000 cfs upstream of its juncture with the Feather River, where the combined capacity of the Feather River and Sutter Bypass is 416,500 cfs upstream of its confluence with the Sacramento River at Fremont Weir and the Yolo Bypass.

The natural Yolo Basin overflow to the west of the Sacramento River was included in the Sacramento River Flood Control Project by confining the extent of overflow through a leveed bypass. The Yolo Bypass conveys floodwaters around the Sacramento metropolitan area and reconnects to the Sacramento River at Rio Vista (RM 14), near Suisun Bay (USACE, 1999). Overflow into the Bypass occurs at Fremont Weir to the north and at Sacramento Weir near Sacramento. Fremont Weir flow begins when flows in the Sacramento River reach 62,000 cfs. Capacity of the Bypass increases from 343,000 cfs at Fremont Weir to 500,000 cfs near the bypass’ mouth at Rio Vista.

The Verona to Colusa reach (RM 98 to RM 143) consists of a leveed river channel. Downstream of Colusa, Tisdale Bypass routes a portion of the river flow in excess of 23,000 cfs at Tisdale Weir (RM 119) to the Sutter Bypass (USACE, 1999). Reclamation Districts 70, 108, and 787 pump flood waters from adjacent closed basin lands into the river. The Knights Landing Outfall is a gravity flow structure and prevents the Sacramento River from flowing into the Colusa Basin. The Knights Landing Ridge Cut conveys Colusa Basin drainage and flood flows into the Yolo Bypass several miles downstream of Fremont Weir. Flood flows passing through the Knights Landing Ridge Cut are somewhat restricted at times by backwater conditions when the Yolo Bypass is at full capacity. Sources of bypass inflow downstream of the Knights Landing Ridge Cut include the Cache Creek Detention Basin, Willow Slough, Putah Creek, and Sacramento Weir (combination of Sacramento and American river flood flows). Near Verona, the Sacramento River, Feather River, Sutter Bypass, and Natomas Cross Canal join together, and flows in excess of 62,000 cfs spill into the Yolo Bypass at Fremont Weir.

Downstream of Verona, the leveed Sacramento River winds its way past the City of Sacramento to the Sacramento-San Joaquin Delta. The Yolo Bypass is located to the west of the river. The Sacramento Bypass routes excess flows at Sacramento Weir (RM 63) to the Yolo Bypass (USACE, 1999). The American River flows into the Sacramento River at RM 60. Flows from the Yolo Bypass re-enter the river near Rio Vista (RM 14). Between the American River and Yolo Bypass junction, portions of the Sacramento River water are divided among several sloughs.

The capacity of the leveed Sacramento River at various locations is listed in Table 9-2.

Table 9-2
Sacramento River Leveed Capacity

Location	Flow (cfs)
Upstream of Moulton Weir	160,000 cfs
Moulton Weir to Colusa Weir	135,000 cfs
Colusa Weir to Butte Slough Outfall Gates	65,000 cfs
Butte Slough Outfall Gates to Tisdale Weir	66,000 cfs
Tisdale Weir to Freemont Weir	30,000 cfs
Freemont Weir to Sacramento Weir	107,000 cfs
Sacramento Weir to Sutter Slough	110,000 cfs
Sutter Slough to Steamboat Slough	85,000 cfs
Steamboat Slough to Georgiana Slough	56,500 cfs
Georgiana Slough to Yolo Bypass Junction	35,900 cfs
Yolo Bypass Junction to Threemile Slough	579,000 cfs
Threemile Slough to Collinsville	514,000 cfs

Source: DWR, 2009.

9.2.2.4 Feather River (Including Lake Oroville and the Thermalito Complex)

The mainstem of the Feather River is regulated by Oroville Dam, which is part of the SWP and SPFC. The dam was completed in 1968 and forms a 3.5-MAF capacity Lake Oroville. From Lake Oroville, the Feather River flows south through the Sacramento Valley where it is joined by two major tributaries. The Yuba River joins the Feather River at Marysville; the Bear River confluence is approximately 15 miles farther downstream. The Feather River then joins the Sacramento River at RM 80.

Operation of the Oroville facilities varies depending upon hydrology and DWR's objectives. Similar to Shasta, Lake Oroville stores winter and spring runoff for release to the Feather River, as necessary, for project purposes. Typically, releases to the Feather River are managed to conserve water while meeting a variety of water delivery requirements, including flow, temperature, fisheries, diversions, and water quality.

Lake Oroville's flood control storage volume varies from 375 to 750 TAF, depending on hydrologic conditions. Flood management releases are based upon a schedule and diagram prepared by USACE (DWR, 2007). Pursuant to USACE's flood control regulations, the maximum controlled release capacity is 150,000 cfs.

The right bank (looking downstream) of the Feather River is leveed downstream of the Thermalito Afterbay to Honcut Creek. Both banks of the river are leveed downstream of Honcut Creek. These levees and the river are part of the Sacramento River Flood Control Project. The capacity of the leveed Feather River at various locations is listed in Table 9-3.

Table 9-3
Feather River Leveed Capacity

Location	Flow (cfs)
Upstream of Yuba River	210,000
Yuba River to Bear River	300,000
Bear River to Sutter Bypass	320,000

Source: DWR, 2009.

9.2.2.5 American River (Including Folsom Lake and Lake Natoma)

Folsom Lake has a maximum capacity of approximately 1 MAF and is located on the American River approximately 15 miles northeast of the City of Sacramento, near the City of Folsom. Construction of the dam was completed in 1956. It is managed by Reclamation to provide flood control, recreation, power, water supply, Delta water quality protection, and fish flows in the American River and Delta (Reclamation, CCWD, and WAPA, 2009). Lake Natoma is located downstream of Folsom and functions primarily as a regulating reservoir to lessen Folsom releases.

The flood control storage volume of Folsom Lake varies from 400 to 670 TAF. The objective release to the American River is 115,000 cfs (Reclamation, 2008). The American River downstream of Carmichael Bluffs is part of the Sacramento River Flood Control Project. The capacity of the leveed reach upstream of Cal Expo (RM 5) is 115,000 cfs, and downstream to the Sacramento River, the capacity is 180,000 cfs.

9.2.2.6 Sacramento-San Joaquin Delta (Including Suisun, San Pablo, and San Francisco Bays)

The Sacramento-San Joaquin Delta, located to the east of San Francisco Bay, represents the point of discharge for the Sacramento-San Joaquin River system. Water flows out of the Delta, through Suisun and San Pablo bays, into San Francisco Bay, and to the Pacific Ocean, creating an extensive estuary where salty ocean water and fresh river water mix. In sum, water from over 40 percent of the State's land area is discharged into the Delta (Reclamation, CCWD, and WAPA, 2009).

The Delta is a complex system of levees, constructed waterways, and control facilities. The levee system is composed entirely of local levees maintained by local interests (DWR, 2009). These levees were initially constructed to control island flooding during high flow, but because of island subsidence, they now have to prevent inundation during normal runoff and tidal cycles (Reclamation and DWR, 2005). There are approximately 1,100 miles of levees providing protection to 76 islands and tracts. Construction and operation of the CVP and SWP has decreased the frequency of levee failure due to overtopping during flood events (Reclamation and DWR, 2005).

9.2.3 Primary Study Area

The larger streams in the Primary Study Area are Funks Creek, Stone Corral Creek, and the Colusa Basin Drain, which are discussed below. The Colusa Basin Drain is a designated floodway according to the Central Valley Flood Protection Board (CVFPB). The 100-year floodplain delineations for the Primary Study Area, depicting areas subjected to flooding and areas with undetermined flood hazards[1], are shown on Figure 9-4. Areas with undetermined flood hazards include the national wildlife refuges, which are not subject to the FEMA's National Flood Insurance Program regulations.

9.2.3.1 Funks and Stone Corral Creeks

Funks and Stone Corral creeks are ephemeral streams that originate on the westside foothills and are tributary to the Colusa Basin Drain. Snow pack is non-existent due to the low elevation of the watershed. Flood runoff is generated directly from large precipitation events. This area is primarily agricultural with rural farmsteads and small communities. The gentle sloping lands are ideal for rice production and managed wetlands, which also contribute to large areas of inundation during flood events. Road, bridge, railroad, and canal alignments can affect the movement of flood water in this area.

The drainage area of Funks Creek at Funks Dam is 43 square miles. Funks Reservoir is not operated for flood control purposes. There are no stream gages on Funks Creek downstream of Funks Dam because a historical stream gage was washed out and not replaced due to the constantly degrading channel. Peak winter flows of approximately 2,000 cfs are common (TCCA, 2005). Because the topography and soil composition of the watershed are similar to those of Stone Corral Creek, where stream flow records are available, and given the comparable drainage areas of the two watersheds, it is reasonable to assume that the 100-year discharge on Funks Creek is similar to that of Stone Corral Creek.

During a 100-year flood event, Funks Creek overflows its bank downstream of the T-C Canal and Funks Reservoir. Flood waters flow to the north along the creek and to the south where they join with Stone Corral Creek. Stone Corral Creek overflows its bank downstream of the town of Sites. The floodplains of both Funks and Stone Corral creeks are intersected by the GCID Canal, which has levees along each bank.

[1] Neither peak flow nor base flood elevations are available from the FEMA Flood Insurance Study. Instead, areas subject to flooding are depicted.

The drainage area of the Stone Corral Creek watershed is 38.2 square miles at a former gaging station near the town of Sites. Twenty-five years of discharge measurements were collected, with interruption from 1958 through 1985 by the U.S. Geological Survey. During that time, there were three years of zero flow: 1972, 1976, and 1977. A maximum mean daily flow of 2,230 cfs occurred on December 24, 1983. An instantaneous peak flow of 5,700 cfs was recorded on January 26, 1983. The 100-year peak discharge upstream of Sutton Road (aka Cemetery Road), west of Maxwell, is 3,650 cfs, and the 100-year peak discharge downstream of the California Northern Railroad is 3,330 cfs (FEMA, 2003).Flooding in the town of Maxwell occurs directly from Stone Corral Creek and overland flow from Funks Creek. Both I-5 and the Union Pacific Railroad significantly impede the movement of flood flows through Maxwell. Downstream of I-5, Funks and Stone Corral creeks combine and create a single floodplain that moves in a southeasterly direction toward the Colusa Basin Drain.

9.2.3.2 Colusa Basin Drain
