a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

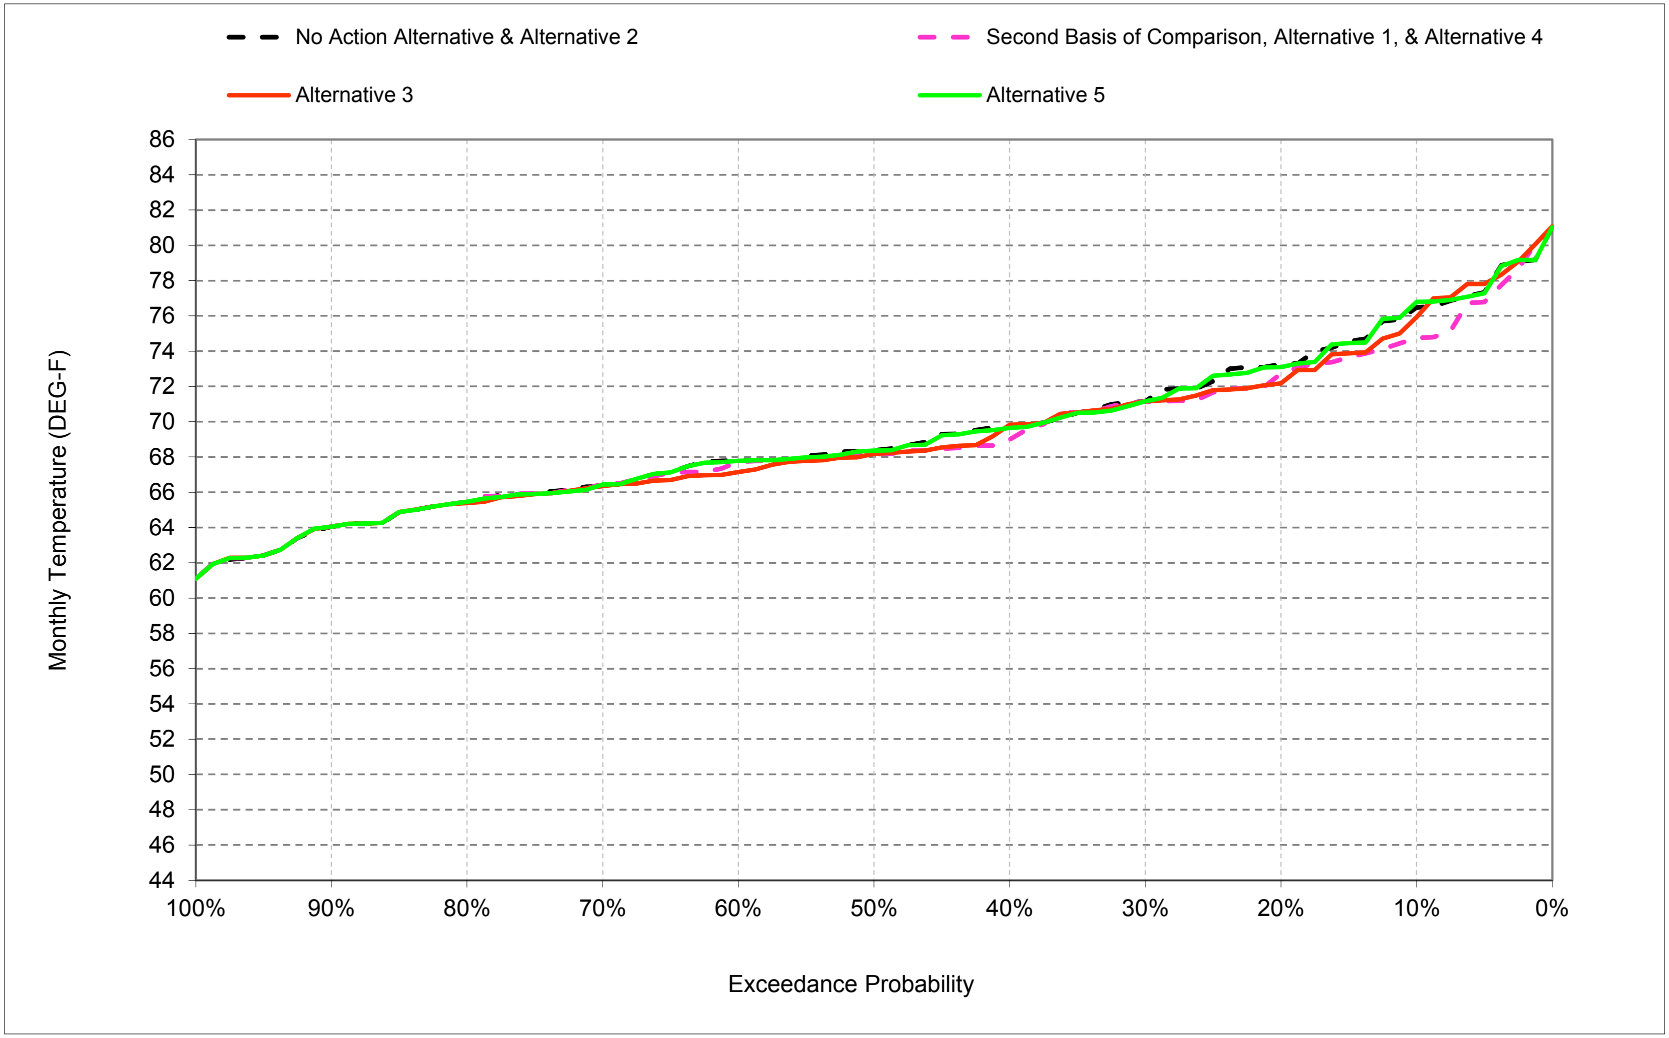
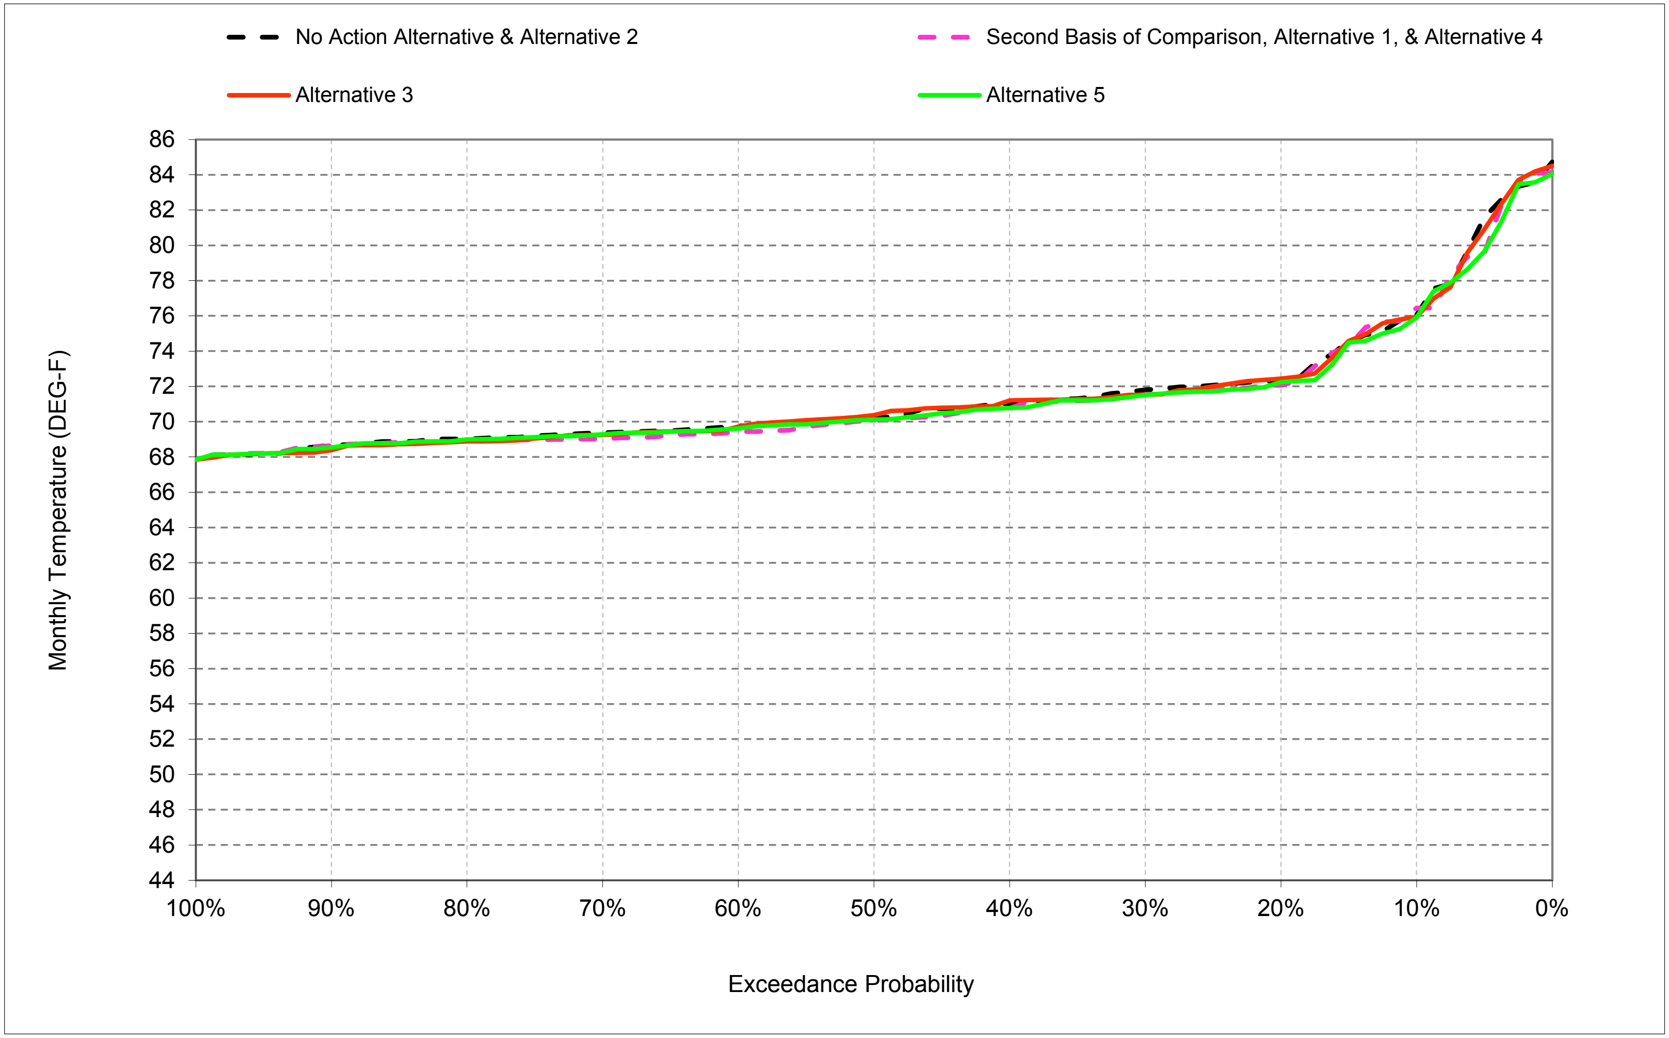
Figure B-14-9. American River at the Mouth, June



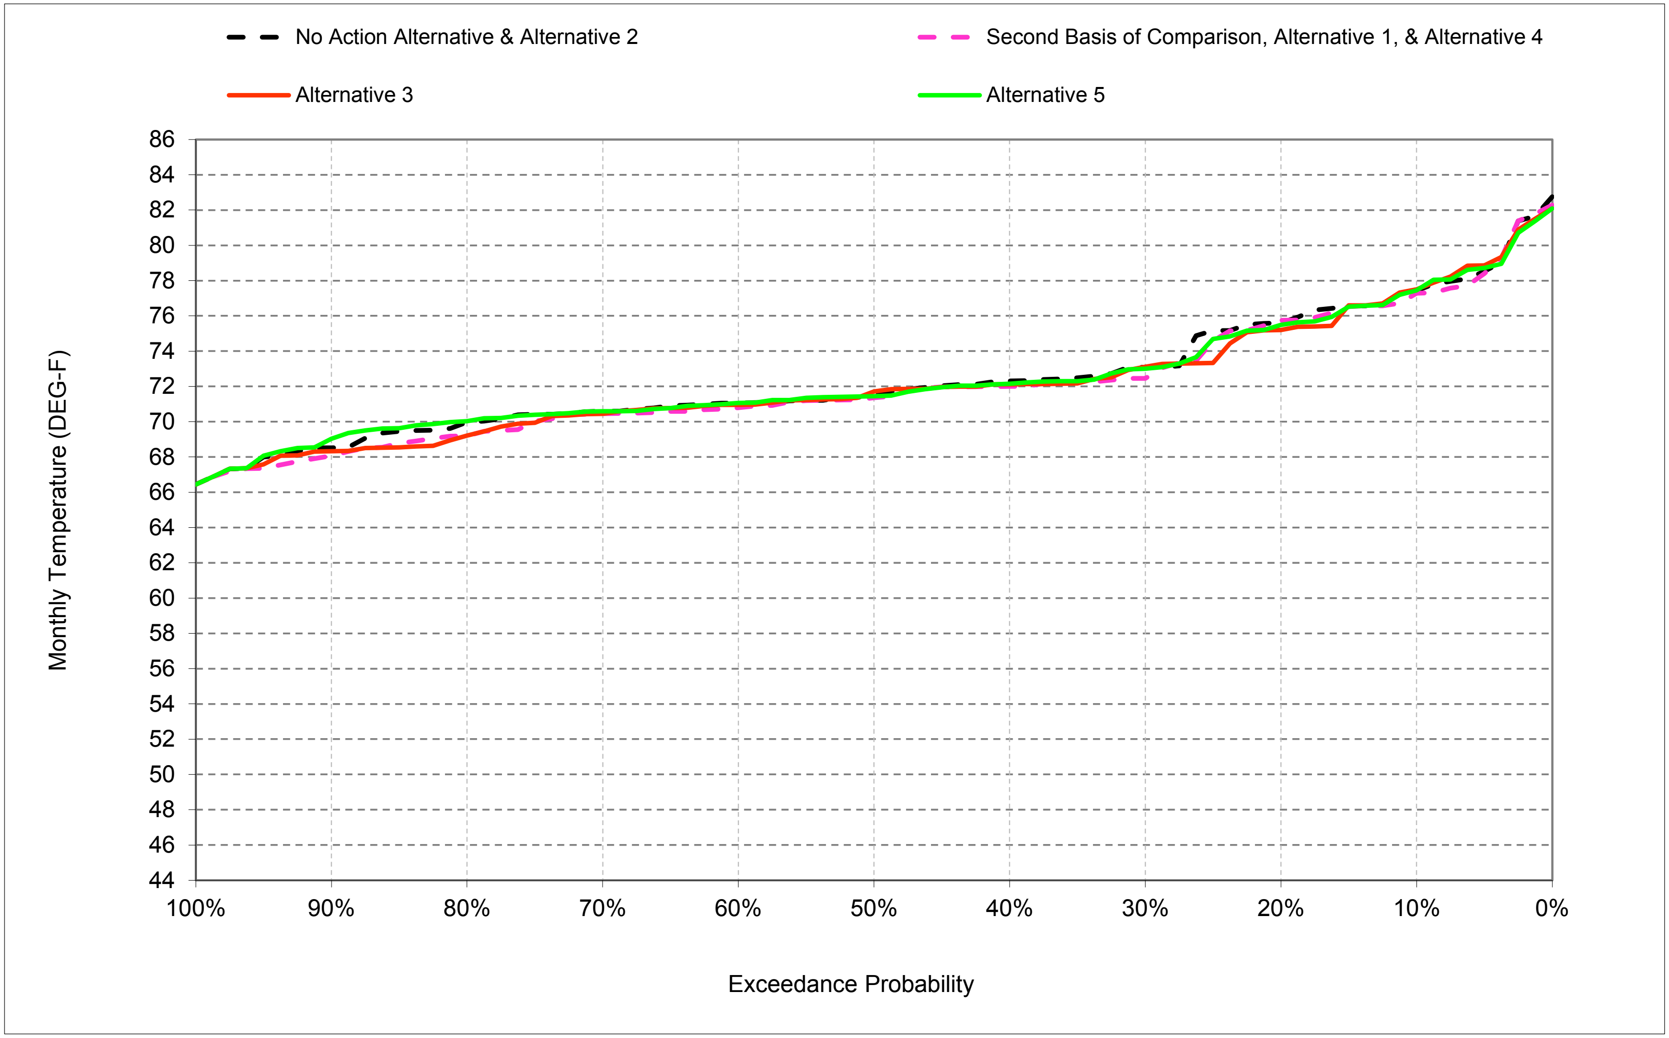
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-14-10. American River at the Mouth, July



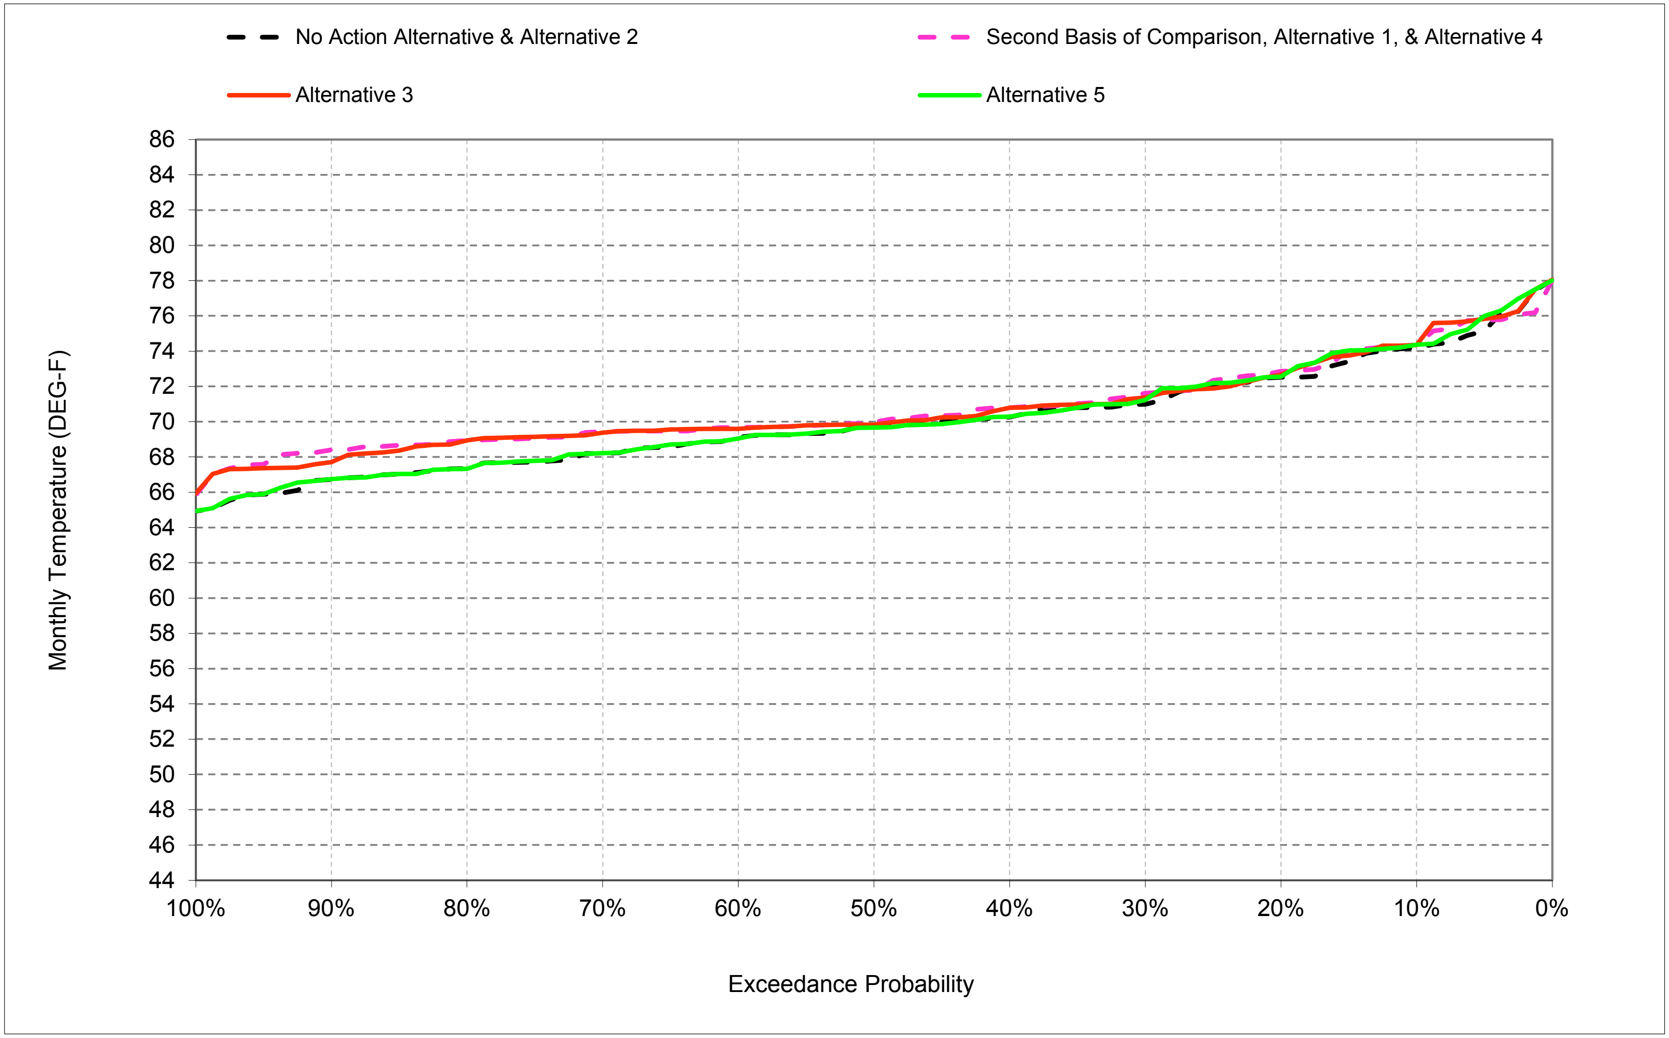
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-14-11. American River at the Mouth, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-14-12. American River at the Mouth, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Qualitative differences, if applicable, are discussed in the text.

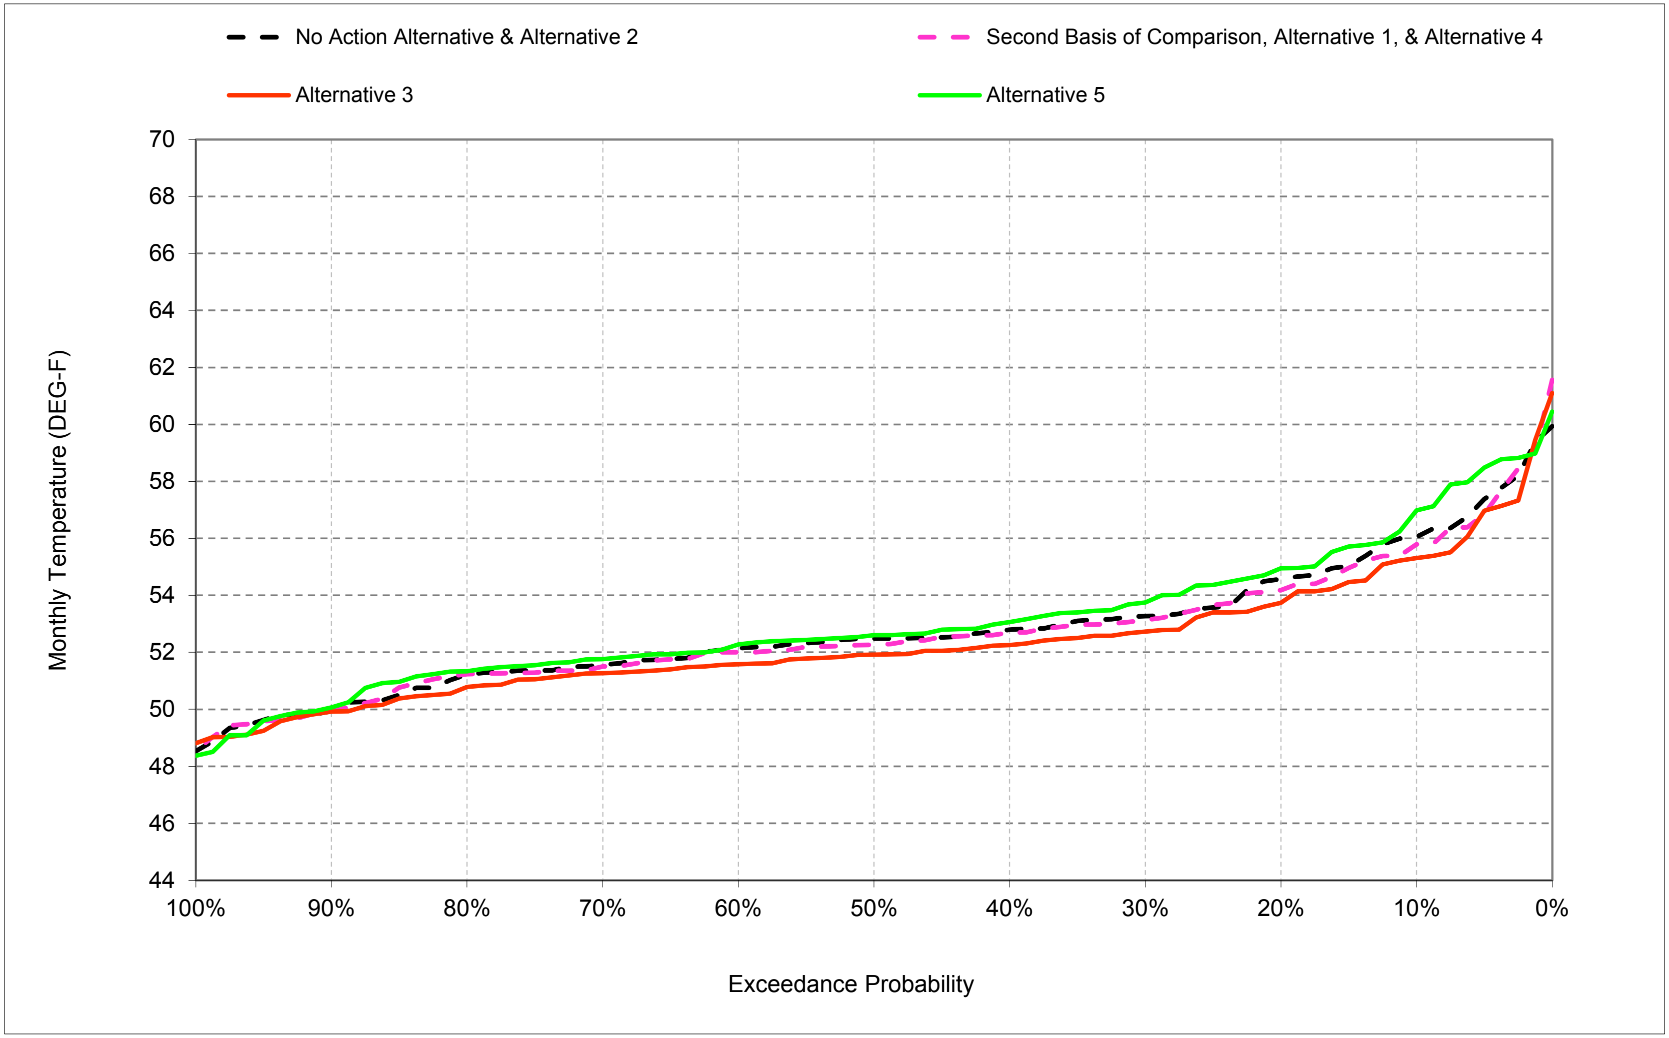
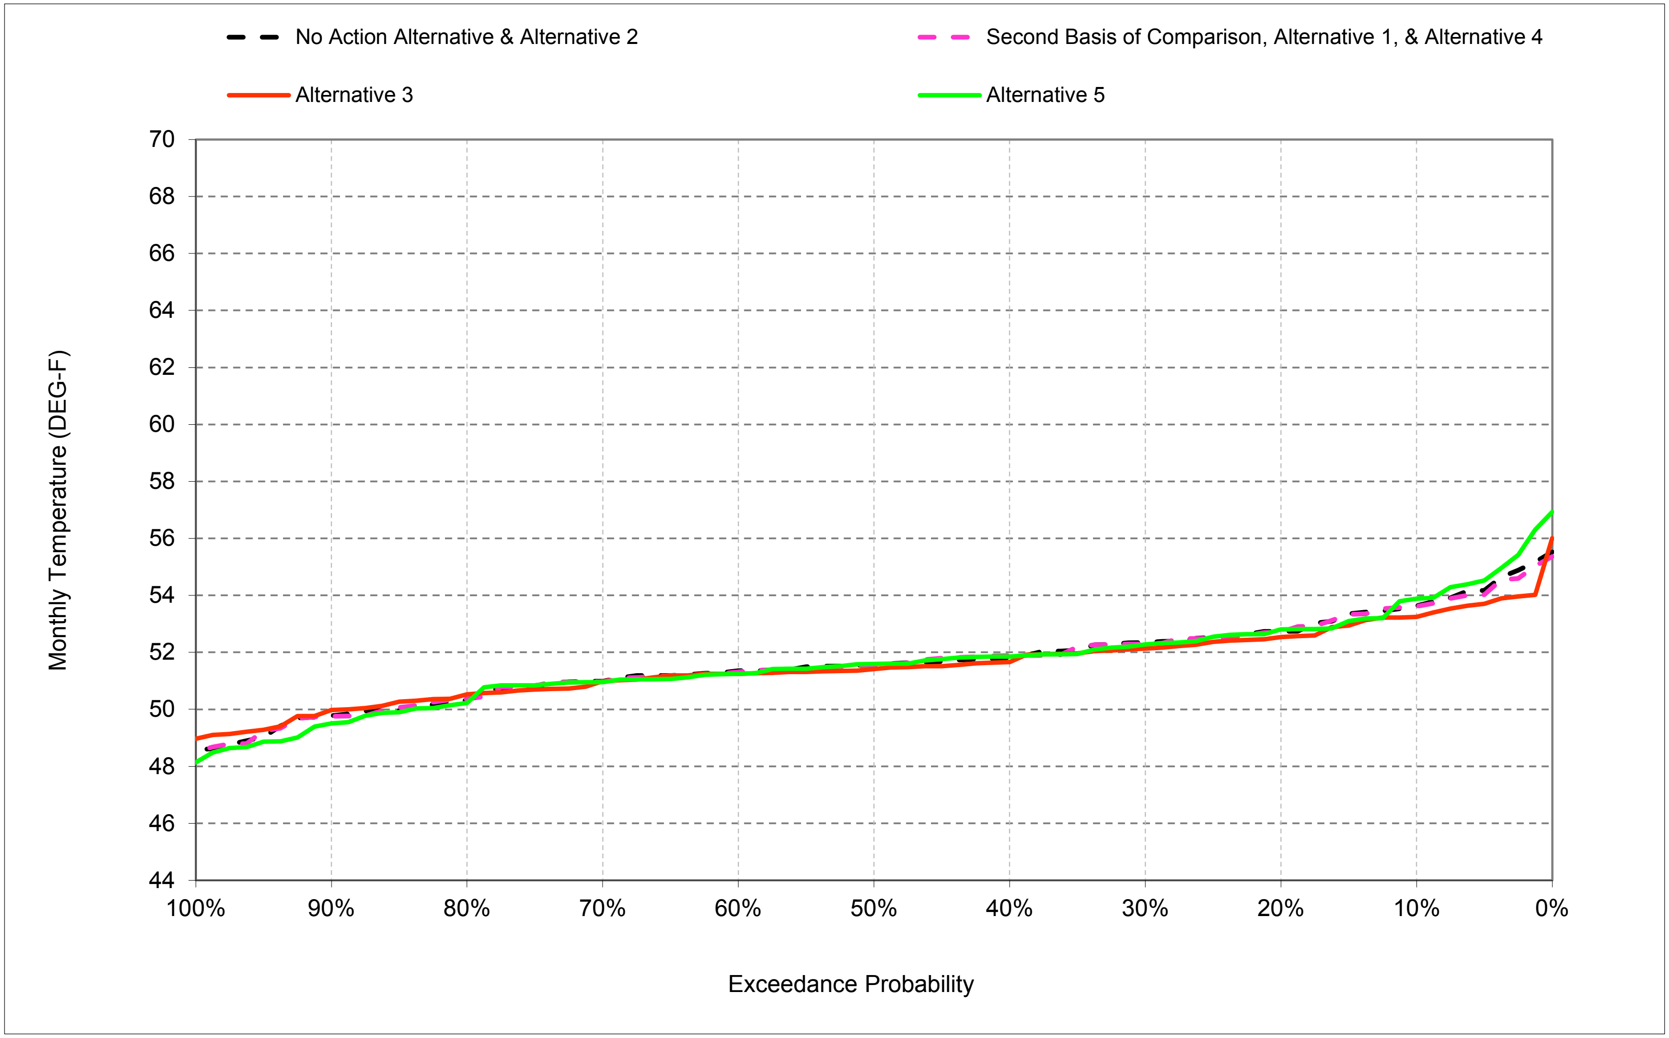
Figure B-15-2. Stanislaus River below New Melones Reservoir, November



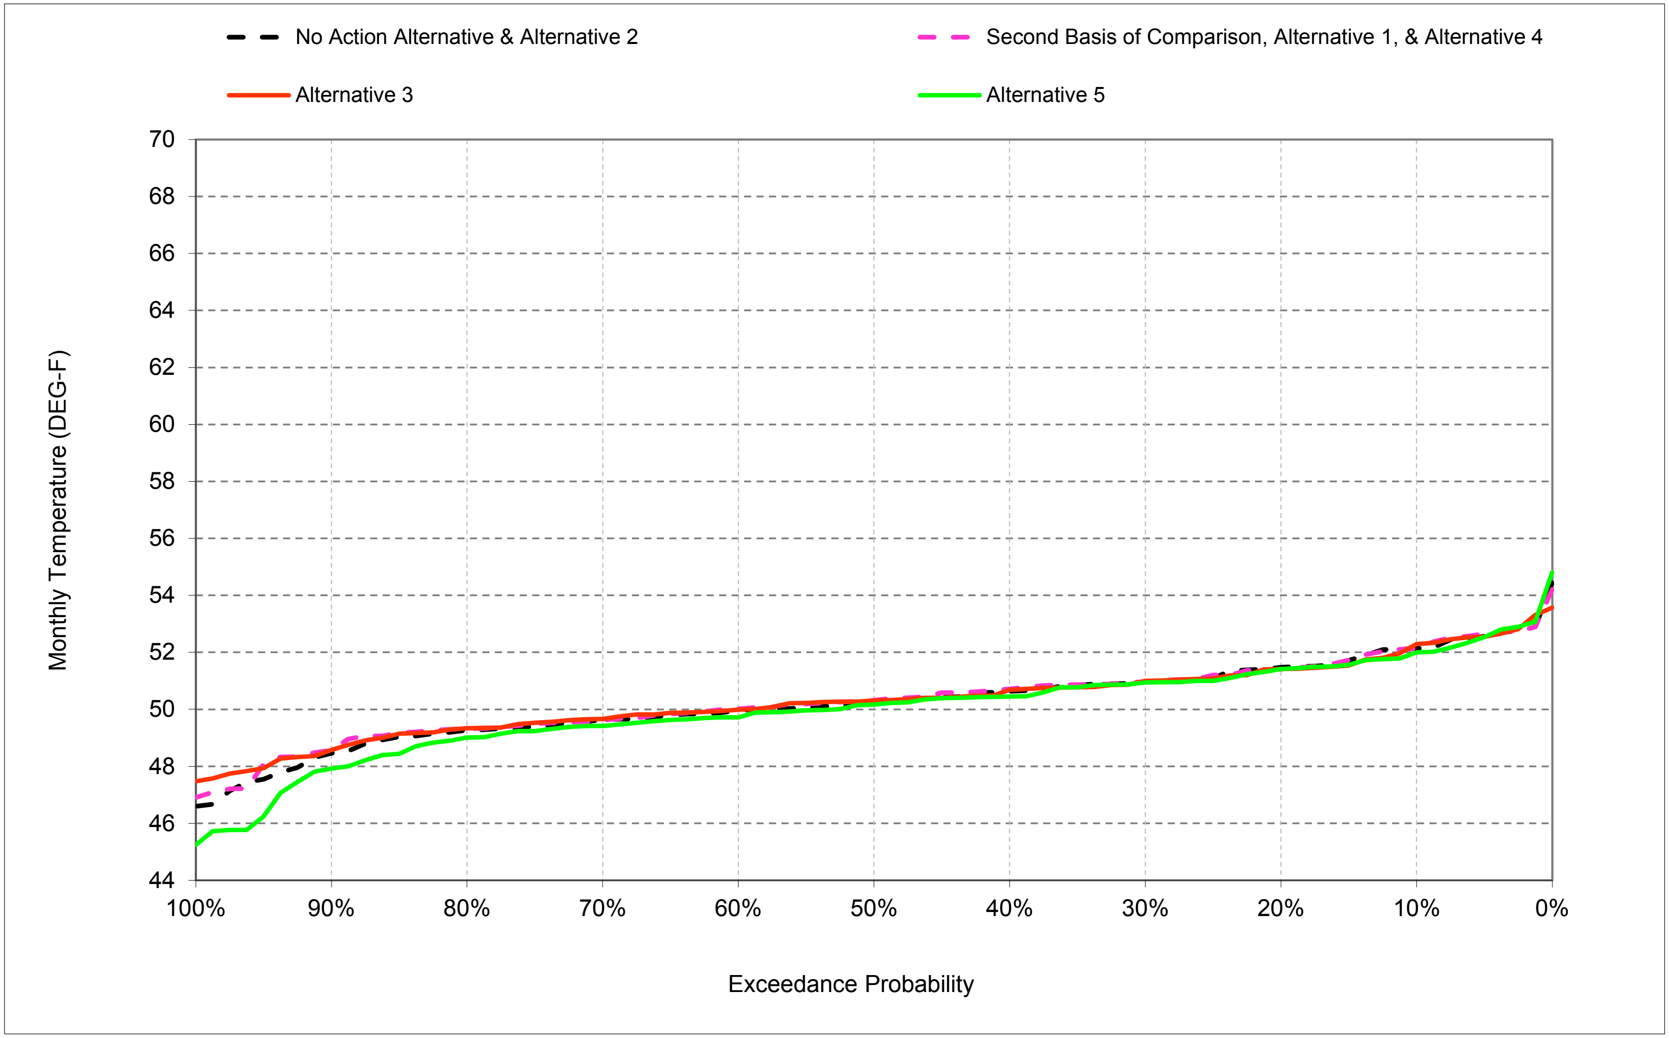
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-3. Stanislaus River below New Melones Reservoir, December



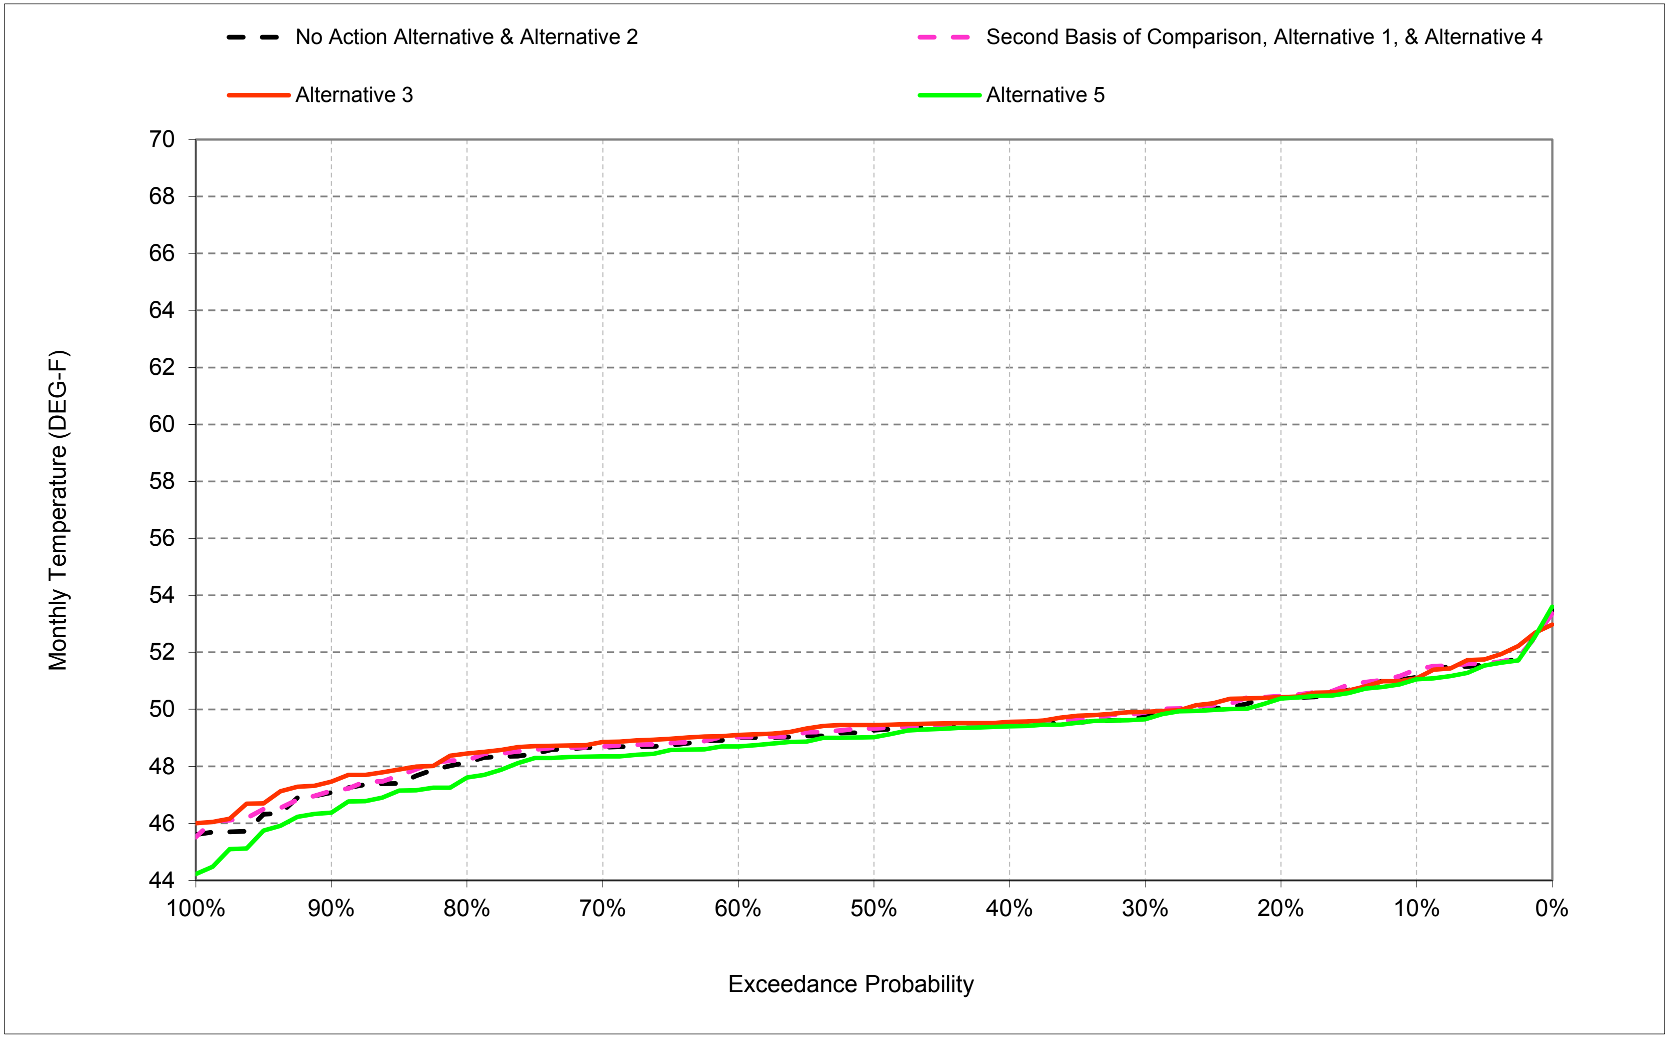
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-4. Stanislaus River below New Melones Reservoir, January



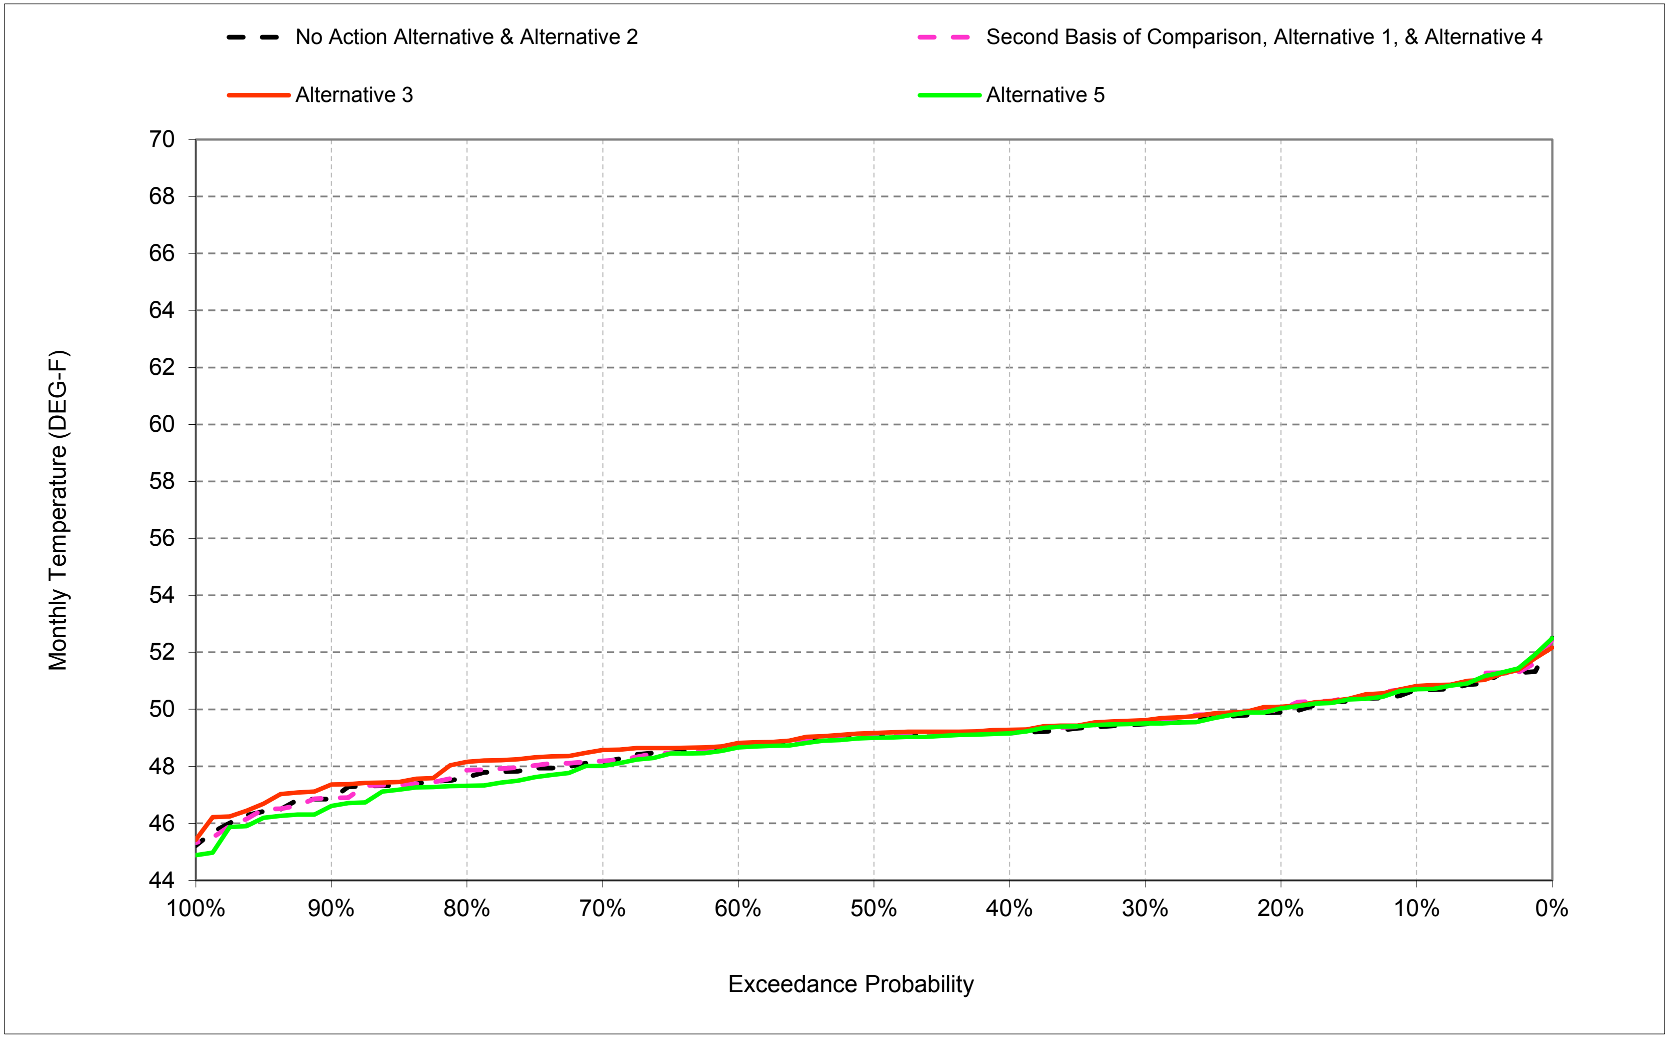
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-5. Stanislaus River below New Melones Reservoir, February



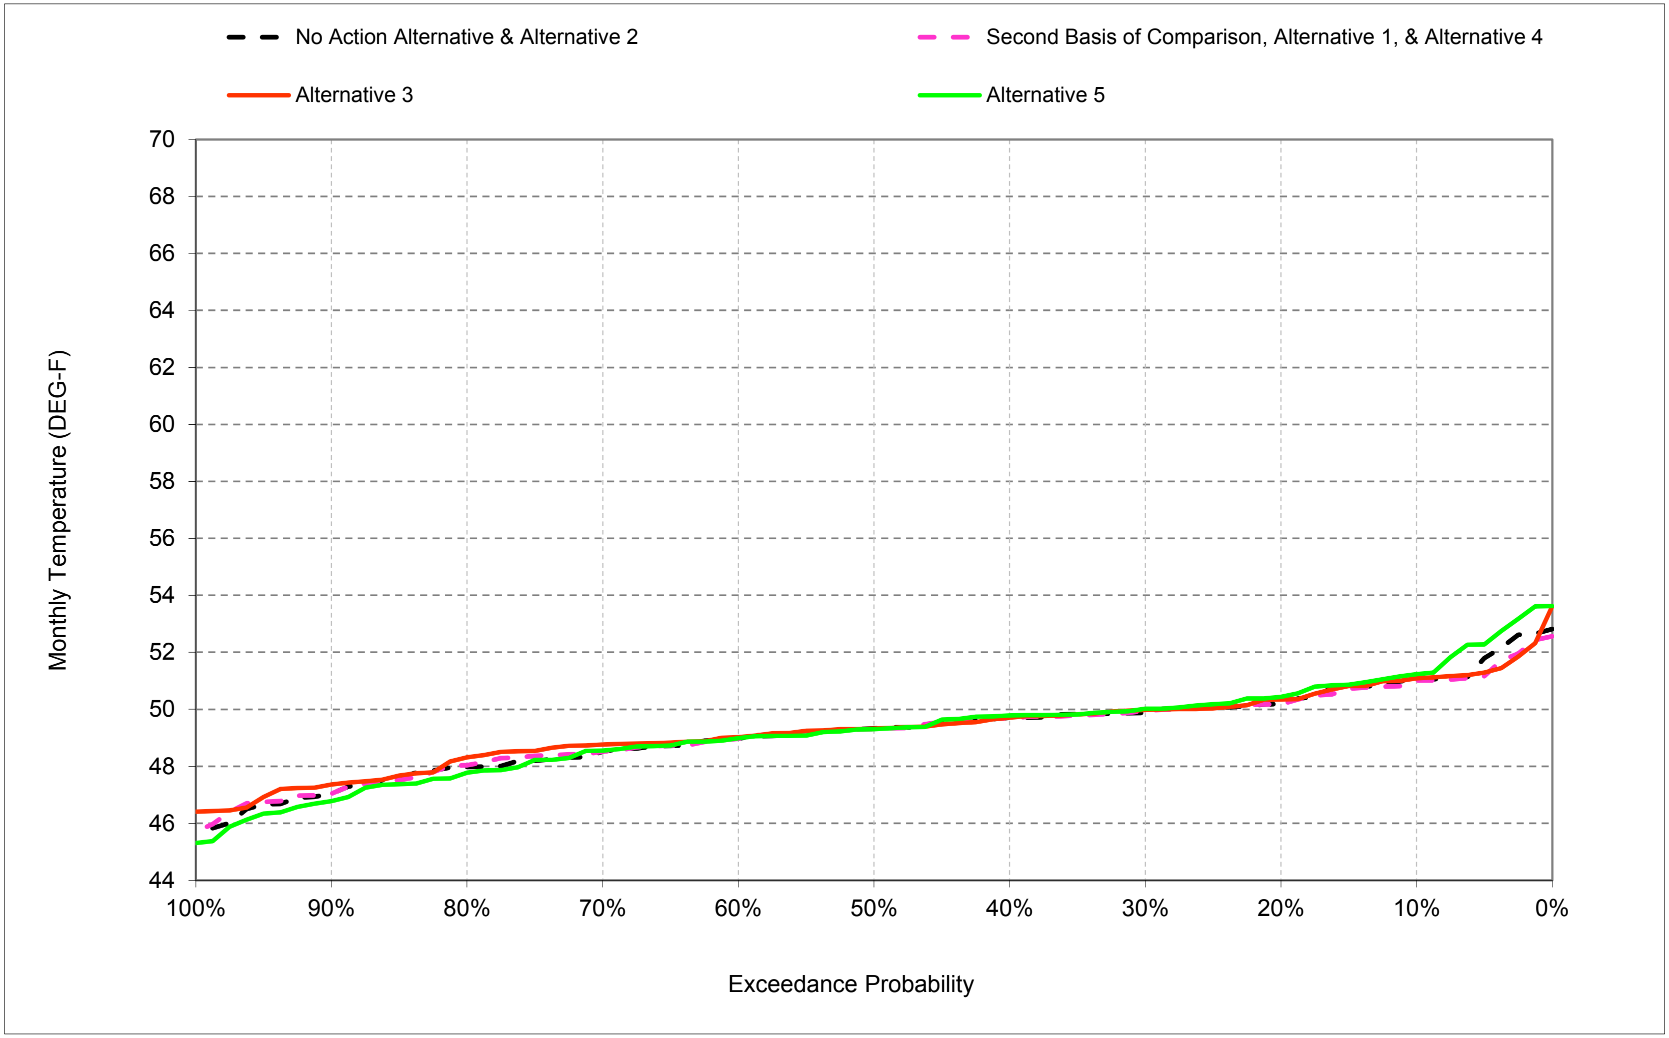
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-6. Stanislaus River below New Melones Reservoir, March



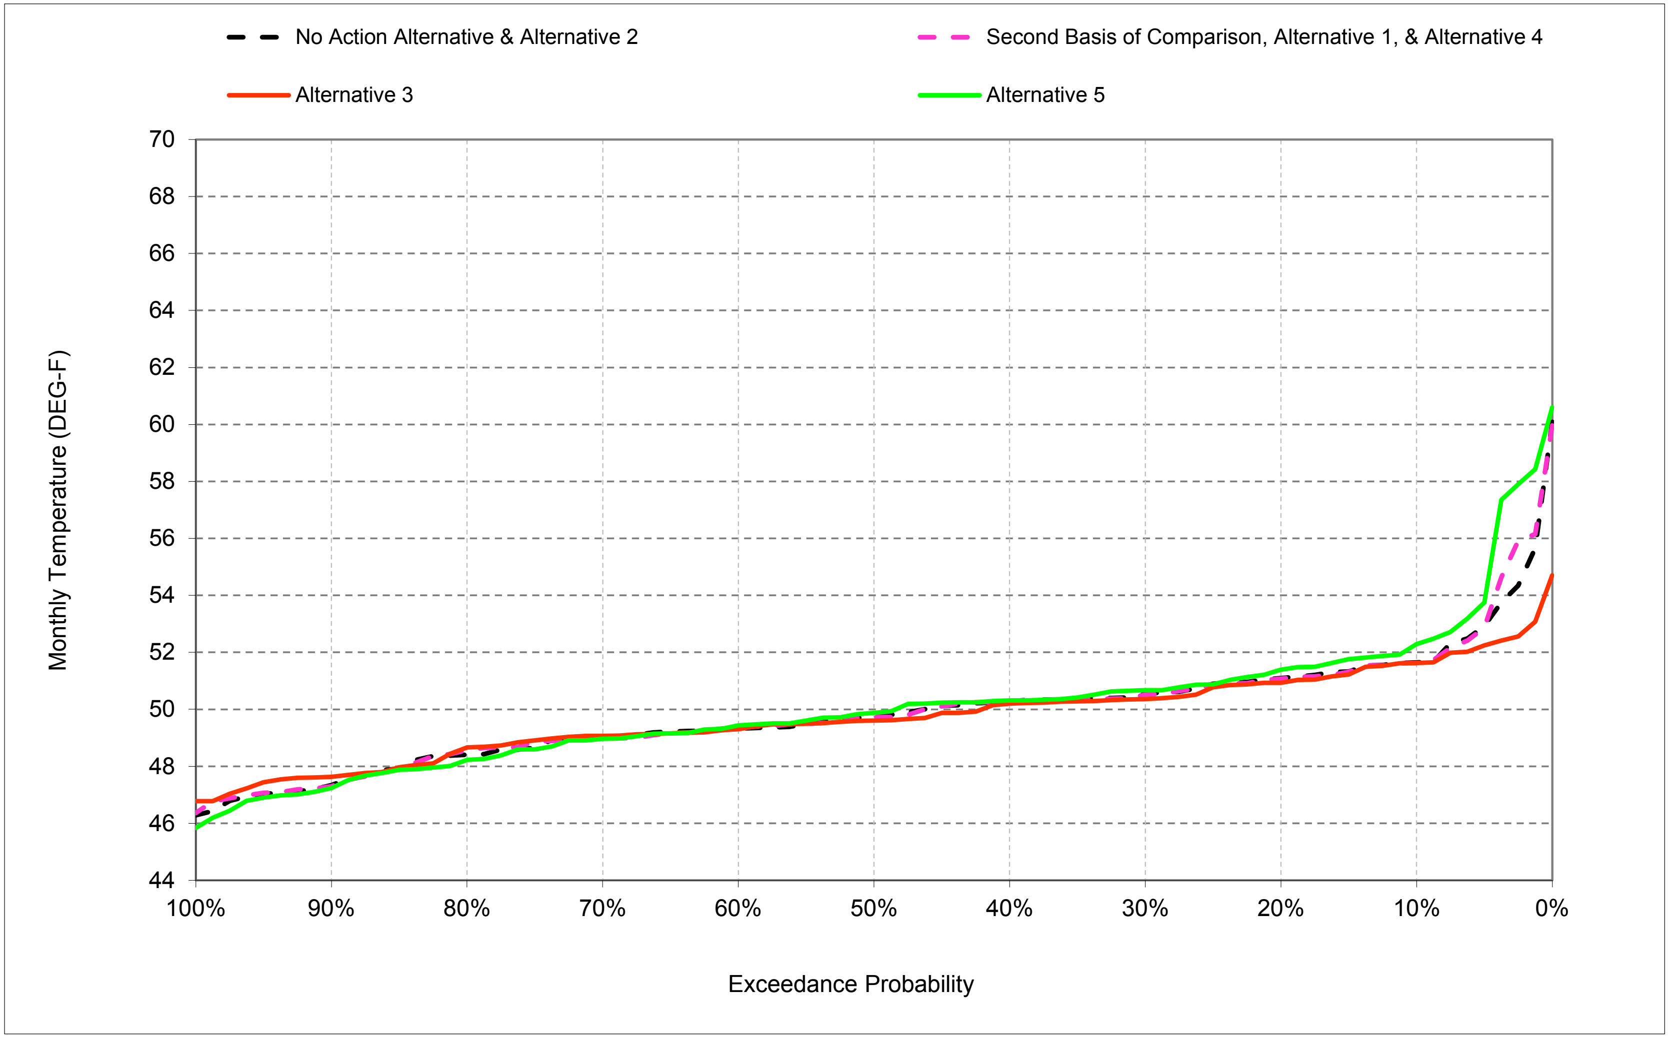
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-7. Stanislaus River below New Melones Reservoir, April



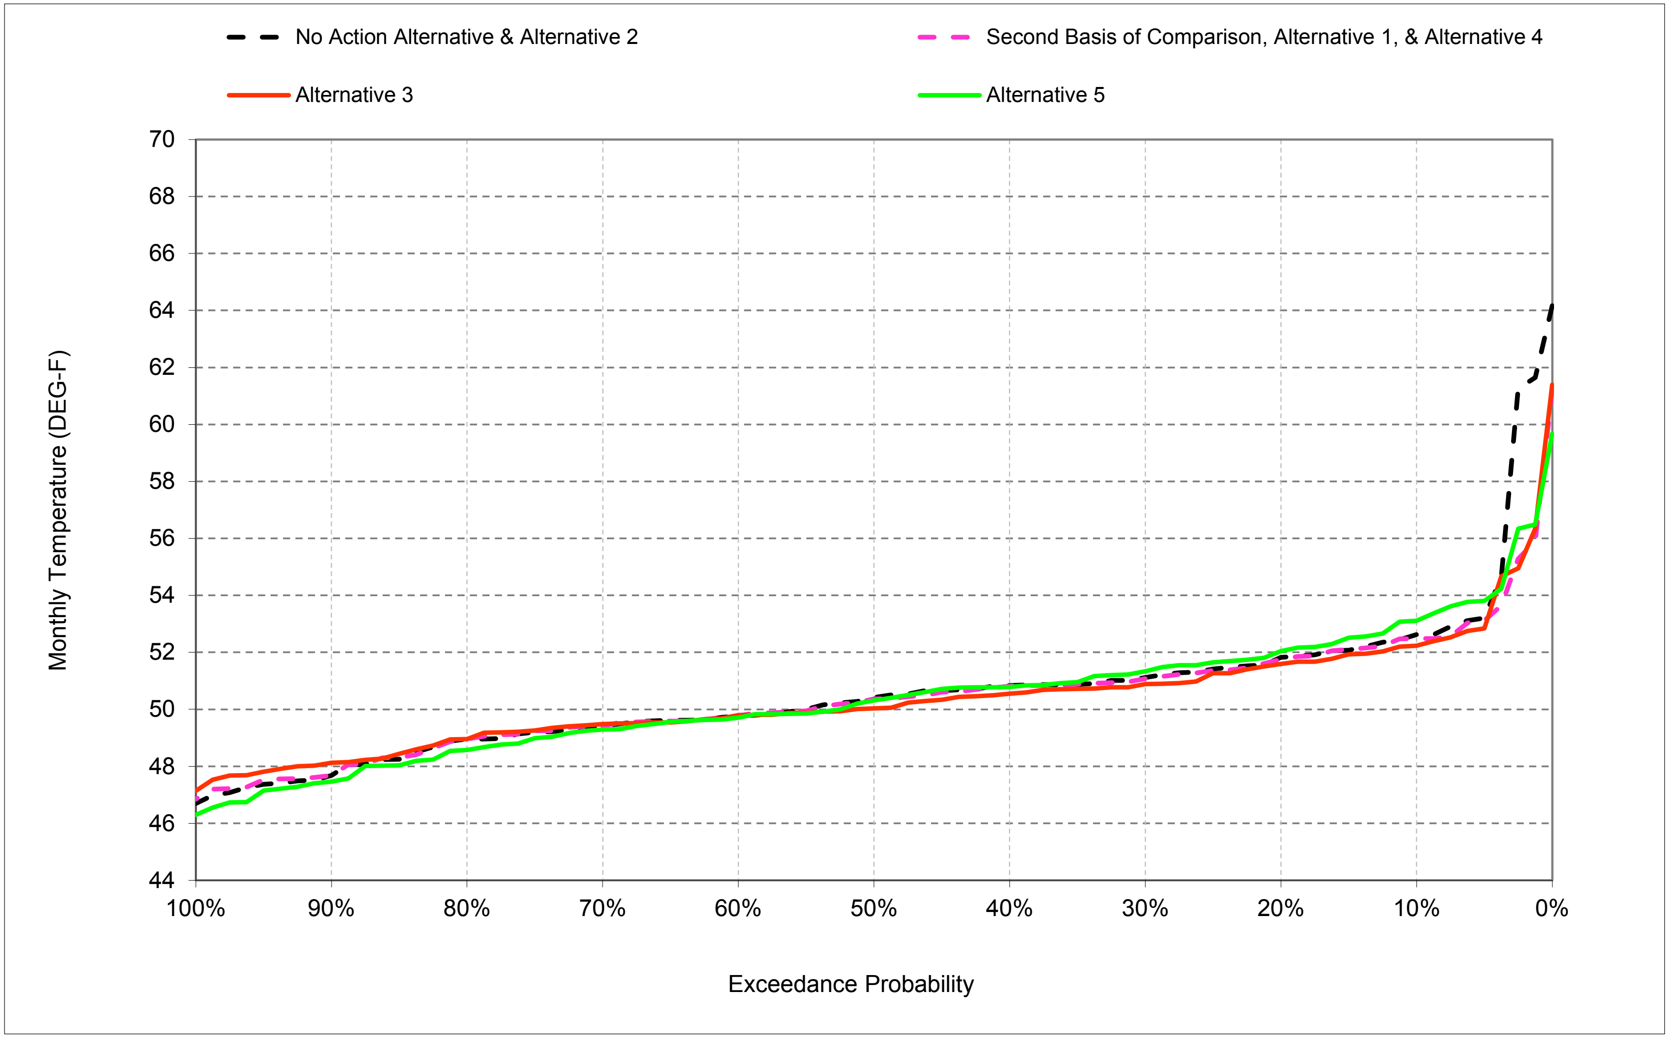
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-8. Stanislaus River below New Melones Reservoir, May



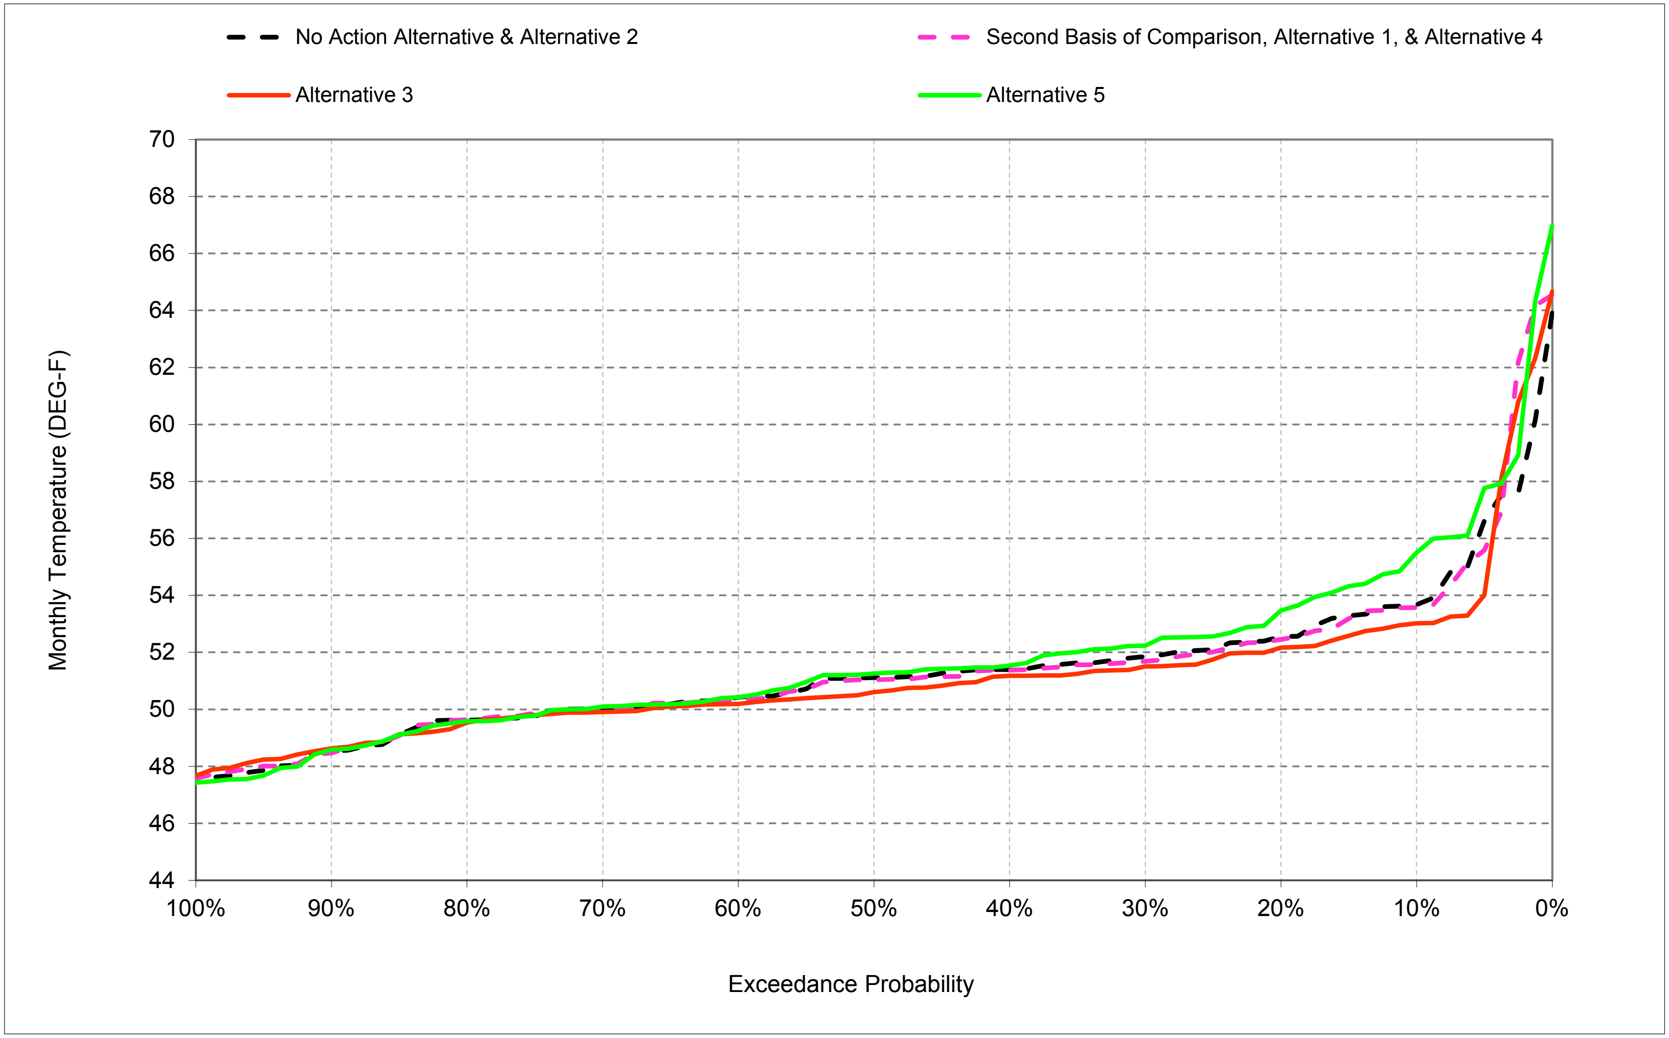
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-9. Stanislaus River below New Melones Reservoir, June



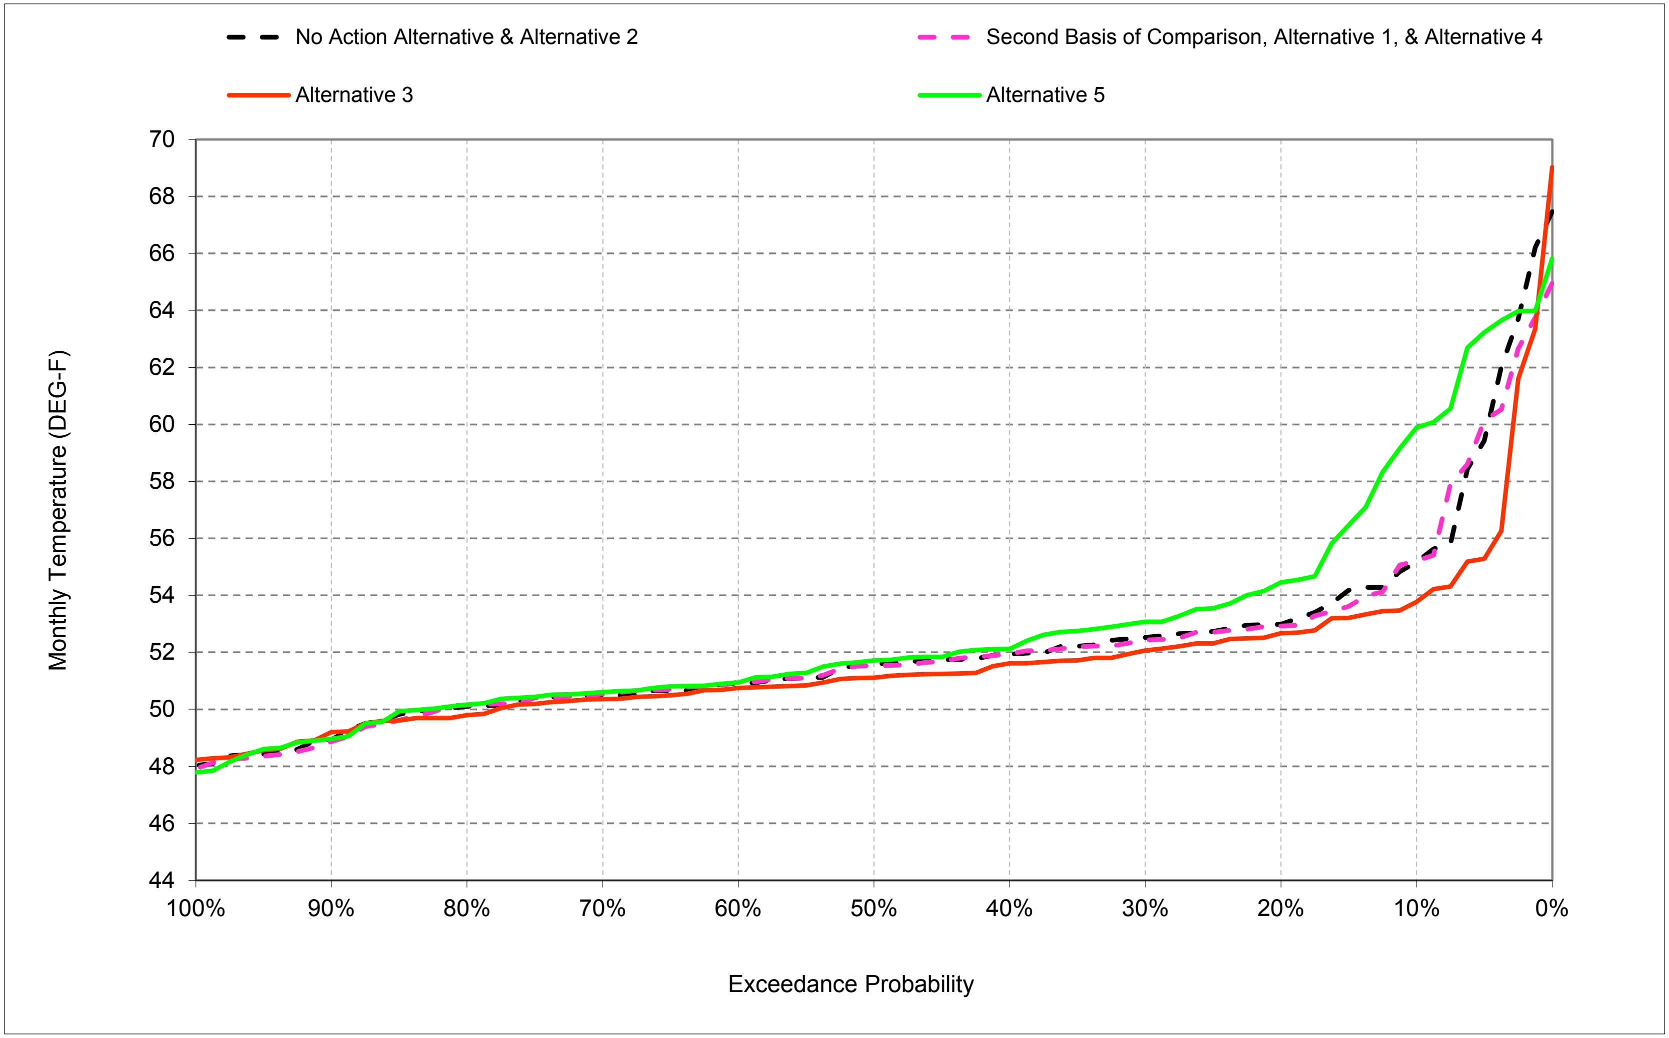
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-10. Stanislaus River below New Melones Reservoir, July



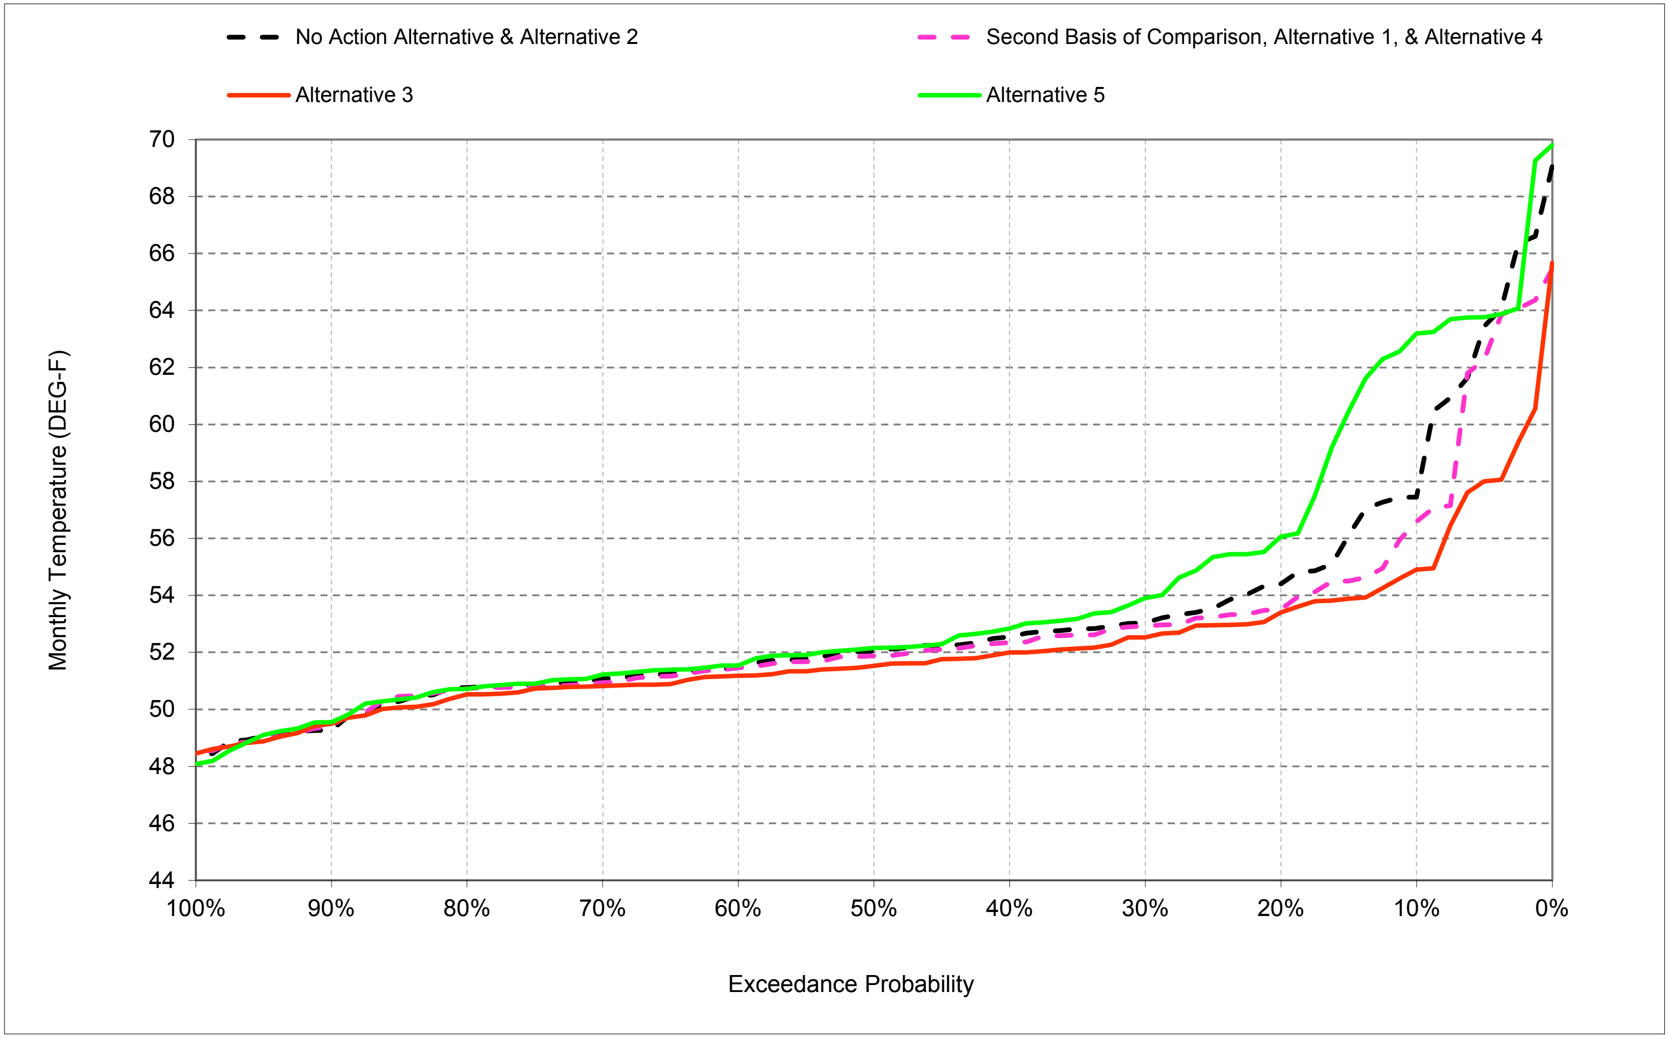
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-11. Stanislaus River below New Melones Reservoir, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-15-12. Stanislaus River below New Melones Reservoir, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

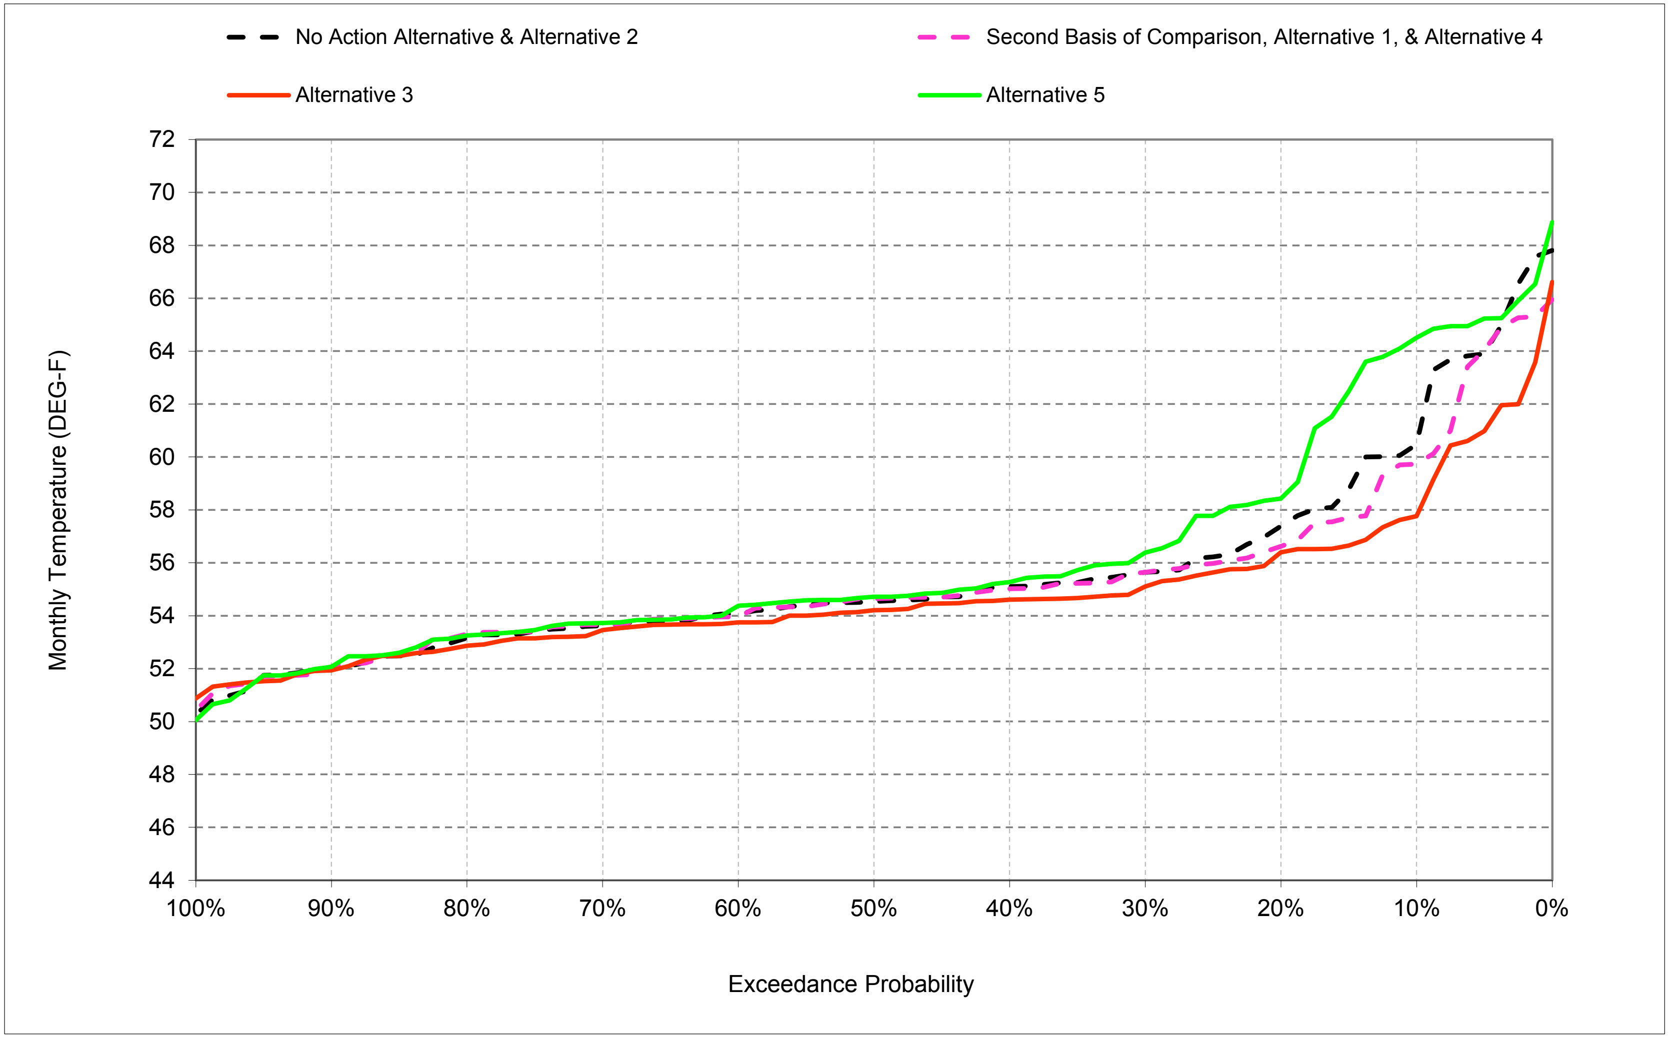
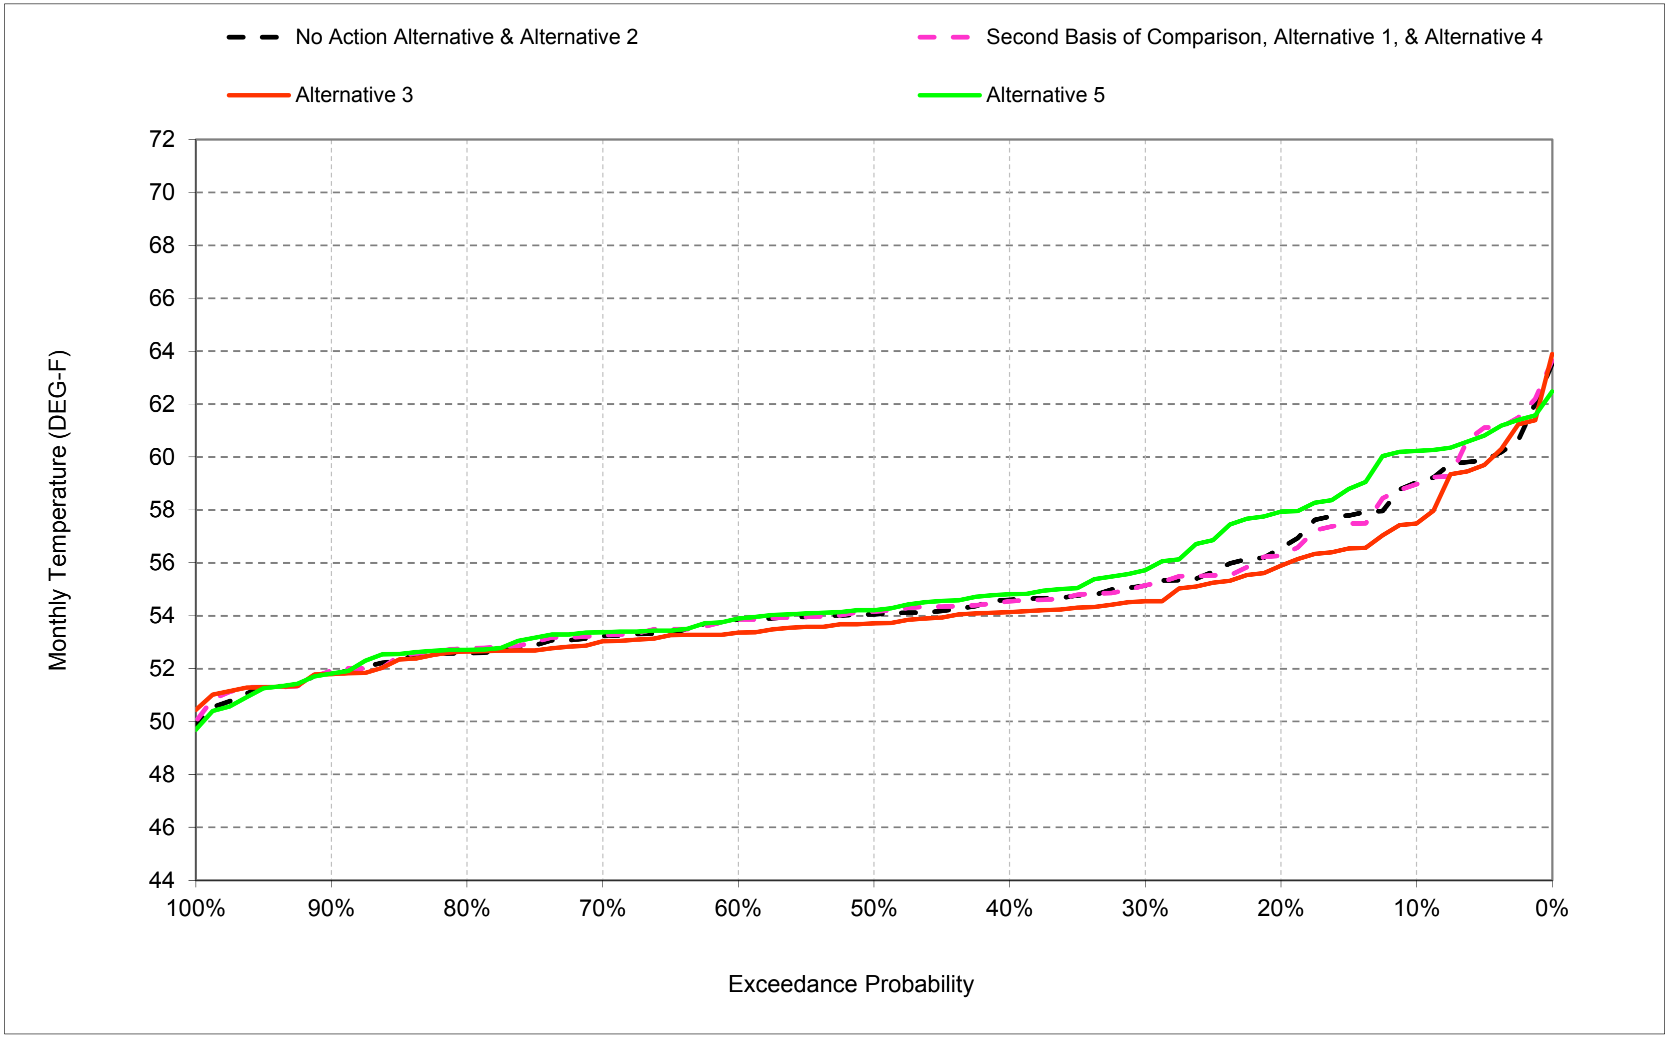
B.16. Stanislaus River below Tulloch Temperature

Figure B-16-1. Stanislaus River below Tulloch Reservoir, October



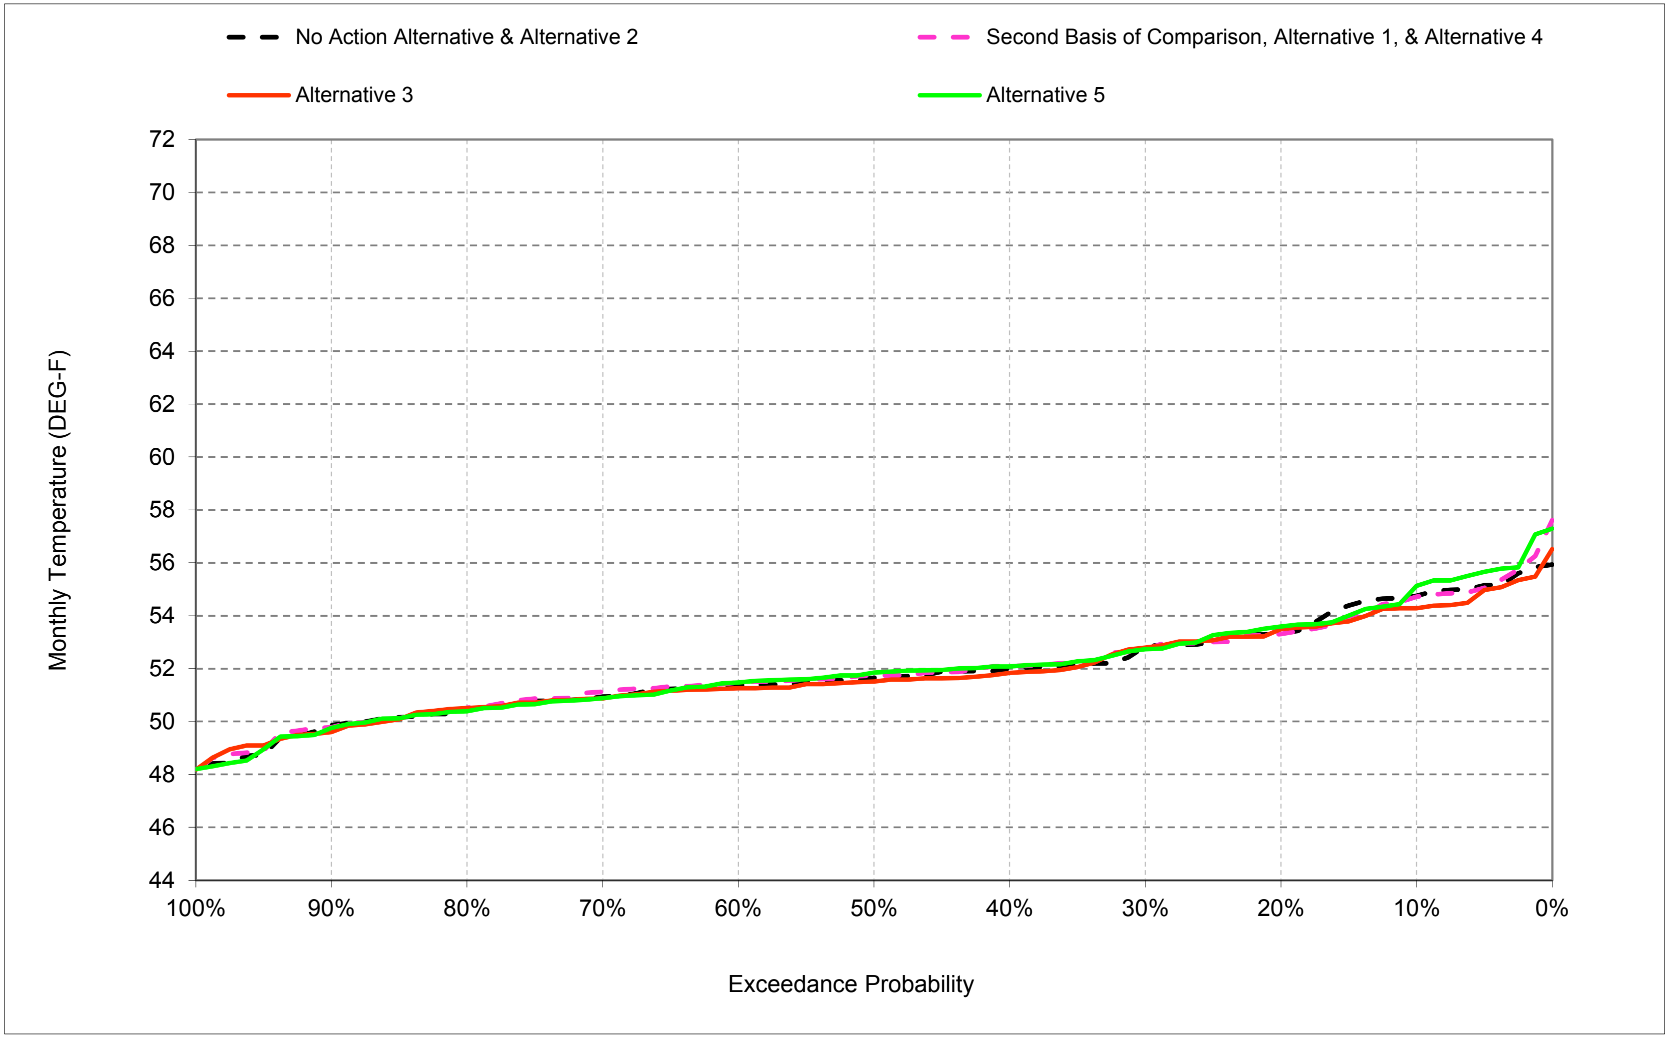
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-2. Stanislaus River below Tulloch Reservoir, November



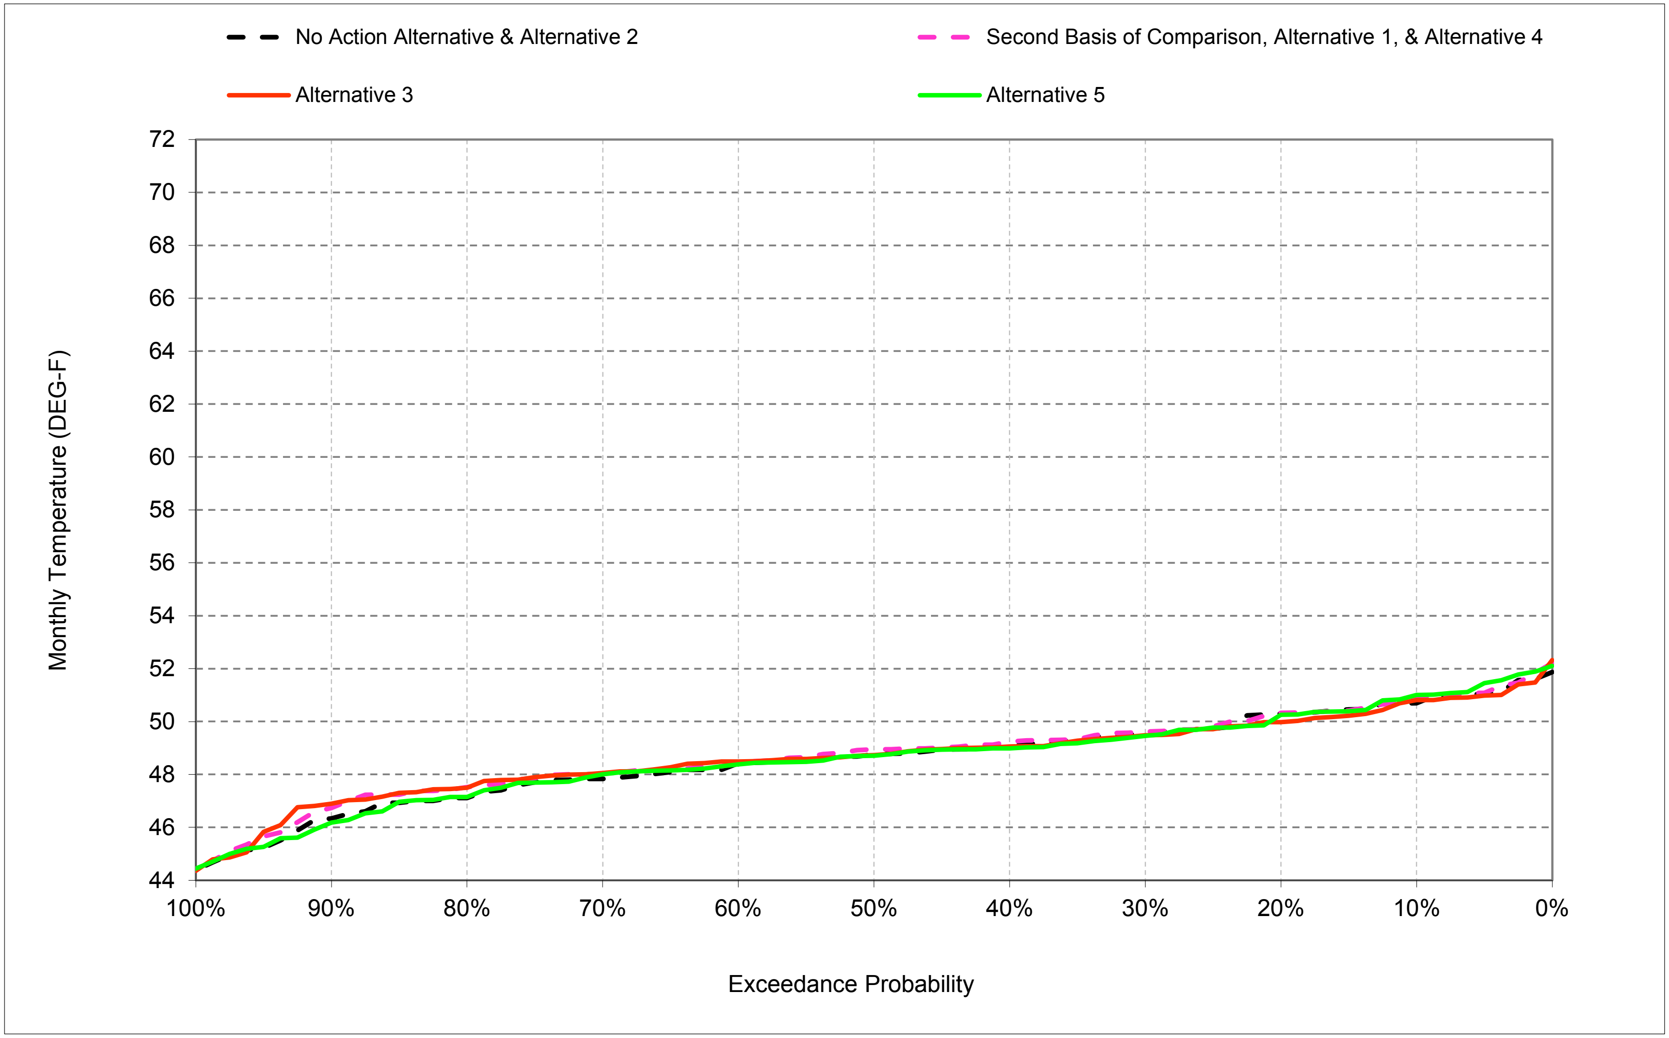
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-3. Stanislaus River below Tulloch Reservoir, December



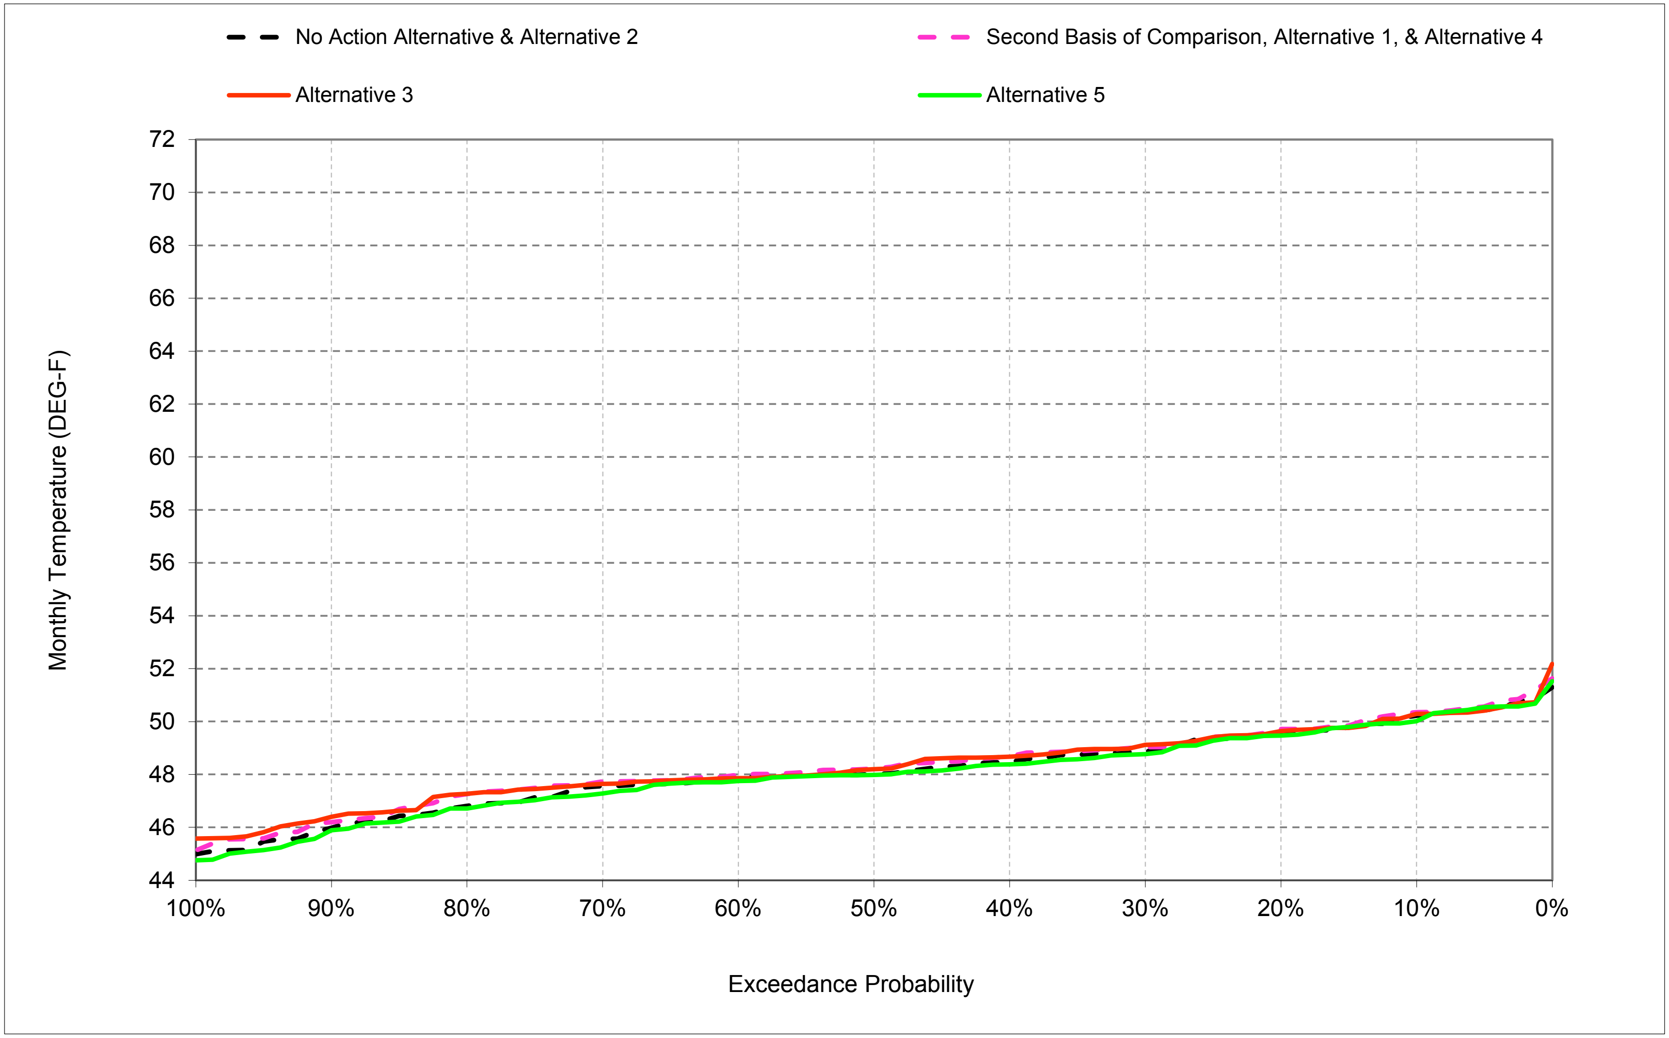
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-4. Stanislaus River below Tulloch Reservoir, January



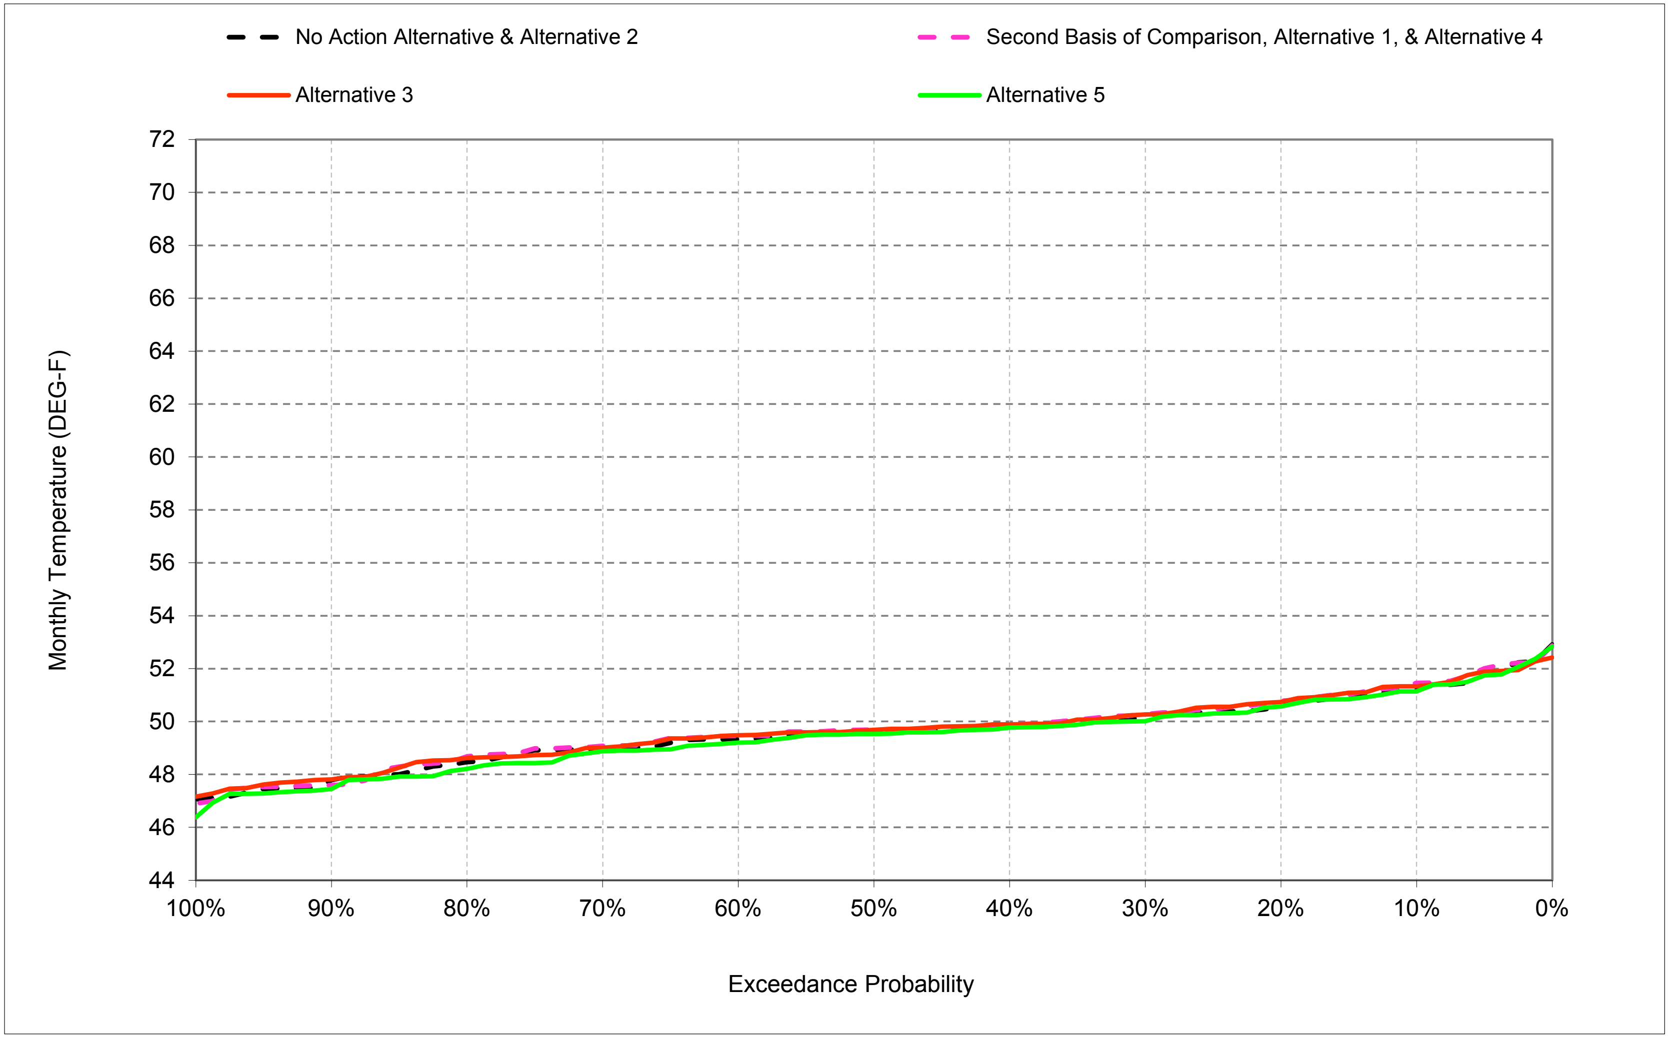
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-5. Stanislaus River below Tulloch Reservoir, February



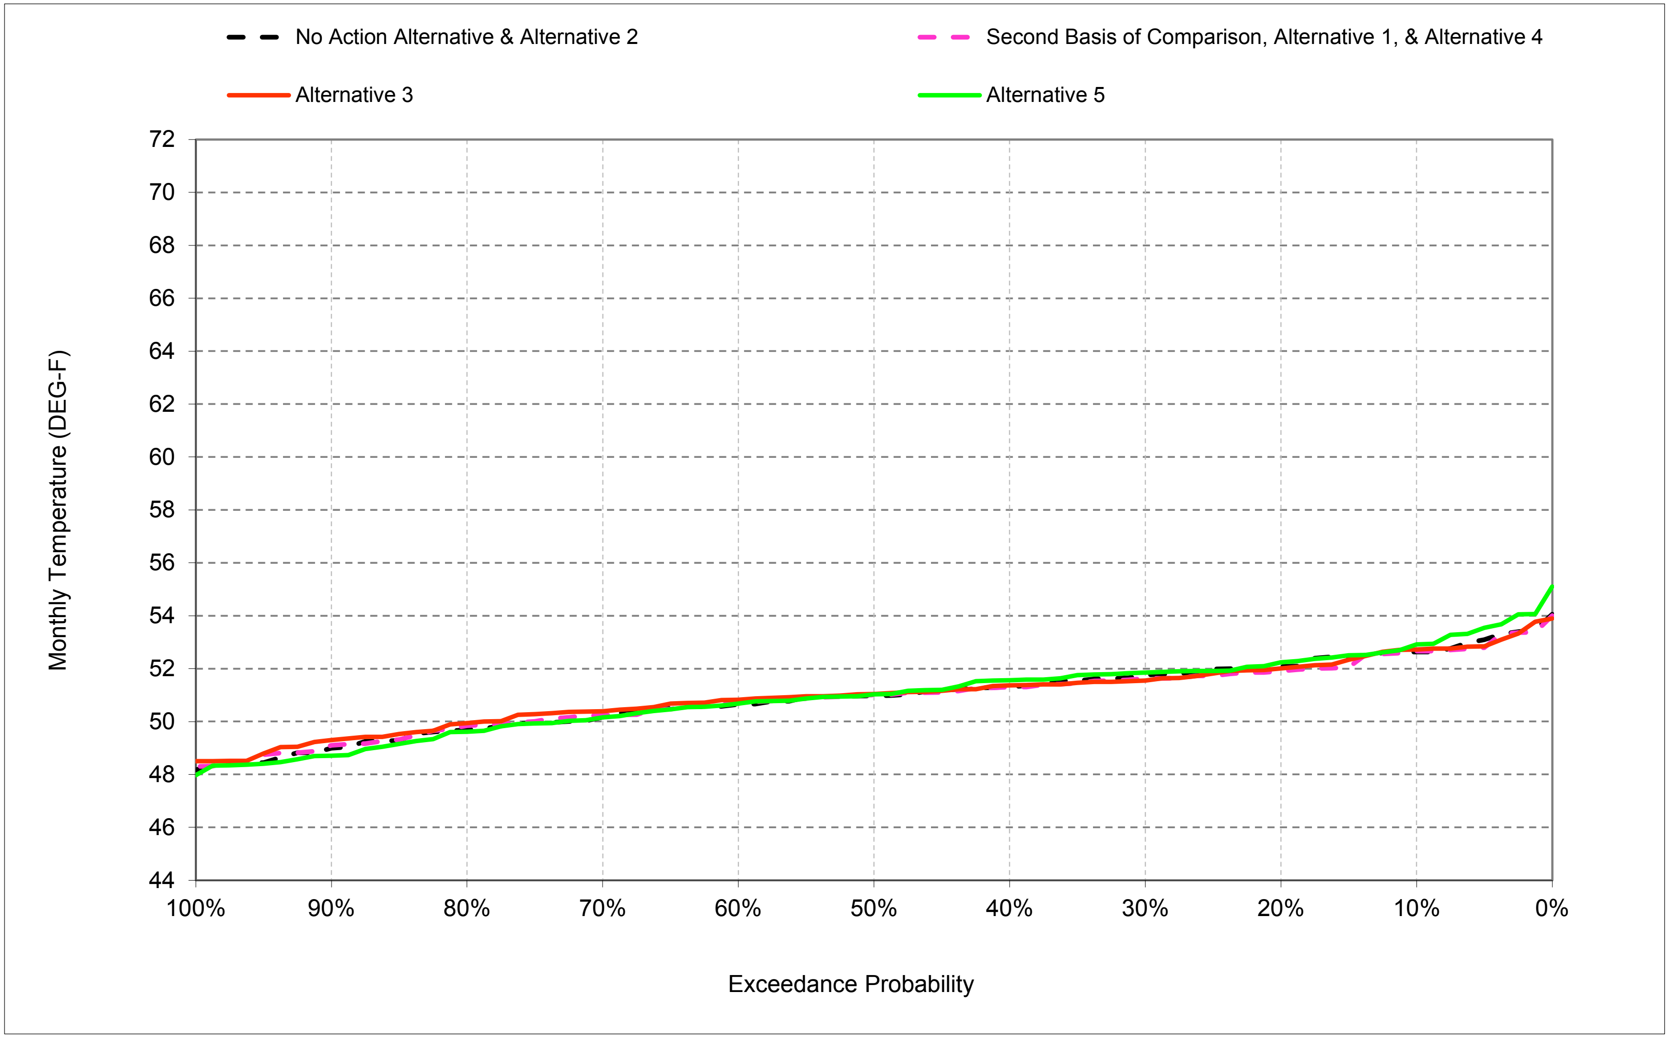
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-6. Stanislaus River below Tulloch Reservoir, March



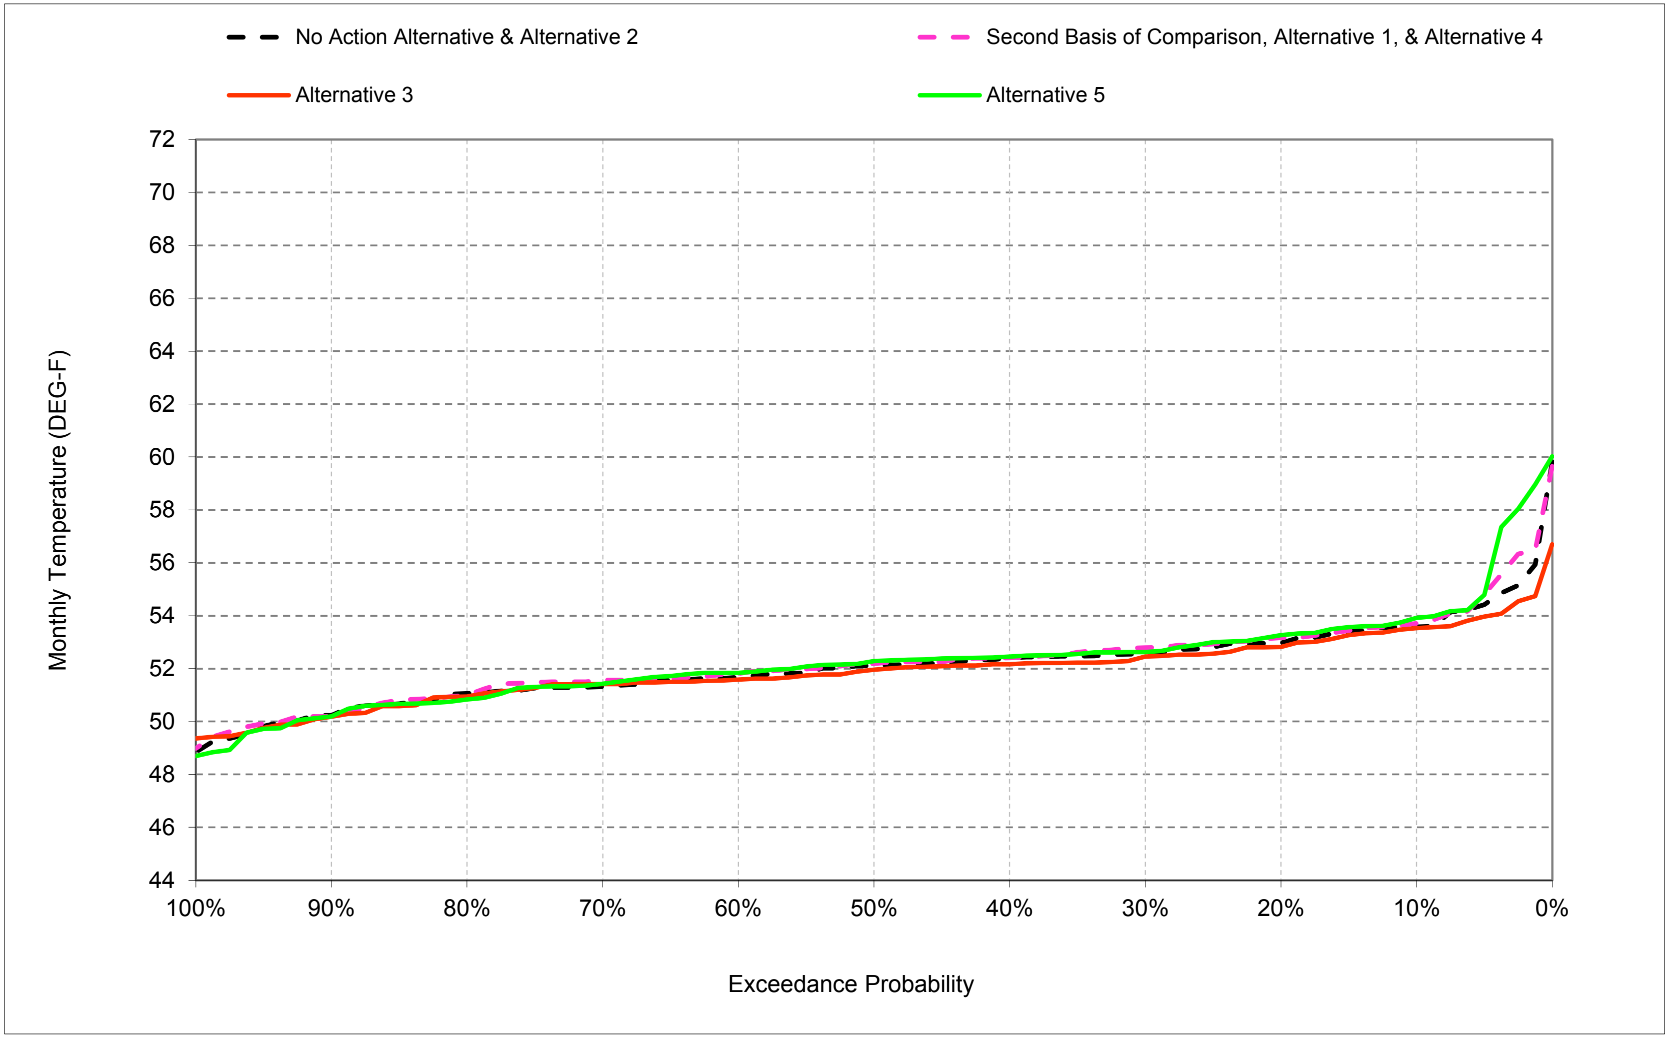
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-7. Stanislaus River below Tulloch Reservoir, April



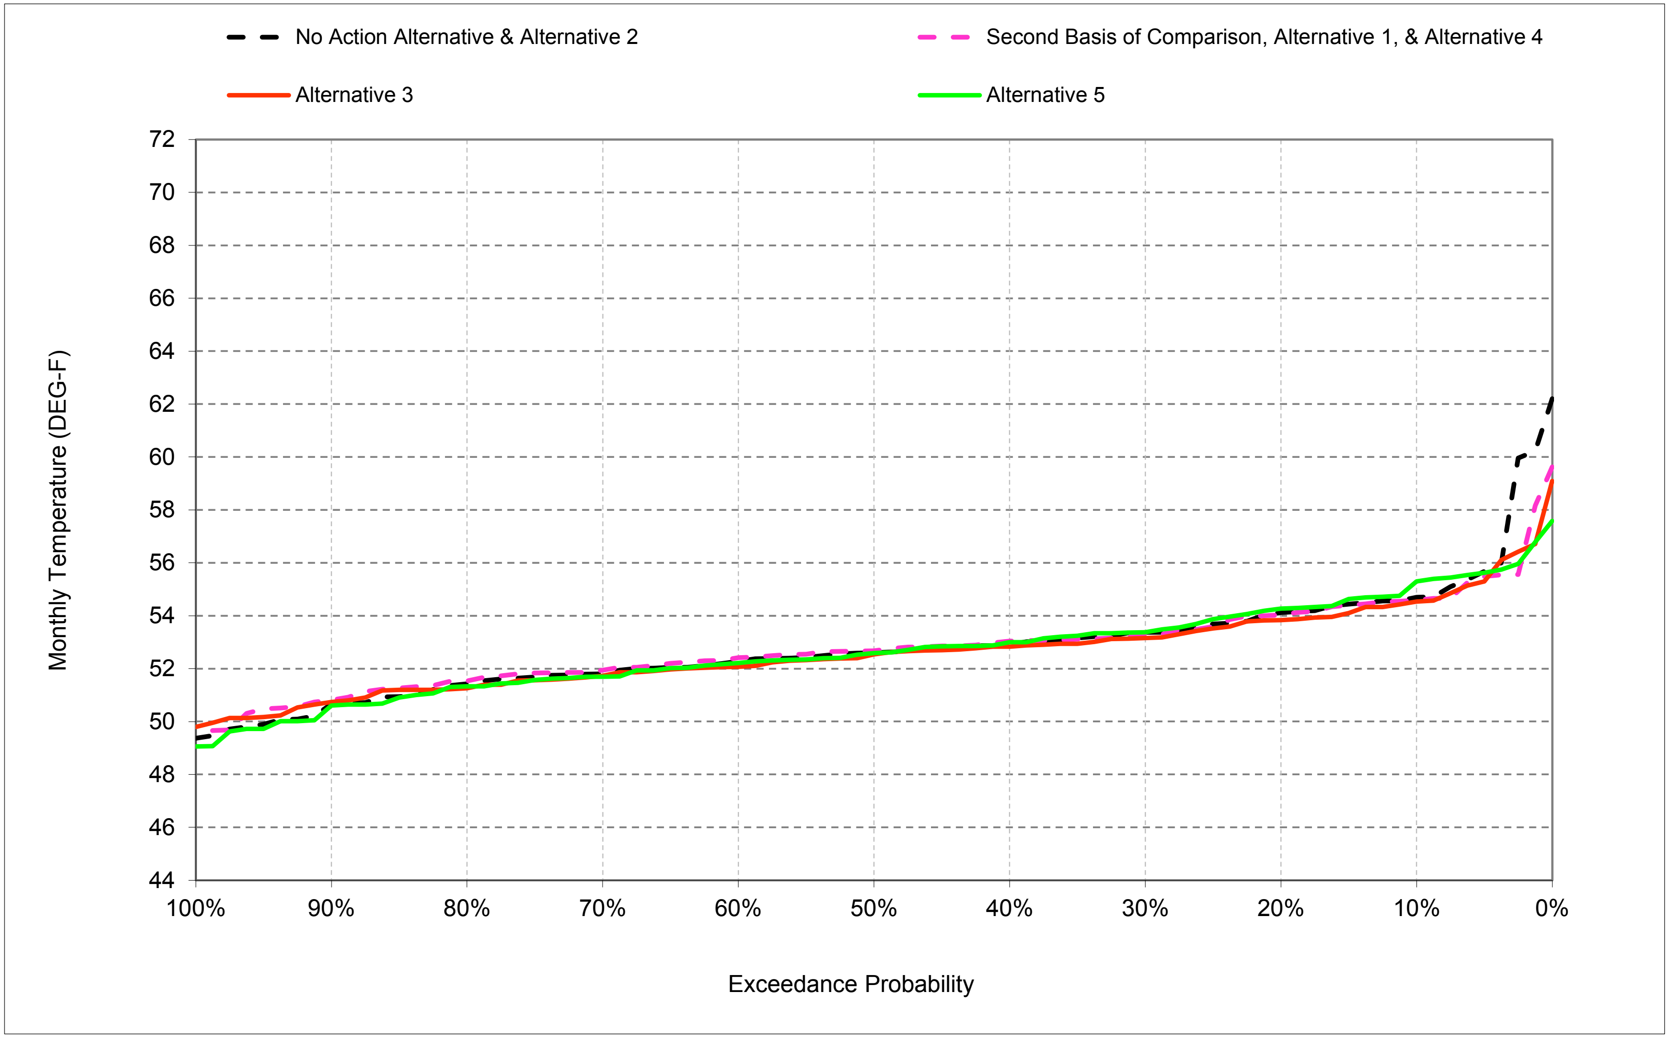
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-8. Stanislaus River below Tulloch Reservoir, May



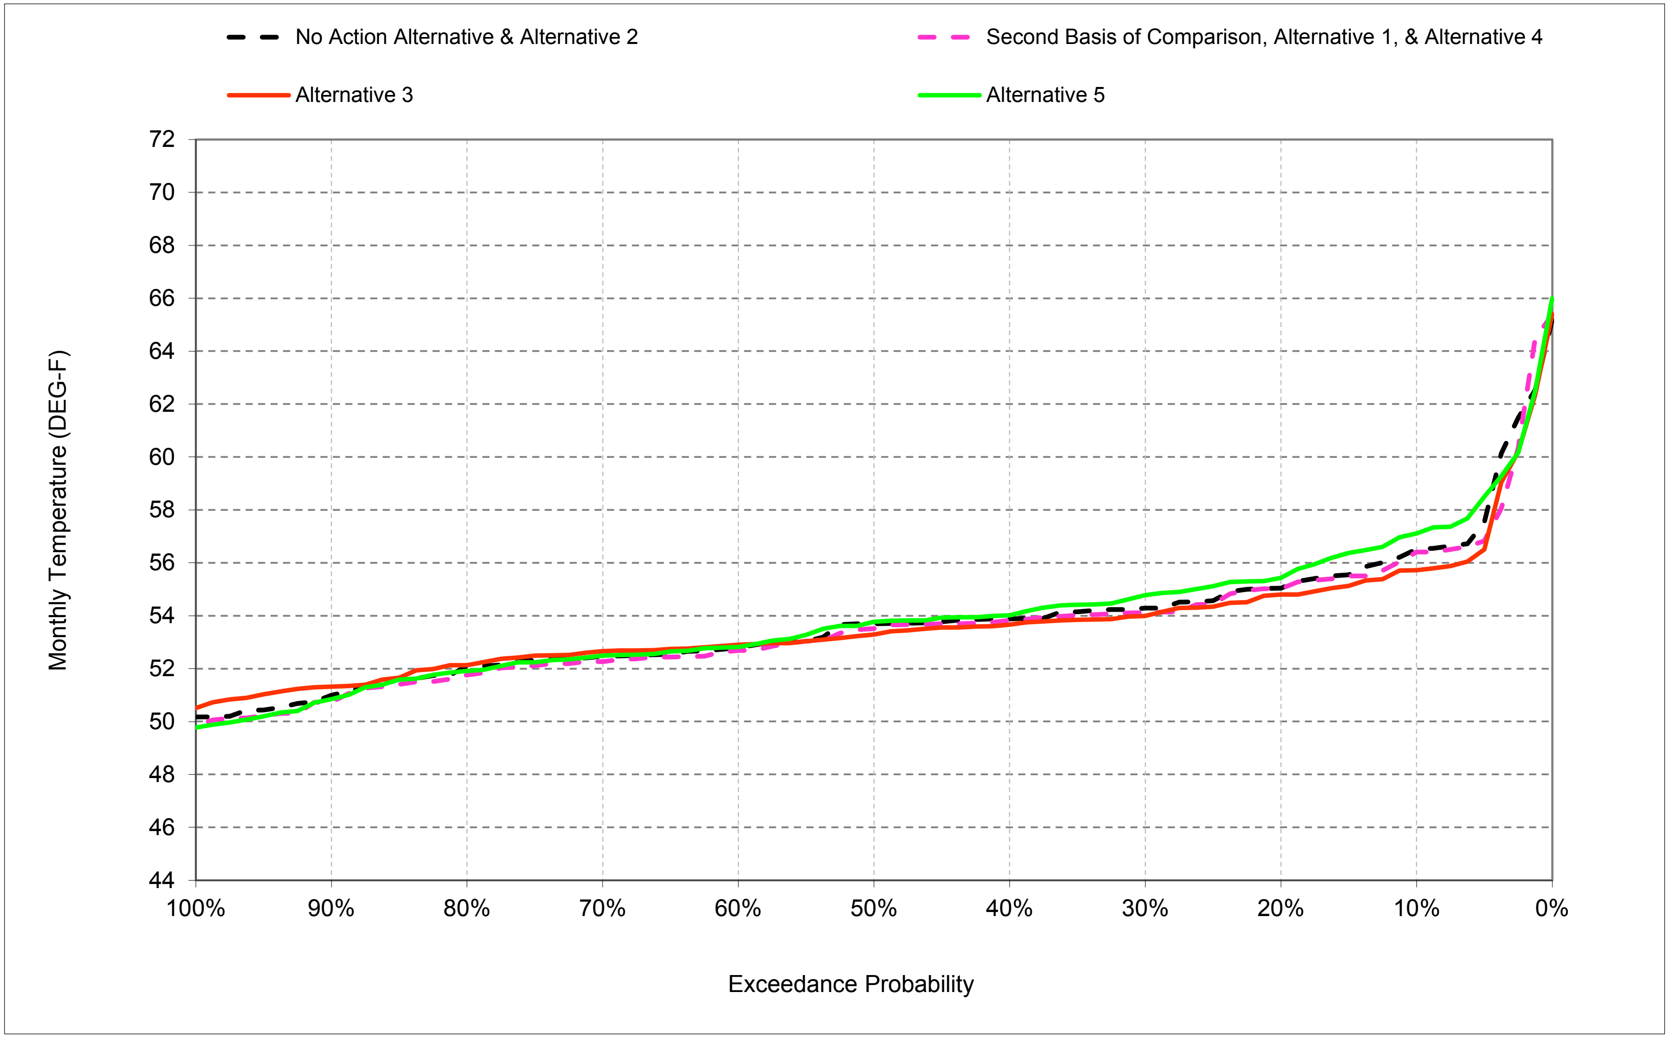
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-9. Stanislaus River below Tulloch Reservoir, June



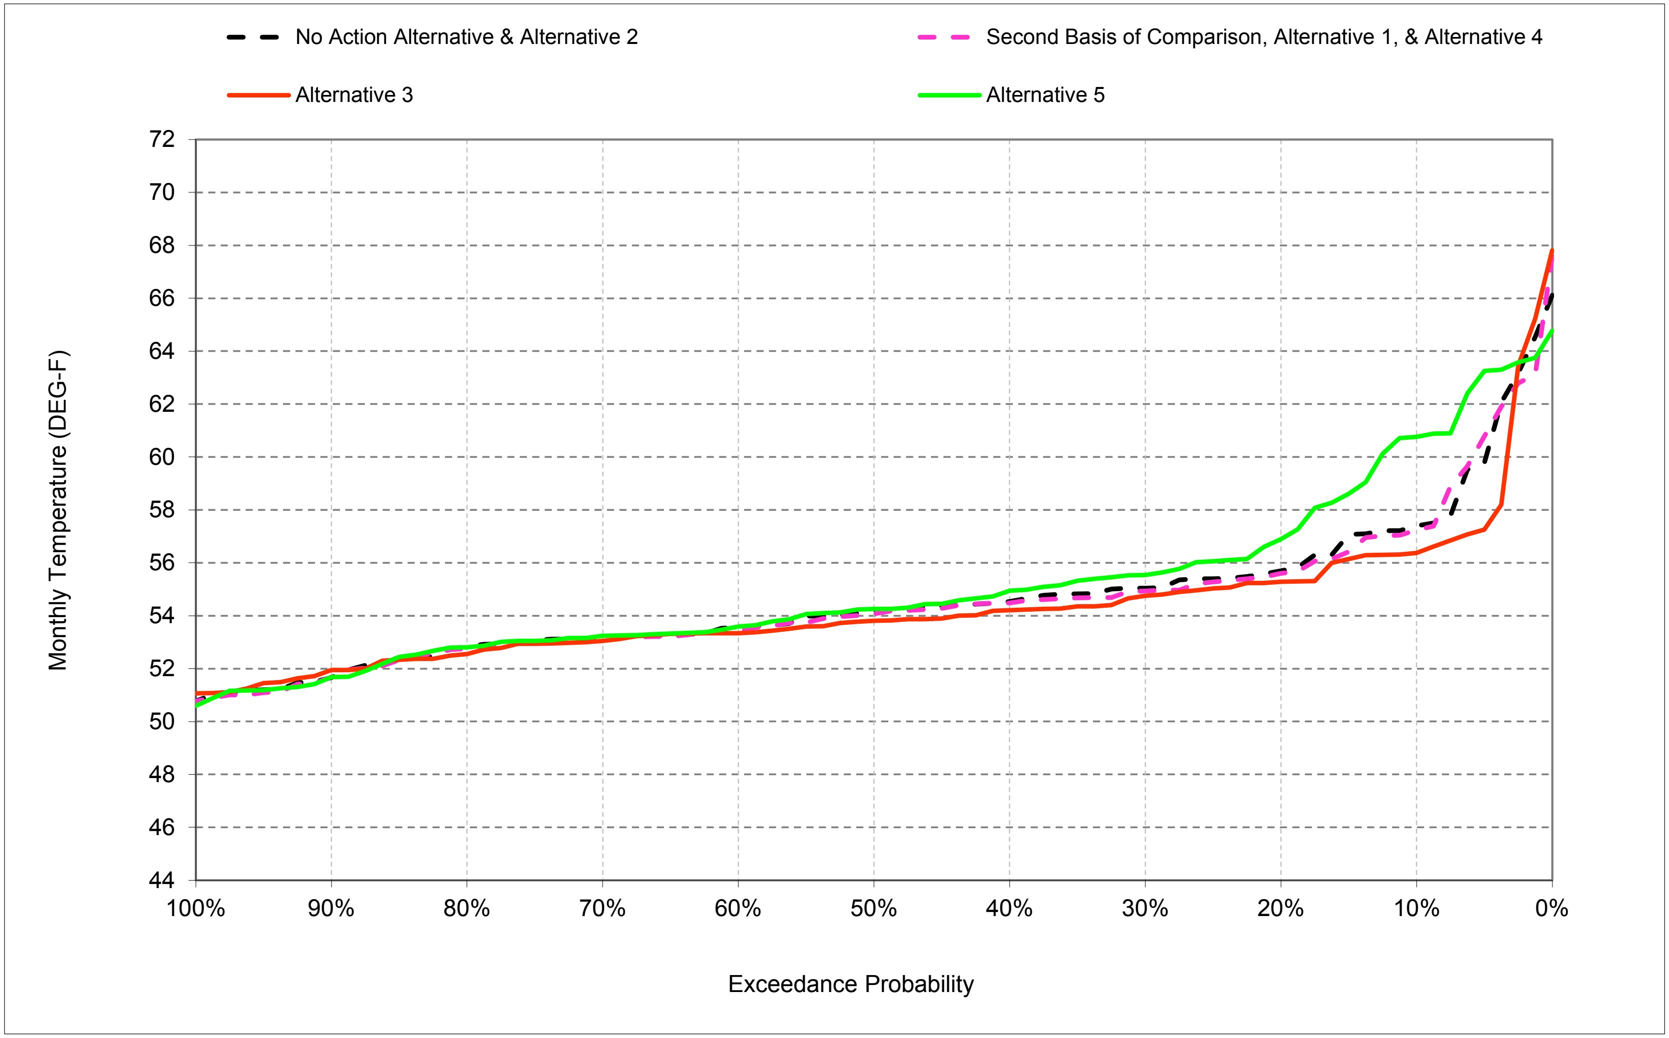
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-10. Stanislaus River below Tulloch Reservoir, July



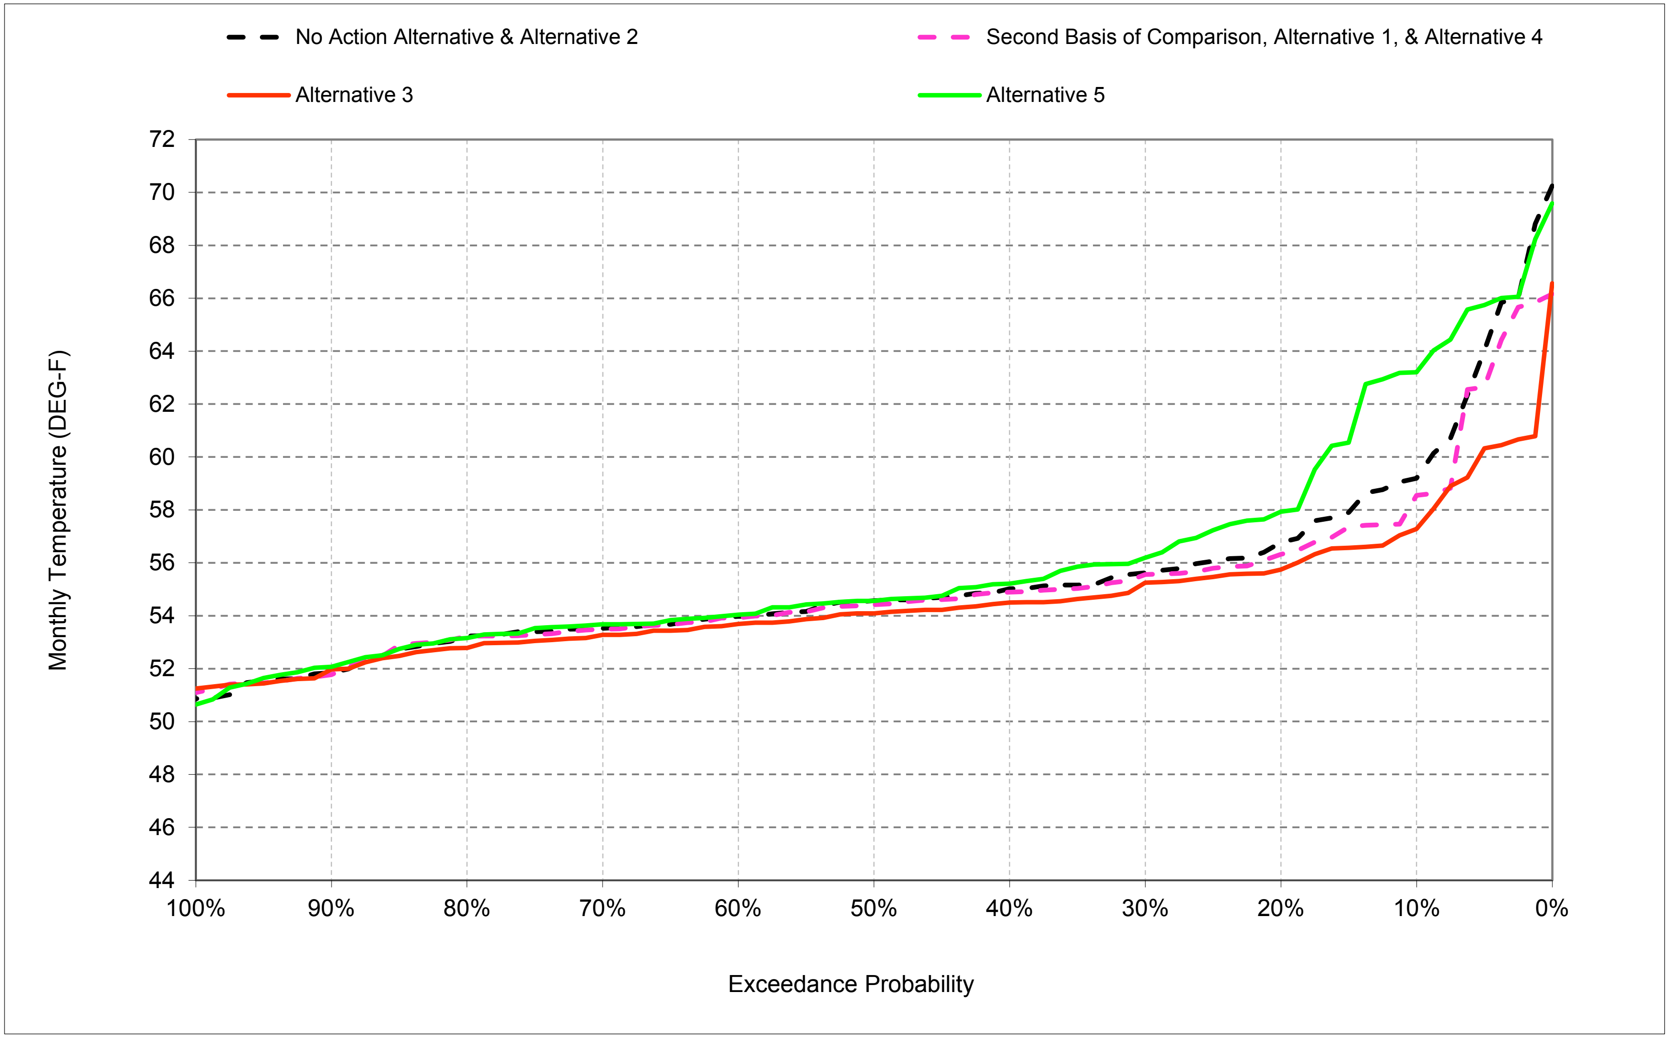
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-11. Stanislaus River below Tulloch Reservoir, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-16-12. Stanislaus River below Tulloch Reservoir, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Qualitative differences, if applicable, are discussed in the text.

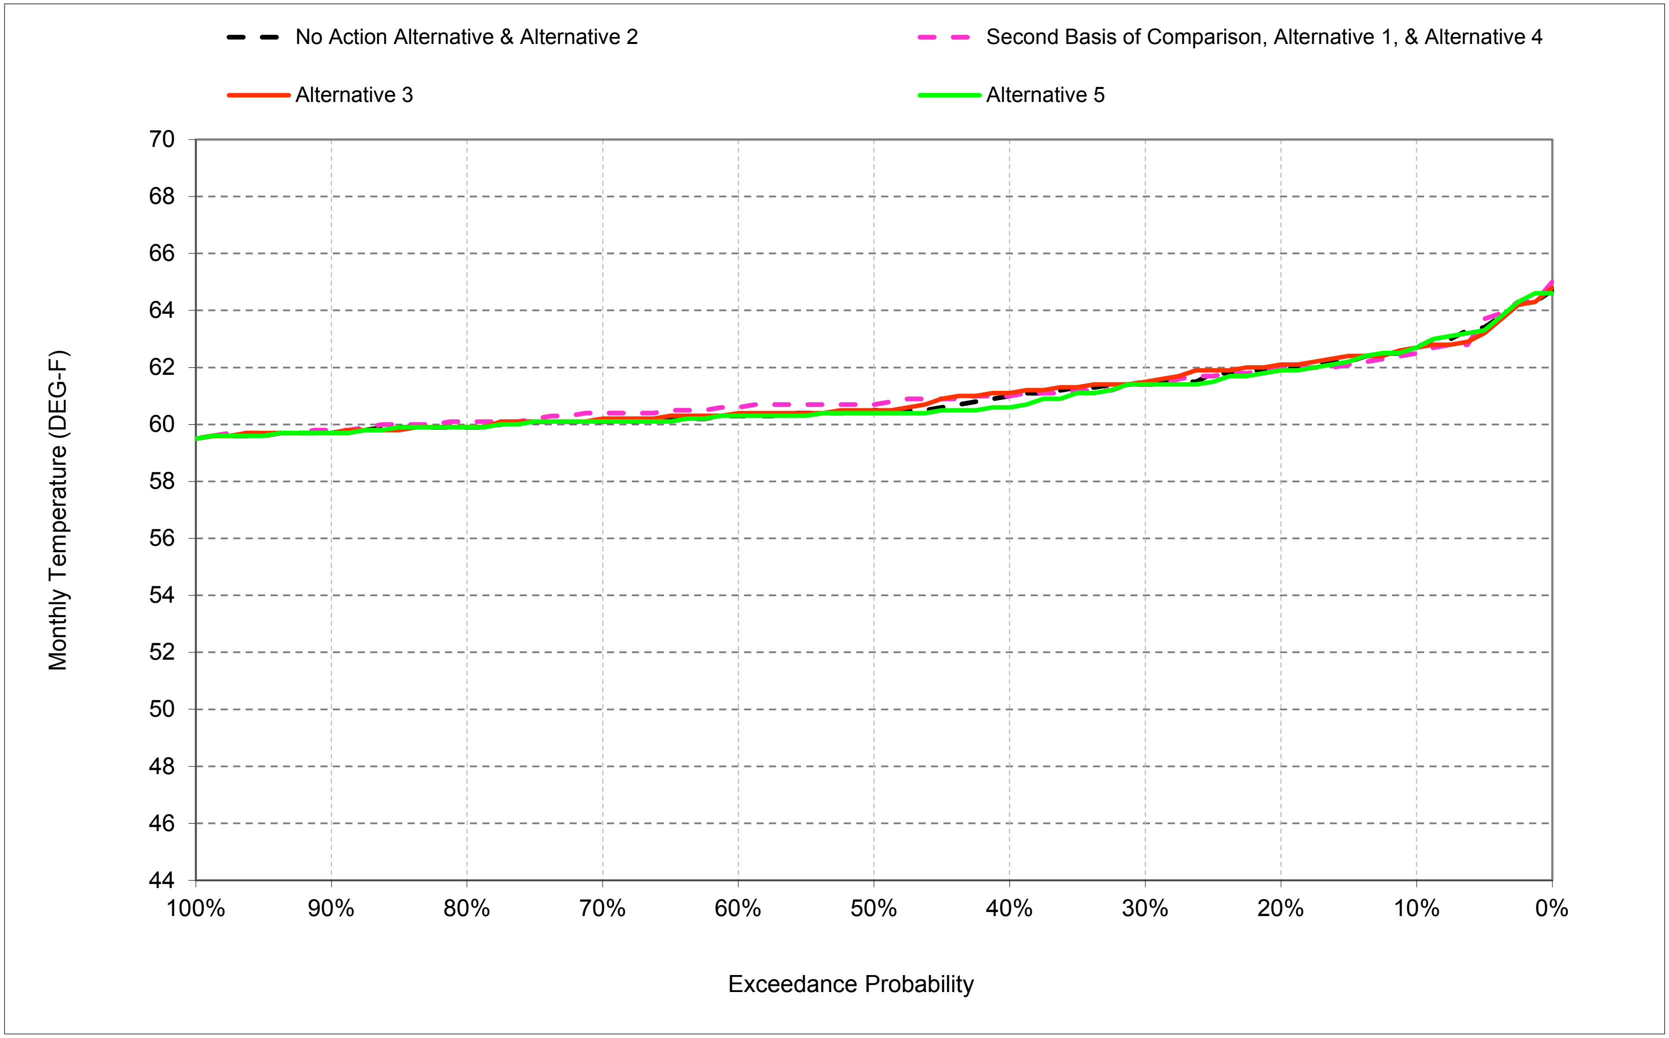
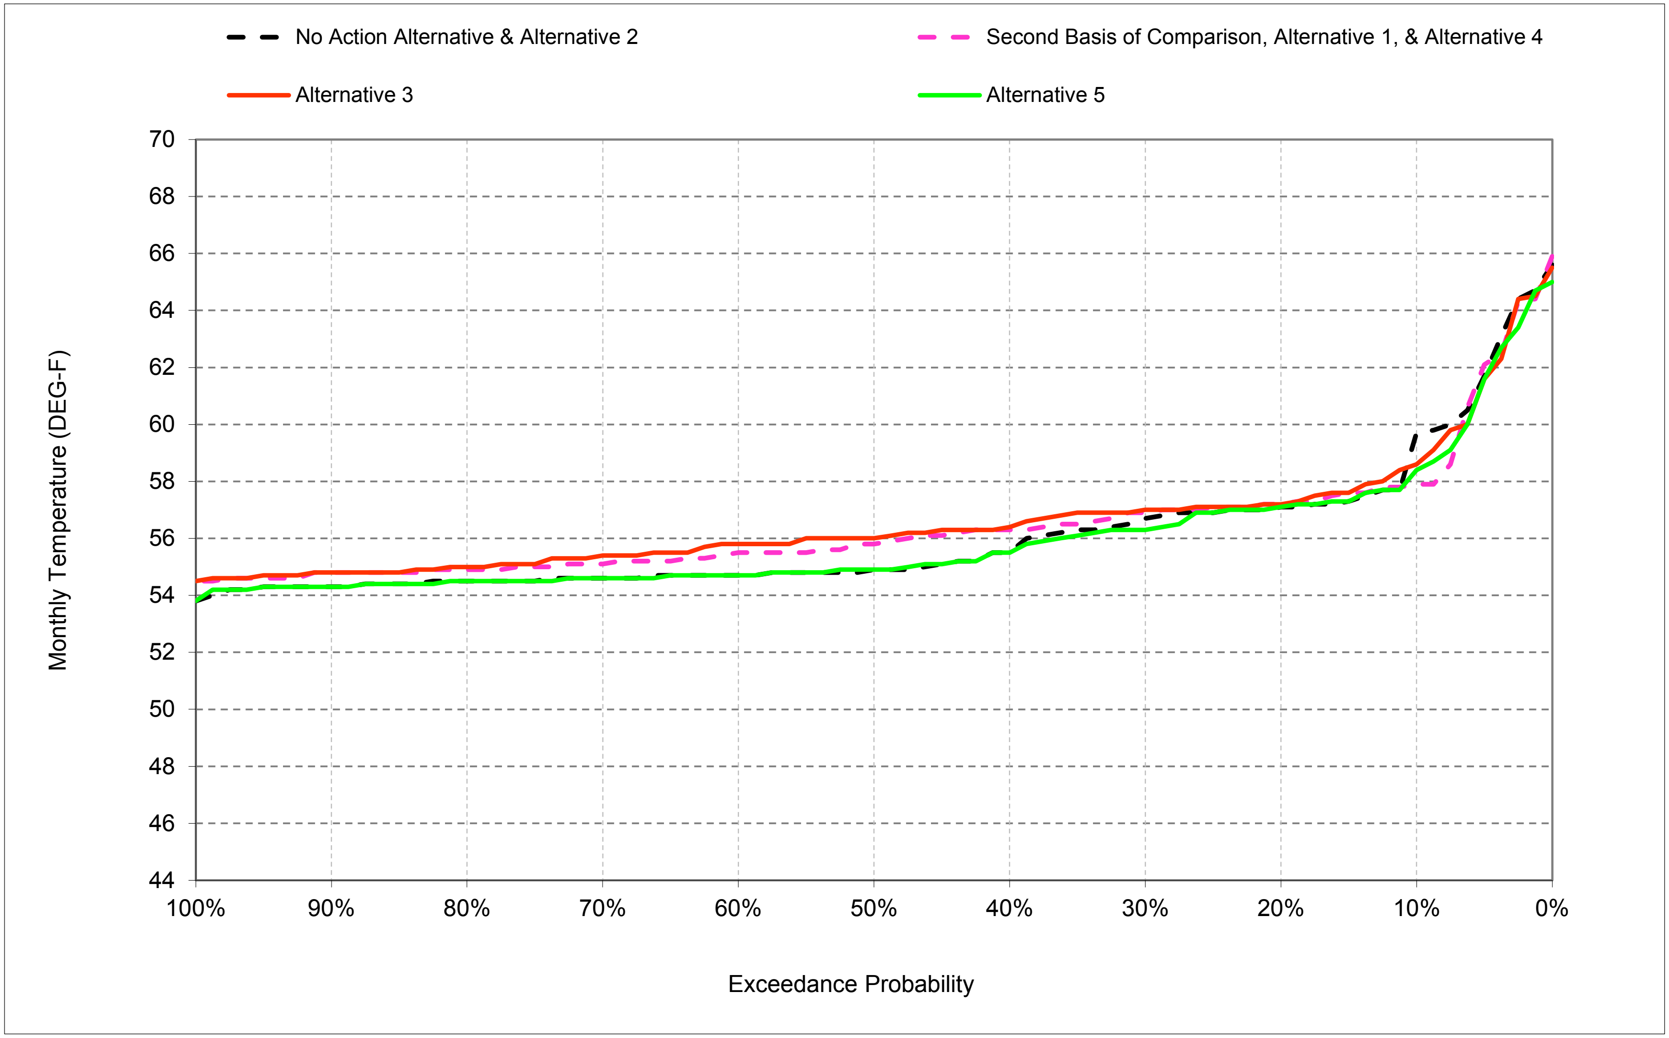
Figure B-20-11. Feather River Low Flow Channel, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-20-12. Feather River Low Flow Channel, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Qualitative differences, if applicable, are discussed in the text.

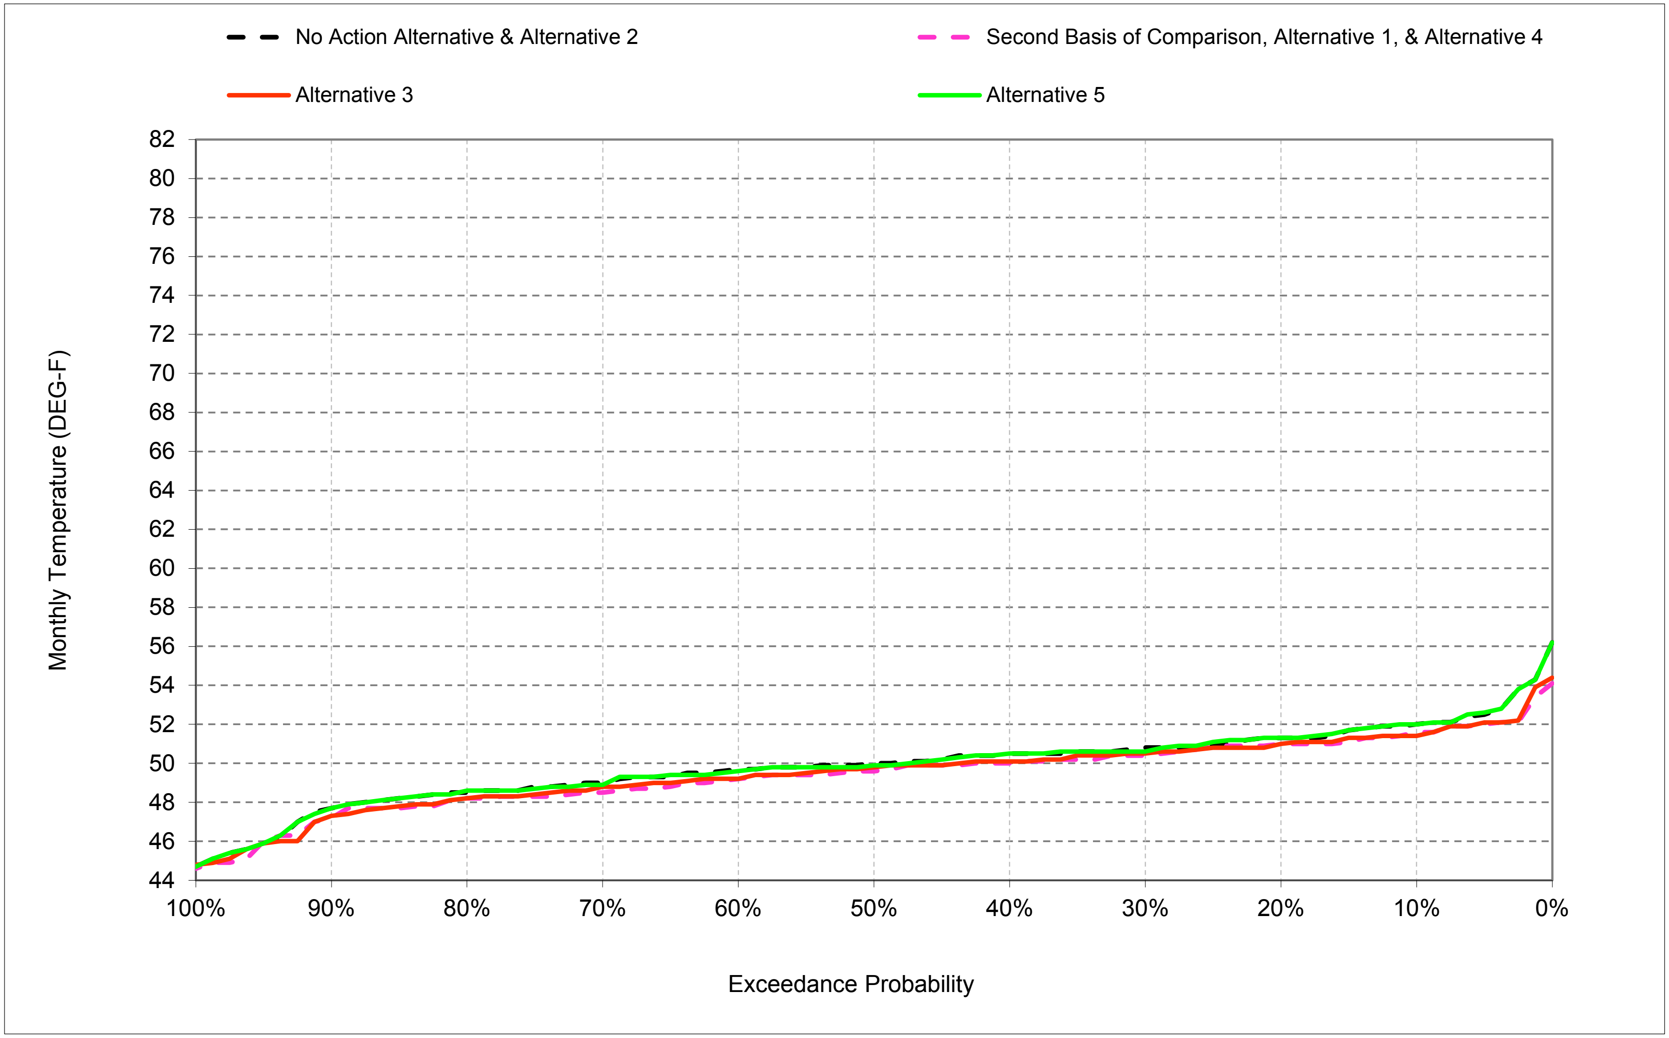
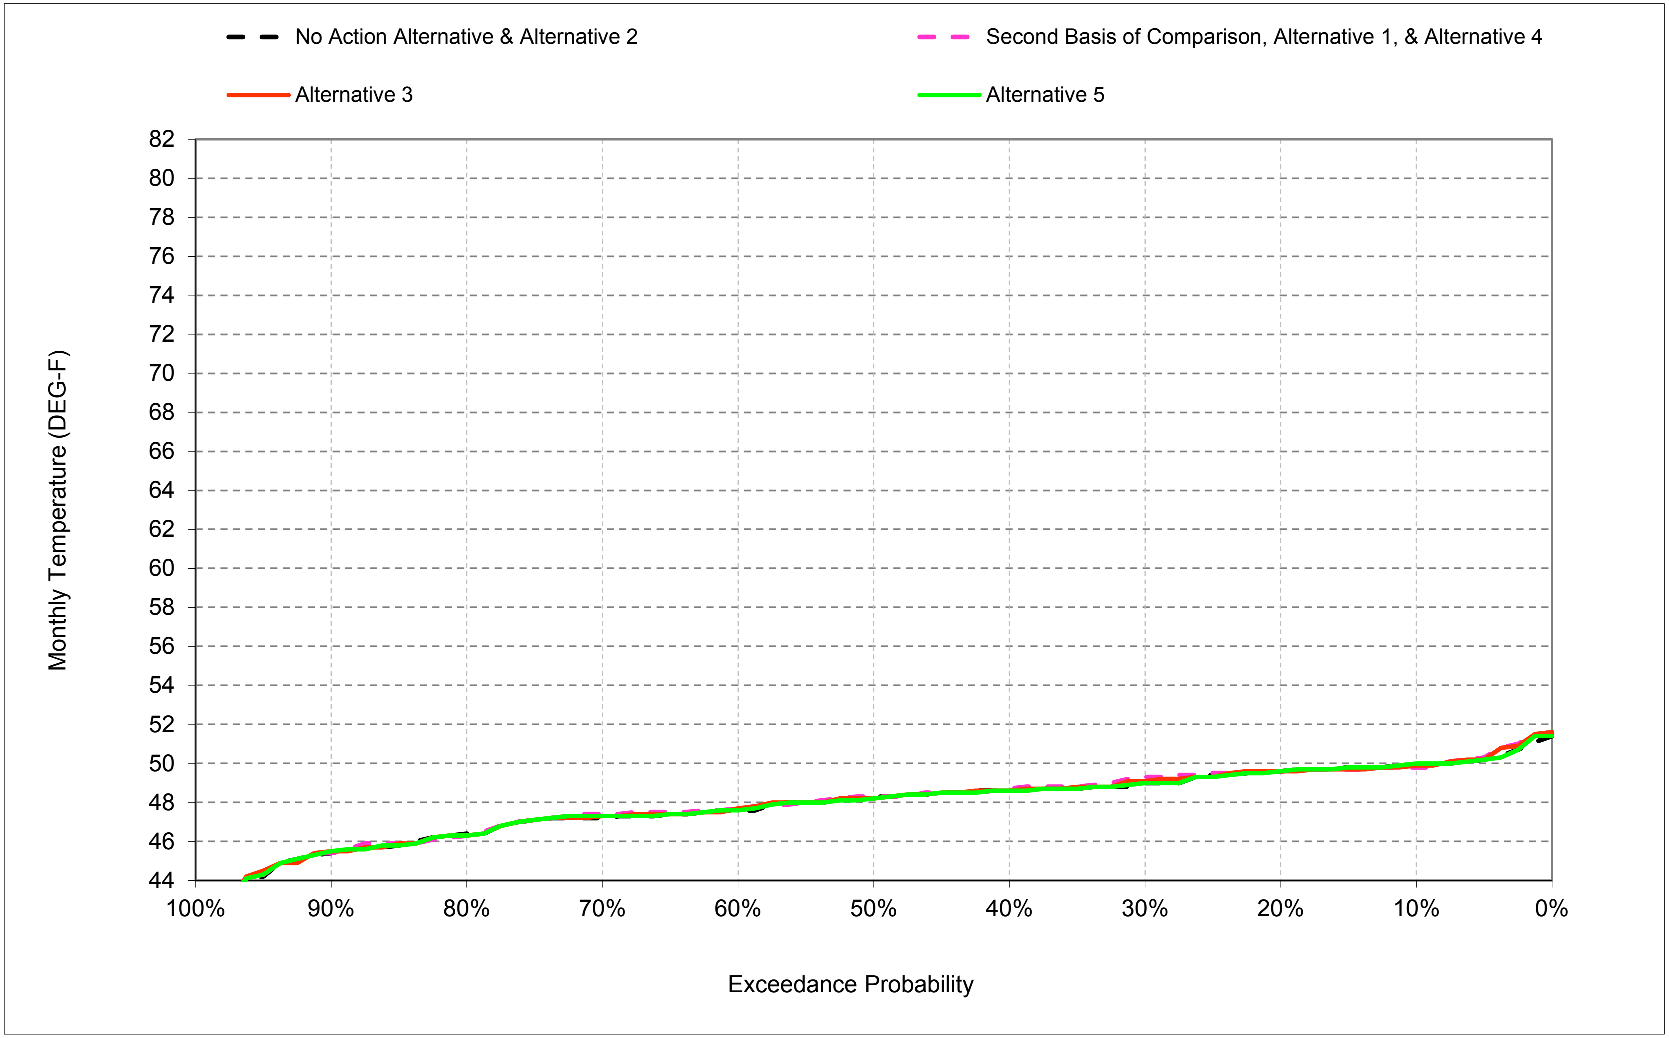
Figure B-21-3. Feather River at Robinson Riffle, December



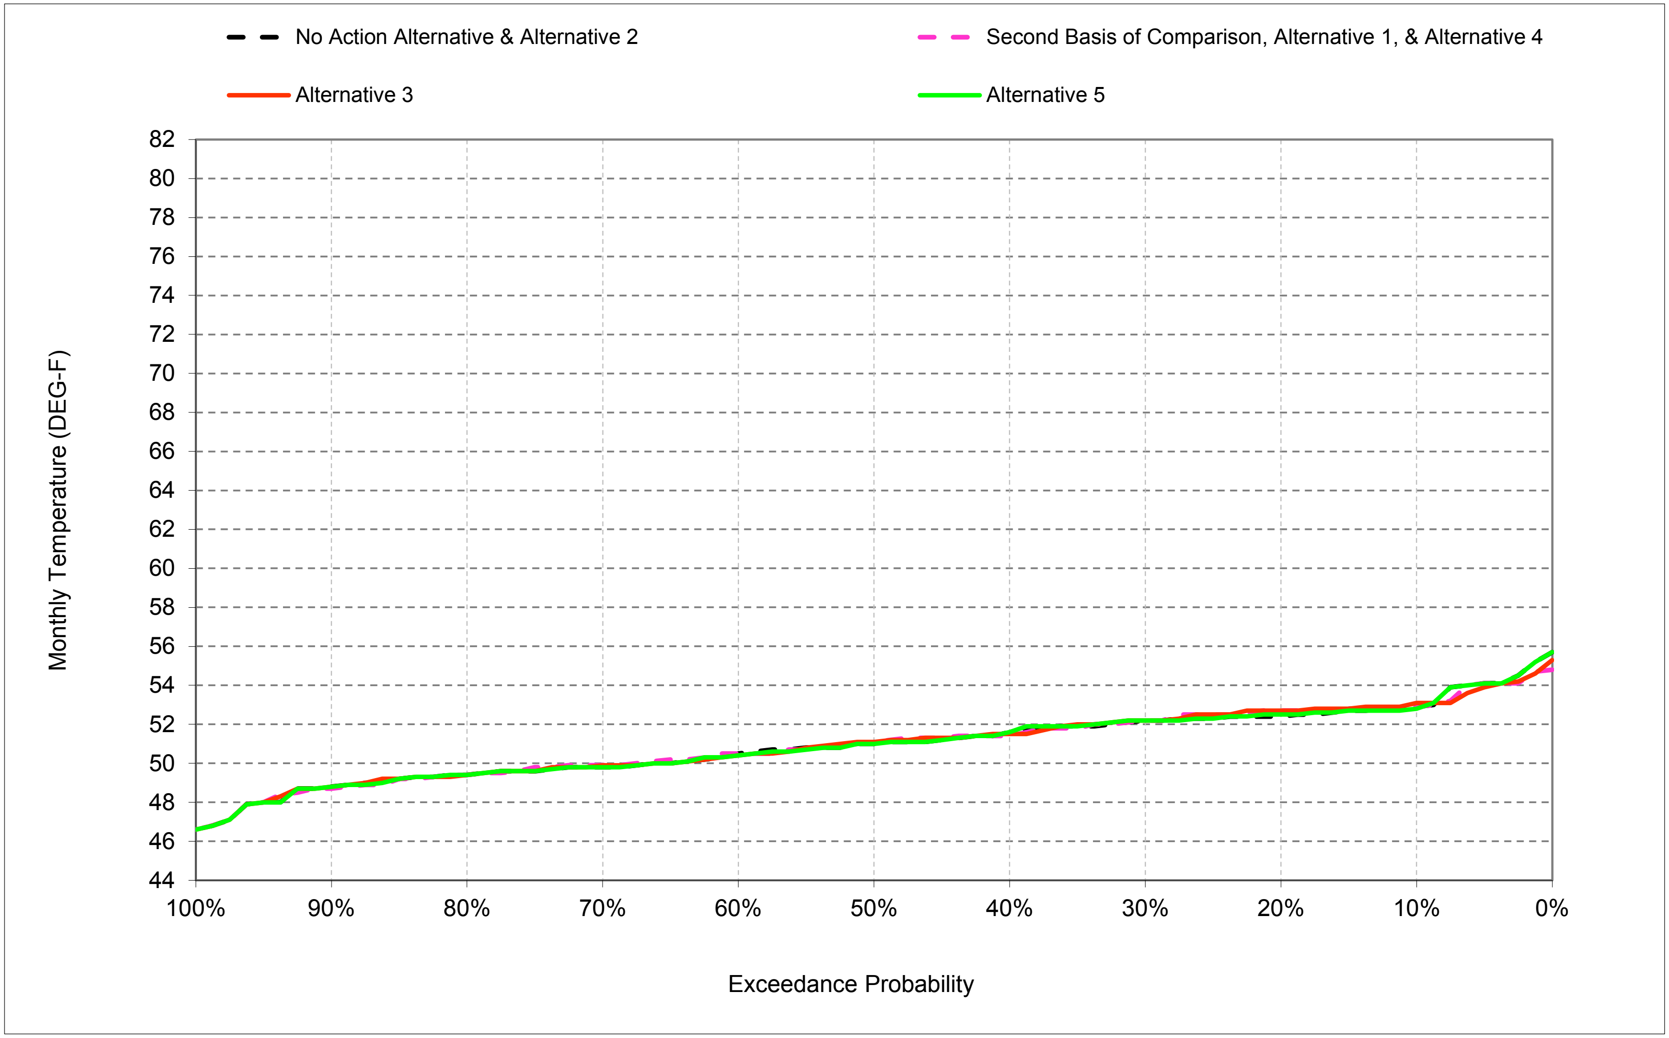
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-4. Feather River at Robinson Riffle, January



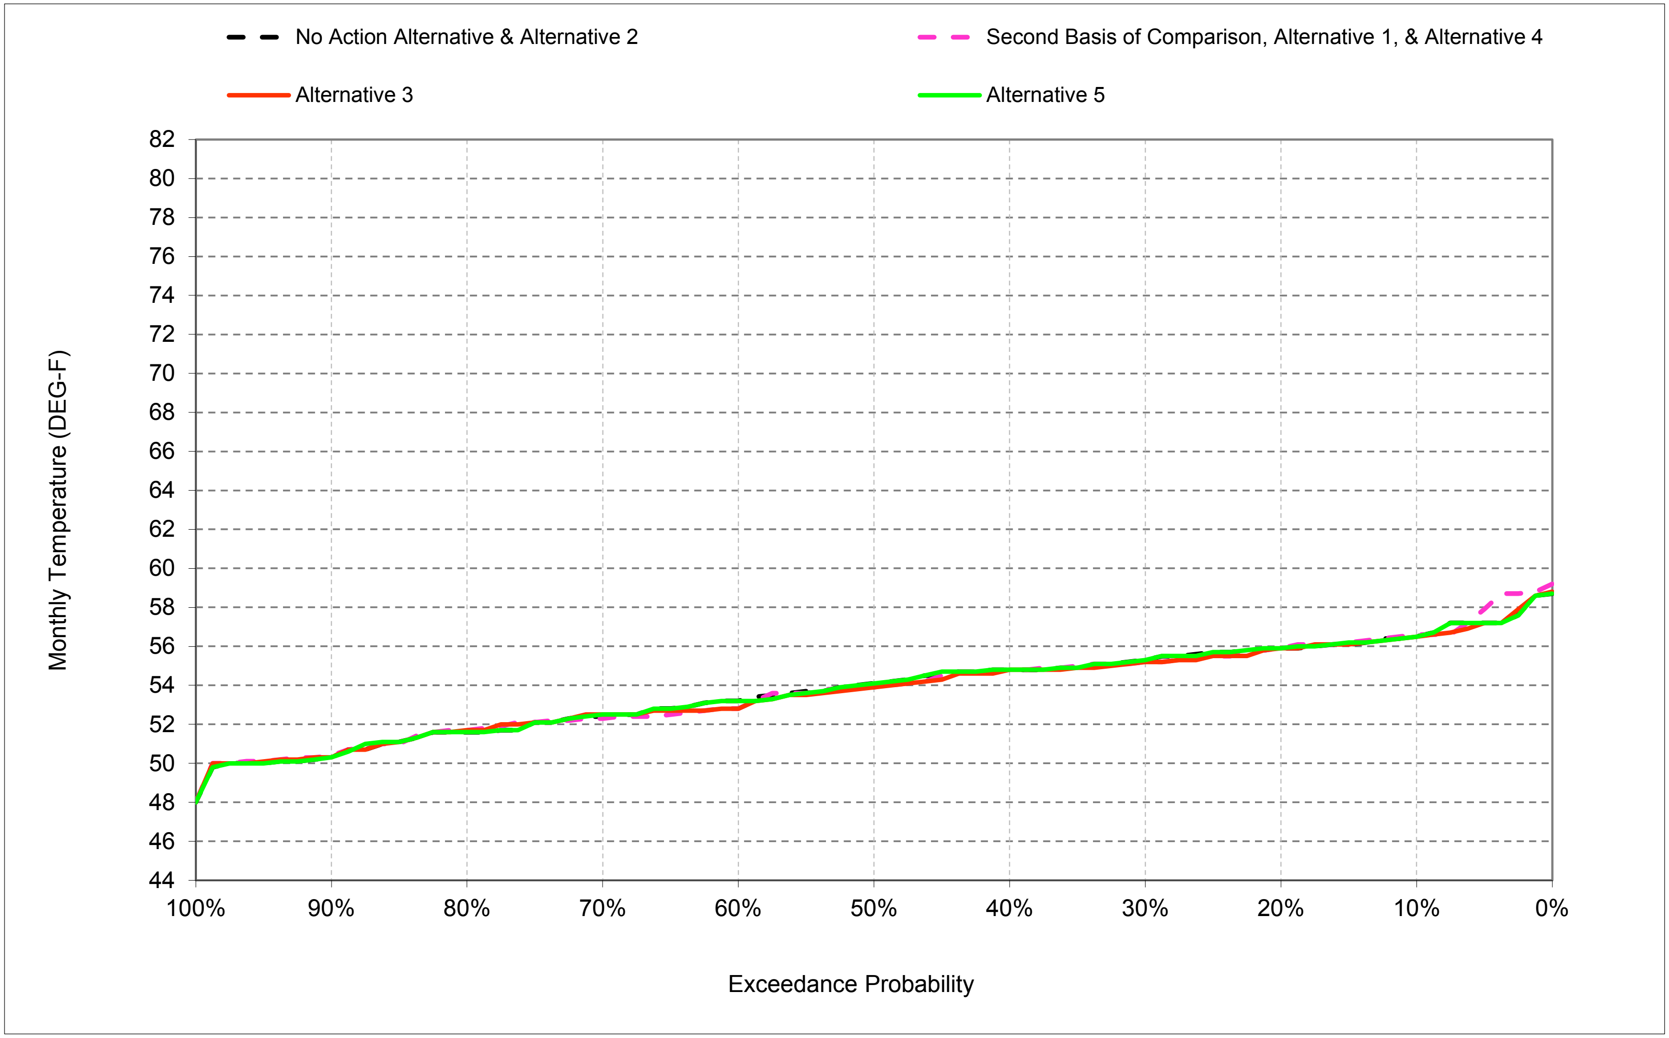
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-5. Feather River at Robinson Riffle, February



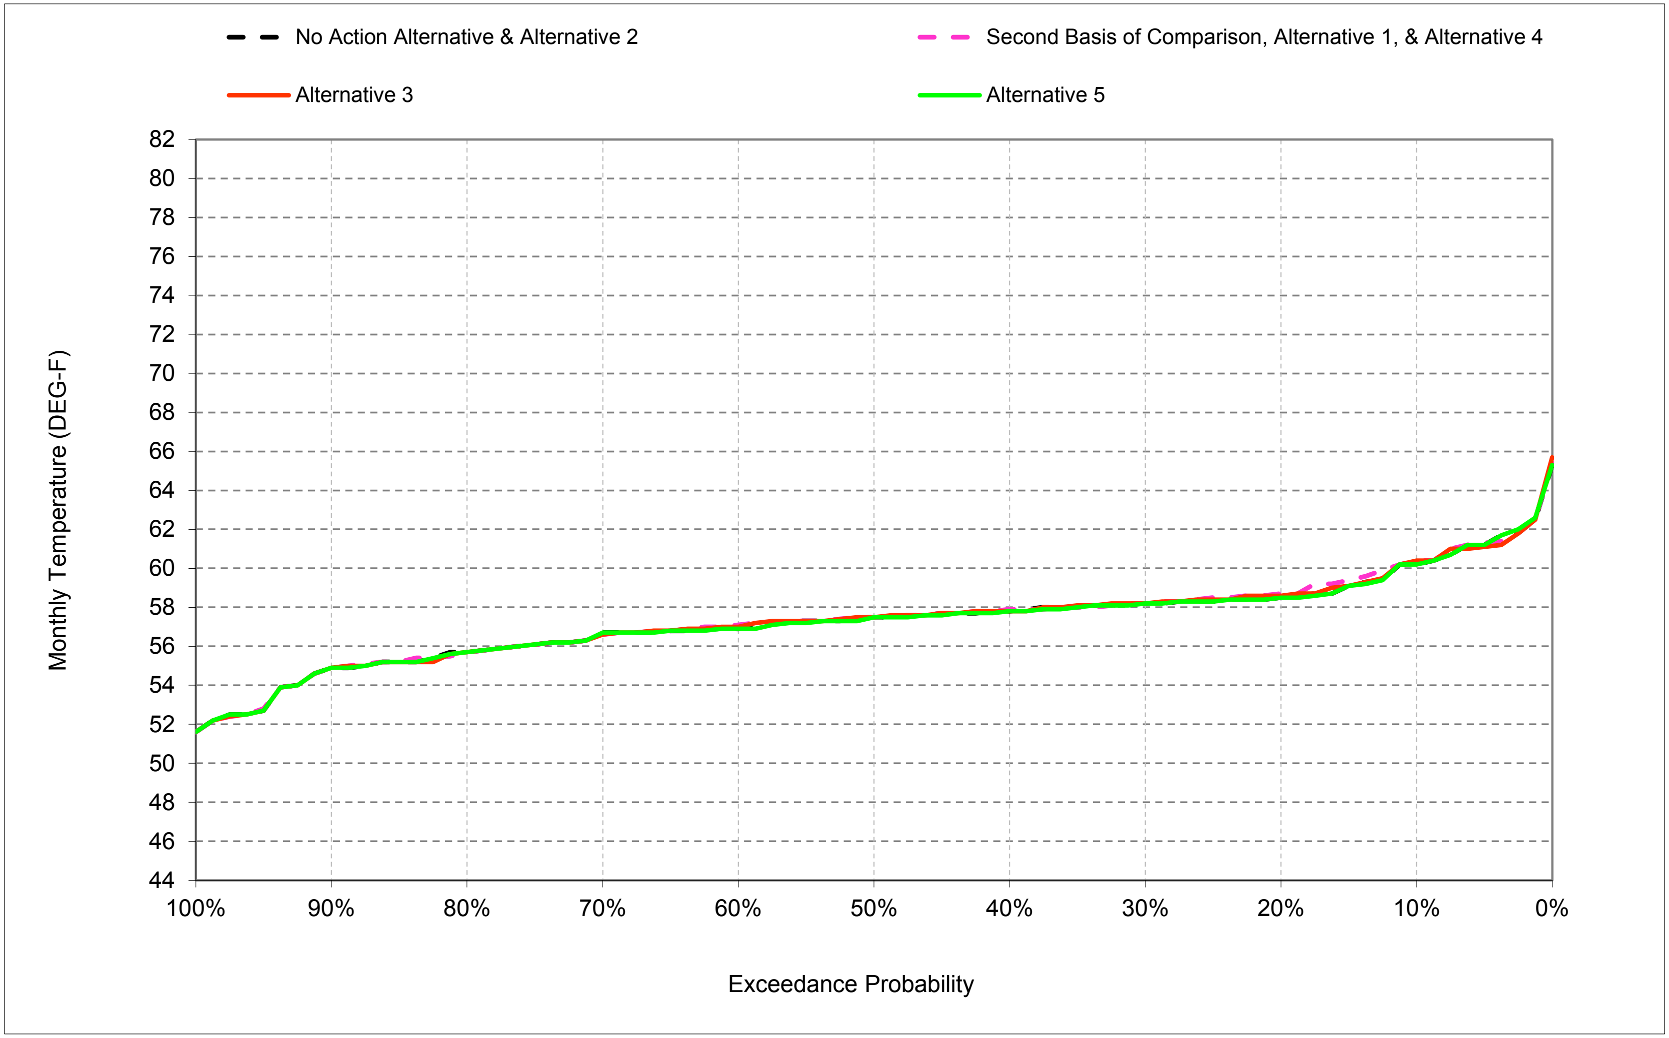
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-6. Feather River at Robinson Riffle, March



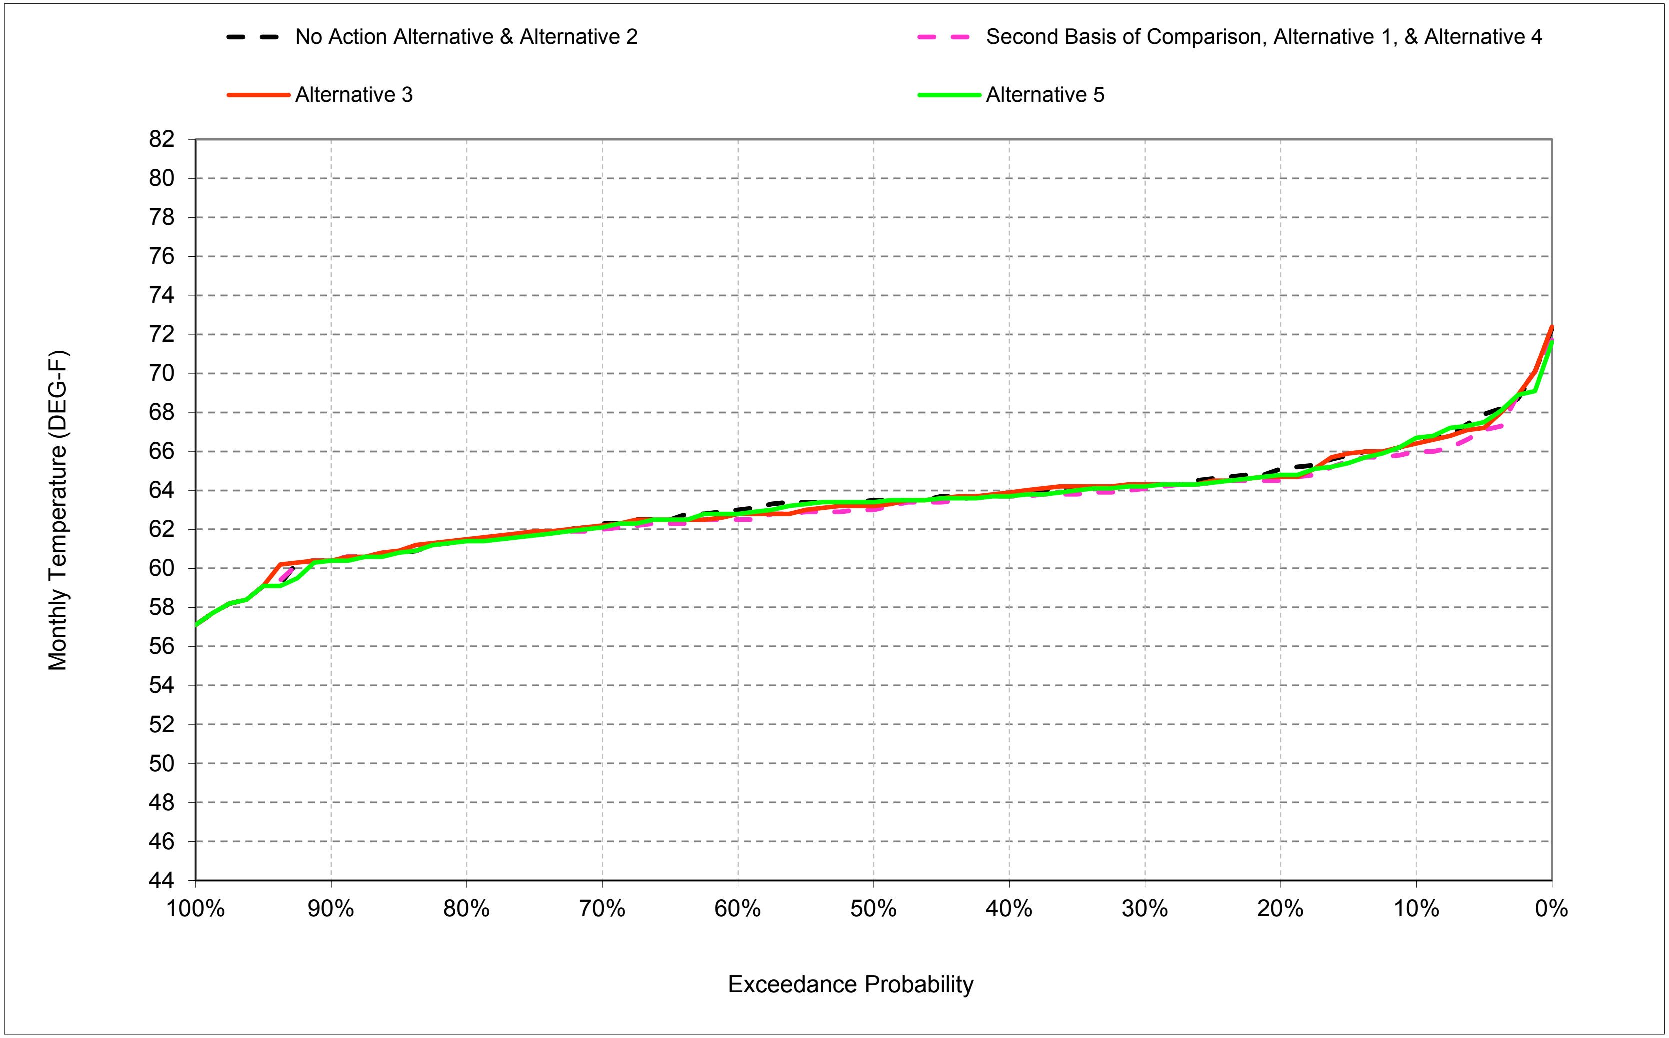
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-7. Feather River at Robinson Riffle, April



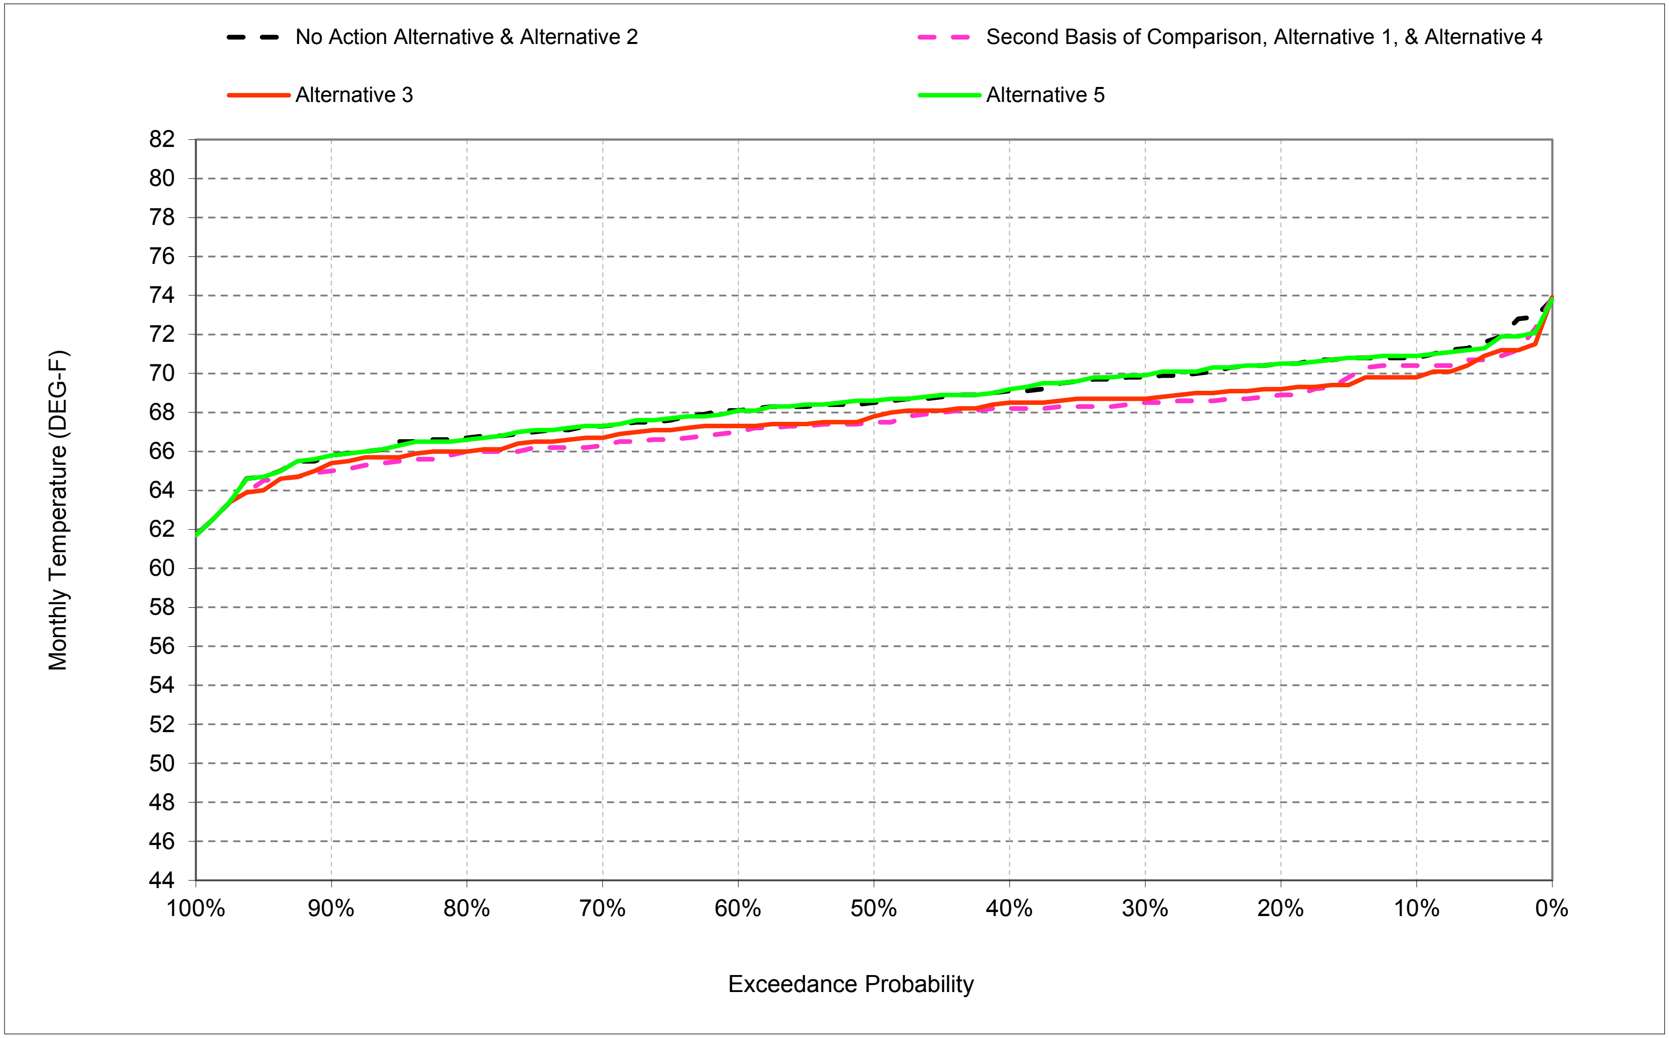
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-8. Feather River at Robinson Riffle, May



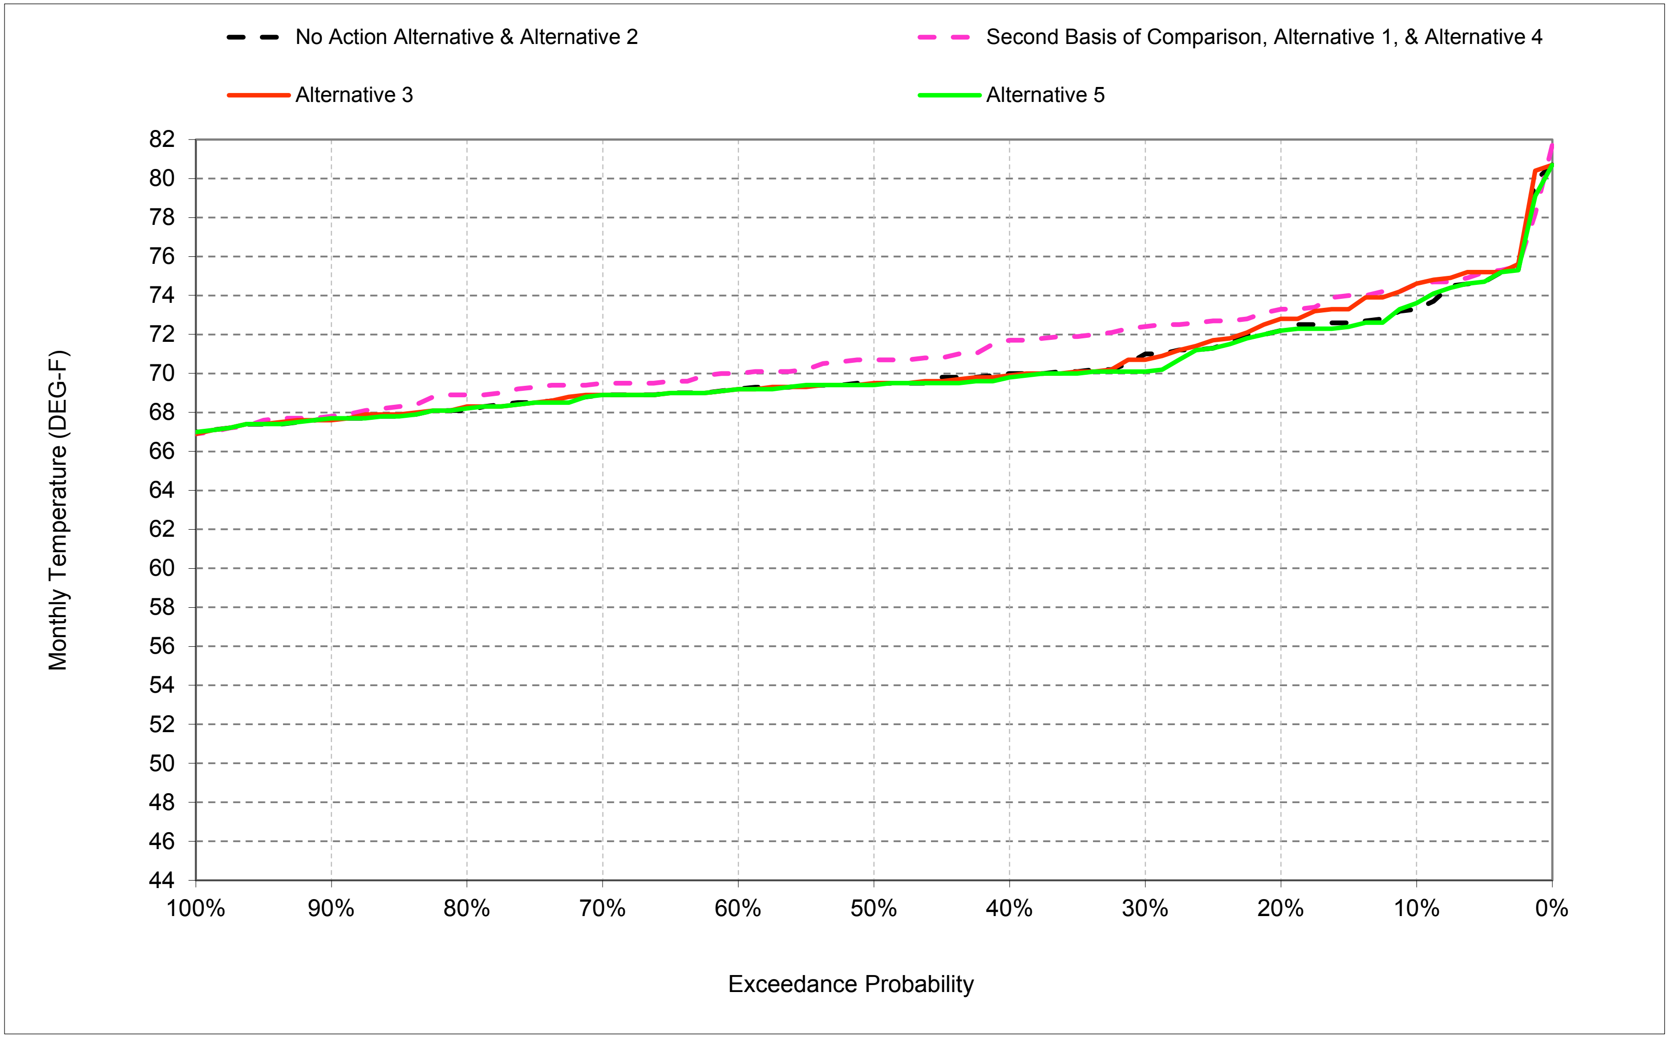
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-9. Feather River at Robinson Riffle, June



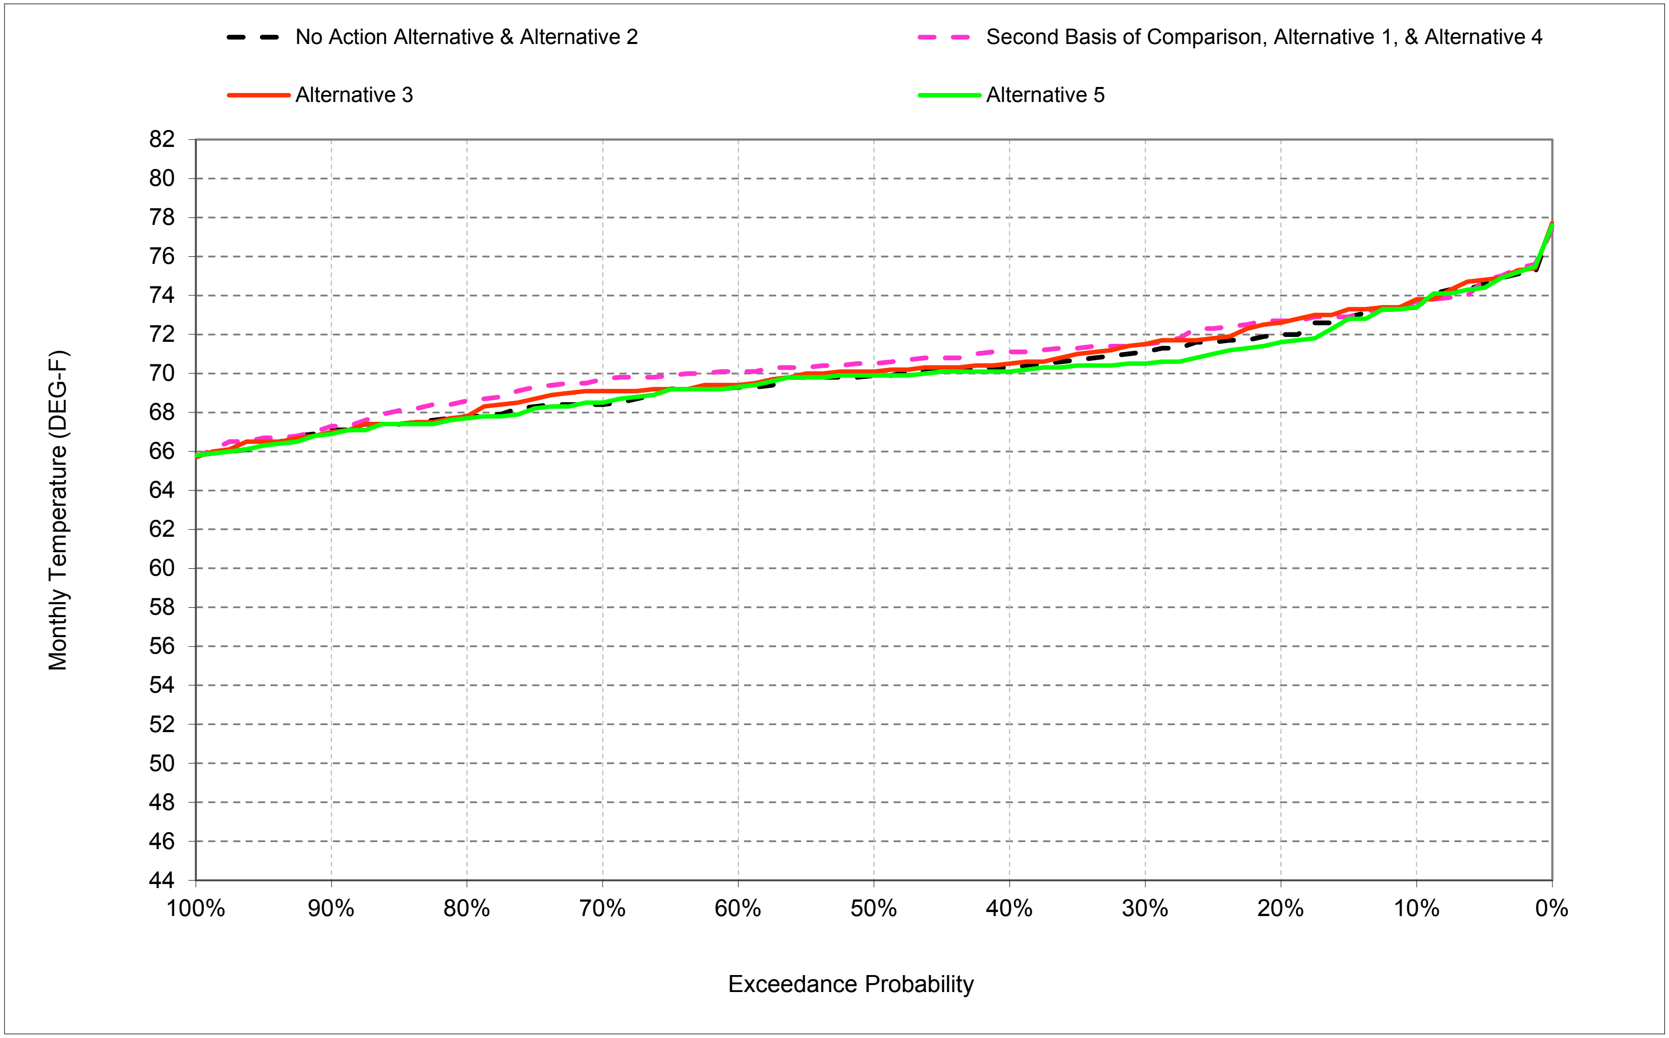
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-10. Feather River at Robinson Riffle, July



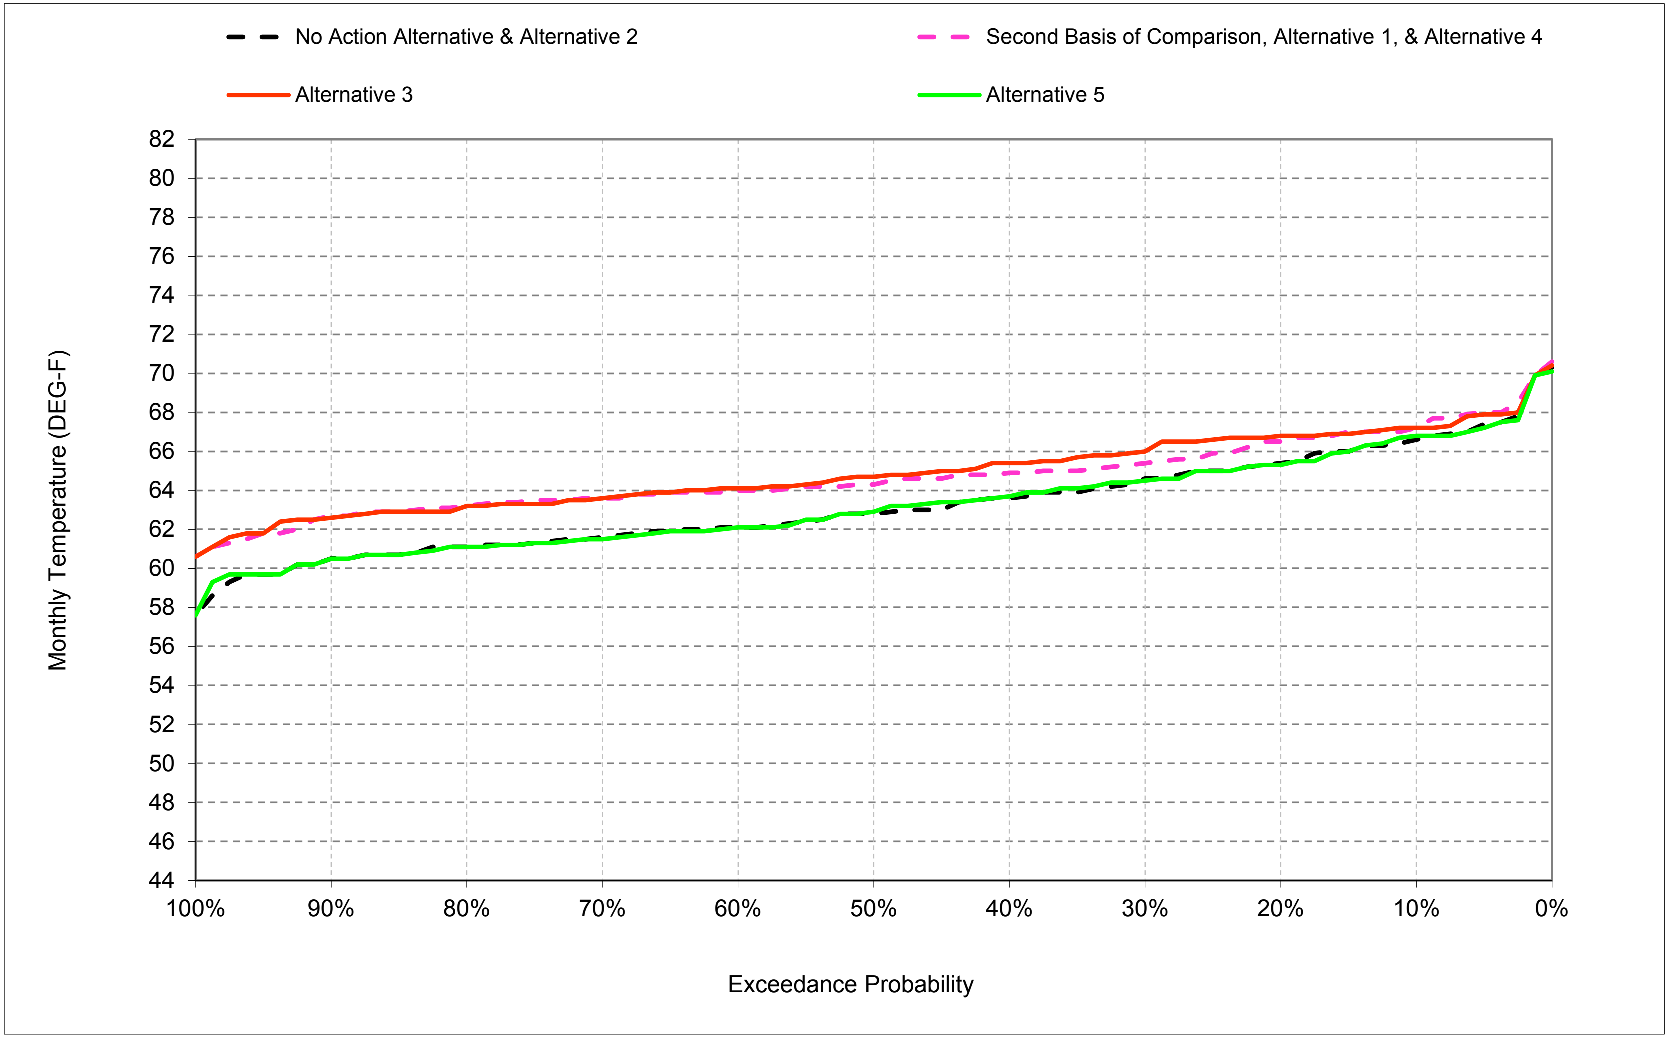
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-11. Feather River at Robinson Riffle, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-21-12. Feather River at Robinson Riffle, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

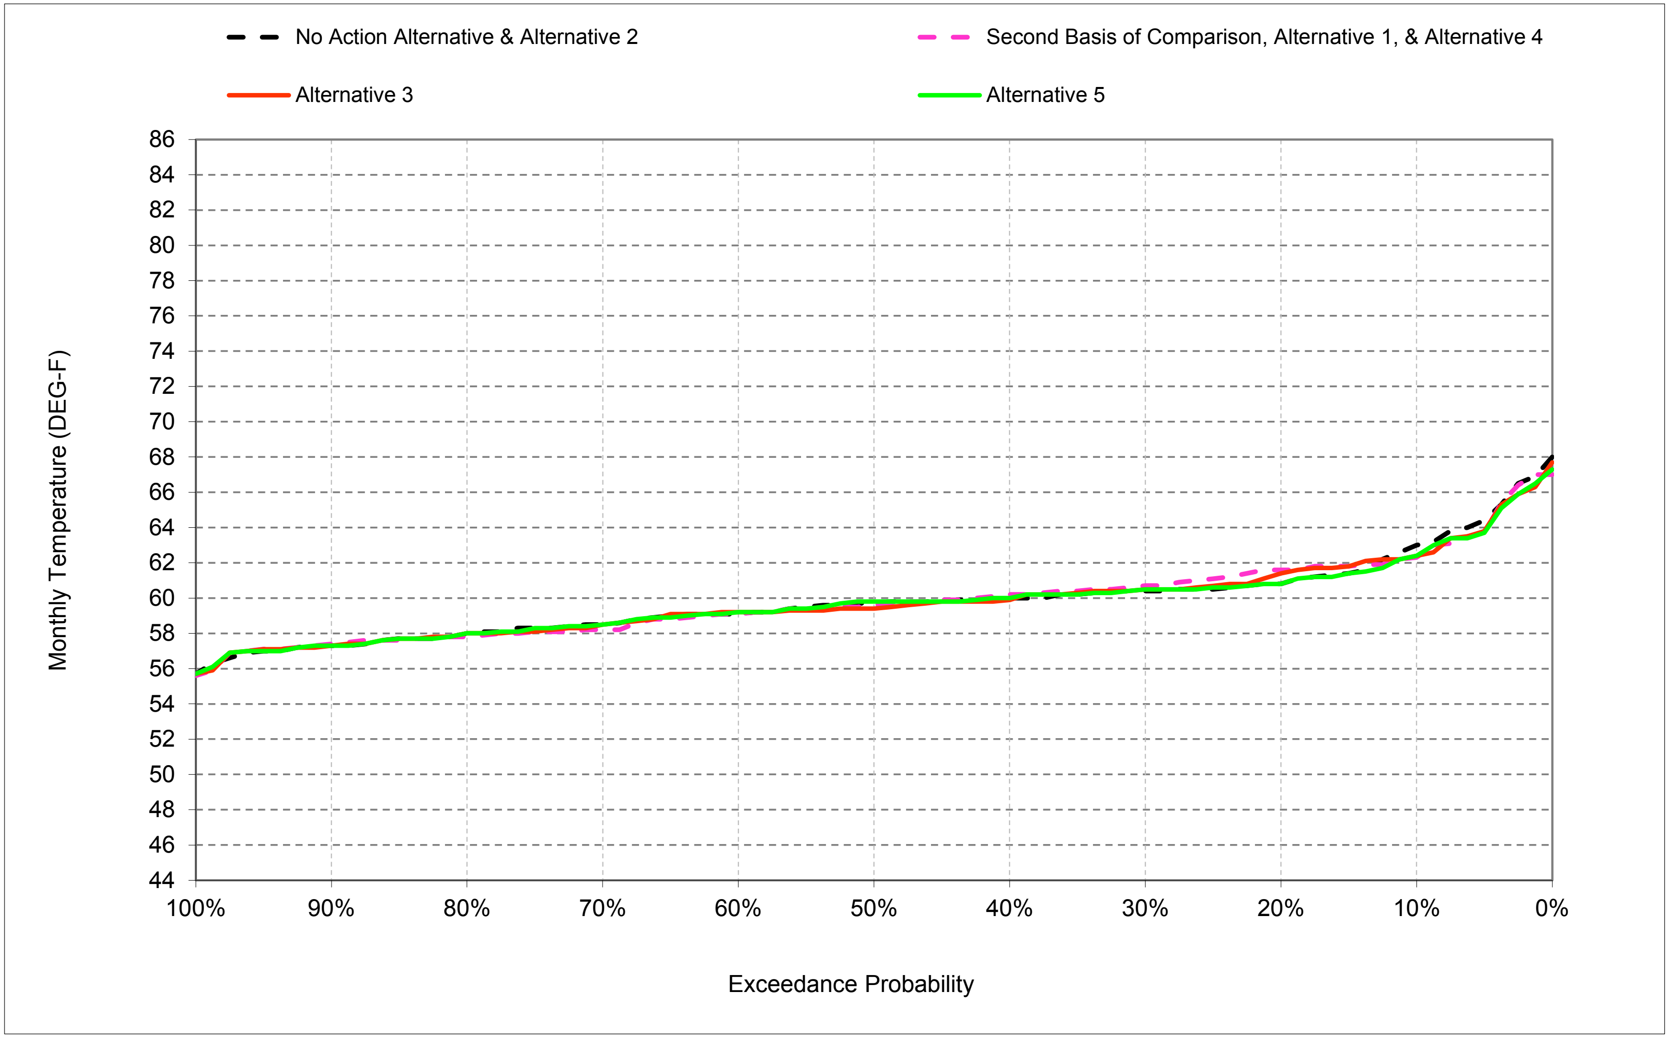
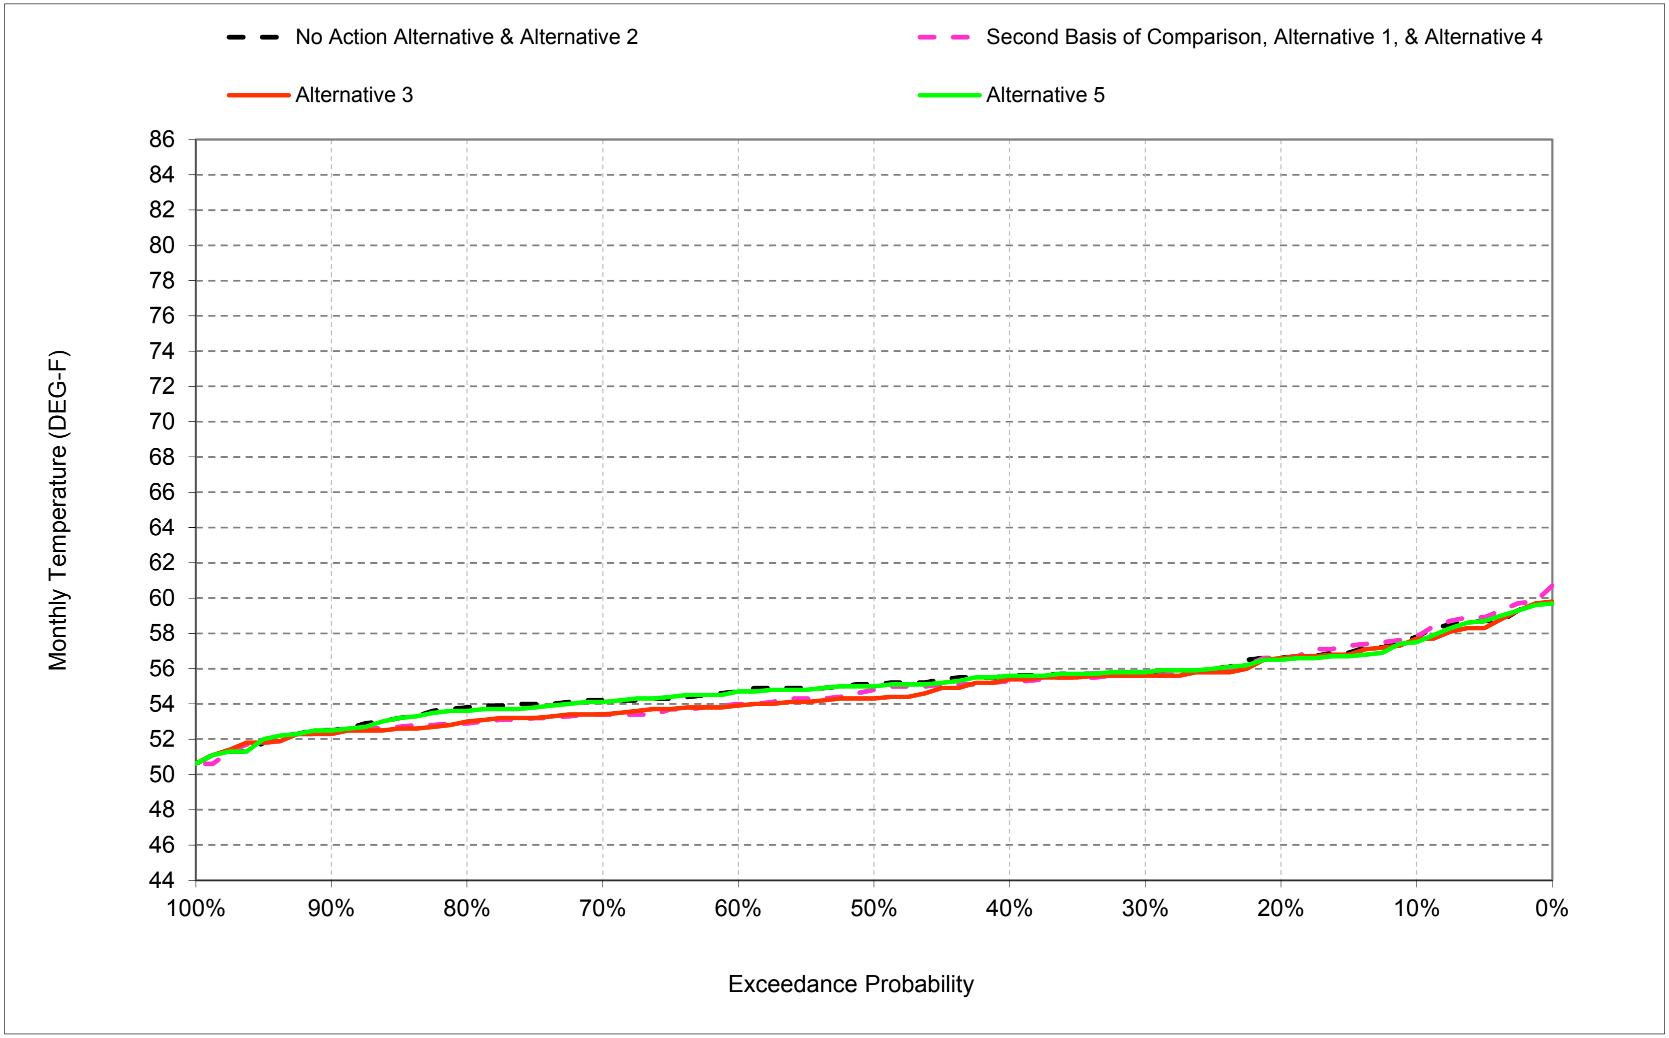
B.22. Feather River at Gridley Bridge

Figure B-22-1. Feather River at Gridley Bridge, October



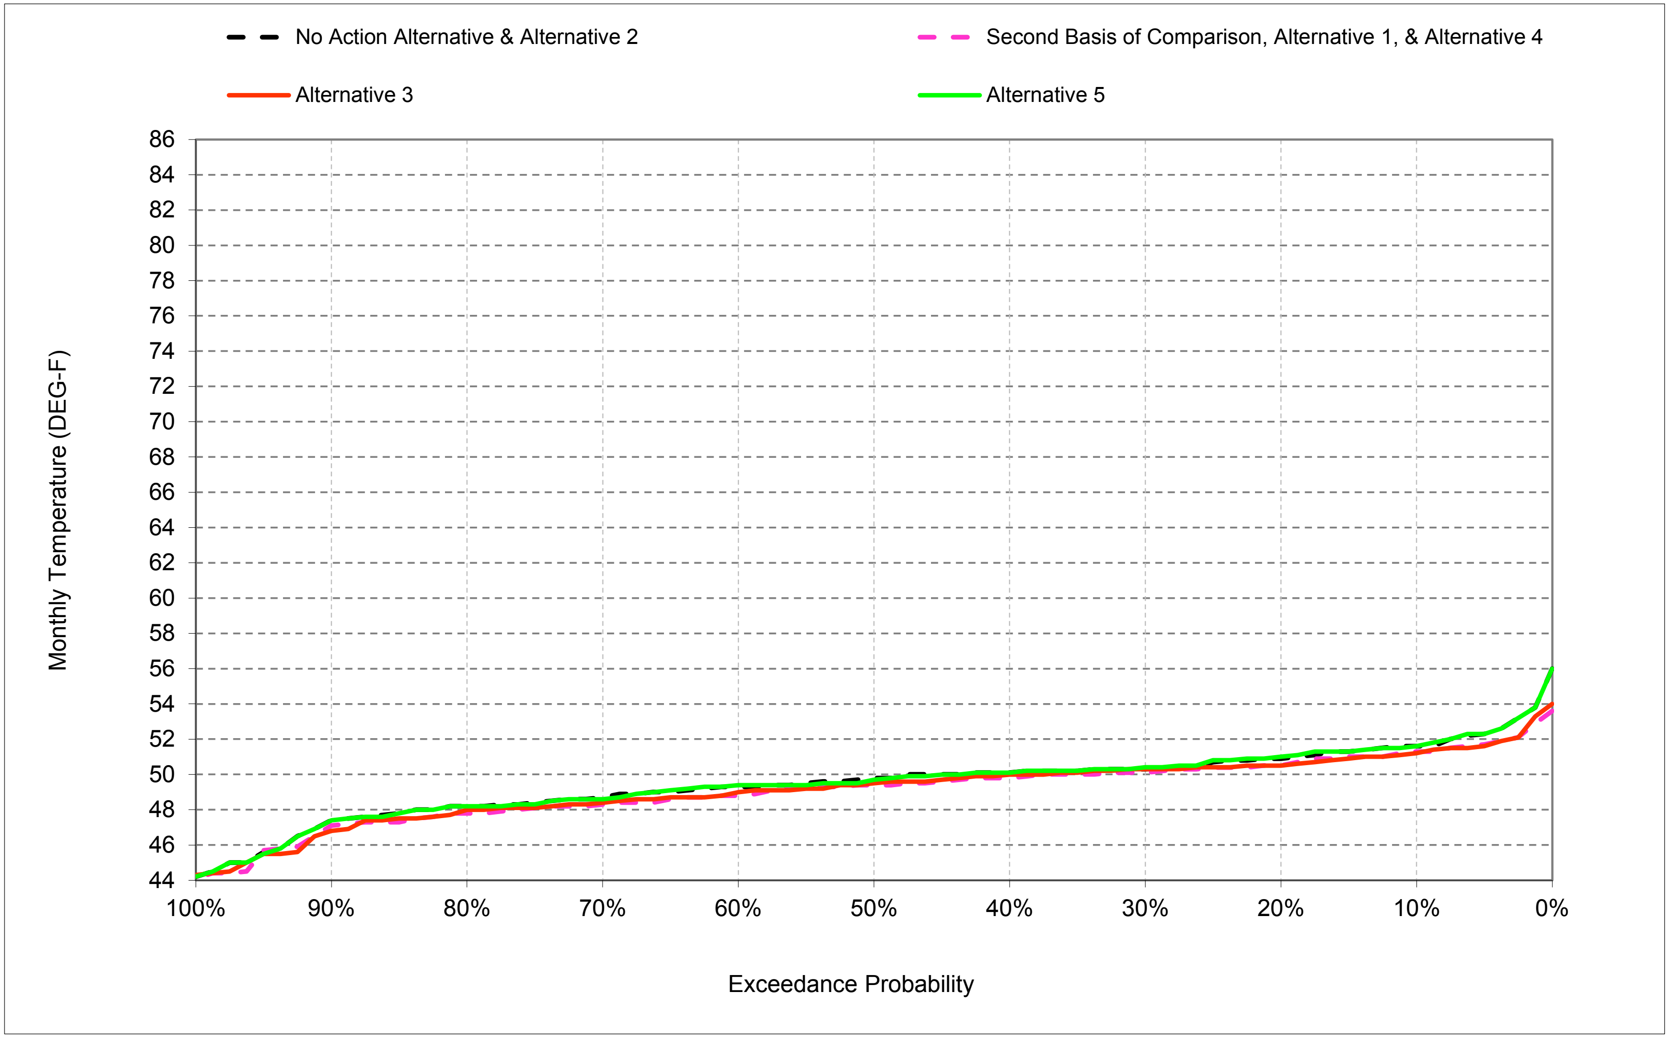
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-2. Feather River at Gridley Bridge, November



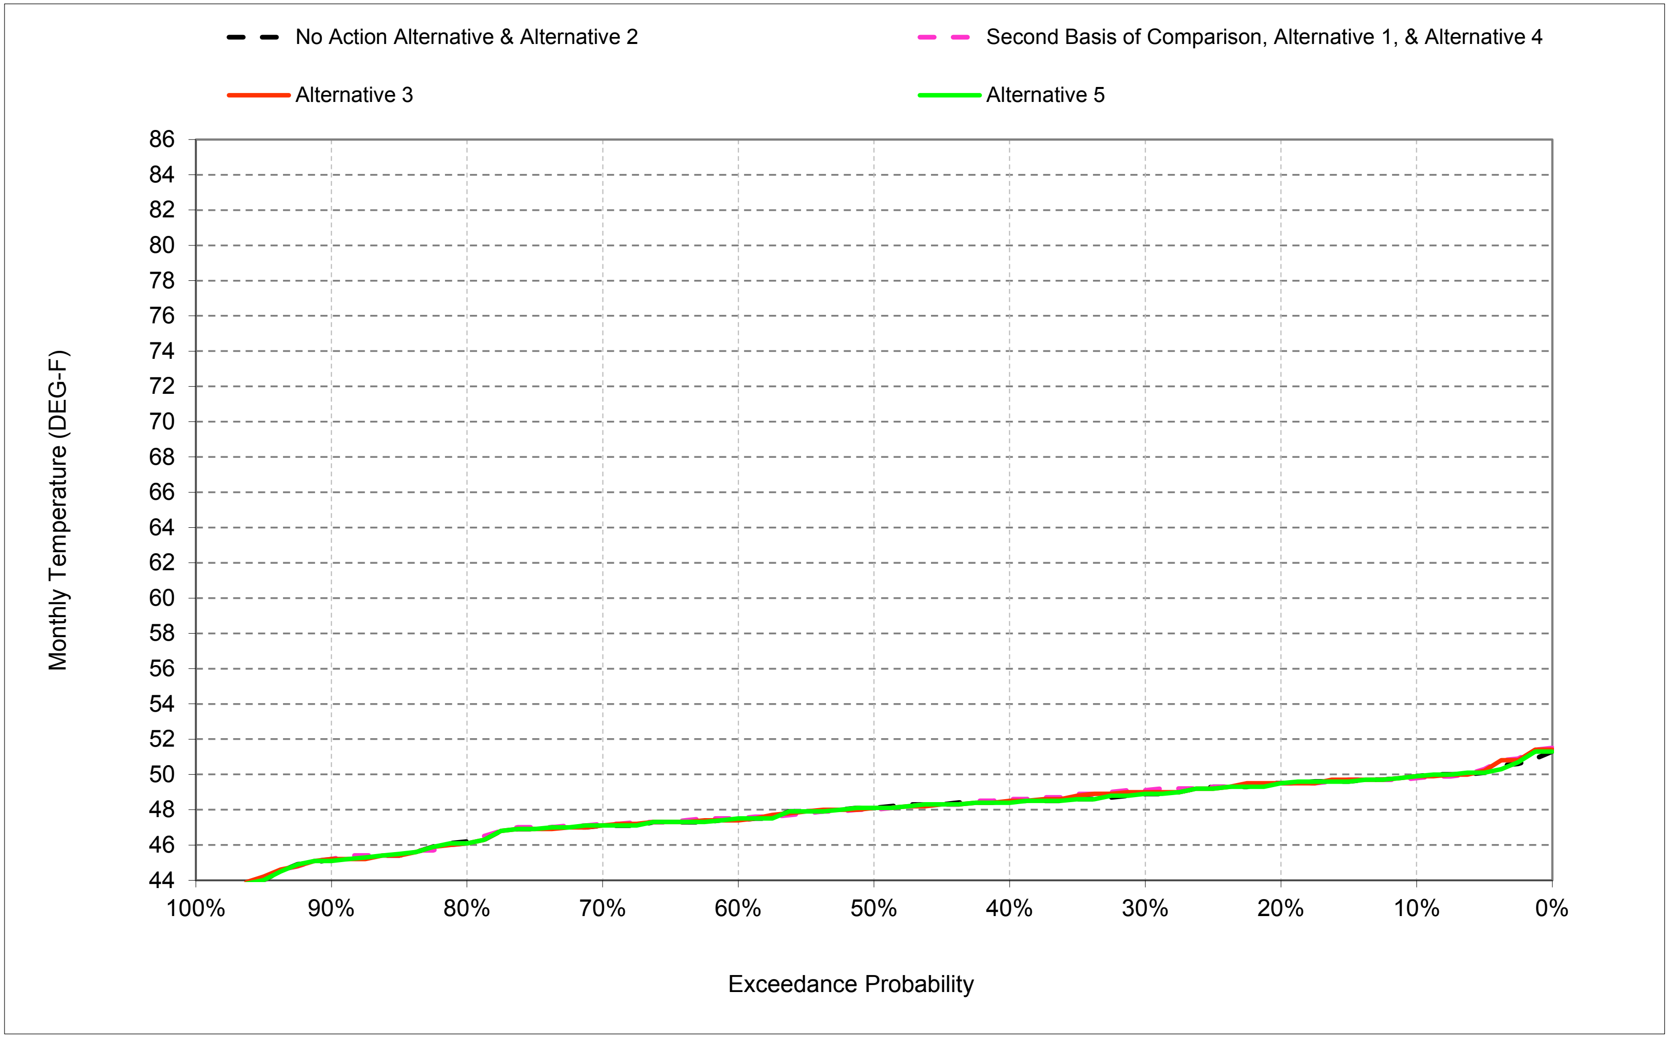
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-3. Feather River at Gridley Bridge, December



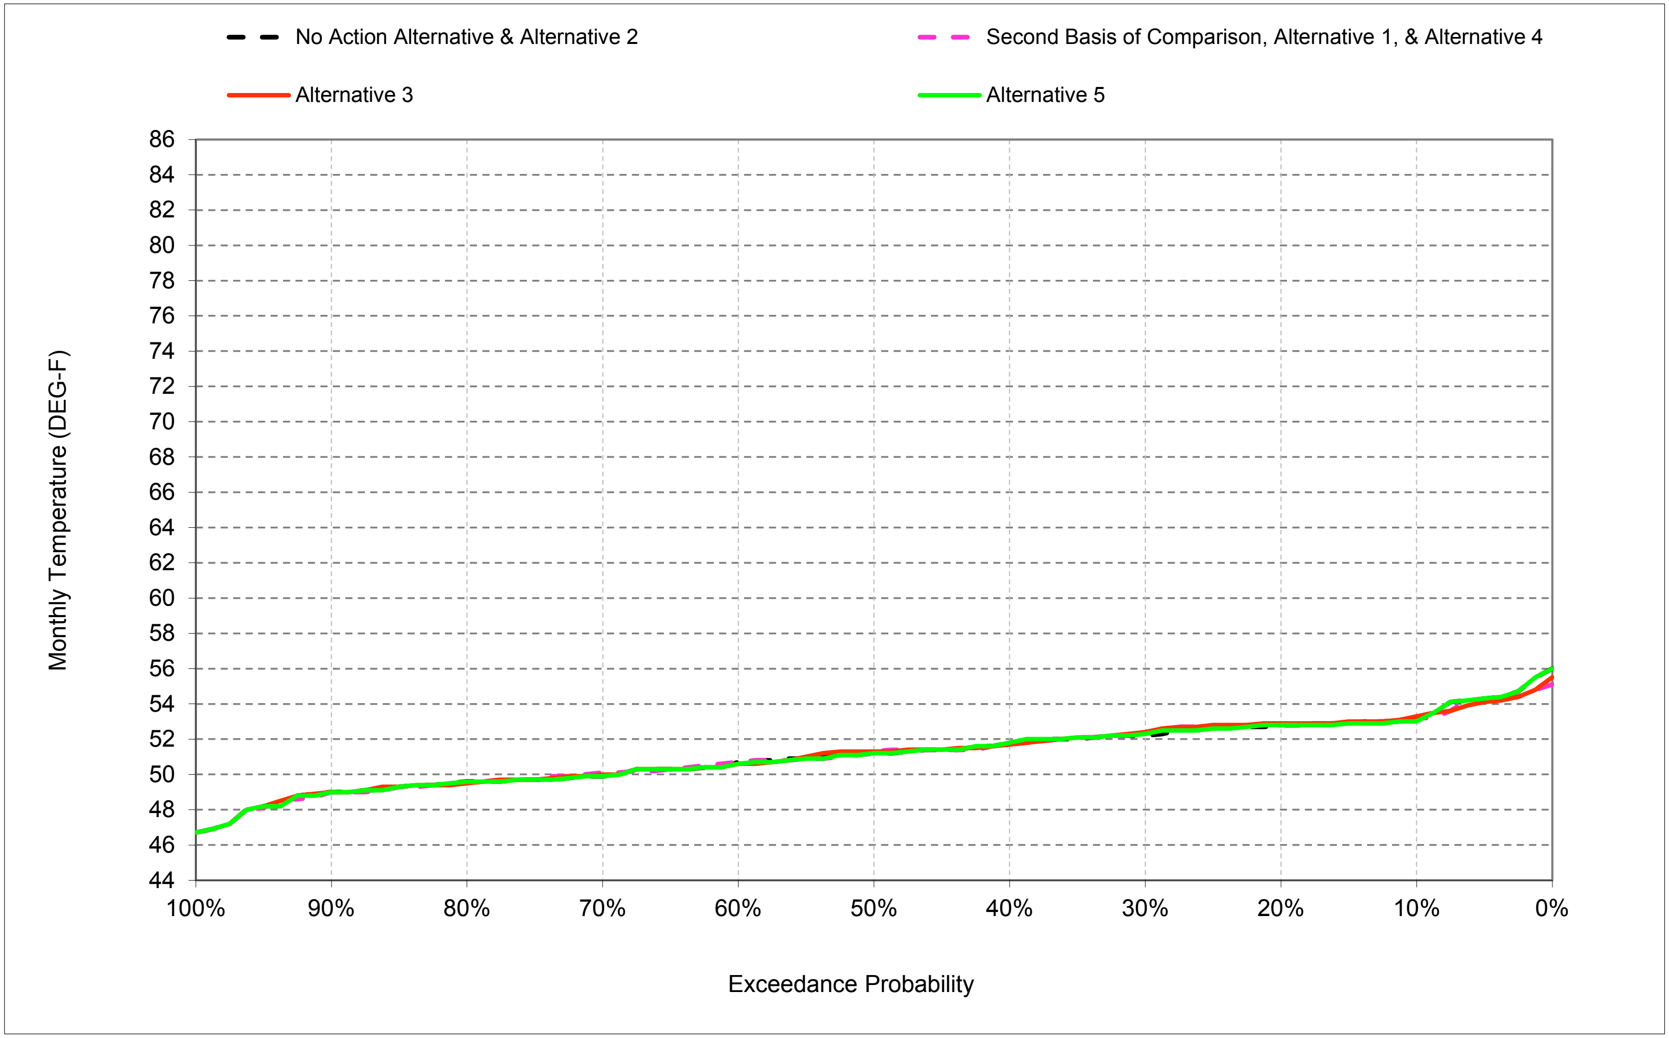
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-4. Feather River at Gridley Bridge, January



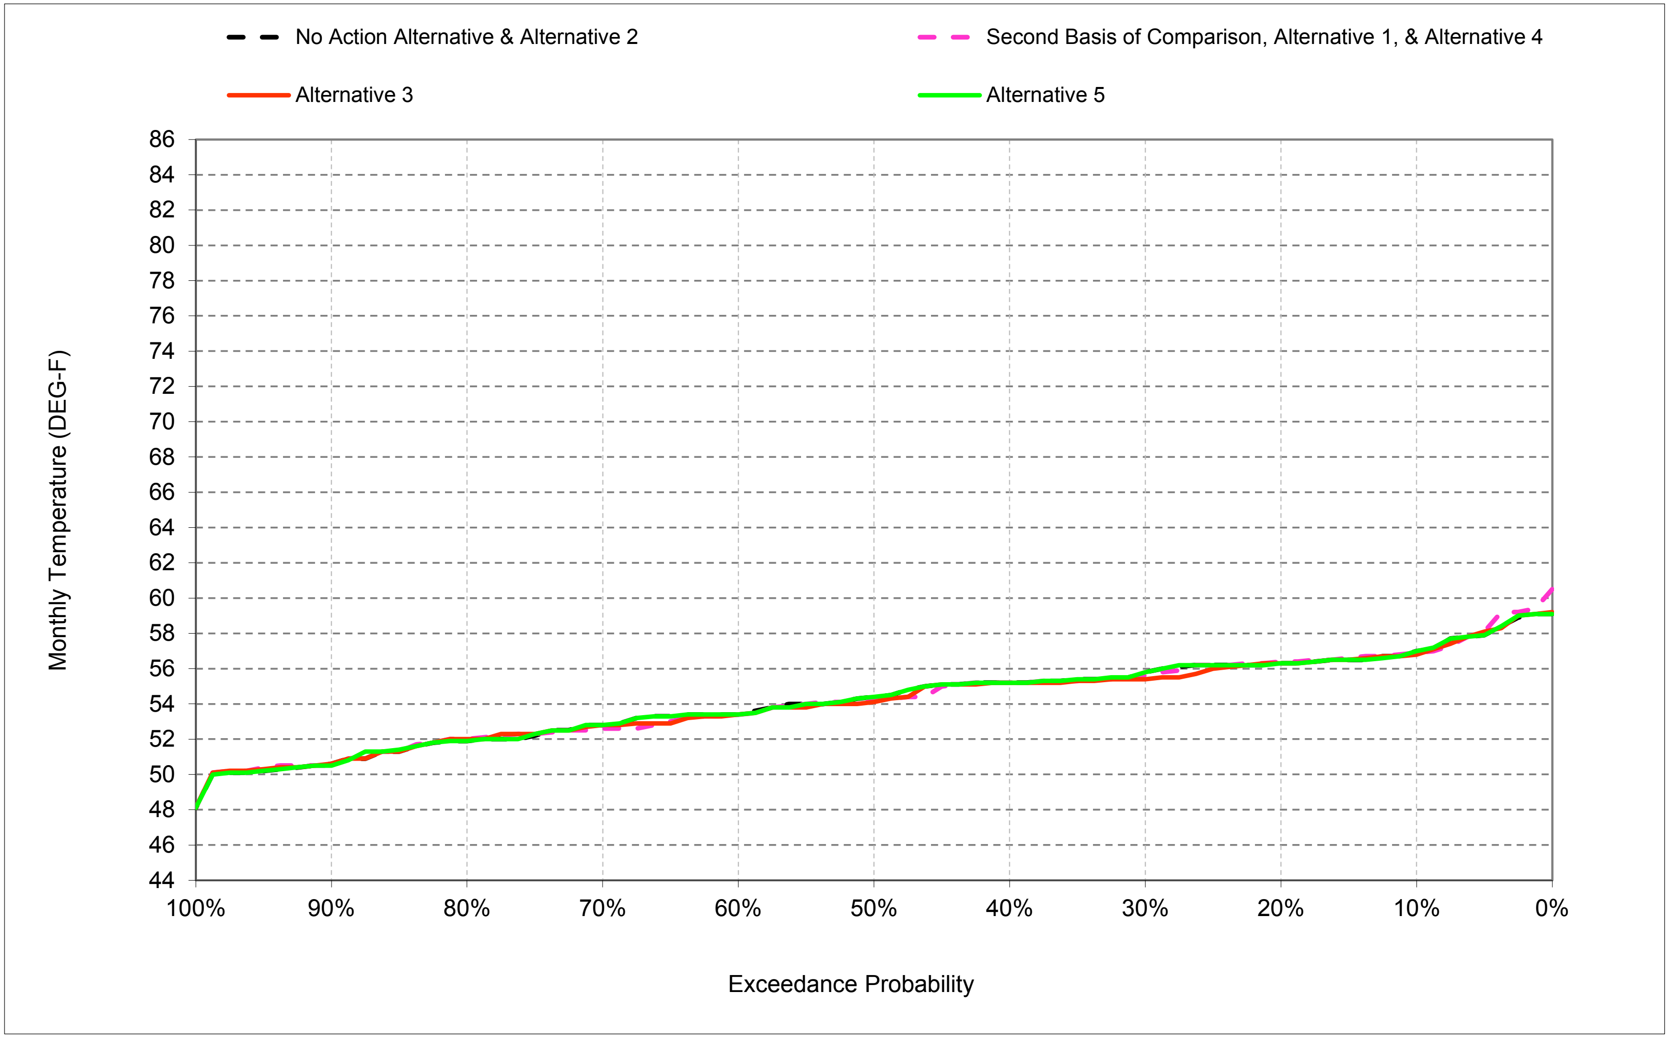
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-5. Feather River at Gridley Bridge, February



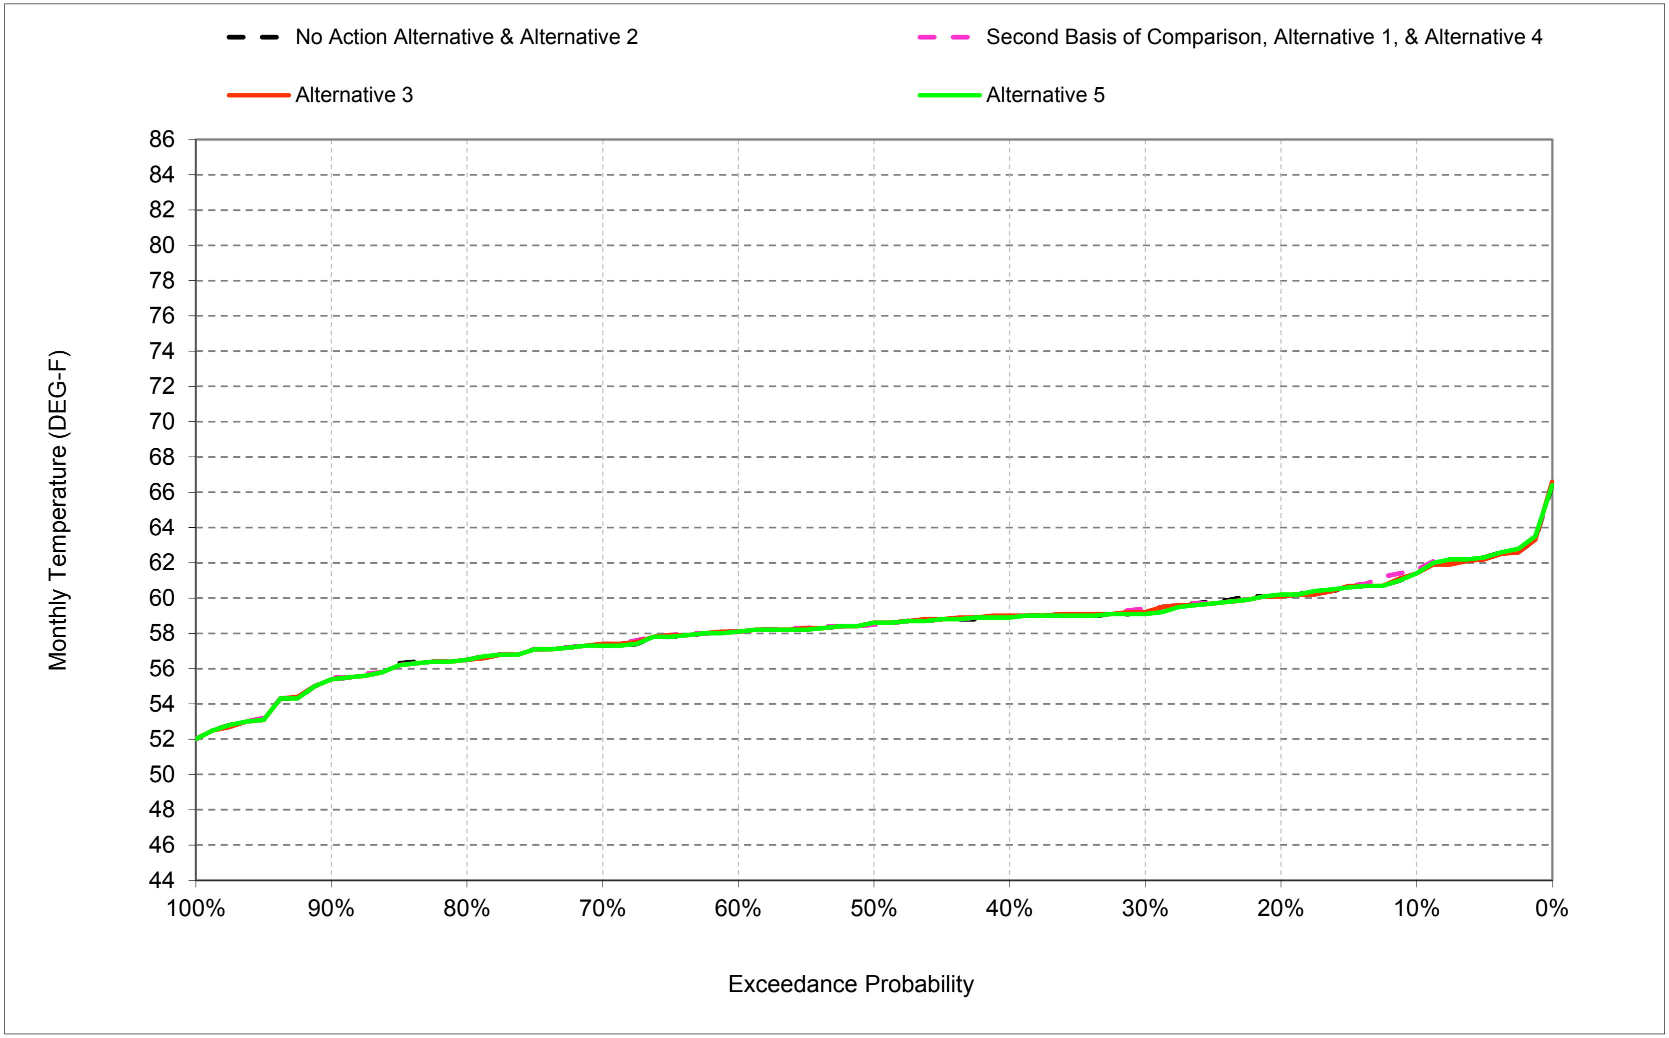
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-6. Feather River at Gridley Bridge, March



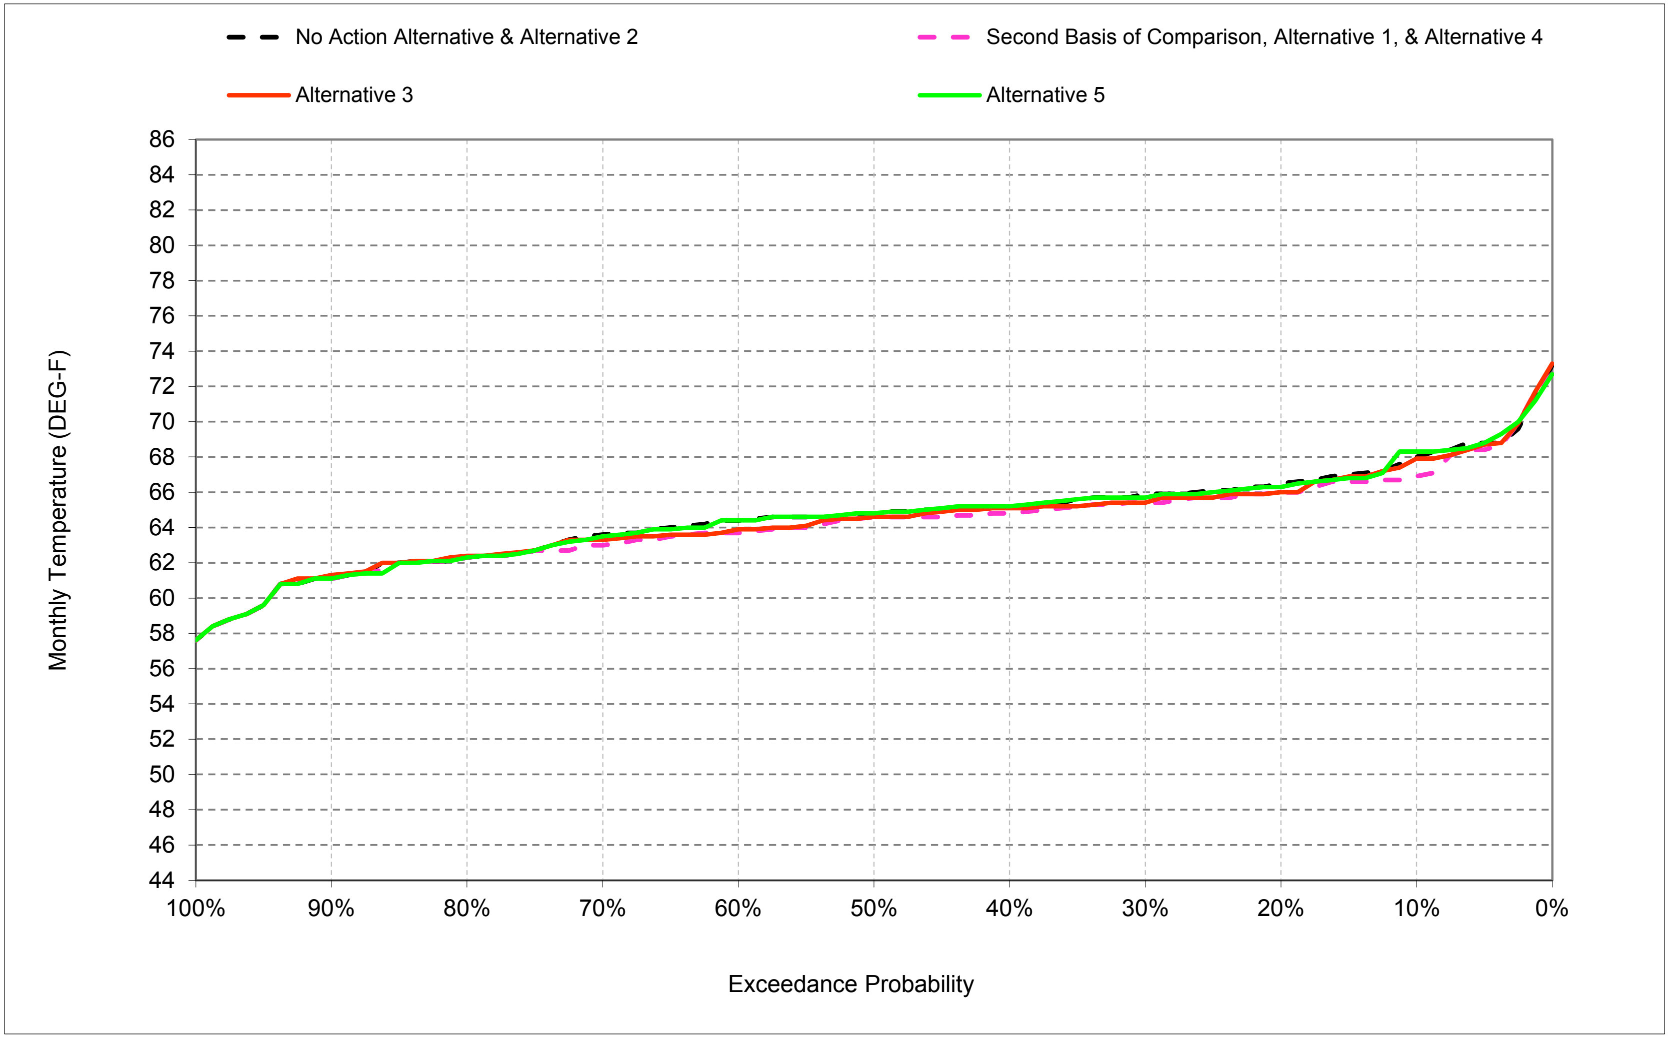
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-7. Feather River at Gridley Bridge, April



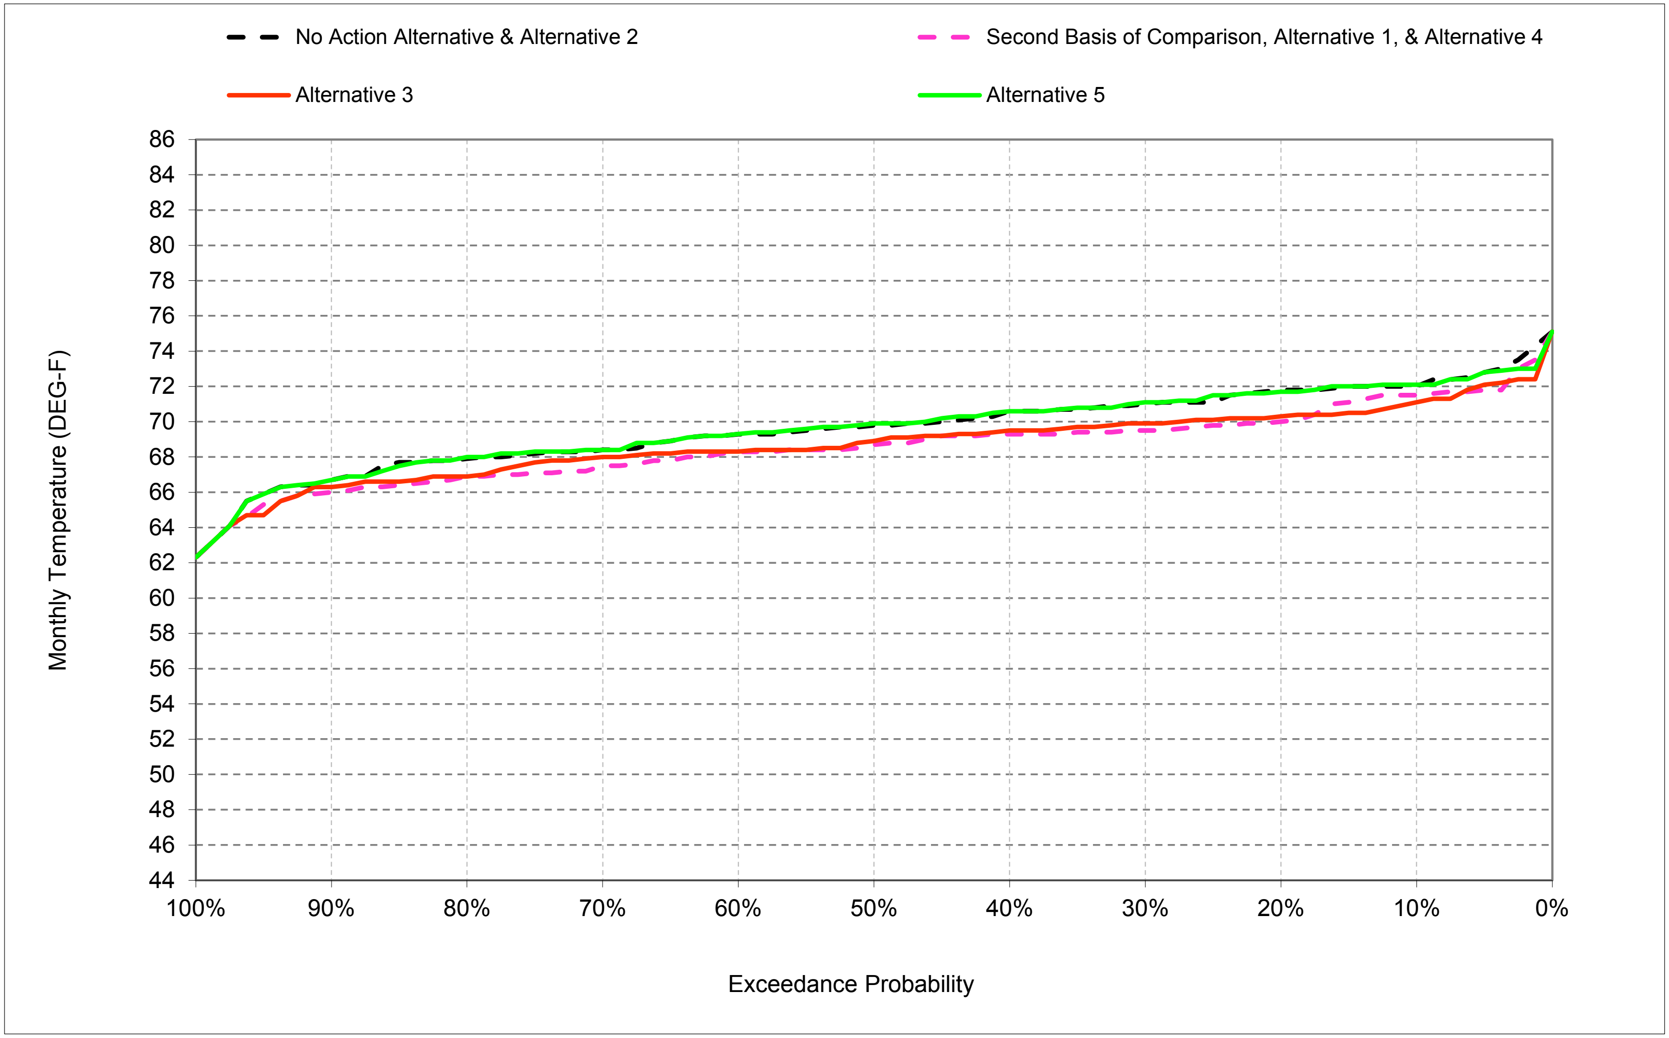
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-8. Feather River at Gridley Bridge, May



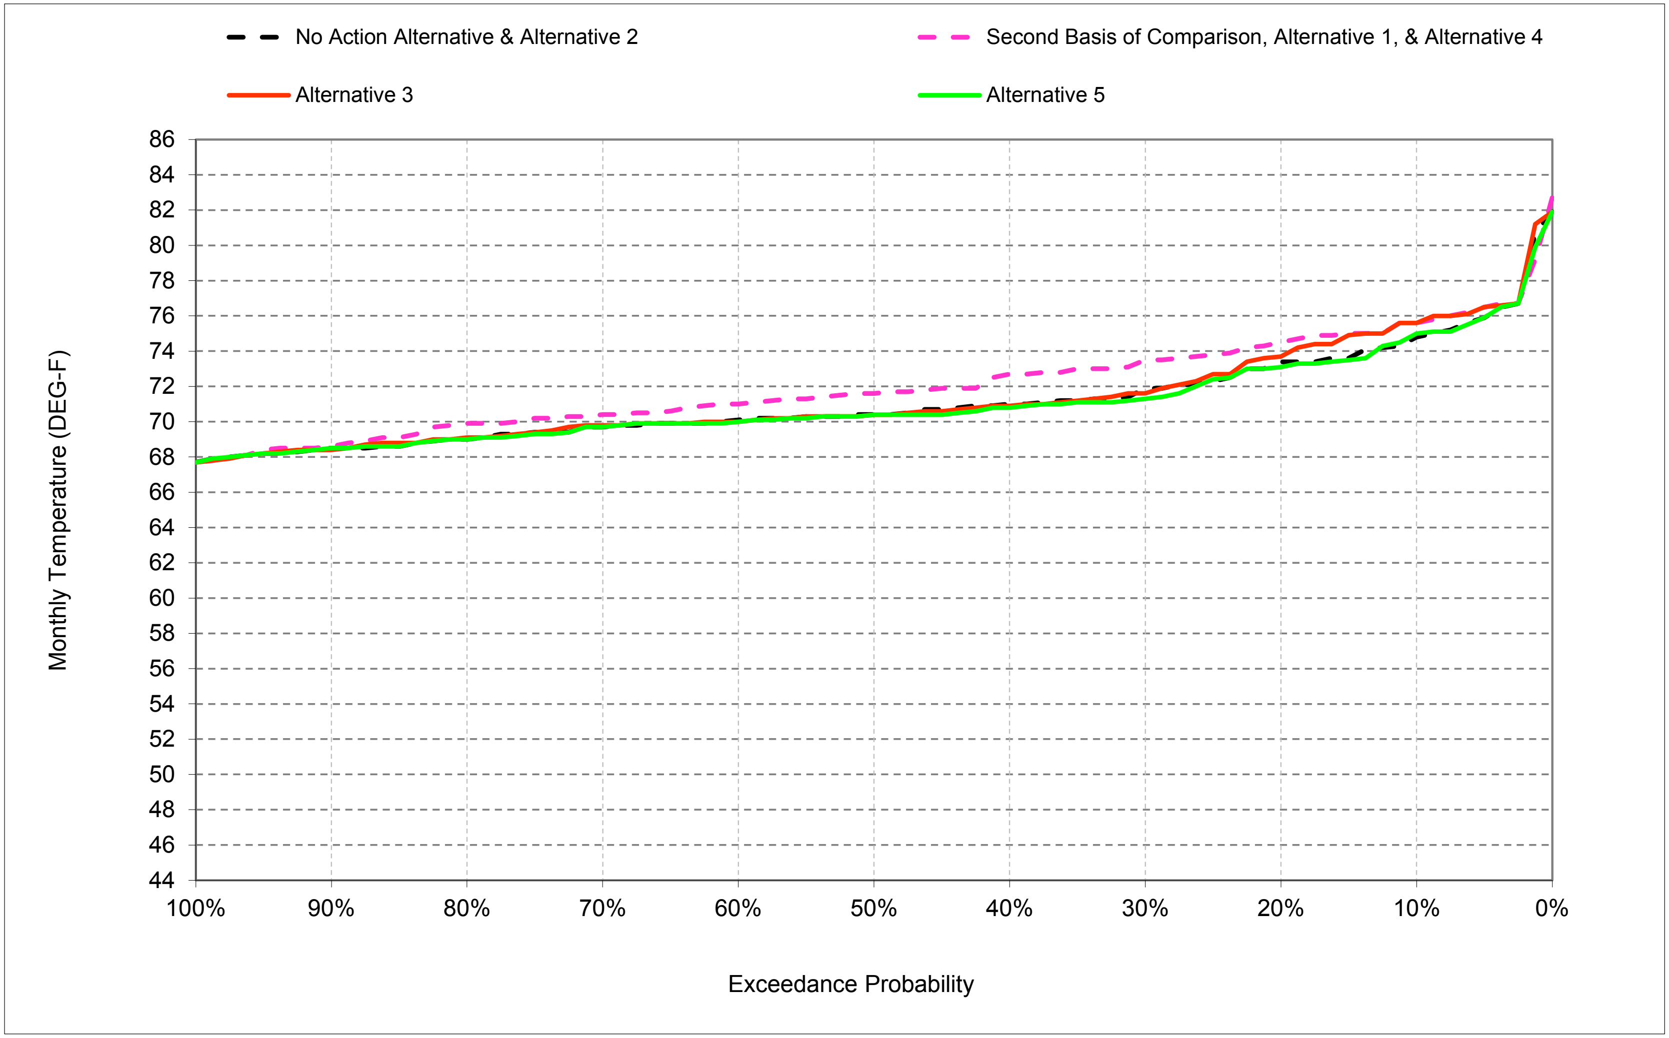
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-9. Feather River at Gridley Bridge, June



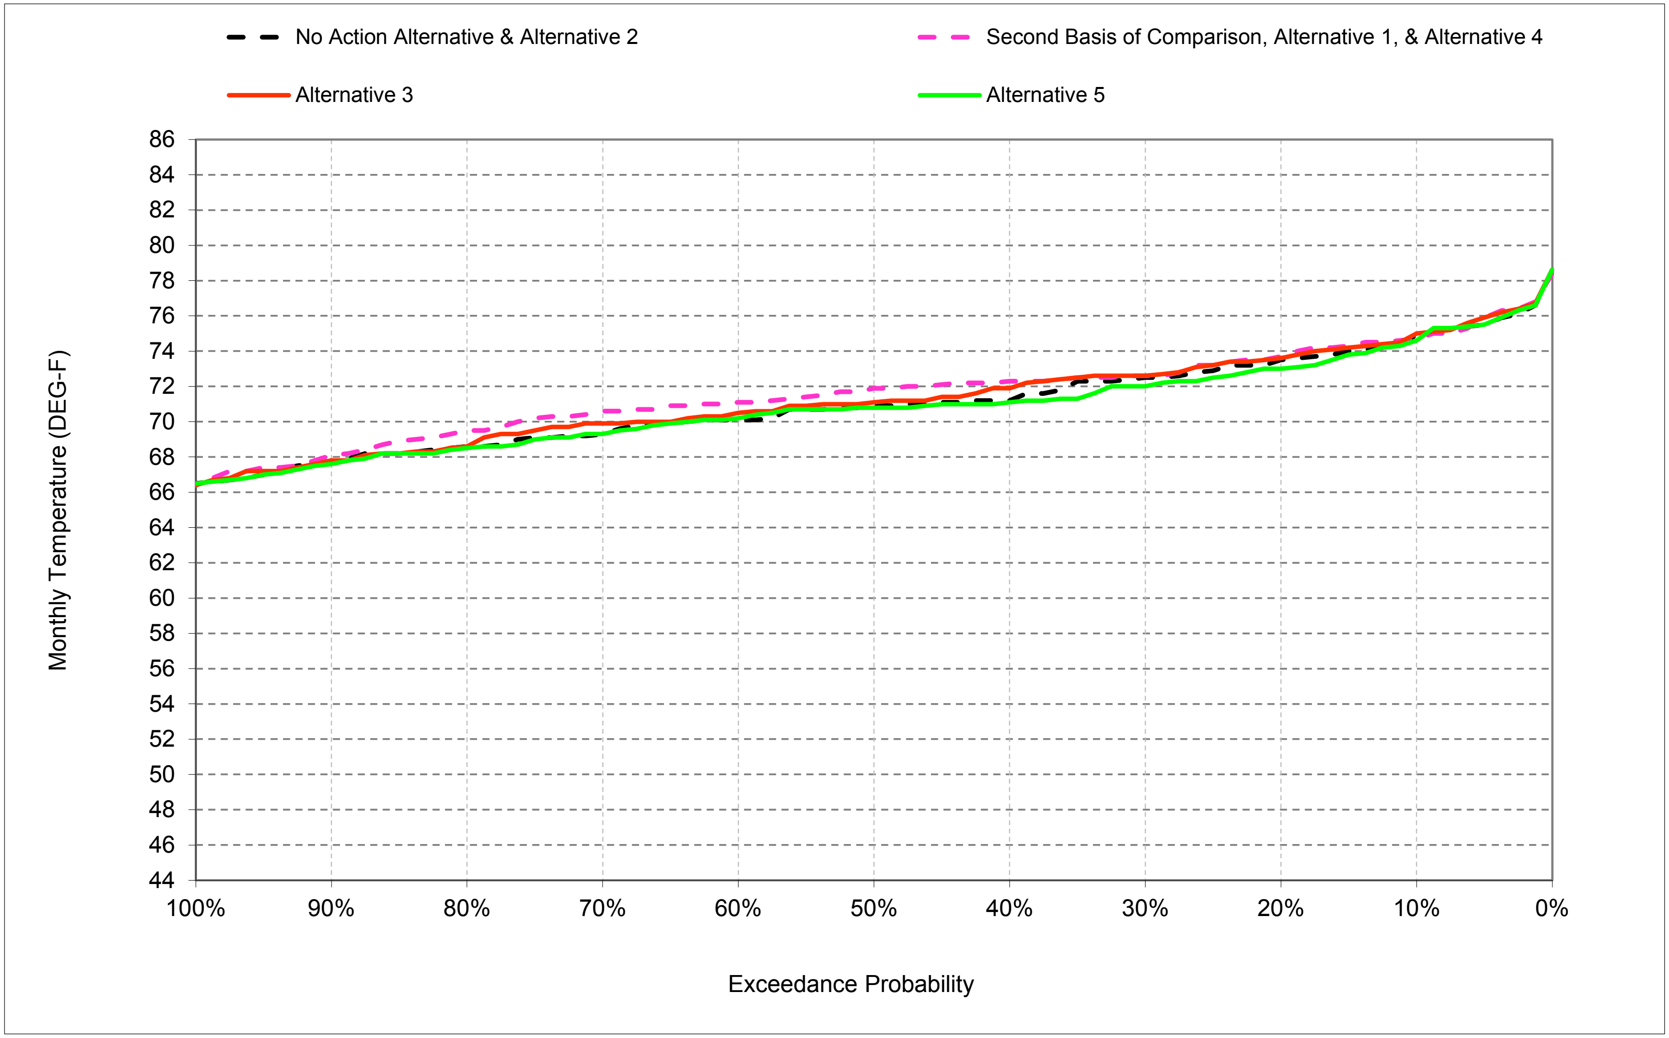
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-10. Feather River at Gridley Bridge, July



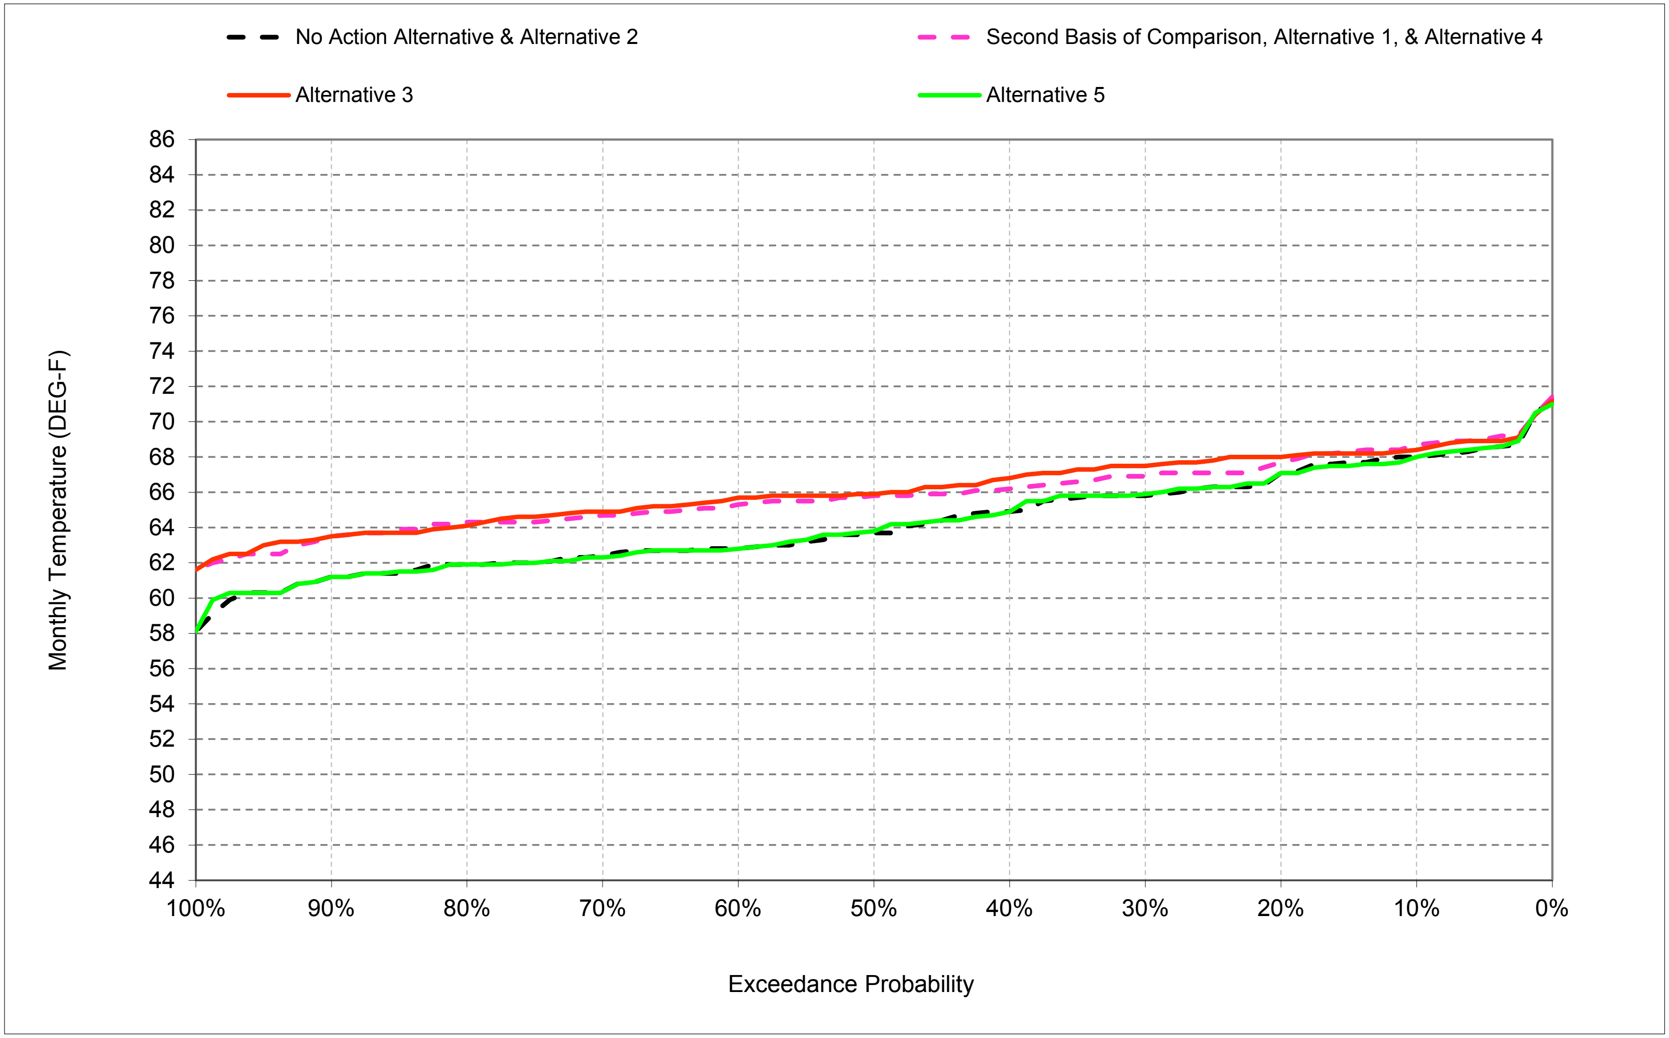
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-11. Feather River at Gridley Bridge, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-22-12. Feather River at Gridley Bridge, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

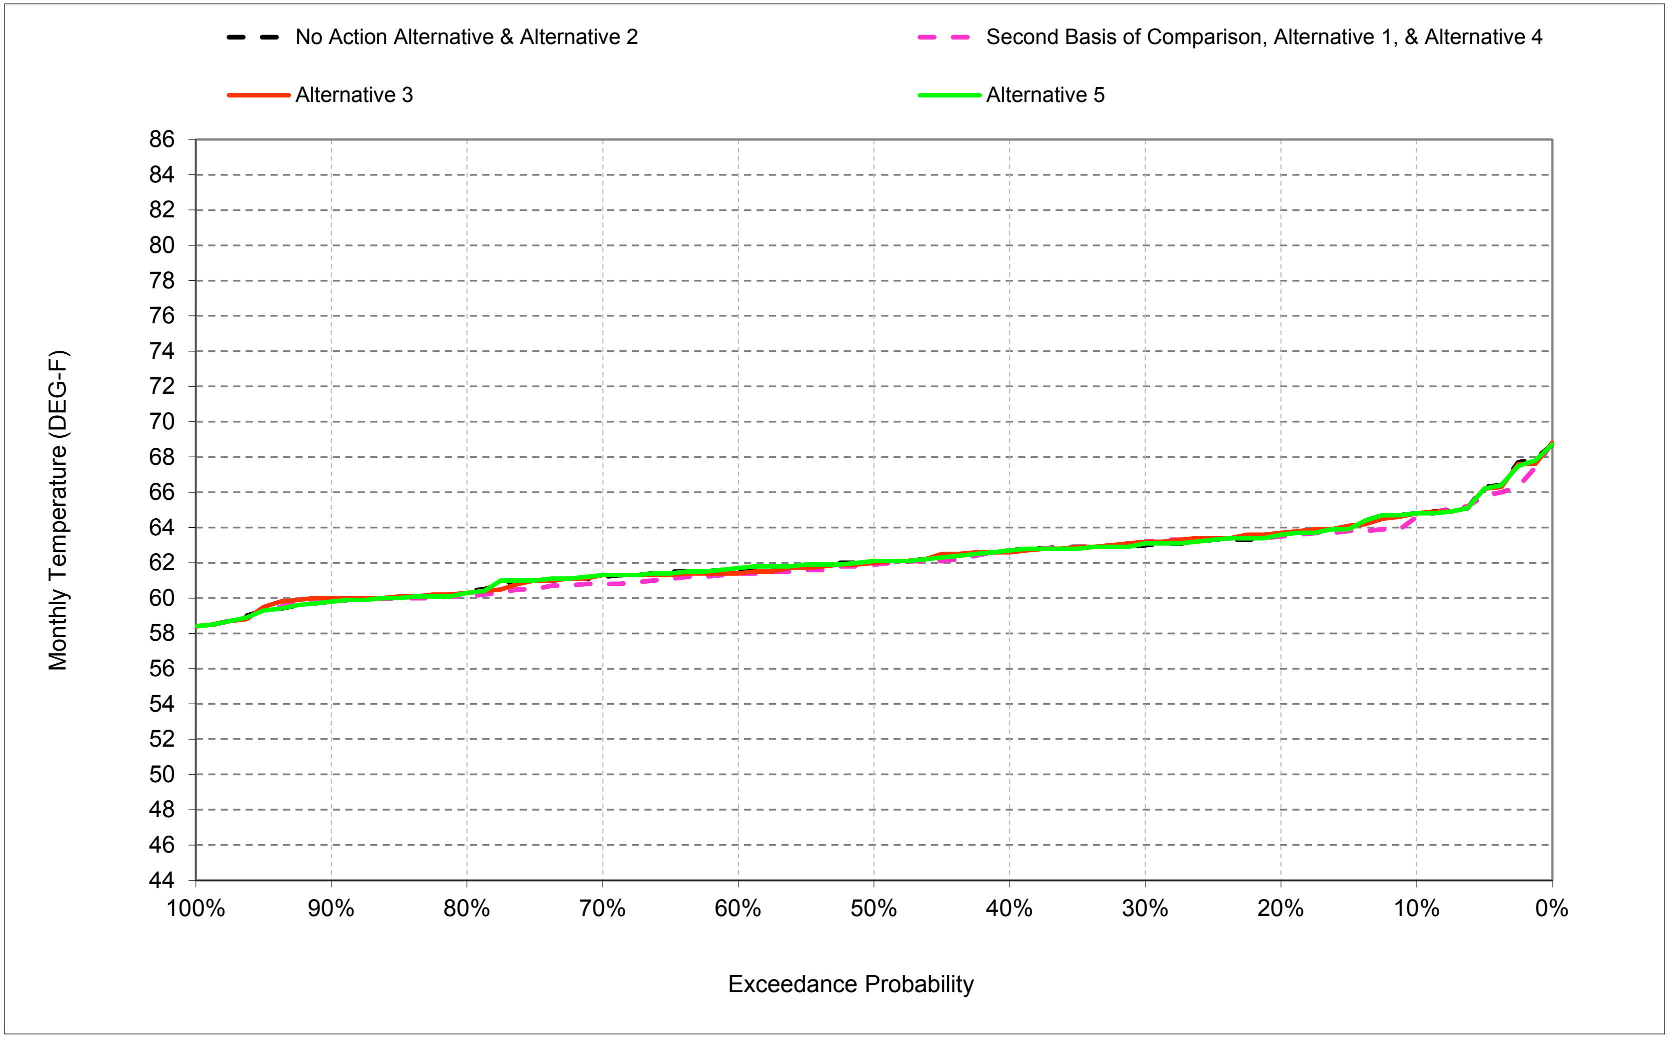
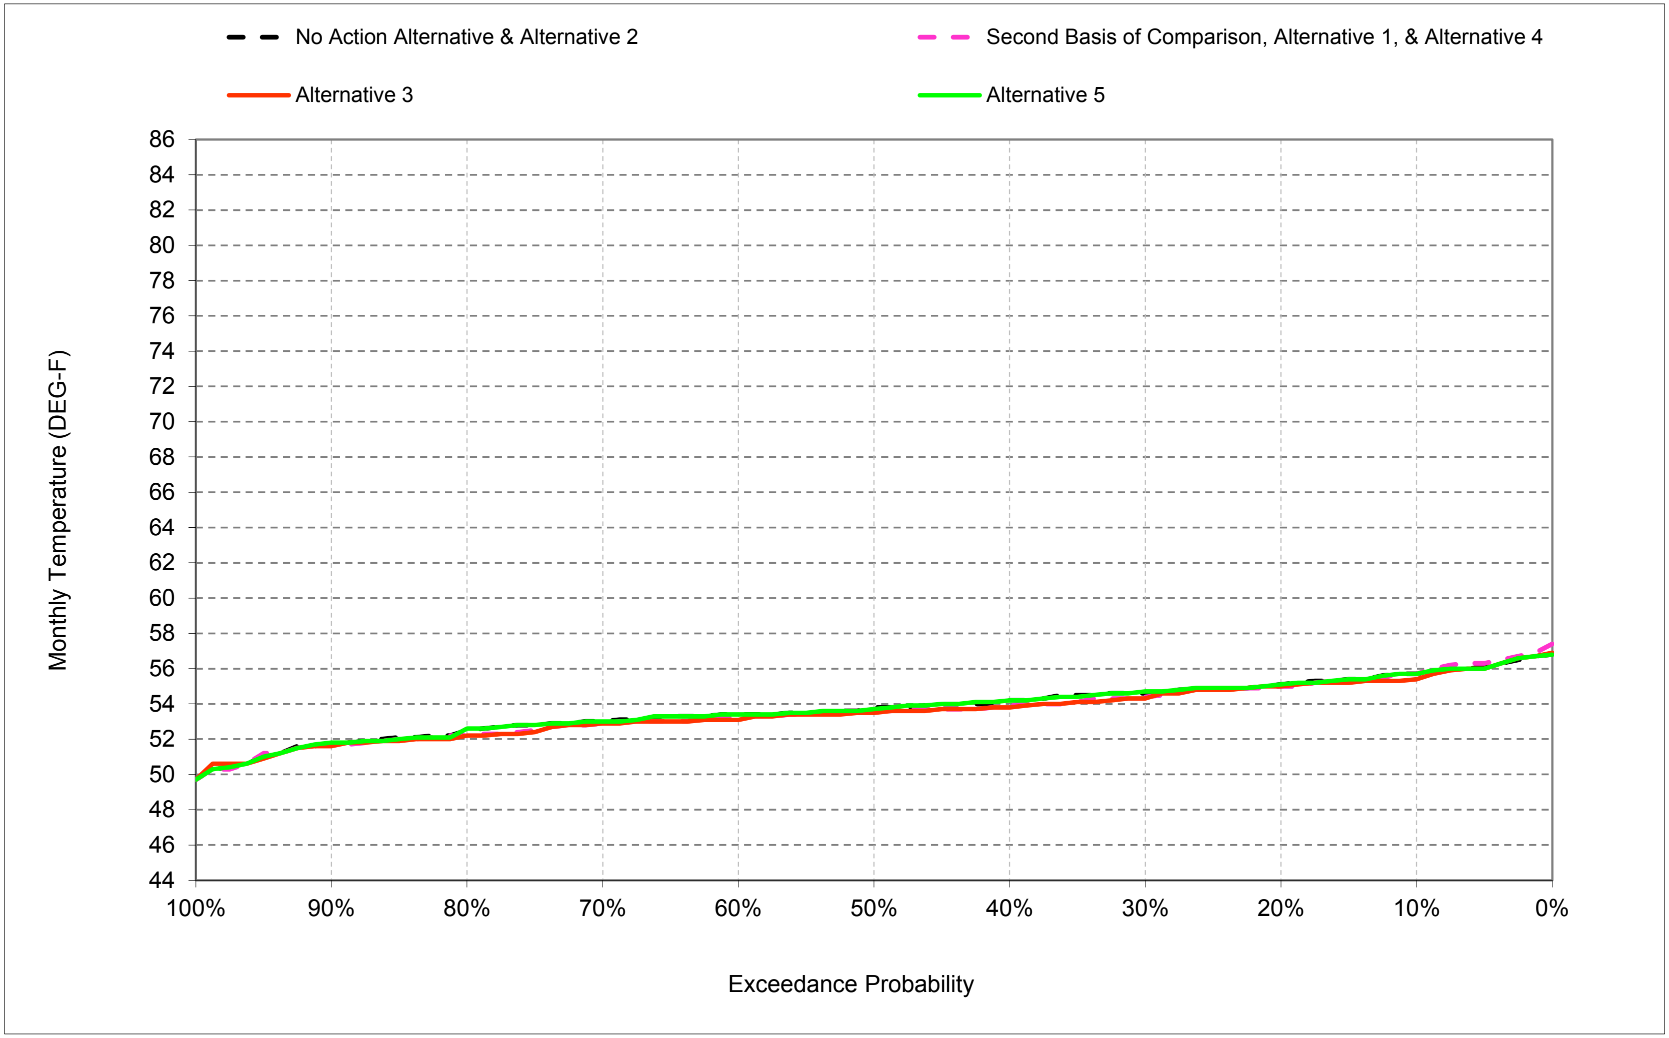
B.23. Feather River at Mouth

Figure B-23-1. Feather River at Mouth, October



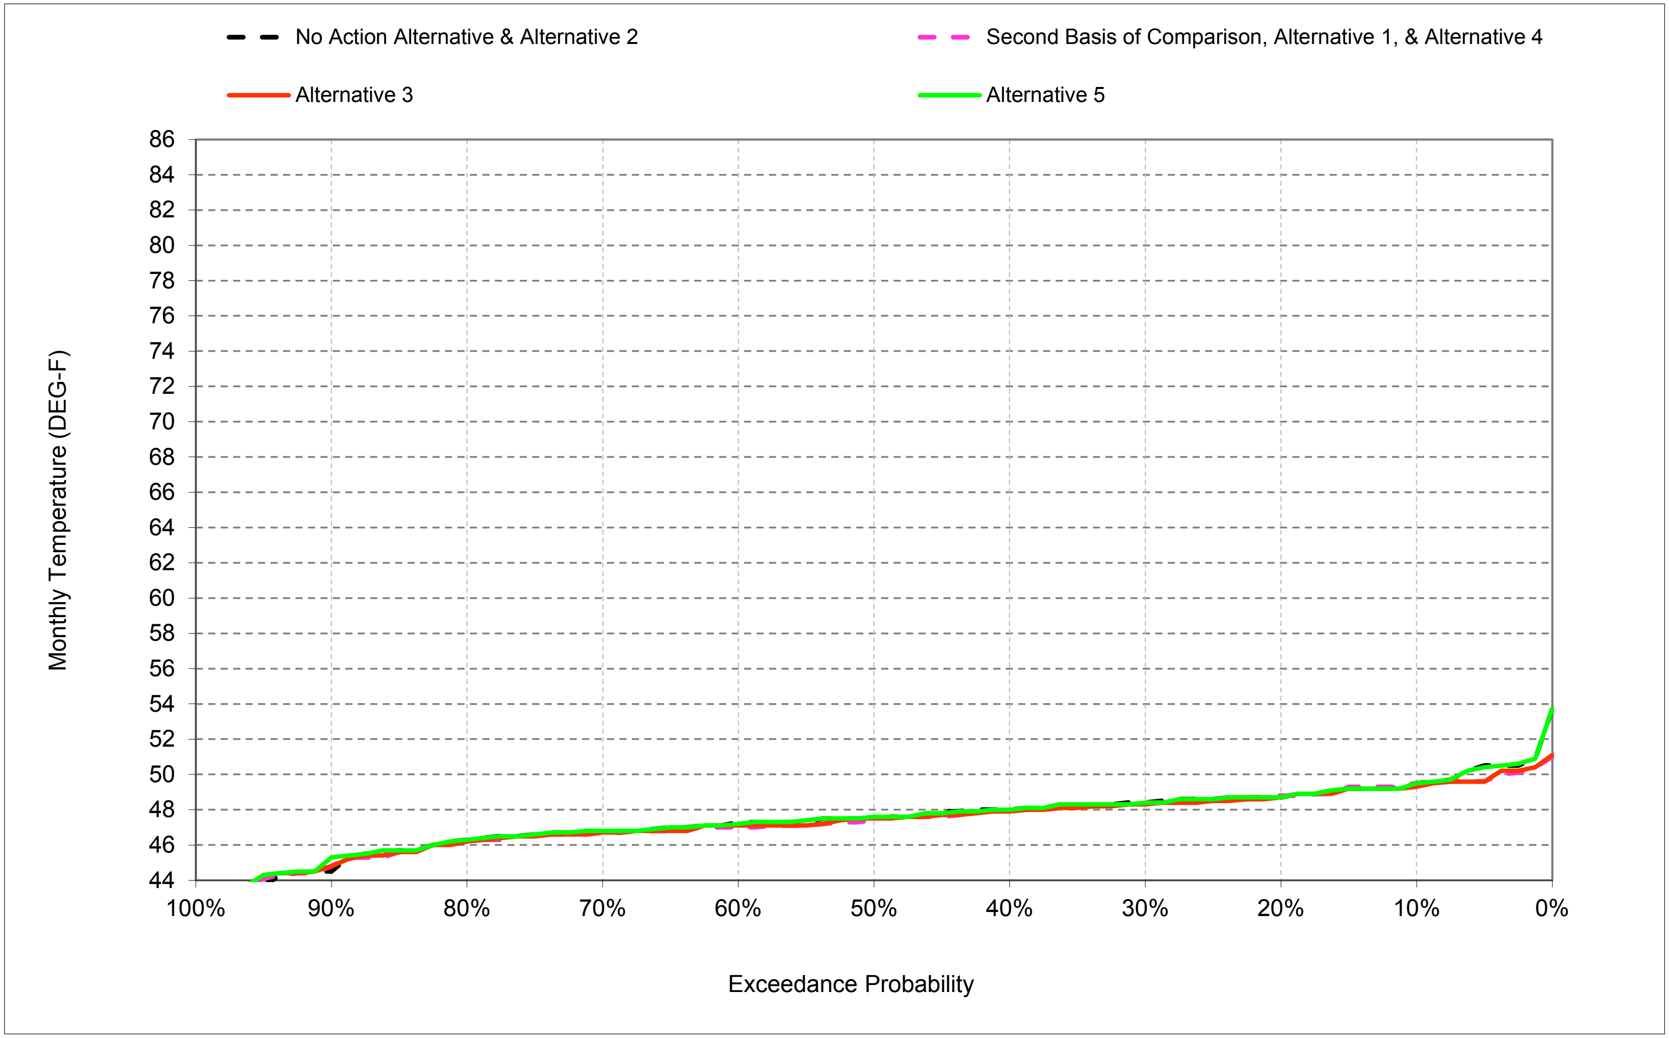
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-2. Feather River at Mouth, November



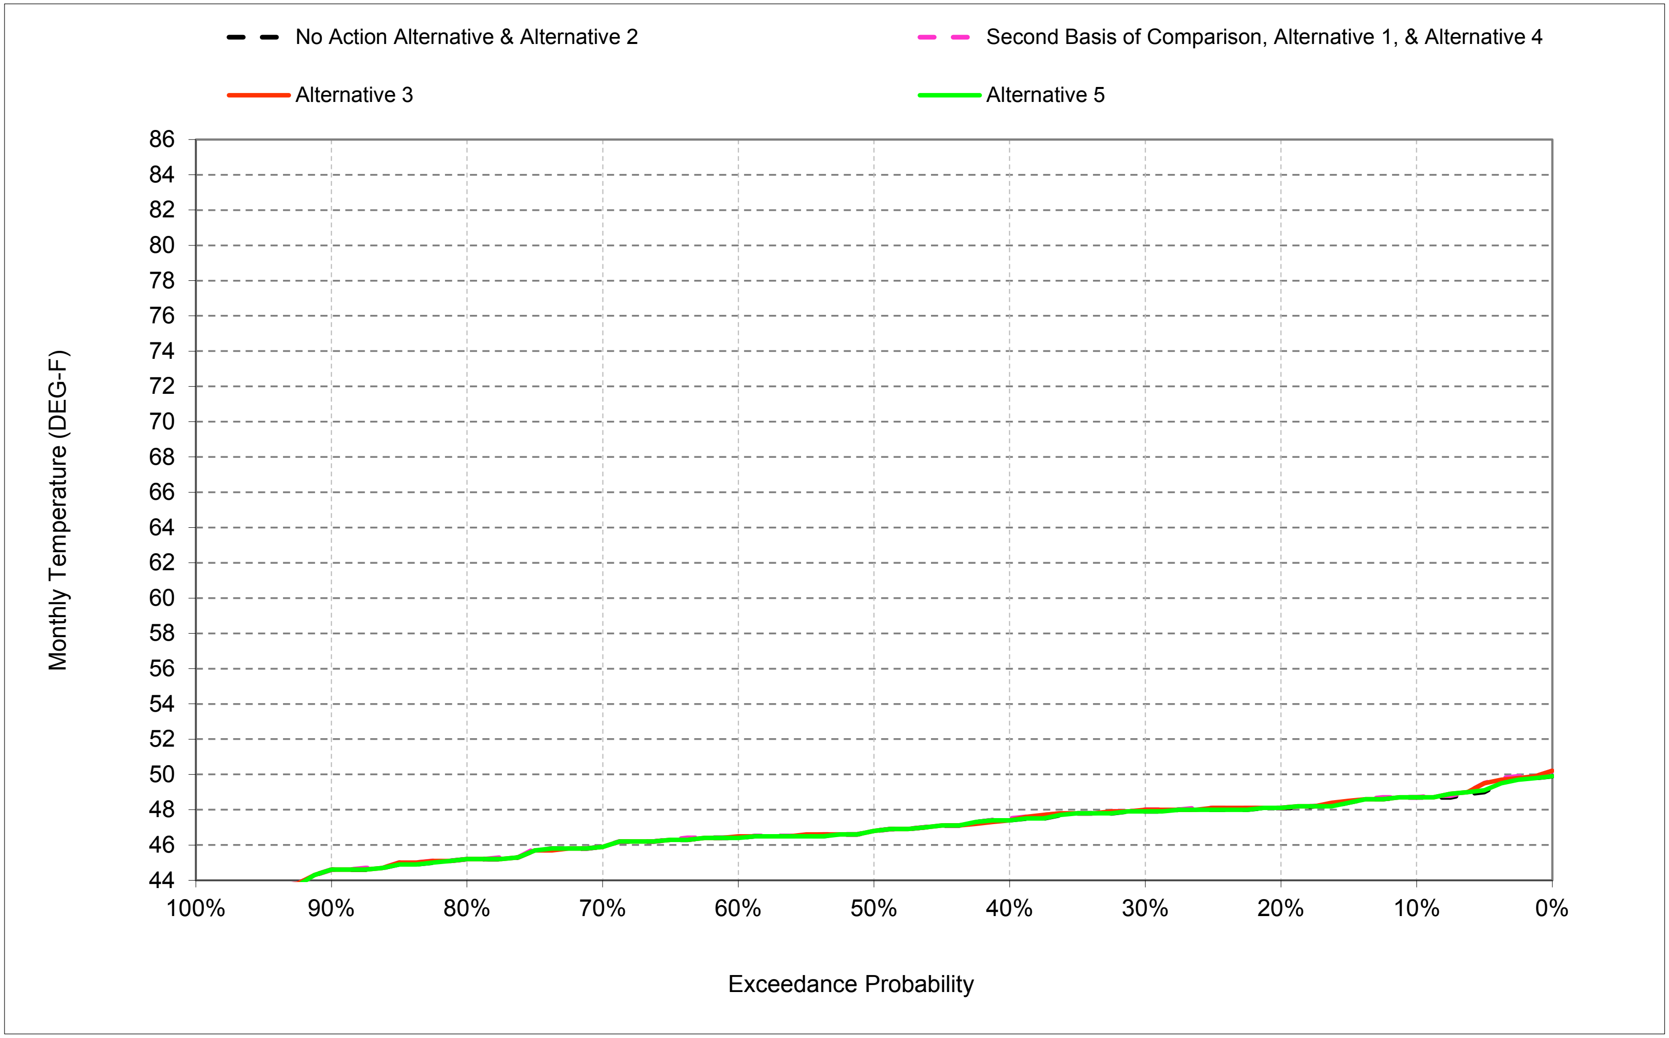
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-3. Feather River at Mouth, December



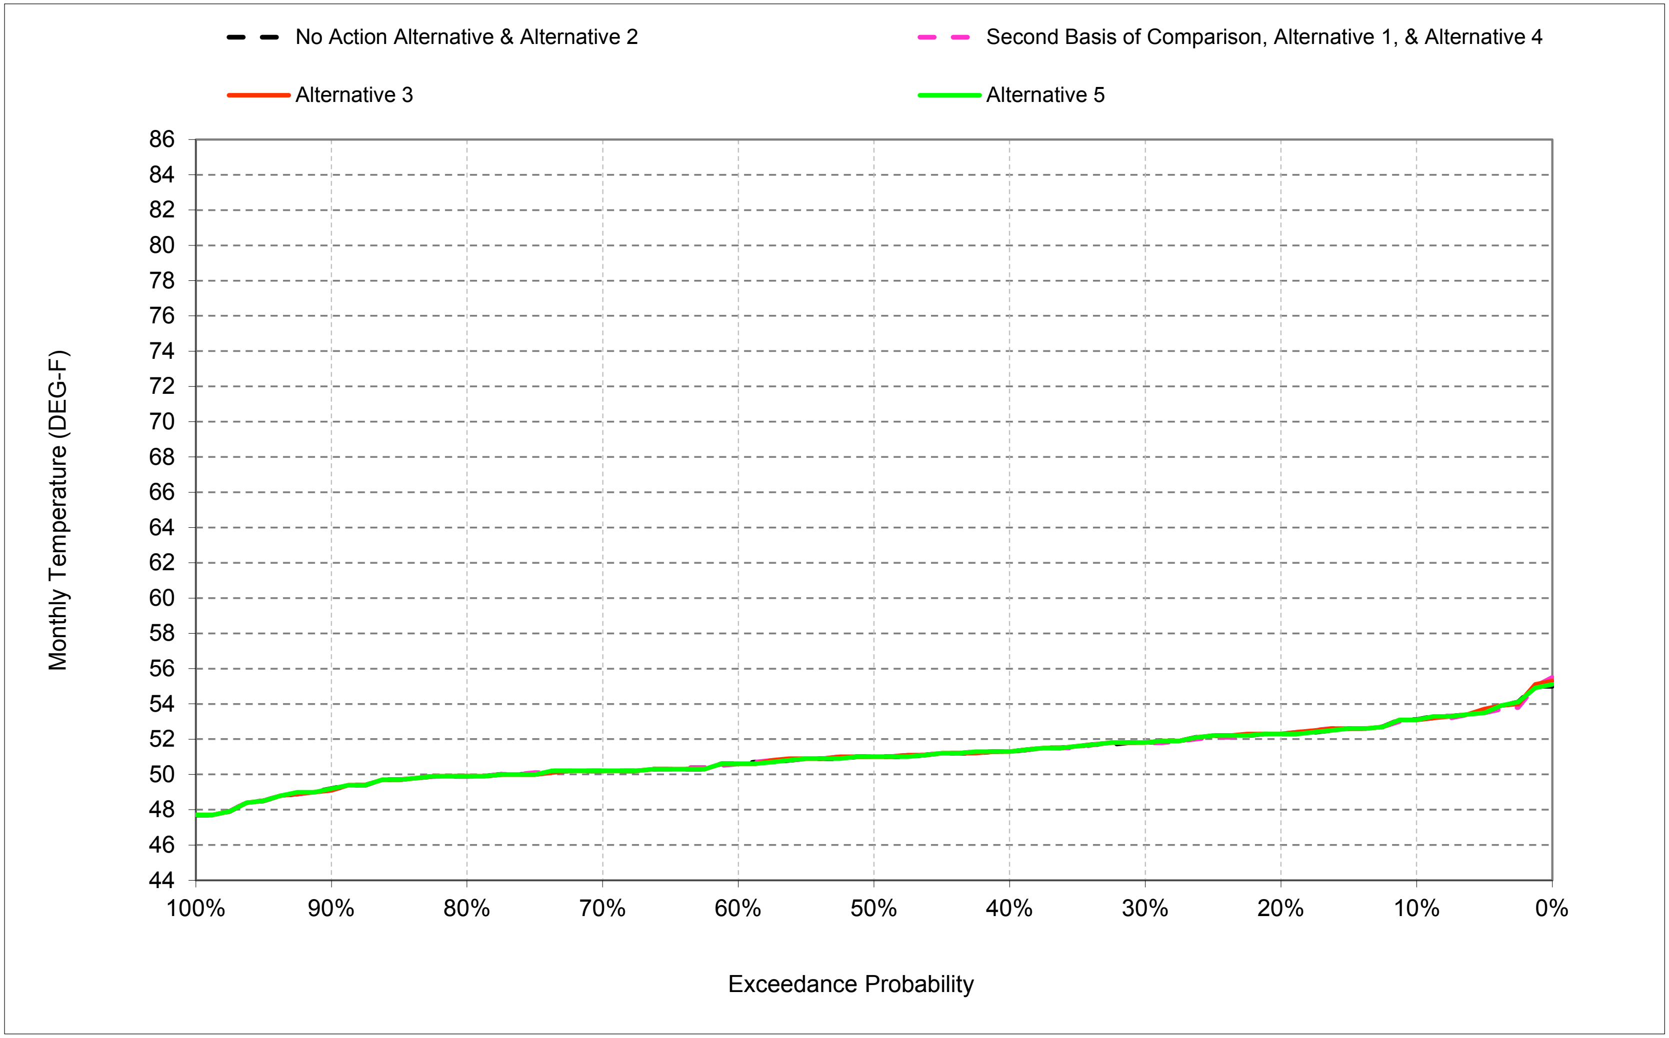
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-4. Feather River at Mouth, January



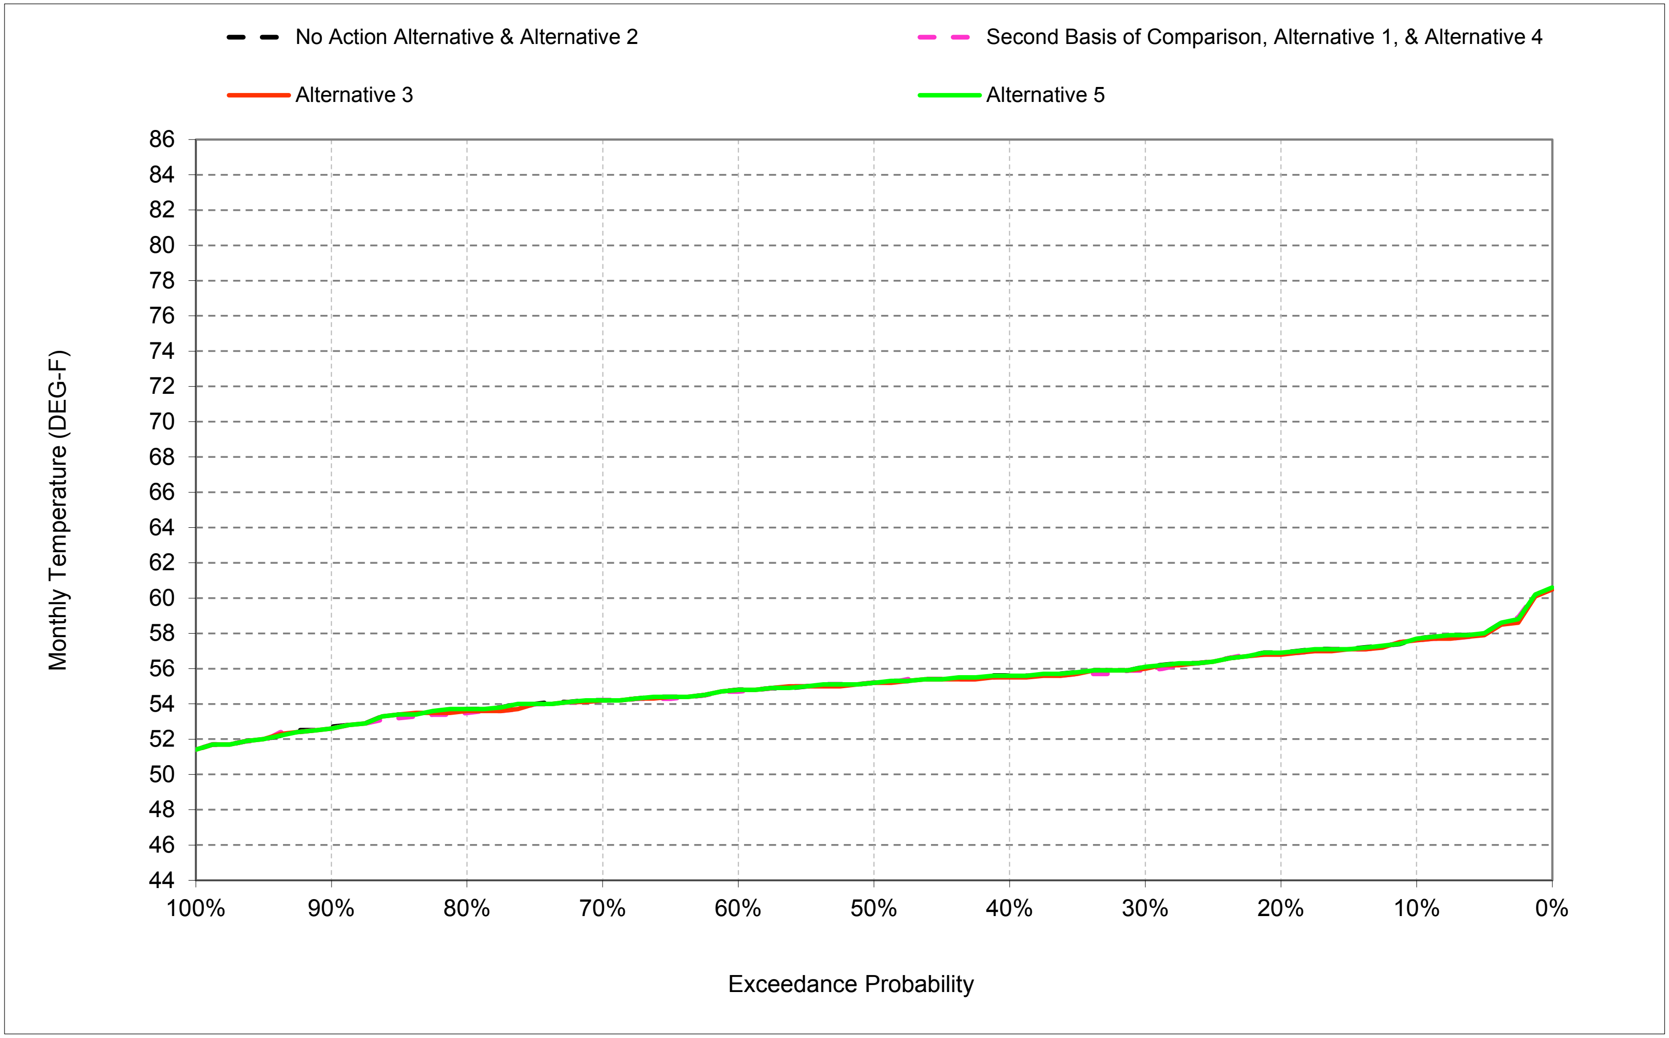
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-5. Feather River at Mouth, February



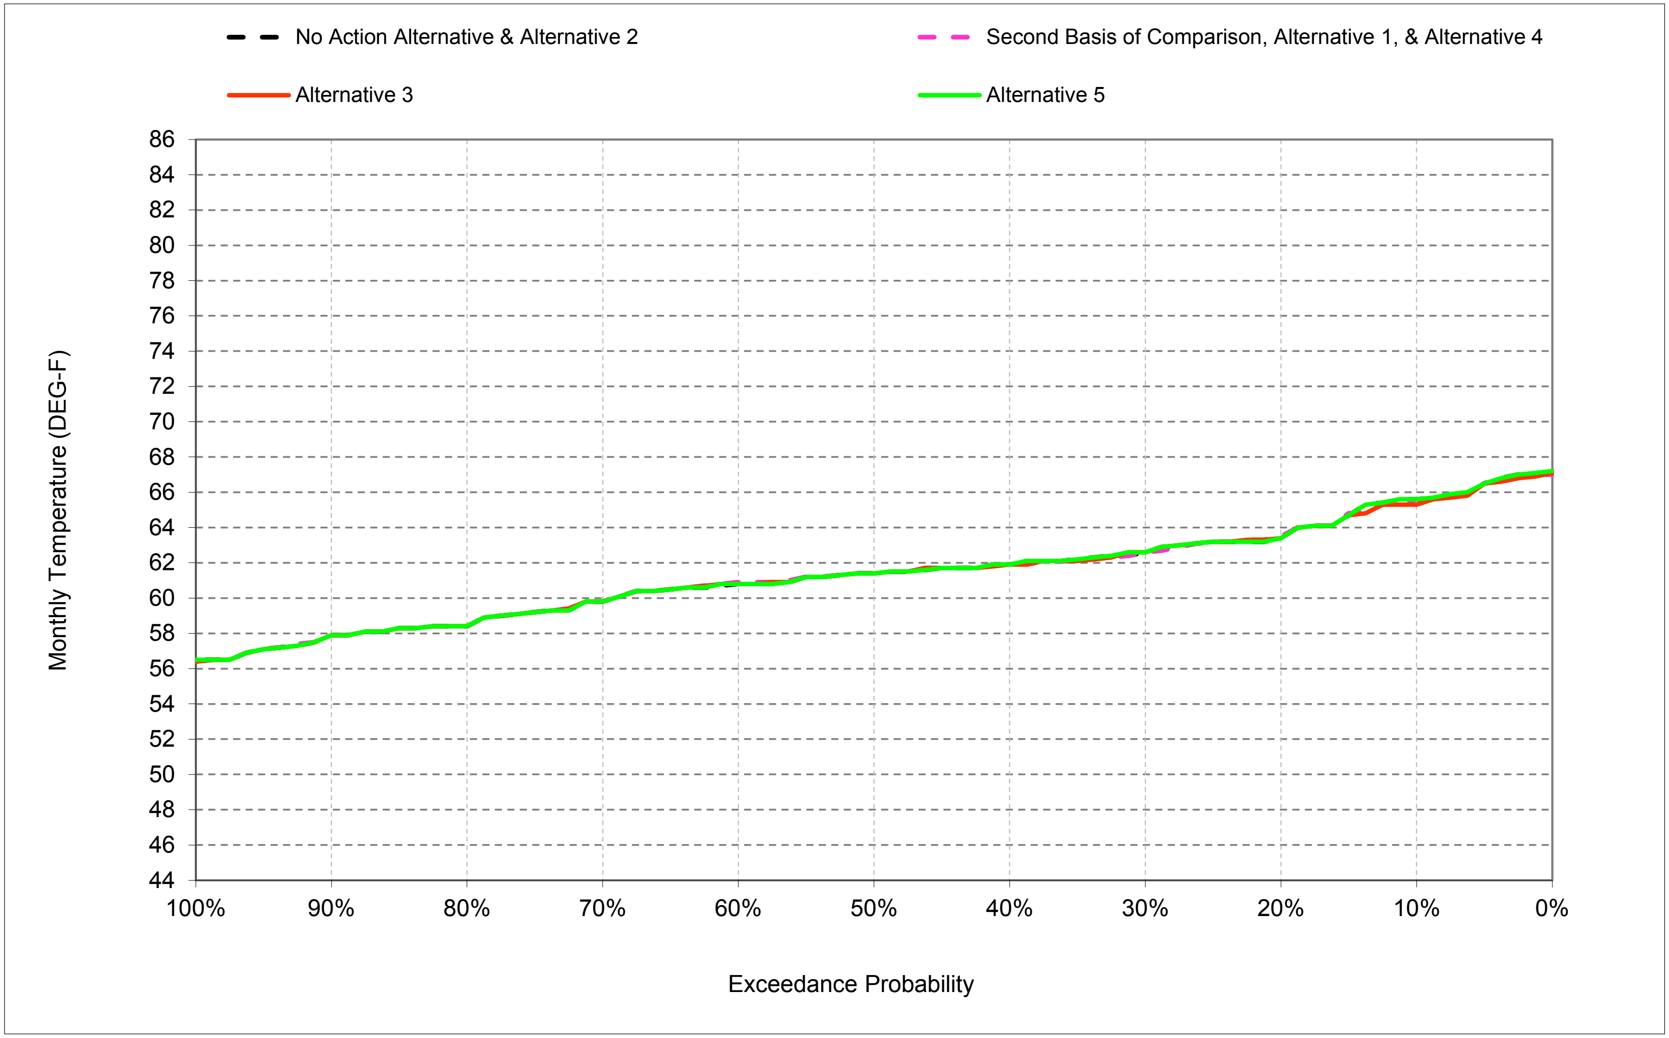
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-6. Feather River at Mouth, March



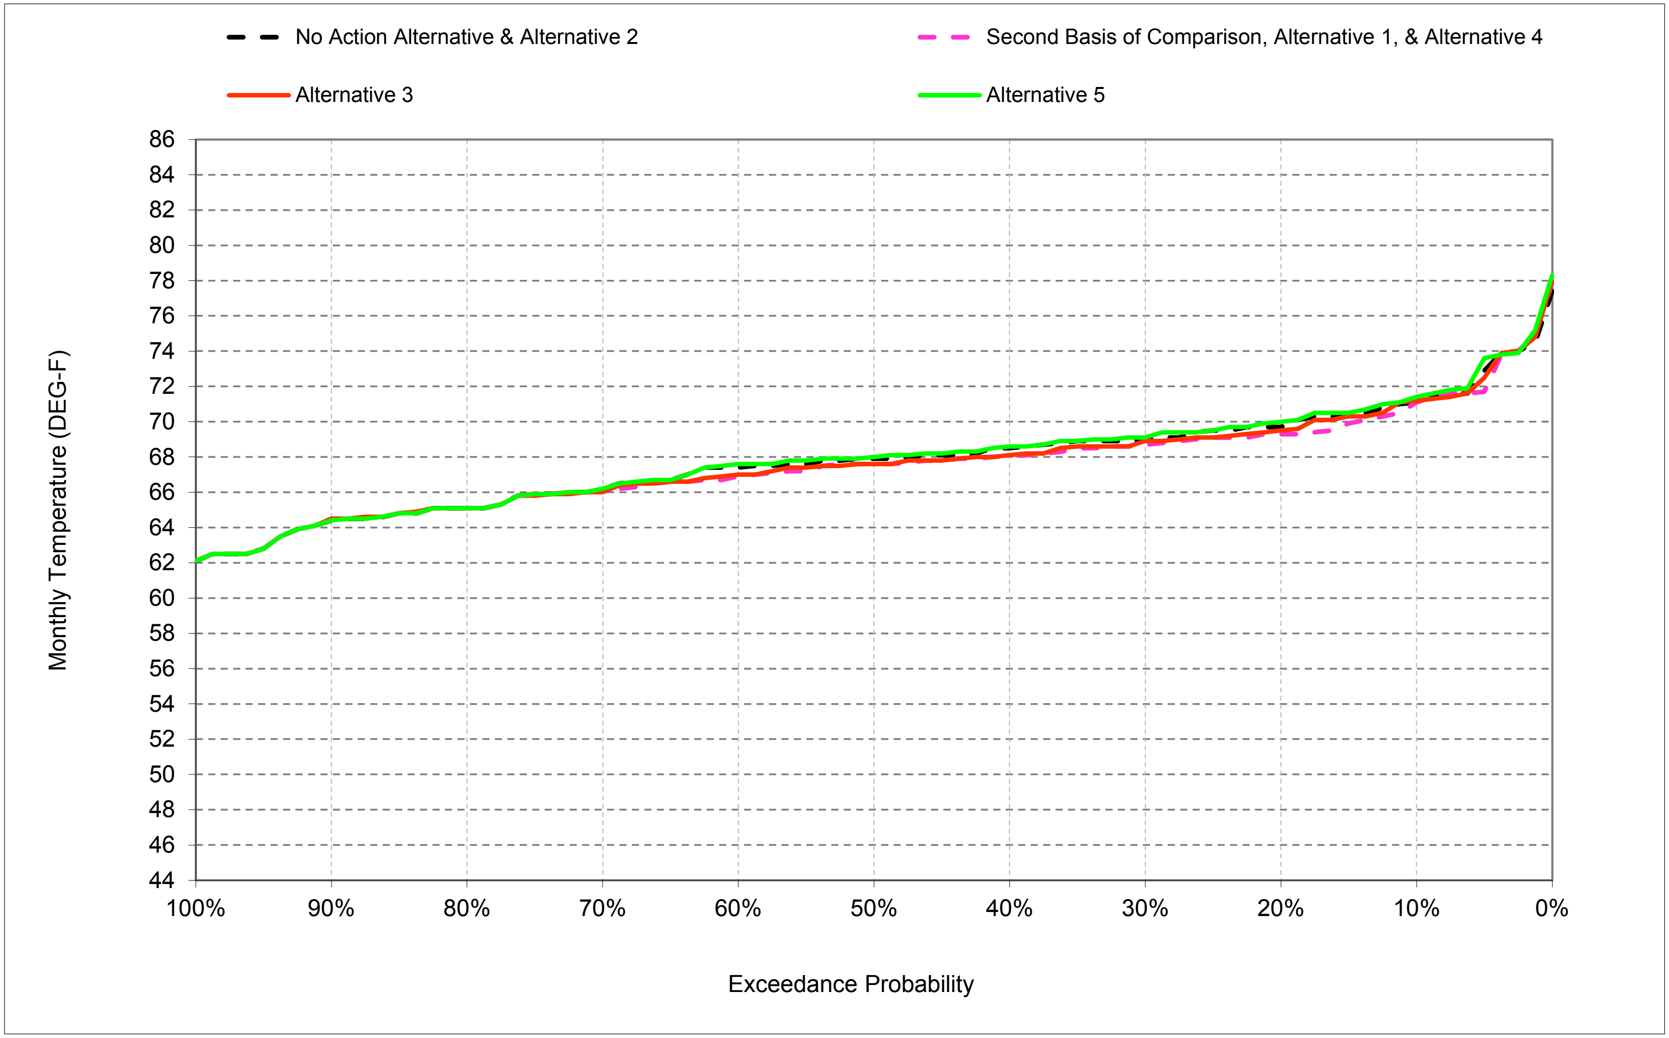
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-7. Feather River at Mouth, April



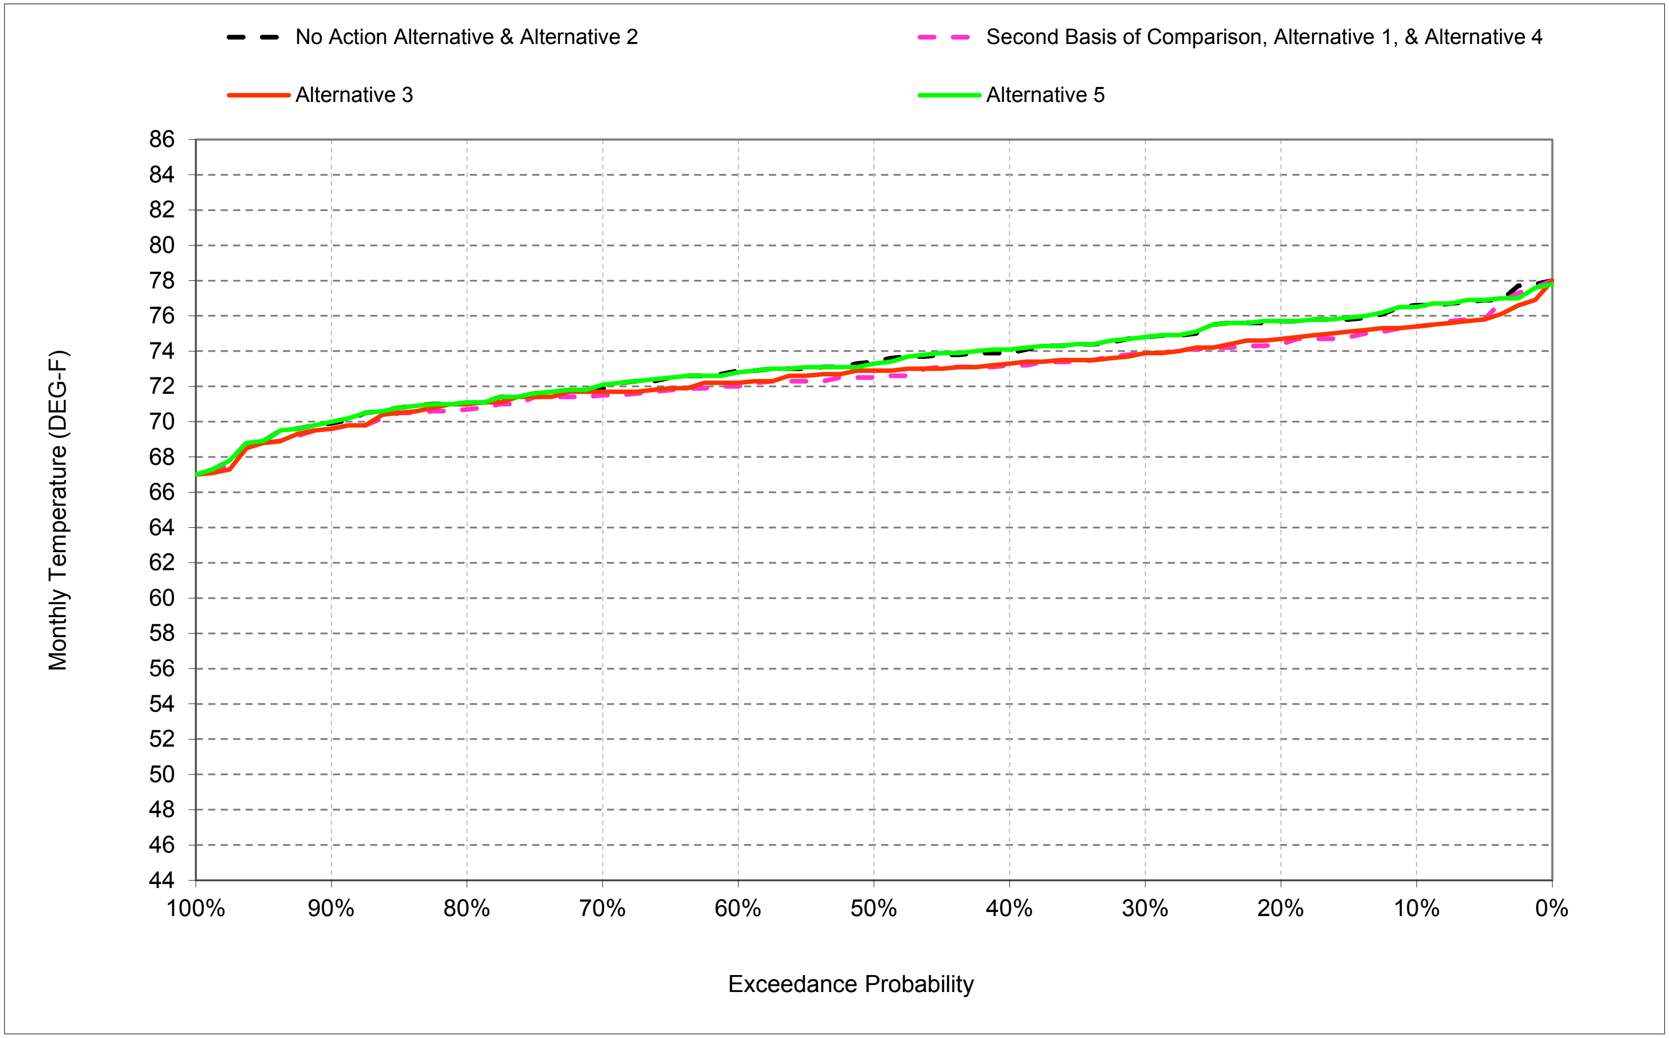
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-8. Feather River at Mouth, May



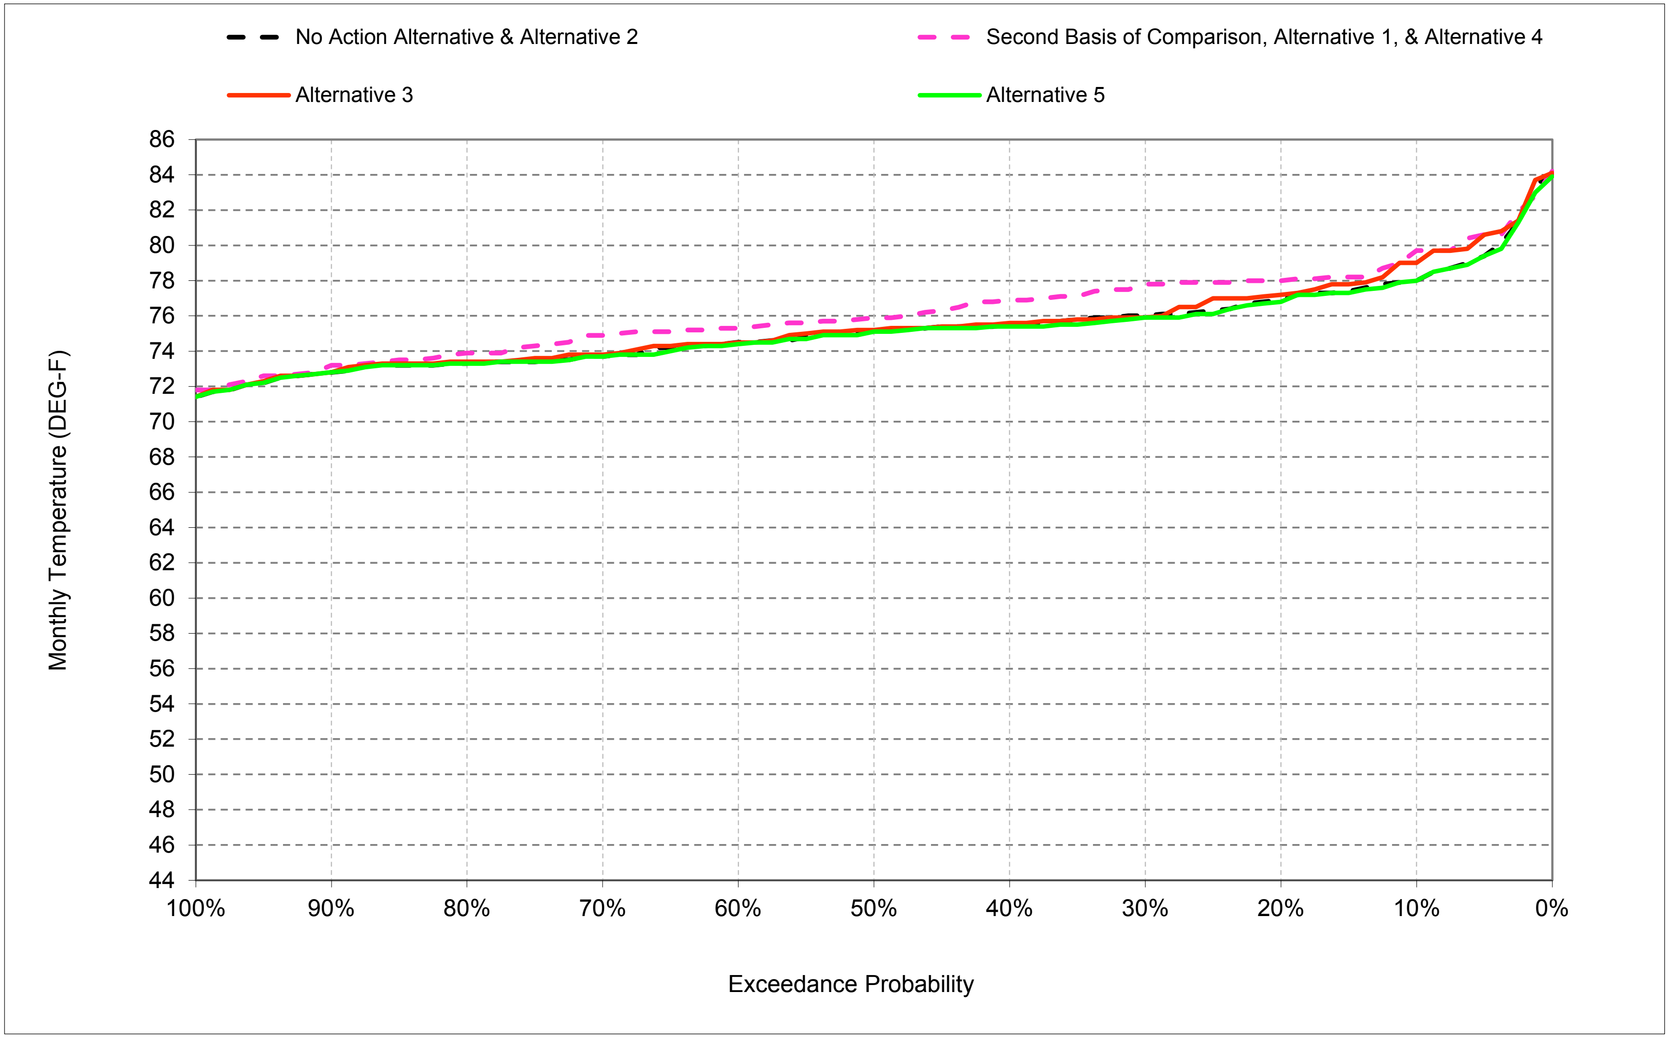
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-9. Feather River at Mouth, June



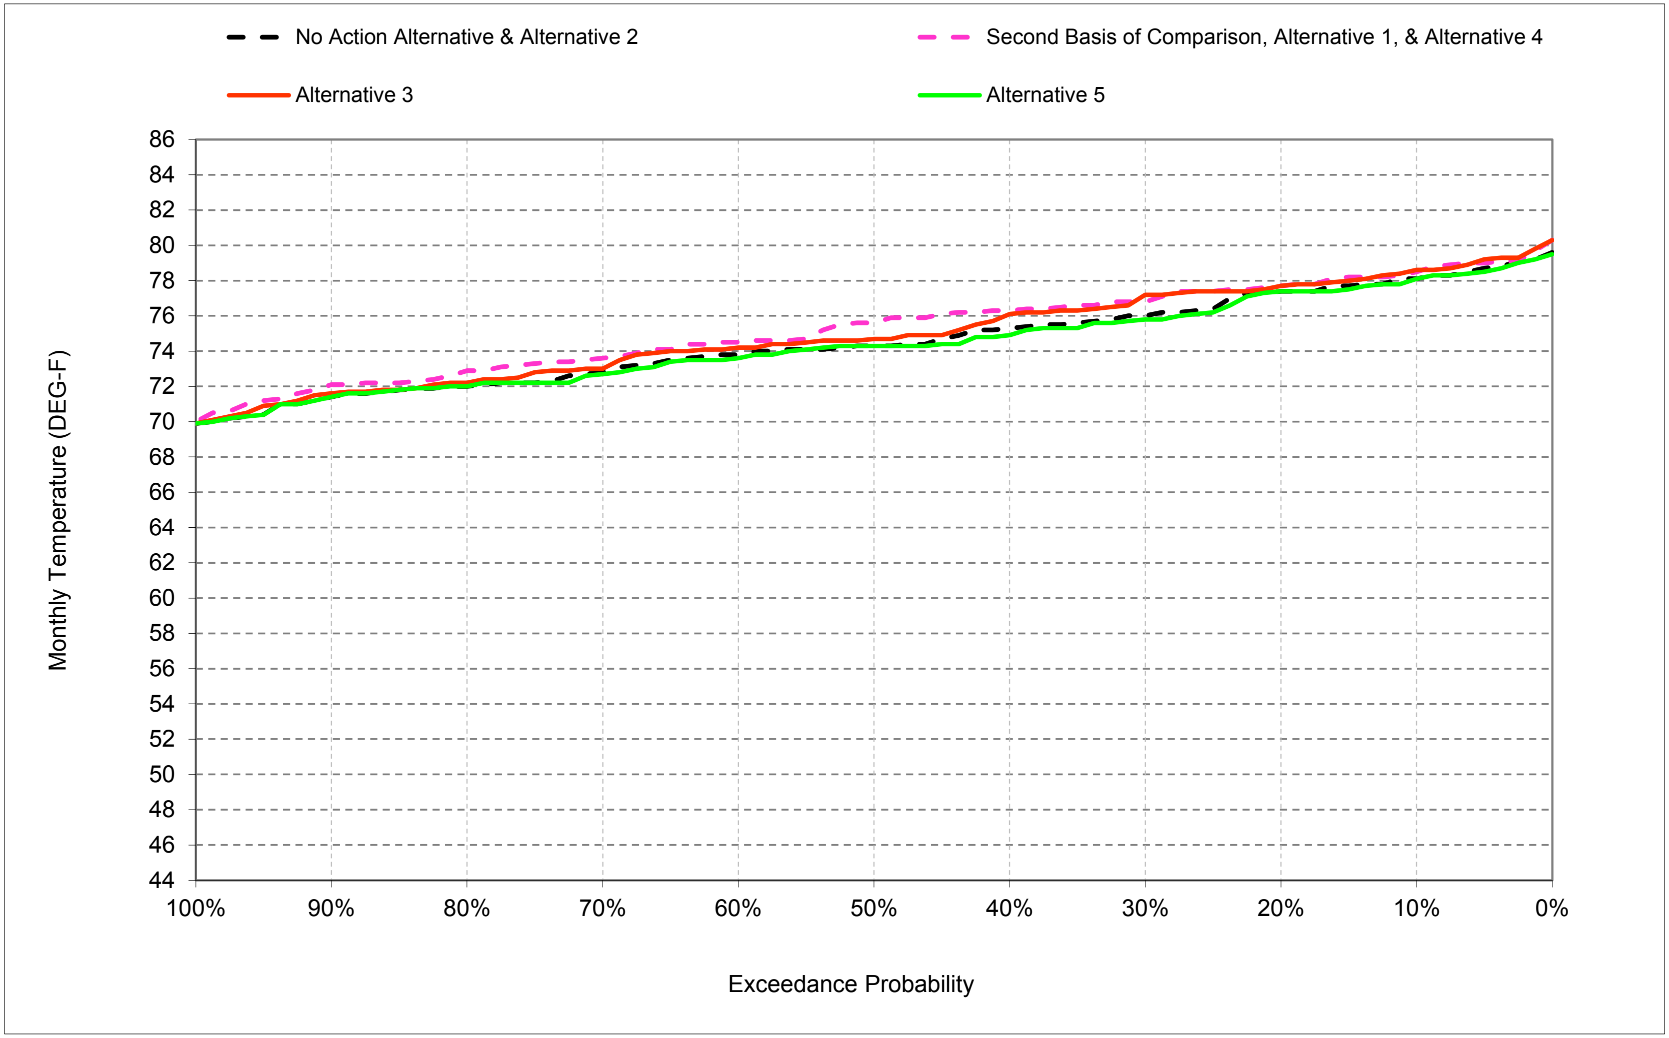
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-10. Feather River at Mouth, July



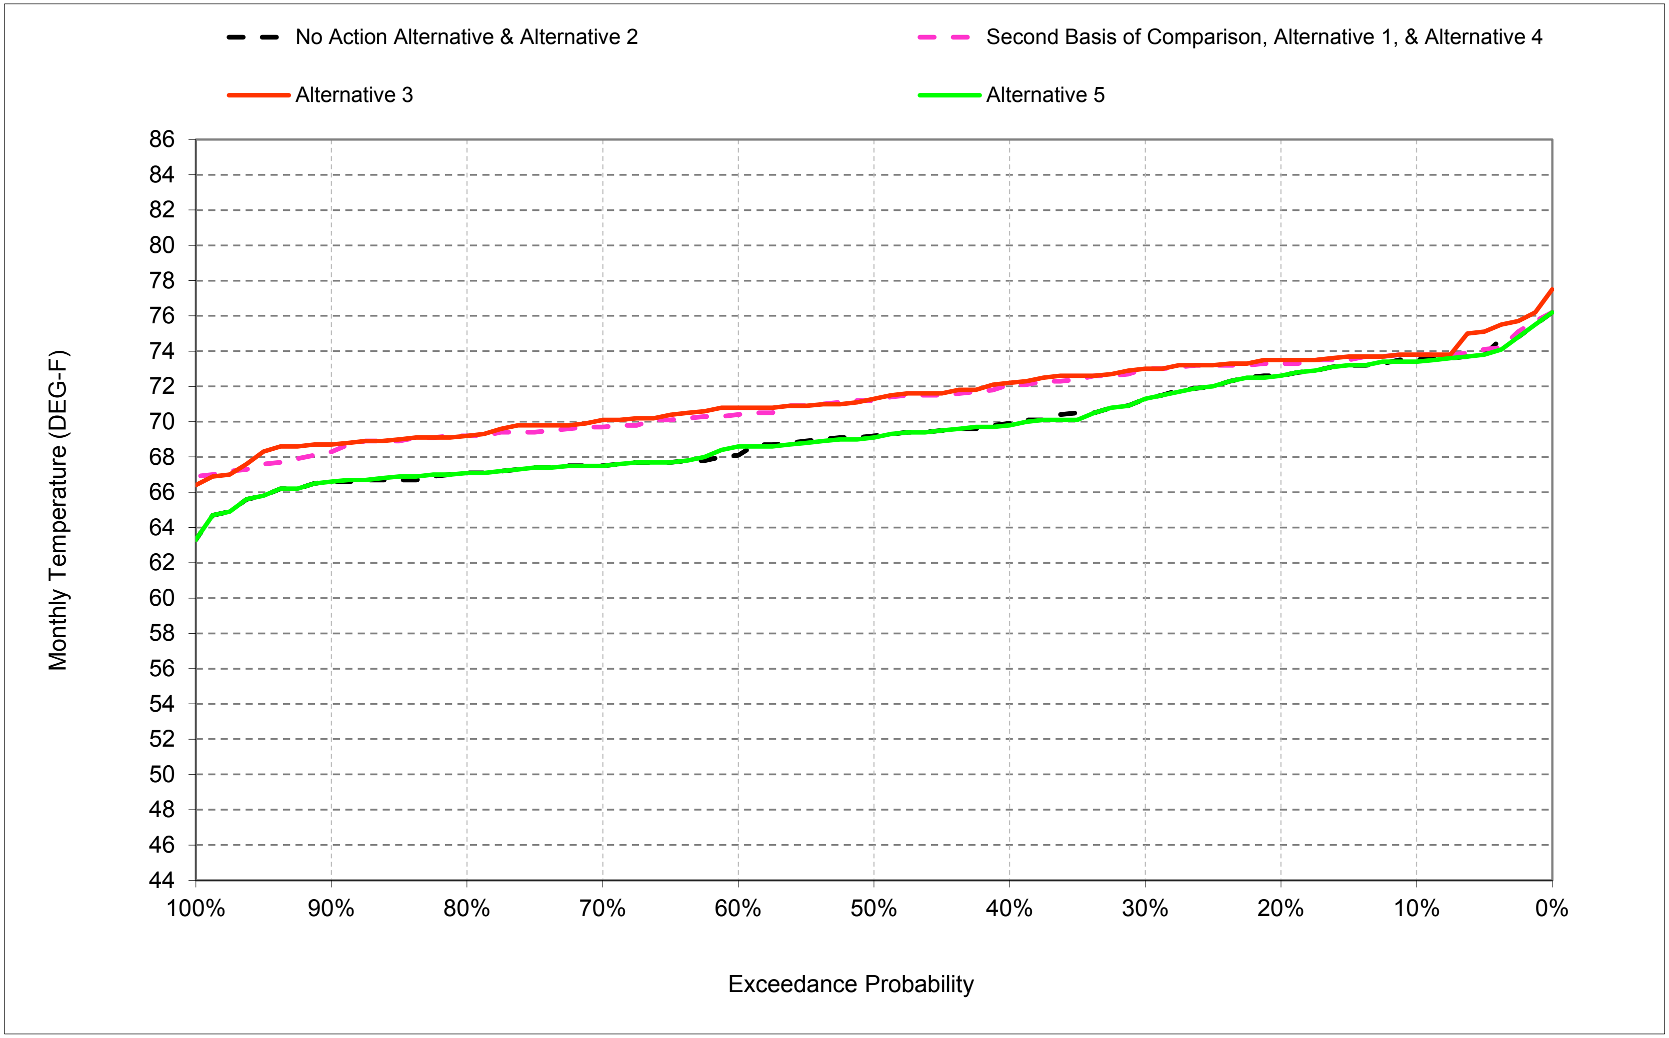
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-11. Feather River at Mouth, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure B-23-12. Feather River at Mouth, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on an 81-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Appendix 6B, Section C

Surface Water Temperature Modeling – HEC-5Q Model Update

Information about the methods and assumptions used for the Coordinated Long-Term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS) analysis on surface water temperature is provided in this appendix. This appendix is organized into three sections that are briefly described below:

- Appendix 6B, Section A: Surface Water Temperature Modeling Methodology, Simulations, and Assumptions
  - The water quality impacts analysis uses the HEC-5Q and Reclamation Monthly Temperature models to assess and quantify effects of the alternatives on the environment. This section provides information about the overall analytical framework linkages with other models.
  - This section provides a brief description of the assumptions for the surface water temperature model simulations of the No Action Alternative, Second Basis of Comparison, and other alternatives.
- Appendix 6B, Section B: Surface Water Temperature Modeling Results
  - This section provides model outputs and a description of the model simulation output formats used in the analysis and interpretation of modeling results for the alternatives impacts assessment.
- Appendix 6B, Section C: HEC-5Q Model Update for Surface Water Temperature Modeling
  - This section provides a detailed description of the compilation and updates of the HEC-5Q models performed during development of the EIS for the Trinity-Sacramento, American, and Stanislaus Rivers.

6B.C.1 Introduction

This section describes tasks that were undertaken to update the Trinity-Sacramento River, American River, and San Joaquin River HEC-5Q models. The work performed was for the Bureau of Reclamation (Reclamation). Four tasks were performed as part of this update:

- A housekeeping task where all existing work prior to the updates was compiled, organized, and modified to create a base version from which all future work would be based from.
- A validation task where the Trinity-Sacramento and American River models were modified to better match observed data.

- A flow mapping task where improvements to the input flows coming from CalSim II were made where necessary.
- A temperature targeting and selective withdrawal task where the logic used to define temperature targets major reservoirs operate as well as the withdrawal logic used to meet those targets was refined.

The following sections in this appendix describe the background for the model updates, the five tasks, and the quality assurance/quality control (QA/QC) process used to ensure the quality of the work.

6B.C.2 Background

In January and February of 2014, there were three separate HEC-5Q modeling toolkits for Trinity-Sacramento, American, and San Joaquin River systems specifically for the EIS and based on CalSim II inputs. These toolkits were developed from models that Don Smith of Resource Management Associates (RMA) had delivered to Reclamation previously. Various issues began to arise with the model output results that resulted in a need to update the model files for several projects. This produced project-specific model versions that were different from the model versions delivered by RMA. After new issues continued to arise, it became apparent that there was a need to implement additional logic to the HEC-5Q model as well as provide organization and documentation for the models.

6B.C.3 Housekeeping Task

This section describes the Housekeeping Task, during which the initial work of compiling the Toolkit took place.

The goal of the Housekeeping Task was to lay out, structure, and compile an initial temperature model toolkit (Toolkit) that would serve to organize all of the existing work for the San Joaquin River, Trinity-Sacramento River, and American River HEC-5Q models as well provide improvements necessary to create a foundation for future improvements to the temperature models. The Housekeeping Task consisted of deciding on the contents of the Toolkit; laying out its structure; and compiling its contents, testing, improvements, and documentation.

The Housekeeping Task first identified the contents of the Toolkit and how it would be structured. It was recommended that there be one central HEC-5Q Toolkit that would contain an individual folder for the San Joaquin River, the Trinity-Sacramento Rivers, and the American River models. Within each river folder, there would be a complete application model (files, data, protocol document, and QA/QC tools) based on CalSim II inputs and that could support climate change scenarios. The river folders would also contain a complete calibration model from which the application model was developed. The Toolkit would support running the model through a batch process, which is the process through which the previous toolkits were run, as well as through the graphical user interface (GUI). Both the batch process and the GUI would utilize the same model files in order to eliminate redundant files. The models would run on the same executables, contained in a folder separate from the river folders (labeled bin). There would also be a folder for the GUI, which would include all the files required to run the GUI and a protocol document. There would also be a central reference document library and a version control folder that would track the source and changes of all the files contained within the Toolkit over the course of the updates.

The reference document library is a compilation of documents that were deemed necessary or useful as references for the user of the Toolkit. Included with the reference document library was the development of an HEC-5Q Quick Start Guide that was requested by Reclamation as part of the updates. This quick start guide provides an overview of how the all the model components work.

The file structure was designed to be compatible with either the use of the Batch Process or the GUI to run the models and to be consistent with the file structure used for the modeling for EIS. Ideally, the use of the GUI would fit within this structure. However, after some investigation into how the GUI locates the required input files, it was determined that using the GUI within the file structure and using only one set of model files for both the Batch Process and the GUI would require code changes to the GUI itself. Therefore, a decision was made to not fully implement the GUI into the Toolkit but to include it anyway.

After identifying the contents of the Toolkit and laying out the structure, the next task was to compile the contents. This involved reconciling different versions of the model files. Table 6B.C.1 shows the model versions that were reconciled for each river.

Table 6B.C.1 HEC-5Q Model Toolkits Reconciled during the Housekeeping Task

River	Models	Toolkits
Trinity-Sacramento	SRWQM** Extension (October 2013)	Remand_SRWQM_Toolkit (January 24, 2014)
San Joaquin	CDFW* SJR Model (June 2013)	Remand_SJR_HEC5Q_Toolkit (February 21, 2014)
American	SRWQM Extension (October 2013)	Remand_FAST_HEC5Q_Toolkit (February 18, 2014)

a. California Department of Fish and Wildlife

b. Sacramento River Water Quality Model

There were substantial differences between the versions of the Trinity-Sacramento River model. The SRWQM model (January 2014) was originally developed in 2002 and modeled only the Trinity River (to below Lewiston Dam) and the Sacramento River (to below Knights Landing). The SRWQM Extension (October 2013) extended the SRWQM model to include the Feather River (from Oroville Reservoir), the American River (from Folsom Reservoir), the Sutter

Bypass, and the lower Sacramento River (to below Freeport). The SRWQM Extension included new meteorological data that the Feather and American River extensions of the model were calibrated to. However, the older Trinity-Sacramento River section of the model was not recalibrated to the new meteorological data.

During compilation of the Toolkit, it was recommended that the Trinity and Sacramento River sections of the SRWQM Extension be the versions used moving forward. Those sections represented the latest modeling logic and nodal layout, including the Sutter Bypass. However, changes had to be made to the SRWQM Extension files before it could be incorporated. First, the Feather River was removed completely from the model files, as well as the lower Sacramento River (from the Feather River confluence to below Freeport) because it receives inputs from the Feather River. Second, a validation procedure was undertaken to adjust the necessary model parameters in order to incorporate the updated Gerber California Irrigation Management Information System (CIMIS) station meteorological data. A detailed description of this validation procedure is described below.

The San Joaquin River and American River versions were mostly consistent between the versions. Changes had been made on the Stanislaus River primarily for consistency with CalSim II. During the Housekeeping Task, an increase in the Tulloch power plant outflow capacity was implemented in the Toolkit. It should be noted that the previous versions of the San Joaquin River model included Electrical Conductivity as an additional output parameter of the model. This capability was removed for the Toolkit.

The American River version had a spreadsheet that computed downstream temperature targets for Folsom Outflow and Watt Avenue and two file changes for consistency with CalSim II. The spreadsheet and file changes were included in the Toolkit. During the Housekeeping Task, implementation of the Folsom Water Supply Intake Temperature Control Device (Folsom TCD) was included. Implementing the logic for the Folsom TCD required a validation run of the American River, which is described in detail below.

Compilation of the Toolkit into the agreed upon file structure included the need to change the reconciled files. These changes included changing path names in the batch files and renaming files so that there was a consistent naming convention across the three different river models. Also, among the changes was the implementation of common executables for the CalSim II pre-processor and HEC-5Q for each of the three models. This would eliminate redundant files and make changes to the CalSim II pre-processor and HEC-5Q codes easier, as code changes would only occur in one file. Also among the changes was the implementation of common executables for the CalSim II pre-processor and HEC-5Q.

In addition to the elements required for the models, model files and data from previous work that were part of the development of the models were compiled. These included the 2002 Sacramento River calibration (RMA 2003), the 2013

American River calibration (RMA 2013), the 2013 Stanislaus River calibration, and the Sacramento River and American River validations described below.

6B.C.4 Validation

This section describes the validation procedures and required updates to the model for the Trinity-Sacramento and American River models.

6B.C.4.1 Trinity-Sacramento River

The Trinity-Sacramento River model was originally developed and calibrated in 2002, using meteorological data from the Gerber CIMIS station (RMA 2003). Since that 2002 calibration, the model code has changed and there are updated meteorological data from the Gerber CIMIS station. During the Housekeeping Task, it was recommended that the Trinity-Sacramento River model incorporate the updated meteorological data from the Gerber CIMIS station. Fully incorporating the updated Gerber meteorological data would require a full recalibration of the model, which was beyond the scope of this project. Instead, a validation task was conducted to produce temperature results similar to the 2002 calibration. The validation task assumed the following conditions:

- 1981-2002 hydrology from the 2002 calibration
- Ambient temperature data that were used in 2002
- Revised meteorology developed in 2012
- Control point configuration consistent with CalSim II
- Bypasses included in the model representation

During the validation process, equilibrium temperature scaling factors for the reservoirs, reaches, reservoir inflows, and tributary inflows were adjusted to match observed data. The scaling factors were adjusted to compensate for higher equilibrium temperatures of the updated Gerber meteorology data. The equilibrium temperatures of the updated Gerber meteorology were higher than the 2002 Gerber meteorology because the updated data were computed without a wind speed scaling factor assumption, while the 2002 data had been computed with an assumed wind speed scaling factor.

Several comparison plots and tables from select locations that are representative of the computed versus observed temperature results of the Trinity-Sacramento River validation are contained in Appendix 6B, Section A. Comparison plots and tables at additional locations can be found in the document titled *Trinity Sacramento River 2014 Validation Plots* included in the file set for this report. In general, the validation task resulted in computed temperatures that had good agreement with observed data. Table 6B.C.2 shows the average computed and observed temperature at select locations in the Trinity-Sacramento River model.

Table 6B.C.2 Average Computed and Observed Temperatures at Select Locations Resulting from the Validation of the Trinity-Sacramento River Model

Location	Average Computed Temperature (^{0}F)	Average Observed Temperature (^{0}F)
Trinity River below Lewiston Dam	48.3	47.9
Sacramento River below Shasta Dam	49.8	58.6
Sacramento River below Keswick Dam	51.0	51.1
Sacramento River below Clear Creek	51.8	51.6
Sacramento River at Balls Ferry	52.7	52.7
Sacramento River at Bend Bridge	53.3	53.8
Sacramento River at Red Bluff	53.8	54.1
Sacramento River at Tehama	54.2	54.2
Sacramento River at Woodson Bridge	55.1	55.1
Sacramento River at Butte City	57.8	57.9
Sacramento River above Colusa Drain	59.4	58.8

6B.C.4.2 American River

The American River HEC-5Q model was developed in 2013 as part of the SRWQM Extension (RMA 2013). Subsequent to this initial development, the model shortcomings listed below were identified and addressed. Implementing the fixes required for these shortcomings required a validation of the American River HEC-5Q model data to make sure they still matched observed data.

6B.C.4.2.1 Folsom Water Supply Temperature Control Device

The Folsom Water Supply Intake Temperature Control Device (Folsom TCD) was not properly represented in the 2013 calibration model, resulting in withdrawal of cold water at depth. The model was modified to represent the withdrawal as a movable port that can move based on the following operating objectives and constraints:

- Minimum submergence limit of 15 feet. The negative value indicates the variable level output as opposed to a fixed port representation that was original envisioned.
- Maximum temperature constraint of 18^0C. The outlet will be lowered to access this or a lower temperature when constrained by the minimum submergence requirement.
- Operating elevation range between 320 feet and 460 feet.

The LD record in Figure 6B.C.1 shows the change in the American River HEC-5Q data file implemented for the Folsom TCD.

```
c....     Diversions
C  field  Original single port diversion
c    (1)     ADV   Area of the diversion withdrawal port in ft2 or m2.
c    (2)     QLDV  Fraction of the diverted flow assigned to the diversion. (TF)
c    (3)     ELDV  Centerline elevation of diversion point in feet or meters. (TEL1)
C            if TELT is negative, the TCD option is triggered

c....        TCD equiped water supply diversion (e.g., American River/Folsom Dam domestic water supply)
c     (3)    ELDV  Minimum depth of submergence - flagged by a minus depth. (TEL1<0.)
c     (4)    LDT   Maximum allowable temperature (C) at active outlet. (TET1)
c            The selected port will be the controling od these two constraint
c     (5)    DWSELDV(1) Centerline elevation of the lowest diversion point (TELP(1)) or
c            -1 for moveable outlet that can access any element

c...         If DWSELDV(1) = -1 (moveable outlet)
c     (6)    DWSELDV(2) Lowest diversion access elevation (TELP(2))
c     (7)    DWSELDV(2) highest diversion access elevation (TELP(3))
```

Current assumptions / data

```
c... Folsom Dam Water Supply TCD - represented as a variable level intake
c... Dec 22, 2014 ... Russ Yaworsky recommendation
c.      Withdrawal target temperature between 63-65F (17.2 - 18.3C)
c.      Lowest accessible level of approximately 320'
c... TCD operation rules as defined by "LD" record data:
c.     minimum submergence constraint = 15'
c.     maximum temperature constraint = 18C
c.     Folsom Water Supply option flag = -1
c.     Operating elevation range between 320 & 460
LD   135     1.0   -15.0    18.0      -1     320     460
```

Figure 6B.C.1 Change in the American River HEC-5Q Data File for the Folsom Water Supply Intake Temperature Control Device

6B.C.4.2.2 Folsom Inflow Temperatures

Inflow temperatures were lowered relative to observed data in the 2013 calibration model to compensate for the low level extraction of cold water by the fixed depth domestic water supply outlet. These inflow temperatures were increased relative to the 2013 calibration model temperatures with the implementation of the new Folsom TCD logic.

6B.C.4.2.3 Folsom Evaporation

A change in the L2 record (see Figure 6B.C.2) was made to account for the separation of evaporation in CalSim II. The standard version of HEC-5Q will only accommodate a single diversion; however, CalSim II reports evaporation as a flow equivalent rate (E8) which is represented as a surface diversion in HEC-5Q while the Folsom Lake domestic water supply diversion (D8) is diverted at depth. Therefore, these two rates cannot be combined for accurate temperature simulation. From a flow accounting perspective (HEC5), the total flow diverted from the lake is E8+D8. By setting IQDEV = 2, the evaporation component of total diversion is defined as a DSS path using the ZR Record and subtracted from E8+D8 in HEC-5Q.

```
c. Reservoir evaporation using CALSIMII operation data
c. HEC5Q can accommodate only one diversion.  CALSIM reports evaporation as a flow equivalent
c. rate which is represented as a surface diversion in HEC5Q.
c. Folsom also has a domestic water supply that is diverted at depth, therefore it cannot
c. be combined with evaporation.  By setting IQDEV = 2, the evaporation component of
c. total diversion is defined as a DSS path using the ZR Record.
c.  FK2R    FK2C    FK2S   SFMET1  SFMET2  sfmet3   IQDEV

```

Figure 6B.C.2 Change in the American River HEC-5Q Data File to Separate Evaporation from Total Diversion at Folsom Dam

6B.C.4.2.4 River Mile Correction

The river mile location of Nimbus and Folsom Dams were improperly defined in the 2013 calibration model. A half-mile reach was inserted below Nimbus Dam to match the river mile locations of Nimbus and Folsom Dams in the HEC-RAS model. The Nimbus Dam went from river mile 22 to 22.5 and Folsom Dam went from river mile 28.7 to 29.2. This change affects temperature results.

In general, the validation resulted in good agreement between computed and observed temperatures. The average computed and observed temperatures at select locations in the American River model are shown in Table 6B.C.3.

Table 6B.C.3 Average Computed and Observed Temperatures at Select Locations Resulting from the Validation of the Trinity-Sacramento River Model

Location	Average Computed Temperature (⁰F)	Average Observed Temperature (⁰F)
American River below Nimbus Dam	56.5	56.7
American River at William Pond Park	57.7	57.7
American River at Watt Avenue	58.5	58.3

6B.C.5 Flow/Boundary Condition Mapping

HEC-5Q receives flow inputs from CalSim II through the CalSim II_HEC-5Q pre-processing executable. Monthly CalSim II flow and storage time series outputs are read into the executable where they are combined and mapped to nodes in the HEC-5Q model based on specifications in the [River model]_CS.dat (e.g. SR_CS.dat) file, converted to daily time series, and stored in the HEC-5Q input DSS file (CalSim II_HEC5Q.DSS). In the case of the storage time series, a daily patterning procedure is applied. As part of the temperature model updates, several modifications were made to improve the flow mapping of CalSim II to HEC-5Q. Additionally, HEC-5Q provides flow and temperature inputs to several fisheries models. These modifications are described below.

6B.C.5.1 Sutter Bypass Boundary Conditions Mapping

During modifications of the SRWQM Extension model files for the Trinity-Sacramento River model, it was determined that there was some incorrect mapping with the CalSim II schematic at Butte Creek. Specifically, there was double-counting of the Butte Creek Inflow at the Knights Landing control point. In CalSim II, Butte Creek inflow is input into the Sutter Bypass. However, in the SRWQM Extension, that inflow was added directly into the Sacramento River, causing higher flows in the Sacramento River at Knights Landing in the HEC-5Q model as compared to CalSim II. The Butte City inflow record (specifically IN118 in the SR_CS.dat file) was removed in the SR_5CS.dat file for the final Trinity-Sacramento River model.

6B.C.5.2 American River Flow Mapping Change

The control point resolution below Nimbus Dam was inadequate in the 2013 calibration model to properly allocate the City of Sacramento withdrawal. This lack of resolution presented a problem in relating HEC-5Q flows to CalSim II flows. The additional control point that localizes the City of Sacramento withdrawal is shown on Figure 6B.C.3. The additional control point (CP) #572 results in the depletions / accretions being distributed uniformly between CP 572 and CP 578 (mile 7.5 to mile 22.0). The City of Sacramento diversion is applied at CP 570. This change only has a small impact on temperature (it reduces temperatures at Watt Avenue up to +/- 0.5^{0}F).

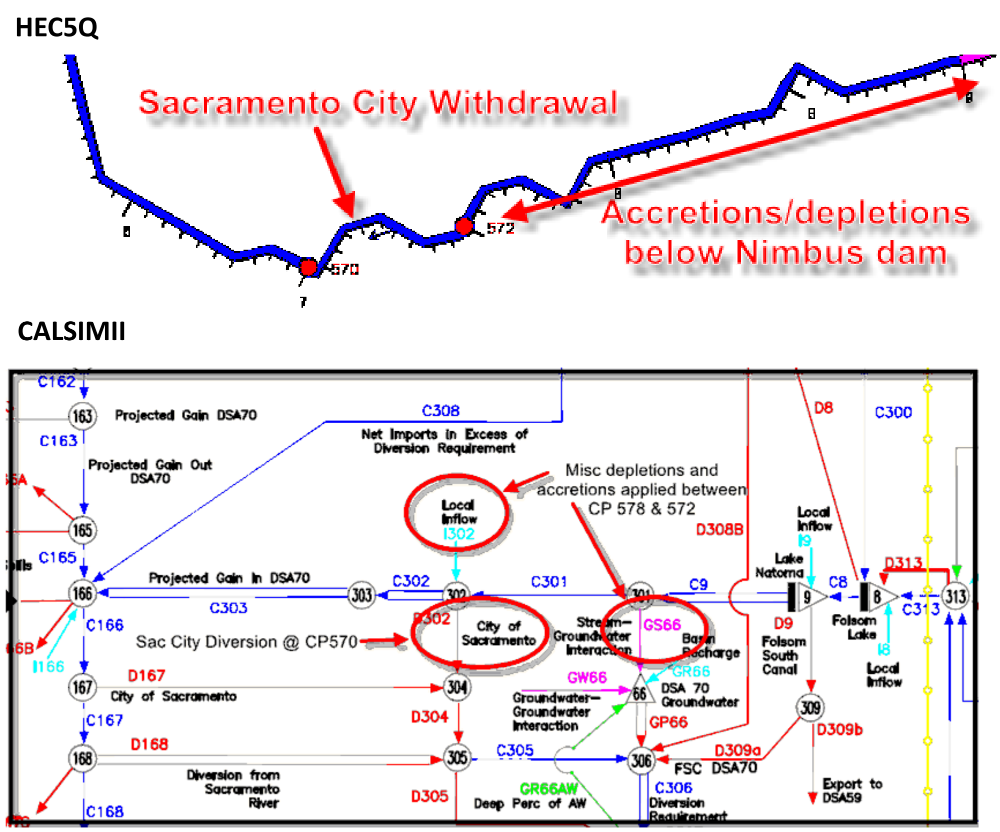

Figure 6B.C.3 Schematics of HEC-5Q and CalSim II Models with Additional Control Point 572

6B.C.5.3 Stanislaus River

The flow mapping between CalSim II and HEC-5Q in the Delta-Mendota Canal section of the San Joaquin River model is currently inadequate and results in serious flow differences. To fully address this requires a modification to the CalSim II schematic, which is beyond the scope of the work to update the temperature models. Since the EIS only focuses on temperature effects from Reclamation operations on the Stanislaus and Lower San Joaquin Rivers, the San Joaquin River model was reduced to only include the Stanislaus River and the San Joaquin River from the Stanislaus River confluence to the head of Old River. A requirement of this model to run and simulate temperatures at Vernalis was to develop a boundary condition time series of inflow temperature at the San Joaquin River above the Stanislaus River confluence. This time series would incorporate all the upstream temperature effects due to water operations above this point in the San Joaquin River basin (including Friant, Mendota Pool, and the Tuolumne and Merced Rivers). This time series was generated with the February 21, 2014 San Joaquin River HEC-5Q model using the EIS No Action Alternative Q5 CalSim II results for inputs.

6B.C.5.4 Mapping to Fisheries Models

The capability of mapping HEC-5Q flow and temperature outputs with three fisheries models was added to the Sacramento River model, including SALMOD, Reclamation Mortality model, and Cramer Fish Sciences models.

6B.C.6 Temperature Target, Selective Withdrawal, and Operational Outputs

This section describes the temperature targeting and/or selective withdrawal changes and procedures for the Trinity, Shasta, and Folsom Dams. These changes were completed after the validation was deemed appropriate because the temperature targets do not affect the matching of the observed temperatures; the validation period of record occurred when the Trinity Dam auxiliary outlet and Folsom Dam low-level outlets were not used.

6B.C.6.1 Trinity River

6B.C.6.1.1 Seasonal Temperature Target Schedule

A simplistic approach for seasonal temperature targets was implemented for the Trinity River. The seasonal targets are shown in Table 6B.C.4. The temperature targets of importance are the 49^{0}F temperatures between August and November when temperature management is the most crucial on the Trinity River and the auxiliary outlet (described in the next section) is allowed to operate. The 60^{0}F temperature target was implemented to force power generation in the model.

Table 6B.C.4 Seasonal Temperature Targets for Trinity Dam to Operate to in the HEC-5Q Model

Date	Temperature Target
January 1	60^0 F
July 31	60^0 F
August 15	49^0 F
November 30	49^0 F
December 1	60^0 F
December 31	60^0 F

Trinity Dam has a low-level (auxiliary) outlet, a morning glory spillway, and a single-level power intake that doubles as a high capacity river outlet. The relevant input data for Trinity Dam in the Trinity-Sacramento HEC-5Q data file are shown on Figure 6B.C.4. (Note that the line numbers are for reference only and are not line numbers in the Trinity-Sacramento HEC5Q data file.) Additional diagrams that were used as the basis for the improvements to Trinity Dam selective withdrawal logic in the Trinity-Sacramento River model are included in later portions of this appendix.

```

Figure 6B.C.4 Input Data Relevant to the Trinity Dam Selective Withdrawal Procedure in the Trinity-Sacramento HEC-5Q Data File

As the auxiliary outlet and power intake are at a fixed elevation, the only available temperature control option is to bypass power generation and divert colder temperature flows to the auxiliary outlet. The allocation between the auxiliary (power bypass) and power flows is designed to meet the seasonal temperature targets described earlier based on the Trinity-specific data described below.

The Line 29 (L5) defines the auxiliary outlet characteristics and serves as the power bypass outlet. The first 72 columns are standard inputs while the additional data beyond column 72 constrain operation rules for power bypass to the auxiliary outlet. The constraints imply that the auxiliary outlet can be throttled to a specified flow rate. In reality, the auxiliary outlet is fully open or completely closed. Therefore, the fraction of the total outflow translates to a time period when the auxiliary outlet is fully open. Power flows would provide the minimum flow requirement for the river above Lewiston Lake. Mixing within Lewiston Lake is assumed to blend the flows of different temperatures.

- Col 73-80: Maximum fraction of the total out flow allowed through the auxiliary outlet (power bypass)
- Col 81-88: Minimum fraction of the total outflow required for bypass through the auxiliary outlet
- Col 89-96: Maximum flow through the auxiliary outlet in cubic feet per second (cfs)
- Col 97-112: Calendar date limits for power bypass to the low-level outlet. These dates override the limits set by the "PT" record.

Lines 31 and 32 (L6 and L7) are standard inputs defining the spillway crest length and power intake area as well as the flow capacity and elevation. The maximum flow for both the auxiliary (L5) and power intake (L7) serve as placeholder data. The actual flow rates are defined within the code as a function of lake elevation. When the flow and elevation conditions fall within the constraints seen in Figure 6B.C.3, the generation flow is added to the river outlet capacity seen in Figure 6B.C.2. From a temperature simulation perspective, there is no difference between power flow and river release flows as they share the same outlet conduit. The power production only adds to the total flow capacity of the common outlet tunnel.

6B.C.6.1.2 Trinity Dam Operations Output

A single comma-delimited output file is generated by the Trinity Dam-specific option. This file is named on the "USBR_OPP " record that triggers the power bypass option. This comma-delimited file ("Trinity Power Bypass.txt") when imported into Excel produces a file that summarizes the outlet operation and other pertinent data. The file includes daily lake storage and elevation, flow capacity and allocation to the auxiliary and power outlets, total outflow (release), target and outflow temperature, and spill information. The screen capture shown in Figure 6B.C.5 is an example of the resulting Excel file. There are two flags that indicate constraints on the bypass flow. In the example, August 28 is the day that is constrained by the maximum daily flow limit.

Figure 6B.C.5 Example Trinity Outlet Operations File Generated when Running the Model (The file is titled "Trinity Power Bypass.txt after the Trinity-Sacramento River model is run")

6B.C.6.2 Shasta Dam

6B.C.6.2.1 Seasonal Temperature Target Schedule

A Shasta Dam release temperature target scheduling spreadsheet for the Trinity-Sacramento River model was developed using logic that was derived from the National Marine Fisheries Service 2009 Biological Opinion on the Long-Term Operations of the Central Valley Project and State Water Project (NMFS BO) and actual temperature management operations provided by Reclamation. The spreadsheet generates a PT record that is referenced at line 580 in the Trinity-Sacramento HEC-5Q data file.

6B.C.6.2.2 Shasta Operations Output File

Two comma-delimited files (*.2xl) are produced that summarize the Shasta TCD operation. Both files provide similar information; however, the file "TCD_xx.log0.2xl" contains zeros while "TCD_xx.log.2xl" contains blanks in the computed flows and temperatures columns. The blank-filled file is easier to read but precludes arithmetic manipulation. Figure 6B.C.6 is an example Excel file generated by the "TCD_xx.log0.2xl" text file. This figure separated into two parts for ease of reading.

Figure 6B.C.6 Example Shasta Outlet Operations File Generated in the Model (The file is titled "TCD_xx.log.2xl after the Trinity-Sacramento River model is run")

Columns D-K list the number of shutters and flow allocation to the top, middle, penstock and lower levels. Columns M-S list the leakage flows by elevation ranges. (Note that these leakage flows may have changed due to shutter maintenance and modification.)

Column C equals columns L+T (total release and power flow components) and are identical except when the power flow capacity is exceeded. When the total release exceeds the allowable power flow, the excess is allocated to the sluice gate with the temperature nearest the temperature objective. Use of the spillway occurs only after the power and sluice gate are fully utilized. Columns V-Z list the sluice gate and spillway flows.

The remaining columns report water temperatures. The shutter temperatures (AB-AE) are reported for all possible levels even though there may be no flow.

Temperatures for all possible leakage levels appear in columns AF-AL. Columns AA and AM report the temperature object and the power flow temperature respectively. The remaining columns report the sluice and spillway temperatures only when there is flow.

6B.C.6.3 Folsom Dam

6B.C.6.3.1 Seasonal Temperature Target Schedule

A Folsom Dam release temperature target scheduling procedure for the American River model was developed using logic that was derived from the NMFS BO and actual temperature management operations provided by Reclamation. The spreadsheet generates a PT record that is referenced at line 262 in the American River HEC-5Q data file.

6B.C.6.3.2 Selective Withdrawal Operations

The shutter position and power bypass are set to meet the temperature targets based on the Folsom-specific data described below. Figure 6B.C.7 shows the relevant input data for Folsom Dam in the American River HEC-5Q data file and has additional comments that supplement this text. (Note that the line numbers are for reference only and are not line numbers in the American River HEC-5Q data file.)

```
11 c... Folsom Dam shutter operation  (Reference Figure 5, 2013 project report)
12 c.    P1 - Centerline of the power penstocks
13 c     P2 thru P4 - Centerline elevation of the shutter openings (crest elevation + 26/2)
14 c.    Center line     307     Power Penstocks
15 c.    Crest elev              336     362     401  (add 13' to crest elevation - P2, P3 & P4 of L7 Record)
16 c.    Note that the depth of submergence "Dout" is referenced to the centerline of the equivalent port representation
17 c.    e.g. elevation submergence limit for the upper port is 414+20-401 = 33'  The minimum required
18 c.    submergence is 27' so the L7 data provide a 6' safty factor (approx 1/2 the height of each shutter)
19 c. Minimum fraction of flow through any port before any change          |       |
20 c   Aout    Qmax      P1      P2      P3      P4      P5      P6    Dout
21 c. CL/crest elev     307     336     362     401  (add 13' to crest elevation - P2, P3 & P4)
22 L7   400    8000     307     349     375     414                      20       1     .10
23 c.. check this      ^^^^^   may be 290'??? 307' from Figure 5, August 2013 report
24 c.  Two adjacent ports may be operated, flow allocation between ports as a function of target temperature.
25 c. The character string "Save opp:" combined with the Control Point Number 590 triggers this outlet option
26 c. The output file "Folsom.TCD.Opp" summarizes outlet structure operation.  "FOLSOM.TCD.2XLS" is a
27 c. comma delimited reformatted version of the summary table.
28 c. The word "lower" followed by a series of months defines the period when all shutters are lowered
29 c. (subject to elevation constraints)  Two shutter operation approaches during spilling are available.
30 c. If "spill#1" is present of the Save_opp record (example), all shutters lowered with all units at 2,680 cfs
31 c. If "spill#2" is present, two elevations for the three sutters are based on temperature objective
32 c. (e.g., two at 5,360 cfs, one at 2,680 cfs) - both options subject to submergence constraints
33 c. (subject to elevation constraints)
34 c. The "plus" option will add an elevation increment (ft) to the withdrawal elevation to delay adding a shutter (raising environment)
35 Save opp: Folsom.TCD.Opp  Lower   Dec  Jan   Feb   March          spill#1
```

Figure 6B.C.7 Input Data Relevant to the Folsom Dam Selective Withdrawal Procedure in the American River HEC-5Q Data File

Line 19 (L5) defines the low level outlet characteristics that serves as the power bypass outlet. The first 72 columns are standard inputs while the additional data beyond column 72 control operation of the power bypass. The following three inputs provide limit on flow and date limits for power bypass.

- Col 73-80: Maximum fraction of flow through the low level power bypass
- Col 81-88: Minimum fraction of flow through the low level power bypass
- Col 89-96: Maximum flow through the low level power bypass
- Col 97-112: Calendar date limits for power bypass to the low level outlet

Line 29 (L7) is a standard input for representing a multi-port withdrawal structure. For the Folsom Lake TCD (shutters) option, the standard inputs are used to define the penstock (all shutters raised) and three possible shutter elevations and the shutter submergence criteria. The value defined in columns 81-88 (.10) is the threshold fraction of the total flow required for a shutter change.

Line 36 initiates the Folsom Dam-specific option. The character string "Save opp:" ("USBR_opp" is an alternate flag) combined with the control point number 590 triggers this outlet operation option. Two adjacent shutters are operated and flow is allocation between shutters to provide an outflow that approximates the target temperature. Following the file naming, a series of months (e.g., December thru March) may be included to specify that shutters be set in the lowered position. During tainter gate operation, the shutters are operated to meet the temperature objective after correcting for the temperature of the spill. Including "SPILL#1" following the months will force the outflow at the highest possible level, thus conserving the cold water resource.

6B.C.6.3.3 Folsom Dam Operations Output

There are two output files generated by the Folsom-specific option. The "Folsom.TCD.Opp" is a text file that is produced as the simulation progresses. This text file is reformatted to produce a file with a "2xls" file extension upon completion of the temperature simulation (this file will not be created if the run ends prematurely). This comma-delimited file, when imported into Excel, produces a file that summarizes the Folsom shutter operation and power bypass. The file includes daily flow allocation, outflow temperature, temperature compliance, lake elevation and storage information. An example of the resulting Excel file is shown on Figure 6B.C.8. There are two flags in column A that indicate operation constrained by lake elevation or specified shutter lowering. Shutter changes are indicated by "TRUE" in column C. Shutter changes are indicated when a shutter level is discontinued and when a new shutter level is added. In reality, the two shutter changes indicated on September 22 and 26 would actually be one change in which the "middle raised" shutter (one or two shutter bays) would remain unchanged while both remaining shutters in the "upper raised" position would be removed to move from the "upper raised" condition to the "lower raised" condition. The number of shutter bays at the indicated level is not considered in the flow allocation. Therefore, the total generation flow for a shutter level may exceed the capacity of a single penstock. Power bypass assumes that all shutters are raised and the power bypass fraction is indicated only by flow. There are temperatures circled in red in the sample output that have no corresponding flow. These temperatures indicate that a shutter change would have occurred if not for the minimum flow requirement.

Shutter Position (U-Upper raised _ M-Middle raised _ L-Lower raised _ A-All lowered
El=>> elevation constrained
low>> specified lowering per "Save opp" record

Figure 6B.C.8 Example Folsom Outlet Operations File Generated when Running the Model (The file is titled “Folsom.TCD.Opp.txt after the American River model is run”)

The other Folsom operations output (Figure 6B.C.9) is a text file that summarizes the Folsom TCD operation. The file is named “WS_TCD.txt” and includes the operational information seen below. The output is daily except when the reservoir element location changes and there is an additional line of output during that day.

```

6B.C.7 Quality Assurance/Quality Control

This section describes two different elements of the QA/QC process used to ensure the quality for the Toolkit. The first section describes the update and review process for the Toolkit. The second section describes the spreadsheets that were developed to perform a QA/QC process on application model runs from the Toolkit.

6B.C.7.1 Update and Review Process

Three QA/QC spreadsheet tools were also developed as part of the updates to the Toolkit. The spreadsheet tools are designed to be used for a QA/QC process of all application model runs from the Toolkit.

6B.C.7.1.1 CalSim II and HEC-5Q Comparison Spreadsheet

The first spreadsheet tool HEC5Q_CalSim II_QA/QC_[River Model]_rev06_011615_Template_NAA_Example compares CalSim II storages and flows with HEC-5Q storages and flows to ensure that storages and flows are translating correctly. A procedure for performing a QA/QC of CalSim II and HEC-5Q flows and storages is described in the spreadsheet. Minor differences between CalSim II input flows and HEC-5Q output flows are expected because HEC-5Q storages and flows are modified to meet downstream temperature targets. In addition, not all HEC-5Q output locations map well with CalSim II nodes, which can cause significant flow differences. The flow mapping task reduced this issue but additional changes to CalSim II are required. Expected differences for each HEC-5Q location are described in the spreadsheet and deviations from those expected results are recommended to be investigated for potential issues.

6B.C.7.1.2 HEC-5Q Alternative Comparison Spreadsheet

The second spreadsheet tool HEC-5Q_AltCompare_[River Model]_rev03_012715_Template_Example compares HEC5Q storages, flows, and temperatures between two alternatives to ensure that temperature results make logical sense based on flow and storage differences. A procedure for performing a temperature comparison procedure is described in the spreadsheet. This spreadsheet assumes that a comparison procedure of flows and storages differences has been already been completed as part of review of CalSim II results and that the flow and storage differences are accurate. Use of this spreadsheet requires the user to have performed a prior HEC-5Q and CalSim II QA/QC procedure with the tool described previously for both alternatives. It also requires the user to have a prepared expectation of temperature differences based on their knowledge of the differences between the alternatives.

6B.C.7.1.3 Operation Diagnostic Spreadsheets

The third spreadsheet tool is an operation diagnostic tool [Reservoir] _Operations_Diagnostic_rev01_030515. There is one for Shasta, Trinity, and Folsom Dams. The purpose of the tool is to graphically display the flows and temperatures through the various temperature control structures and outlets for Shasta, Trinity, and Folsom Dams to view how the reservoirs are operating to meet downstream temperature targets.

6B.C.8 Trinity-Sacramento River Model Validation

This section provides comparisons between observed temperature data and computed temperature results from the validation task for the Trinity-Sacramento

River. Figures 6B.C.10 through 6B.C.42 present geographic locations used in the HEC-5Q Model and comparisons of observed and computed data at these locations. Observed results are from Reclamation, Department of Water Resources (DWR), and U.S. Geological Survey (USGS) data. The results indicate overall good agreement between computed and observed data.

6B.C.9 American River Model Validation

Comparisons between observed temperature data and computed temperature results from the validation task for the American River are provided in this section. Figures 6B.C.43 through 6B.C.50 present geographic locations used in the HEC-5Q model and comparisons of observed and computed data at these locations. Observed results are from Reclamation, DWR, and USGS data. The results indicate overall good agreement between computed and observed data.

6B.C.10 Trinity River Outlet Diagrams

Diagrams that were used to simulate the Trinity Dam selective withdrawal procedure and the associated updates to the Trinity Dam outlets in the Trinity-Sacramento HEC-5Q model are presented in this section. Figure 6B.C.51 shows a schematic of the Trinity Dam outlets. Figure 6B.C.52 shows outlet capacity curves for the different Trinity Dam outlets. Figure 6B.C.53 shows the operational and flow vs. head (0 feet head at 1,900 feet lake elevation) characteristics of the Trinity Dam retrofitted turbine.

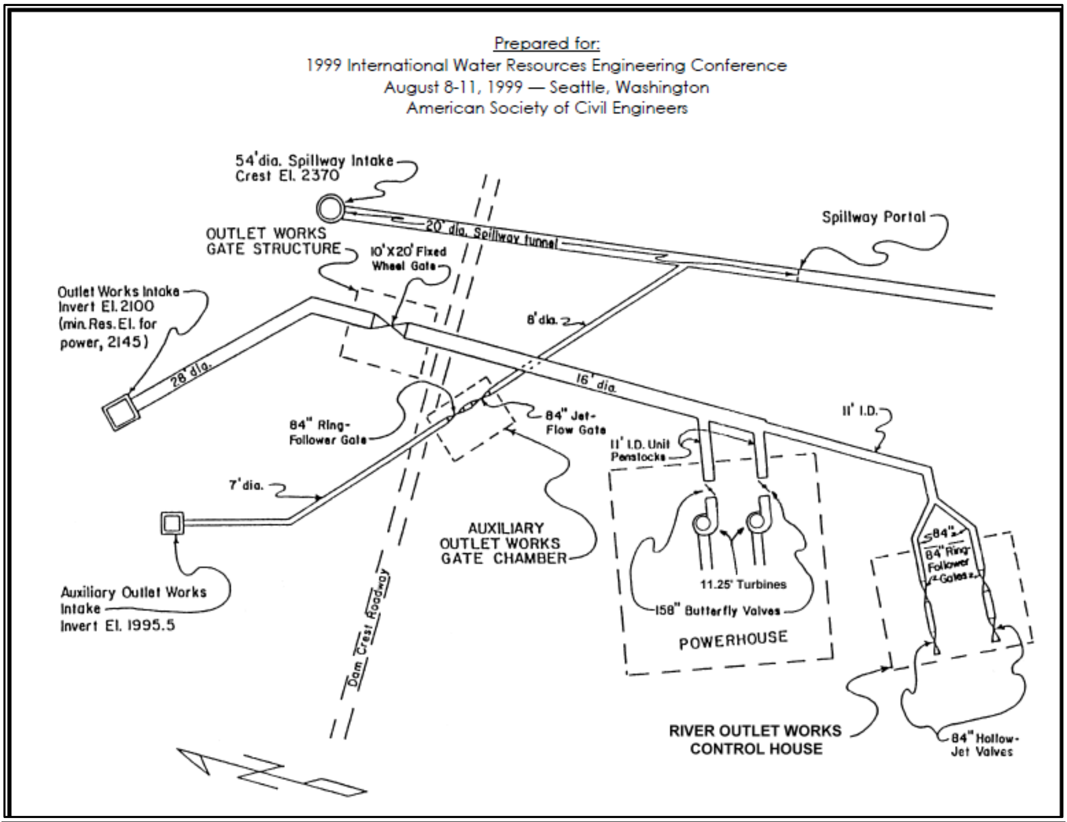

Figure 6B.C.51 Schematic of Trinity Dam Outlets (Wahl and Cohen 1999)

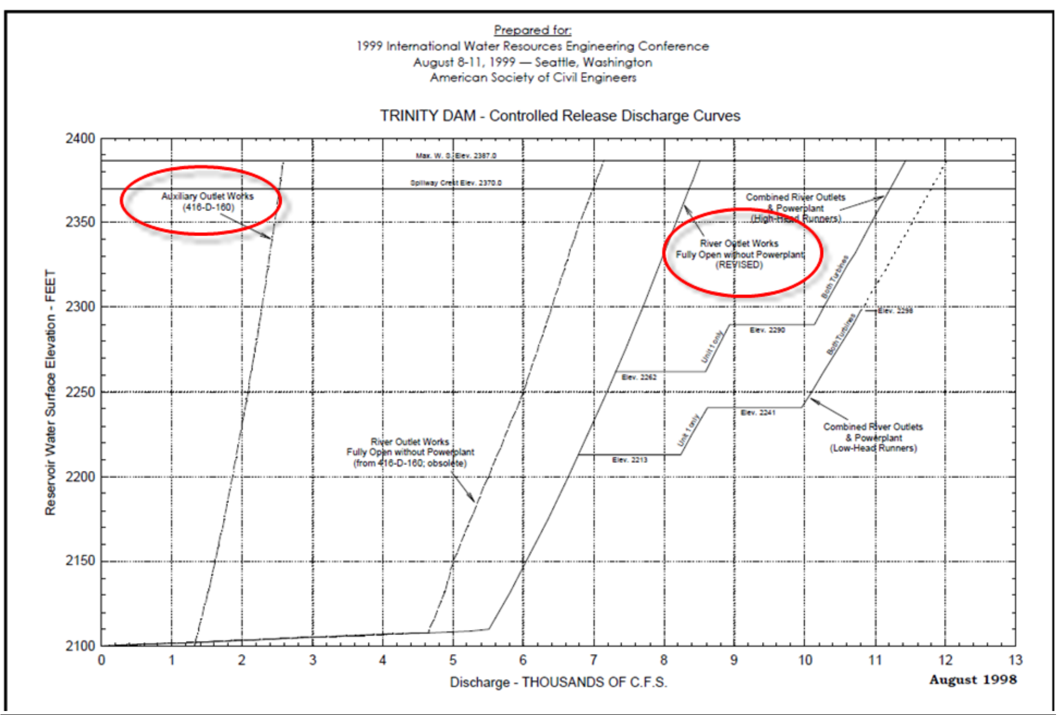

Figure 6B.C.52 Outlet Capacity Curves for Trinity Dam Outlets (Wahl and Cohen 1999)

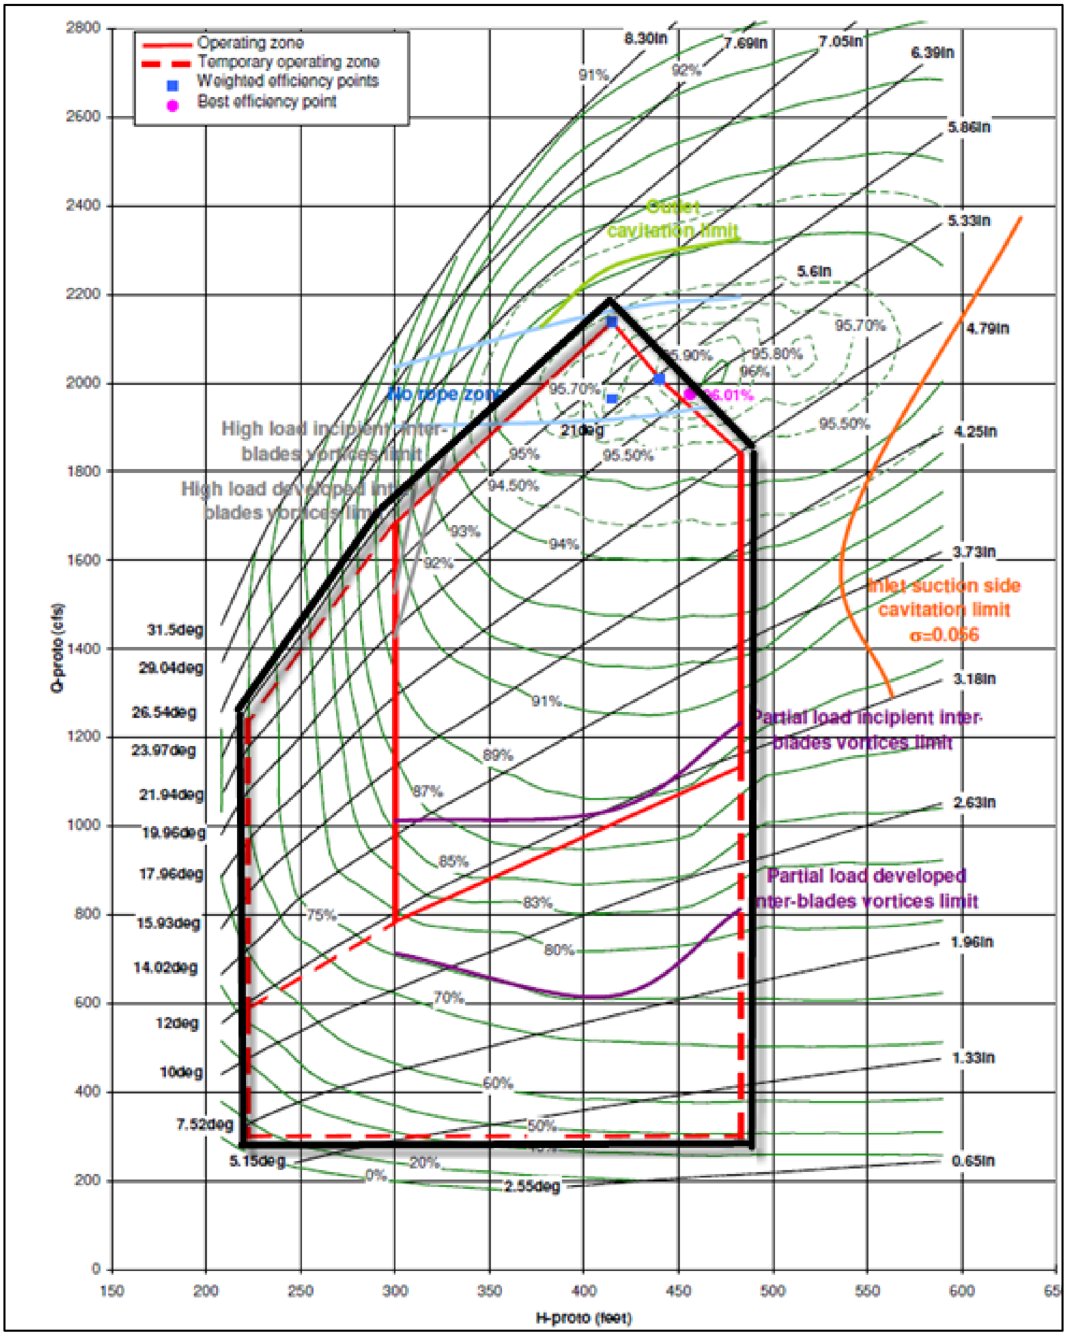

Figure 6B.C.53 Operational and Flow Compared to Total Head (with 0 feet head at 1,900 feet lake elevation) Characteristics of the Trinity Dam Retrofitted Turbine

6B.C.11 Shasta Release Temperature Target Schedules Spreadsheet Development

An approach to setting Shasta Dam release temperature target schedules in accordance with the 2009 NMFS BO, current management of the temperature target locations, and the spreadsheet tool SacR_Temp_Sel_Tool_rev05_FULL_FINAL_3-3-15.xlsm are presented in this section.

6B.C.11.1 Background

The SWRCB Water Rights Order 90-05 and NMFS BO include water temperature criteria in Sacramento River downstream of Shasta Dam. The NMFS BO Reasonable and Prudent Alternative (RPA) I.2.1 sets forth temperature compliance percentages for the summer season at specified locations on the Sacramento River (Table 6B.C.22) for not exceeding 56^0F at the specified location. These compliance percentages do not apply during extended drought periods.

Table 6B.C.22 Compliance Percentage for Not Exceeding 56^0F at Select Locations on the Sacramento River in the NMFS BO

Location	Compliance Percentage in NMFS BO (based on 10-year moving average)
Clear Creek	95 percent of Time
Balls Ferry	85 percent of Time
Jelly's Ferry	40 percent of Time
Bend Bridge	15 percent of Time

Shasta Lake releases are operated to not exceed 56^0F at the compliance locations, to the extent possible. The Sacramento River Temperature Task Group (SRTTG) meets once a month from April to October to discuss temperature compliance actions, as described in Appendix 3A.

Historically, initial compliance locations have been correlated to End-of-April storage, as summarized in Table 6B.C.23.

Table 6B.C.23 Compliance Location Based Upon End-of-April Storage

Compliance Location	End-of-April Storage (TAF)
Clear Creek	<3600
Balls Ferry	3600 – 4000
Jelly's Ferry	4000 – 4400
Bend Bridge	>4400

Figure 6B.C.54 shows the temperature compliance from 1996 to 2014 based on monthly Sacramento River Temperature Reports (Reclamation 2015). Shasta

Dam releases were operated under SWRCB Water Rights Order 90-05 during this entire time period. Operations under the NMFS BO were initiated in 2009.

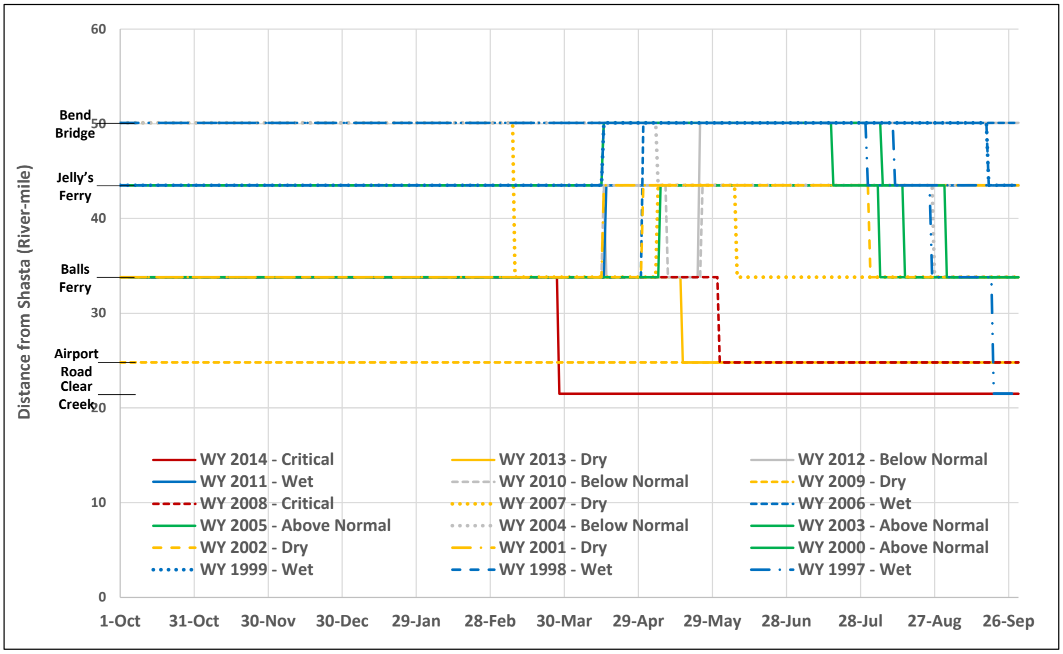

Figure 6B.C.54 Temperature Compliance Locations from 1996 through 2014

As shown in Figure 6B.C.54, the compliance location often changed multiple times in a year as Shasta storage, meteorology, tributary, and fisheries conditions changed through the year. No specific procedure could be identified for when locations were changed. In some years, such as 2007, the location would start further downstream (Bend Bridge), then move upstream (Balls Ferry), then move downstream (Jelly's Ferry), and then back upstream (Balls Ferry). In other years (e.g., 2004), the location would progressively move upstream.

Two general trends were identified. First, the compliance locations tended to be at Balls Ferry, Airport Road, and/or Clear Creek in dryer years (when Shasta Lake storage was low with less cold-water), and at Jelly's Ferry and Bend Bridge in wetter years. Second, the compliance location tended to move closer to Shasta Dam later in the year (as the cold-water pool became more depleted and meteorological conditions became warmer). These two trends, combined with the general operations used by Reclamation to set the initial annual compliance location, were used to help develop the temperature scheduling logic described below.

6B.C.11.2 Temperature Target Spreadsheet Development

This section describes the development of the Sacramento River Temperature Targeting Spreadsheet SacR_Temp_Sel_Tool_rev05_FULL_FINAL_3-3-15.xlsm.

Shasta storage data from the CalSim II EIS No Action Alternative Q5 run dated January 27, 2015 was loaded into the spreadsheet. This storage data set the compliance location for each year of the CalSim II simulation period and the data remain unchanged throughout the temperature schedule development. April storage was chosen as the parameter from which to choose the compliance location because it was specified as the indicator of cold-water pool storage in the NMFS BO. April storage was divided into five tiers, each tier representing a different compliance location based on Reclamation's rule-of-thumb approach for Shasta End-of-April storage shown in Table 6B.C.23. (Note that the storage tier for compliance with Jelly's Ferry is at 4,425 TAF in this procedure instead of 4,400 TAF.)

The four compliance locations (see Table 6B.C.22) were given an annual temperature schedule of monthly Shasta release temperature targets. These targets were developed using the following logic.

- **Step 1:** For each month individually, the difference between the modeled temperature at the compliance location and the modeled temperature below Shasta Dam was calculated for each year.
- **Step 2:** The difference value calculated in Step 1 that represented a specified exceedance for each month was then calculated for all compliance locations. This helped characterize the warming that occurred between Shasta release temperatures and each compliance location. For example, September at Bend Bridge was given a 5 percent exceedance. This exceedance says that only 5 percent of years had a September temperature difference higher than this difference value (e.g. 11.2^{0}F). In other words, warming that occurred between Shasta and Bend Bridge in September for the previous model run was 11.2^{0}F or lower for 95 percent of years.
- **Step 3:** The value calculated in Step 2 was then subtracted from 56^{0}F and this became the Shasta release temperature target for that compliance location in that month. This step assumes that the Shasta release temperature target will meet 56^{0}F or lower at the compliance location for the exceedance percentage number of years. For example, a Shasta release temperature target of 44.8^{0}F in September will meet 56^{0}F or lower at Bend Bridge for 95 percent of years.

The Sacramento River HEC-5Q model was run, using the January 13, 2015 version delivered to Reclamation and the CalSim II data described in previously, and the temperature output was loaded into the spreadsheet. The compliance performance was checked by calculating the percentage of years, over the 81-year simulation period, each compliance location exceeded 56^{0}F for each month and the difference between that percentage and the compliance percentage listed in Table 6B.C.22. Then, using an initial set of exceedance percentages (described in Step 2) and the latest Sacramento River HEC-5Q model code (March 3, 2015) to set the new temperature schedules, the Sacramento River HEC-5Q model was re-run and the temperature output reloaded in the spreadsheet. An iterative process was then performed where the exceedance percentages were adjusted, the Sacramento River HEC-5Q model was re-run and the temperature output was reloaded, and the compliance performance was checked until the compliance performance was deemed satisfactory. The final exceedance percentages (June to December) are listed in Table 6B.C.24.

Table 6B.C.24 Exceedance Percentages for June through December at the Four Temperature Compliance Locations

	June	July	August	September	October	November	December
Clear Creek	75.00	50.00	15.00	5.00	25.00	40.00	50.00
Balls Ferry	75.00	50.00	15.00	5.00	25.00	40.00	50.00
Jelly's Ferry	75.00	50.00	15.00	5.00	25.00	40.00	50.00
Bend Bridge	75.00	50.00	15.00	5.00	25.00	40.00	50.00

January through May were not given exceedance percentages as temperature management during those months is generally not an issue. Instead, January, February, and March were given a constant temperature target of 60.8^0F, which is the average temperature above the thermocline in Lake Shasta. Shasta Lake generally does not stratify during those months so the temperature at the top of the thermocline is assumed to be consistent through the entire depth of Shasta Lake (Rettig and Bortleson 1983). April and May were given a constant temperature of 53.6^0F, which is the average temperature below the thermocline in Shasta Lake. Stratification starts to occur in April and May and it is assumed that there is enough storage in Shasta Lake to conserve the cold-water pool. The final Shasta release temperature targets used in the spreadsheet for each compliance location are shown in Table 6B.C.25.

Table 6B.C.25 Final Shasta Lake Release Temperature Targets Used in the Temperature Targeting Spreadsheet

Location	Shasta Storage (TAF)	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
None	<2000	60.8	60.8	60.8	53.6	53.6	52.6	52.6	51.8	50.8	54.6	56.0	56.2
Clear Creek	<3600	60.8	60.8	60.8	53.6	53.6	52.6	52.6	51.8	50.8	54.6	56.0	56.2
Balls Ferry	<4000	60.8	60.8	60.8	53.6	53.6	51.2	51.5	50.4	49.3	54.1	56.3	56.9
Jelly's Ferry	<4425	60.8	60.8	60.8	53.6	53.6	49.6	50.1	48.7	47.7	53.6	56.7	57.6
Bend Bridge	<9999	60.8	60.8	60.8	53.6	53.6	48.5	49.0	47.4	46.6	53.4	56.9	58.1

This modeling approach does not dynamically change the compliance location that in reality changes throughout the year based on the SRTTG recommendations. While the temperature release targets would not change using for the year with this modeling logic, the logic recognizes that those temperature release targets will not be possible to meet in each year due to changes in Shasta Lake storage and meteorological conditions. If modeled Shasta Lake releases are lower than the temperature target, then it could be considered that the compliance location was moved downstream. In addition, if Shasta Lake releases are higher than the temperature target, then it could be considered that the compliance location was moved upstream.

As an example, the End-of-April Storage from the CalSim II run in Year 1940 is 4,140 TAF. The compliance location is therefore set to be Jelly’s Ferry and the temperature schedule in Table 6B.C.25 is for Jelly’s Ferry. Using those temperature targets, the HEC-5Q model run produces Shasta Lake outflow temperatures that do not meet those temperature targets and thus result in temperatures that do not meet 56^{0}F at Jelly’s Ferry, due to Shasta Lake storage and downstream meteorological conditions. For instance, in July the Shasta Lake outflow was 48.6^{0}F, even though the release target was 50.1^{0}F. This is because Shasta Lake storage was still relatively high to preserve more cold water in the reservoir pool and meteorological conditions were cooler than were typical for July. Thus the release temperature was cooler than the temperature target and as a result, 56^{0}F was met at Bend Bridge. In September, Shasta Lake outflow was 53.7^{0}F, even though the temperature target was 47.7^{0}F. This is because meteorological conditions were warmer than were typical for September. Thus the release temperature was warmer than the temperature target and as result, 56^{0}F could only be met at Clear Creek. A full illustration of modeled Year 1940 and the compliance location changes based on Shasta release temperatures are presented on Figure 6B.C.55.

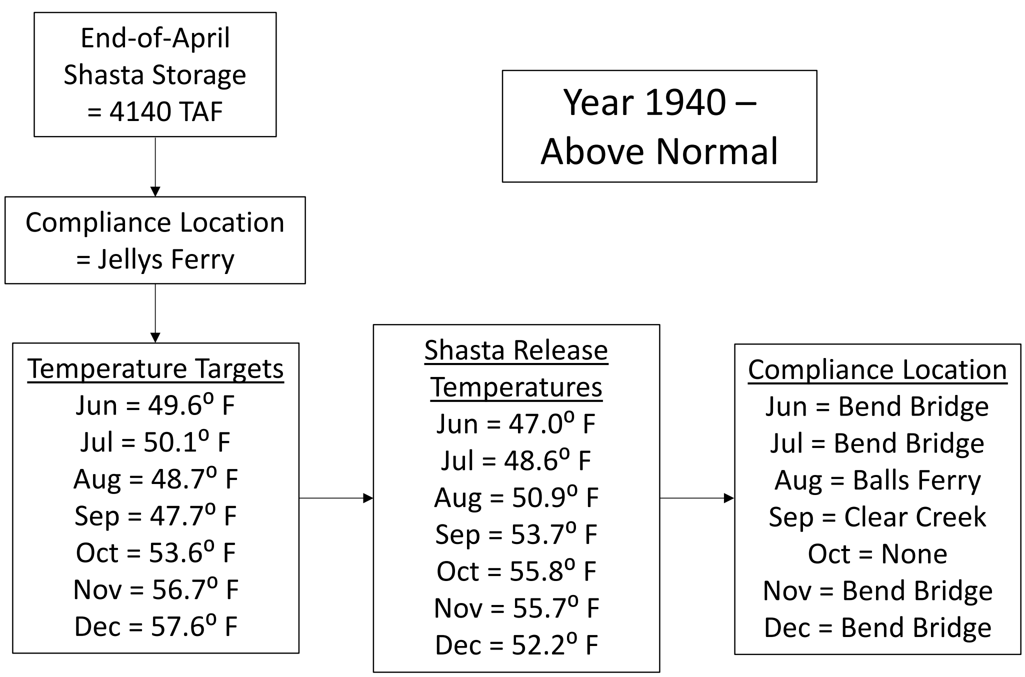

Figure 6B.C.55 Changes in Compliance Location Based on Shasta Lake Release Temperatures for Year 1940

While during all months the temperature target was set based on a compliance location of Jelly's Ferry, the actual compliance location changed. Thus the model passively mimics the SRTTG changing the compliance location based on Shasta Lake storage conditions and downstream meteorological conditions.

The chosen compliance location based on End-of-April storage and the actual compliance location achieved over the 81-year simulation period are shown on Figure 6B.C.56.

Figure 6B.C.56 Simulated Compliance Location Target and Achievement for Each Year over the 81-Year CalSim II Period

6B.C.11.3 Temperature Compliance Performance

As shown in Table 6B.C.26, the compliance location achieved during each month for each year over the 81-year simulation period mimics the general trends described previously. During dry periods (e.g., 1985 to 1992), the compliance location generally starts out at the upstream locations Clear Creek and Balls Ferry. Over the course of each year, the compliance location moves progressively upstream.

Table 6B.C.26 shows the percentage of years the HEC-5Q model (using the CalSim II data described earlier and the temperature targets shown in Table 6B.C.25) met 56^{0}F at each compliance location and the years short of meeting the compliance percentage.

Table 6B.C.26 Compliance Performance of the Final Temperature Targets

Location and Percentage of Years Required for Compliance	Jun	Jul	Aug	Sep	Oct	Nov	Dec
	Percentage of Years 56^{0}F Was Met at Each Compliance Location (N=81 Years)						
Clear Creek (95 percent of years)	98	89	72	57	62	91	100
Balls Ferry (85 percent of years)	90	86	62	42	47	93	100
Jelly's Ferry (40 percent of years)	75	69	33	26	33	91	98
Bend Bridge (15 percent of years)	54	47	7	14	26	95	98
	Number of Years Short of Compliance						
Clear Creek (95 percent of years)	-	5	19	31	27	3	-
Balls Ferry (85 percent of years)	-	-	19	35	31	-	-
Jelly's Ferry (40 percent of years)	-	-	5	11	5	-	-
Bend Bridge (15 percent of years)	-	-	6	1	-	-	-

6B.C.12 Folsom Release Temperature Target Schedules Spreadsheet Development

An approach to setting Folsom Dam release temperature target schedules for temperature management on the Lower American River based on NMFS BO and is an accompanying document to the spreadsheet tool AmerR_Temp_Sel_Tool_rev15_FULL_FINAL_3-16-15.xlsm is presented in this section.

6B.C.12.1 Background

The NMFS BO RPA II.2 sets forth a temperature requirement for the Lower American River at the Watt Avenue Bridge to not exceed 65^{0}F from May 15 to October 31.

In order to meet the NMFS BO temperature requirement, Reclamation manages Folsom Dam release temperatures based on temperature schedules set forth in Appendix 2-D of the NMFS BO. These schedules set monthly temperatures at Watt Avenue for Folsom Dam to operate to from May to October (temperature management season) based on forecasted Folsom storage and inflow. The initial temperature schedule for each year is determined based on an operations plan developed by Reclamation and approved by the American River Operations Group (ARG). However, these schedules are based on forecasted conditions. As conditions actually happen throughout the temperature management season, due to changes in Folsom Lake storage and inflow, current meteorological conditions, and/or the state of fisheries in the river, the Watt Avenue temperature target schedule is adjusted based on recommendations from the ARG.

It was possible to model the initial annual temperature target schedule for Folsom Lake to operate to for the year because storage and forecasted inflow are known quantities in CalSim II. However, modeling the dynamic adjustment of the Watt Avenue temperature target based on current storage and meteorological conditions was not going to be possible. Thus logic was developed to create a temperature target selection procedure that set a specific schedule for each year that remained unchanged. This logic is described in the following section.

6B.C.12.2 Temperature Target Spreadsheet Development

The development of the Sacramento River Temperature Targeting Spreadsheet AmerR_Temp_Sel_Tool_rev15_FULL_FINAL_3-16-15.xlsm is described in this section.

Folsom storage and inflow data from the CalSim II EIS No Action Alternative Q5 run dated January 27, 2015 was loaded into the spreadsheet. This CalSim II data remained unchanged throughout the temperature schedule development. May Folsom Storage plus June to September average inflow to Folsom (storage plus inflow) was calculated in the spreadsheet. This was a simplification of the forecasting approach that is used to set the actual temperature targets, as it only took into account June through September inflow.

Appendix 2-D of the NMFS BO lists 72 different temperature target schedules for May through October. Each schedule changed the temperature target for one month only. It was deemed unnecessary to incorporate all 72 schedules due to the simplified forecasting approach described above that only focused on June to September inflow. This reduced the 72 schedules to schedules that focused primarily on temperature management during June through September. Ultimately the 72 schedules were reduced to 22 schedules as these schedules were deemed to adequately represent the variance in temperature targets during June through September.

Then, using an initial set of storage plus inflow tiers assigned to each temperature schedule number, the schedule number for each year of the CalSim II period of record was calculated. Then the average storage plus inflow for each tier was calculated. For example, there were 8 years over the simulation period that had a schedule number of 11 and the average storage plus inflow was 1,415 TAF. The average storage plus inflow calculated for each tier was plotted versus the schedule number, as shown in Figure 6B.C.57.

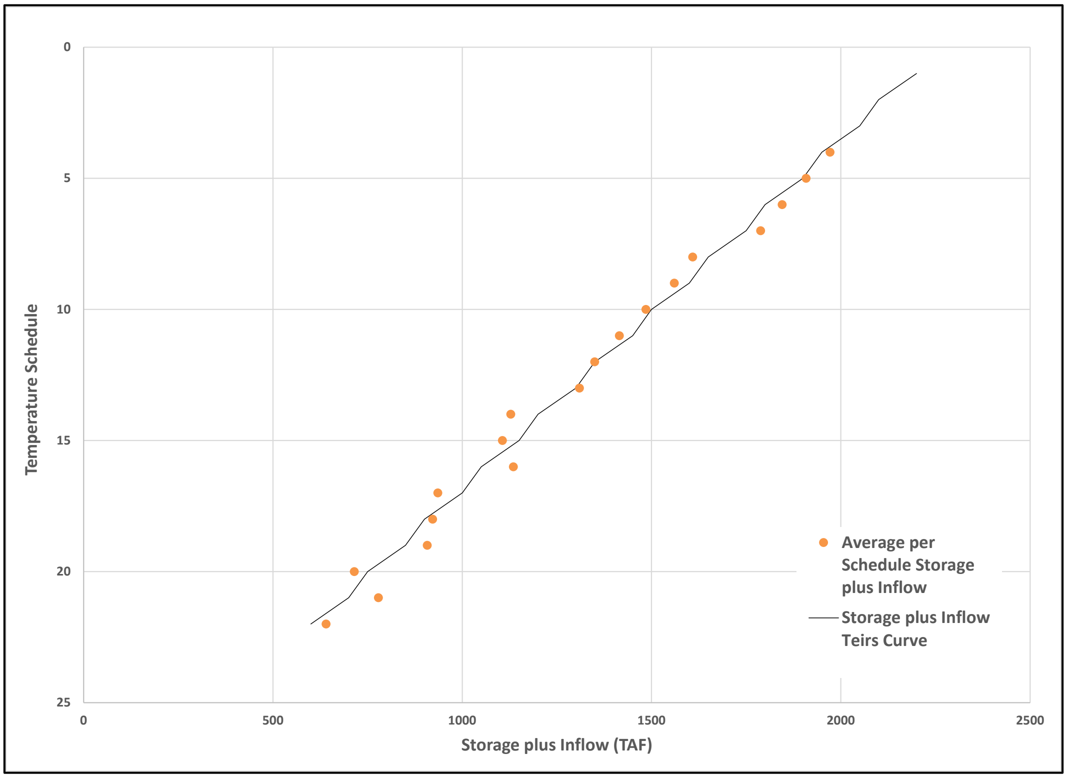

Figure 6B.C.57 Temperature Schedule Number and Average Folsom Lake Storage plus June-September Inflow for each Schedule Number

The schedule shown in the plot was used to calculate the final storage plus inflow tiers used in the spreadsheet.

Using the regression equation shown in Figure 6B.C.57, the final storage plus inflow tiers to be used for the spreadsheet were calculated (see Table 6B.C.27).

Table 6B.C.27 Final Watt Avenue Temperature Target Schedules (Yellow highlighted cells indicate a change from the previous schedule)

Schedule	Storage plus June-Sept. Inflow	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
1	0	56	56	56	63	61	61	62	62	61	57	56	56

15	1600	56	56	56	63	68	68	69	69	68	68	59	56
16	1650	56	56	56	63	69	69	69	69	69	68	59	56
17	1750	56	56	56	63	69	69	70	70	69	69	60	56
18	1800	56	56	56	63	70	70	70	70	70	69	60	56
19	1900	56	56	56	63	70	70	71	71	70	70	61	56
20	1950	56	56	56	63	71	71	71	71	71	70	61	56
21	2050	56	56	56	63	71	71	72	72	71	71	62	56
22	2100	56	56	56	63	72	72	72	72	72	71	62	56

January, February, March and December were given temperature targets of 56^{0}F for all temperature schedules as a default. During these months, temperature management is generally not an issue. April was given a temperature target of 63^{0}F to conserve cold water in the reservoir pool at the start of the temperature management season.

Establishing the temperature target schedule sets the temperature targets at Watt Avenue. However, Folsom Dam can only actually operate to release temperatures, with the goal that those release temperatures will ultimately meet the Watt Avenue temperature target after ambient warming occurs. To calculate the Folsom release temperatures, the following logic was developed.

- **Step 1:** The American River HEC-5Q Model was run using the January 13, 2015 version delivered to Reclamation, the CalSim II data described previously, and an initial Watt Avenue and Folsom Dam temperature target schedules. The temperature output from that HEC-5Q model run was loaded into the spreadsheet.

- **Step 2:** For each month individually, the difference (shift) between the modeled temperature at Watt Avenue and the modeled temperature below Folsom Dam was calculated for each year.
- **Step 3:** The annual shift calculated in Step 2 that represented a specified exceedance for each month was then calculated. This helped characterize the warming that occurred between Folsom release temperatures and Watt Avenue. For example, September was given a 50 percent exceedance. This exceedance says that 50 percent years had a September temperature shift higher than this shift value (e.g., 0.6^0F). Therefore, warming that occurred between Folsom Dam and Watt Avenue in September for the previous model run was 0.6^0F or lower for 95 percent of years.
- **Step 4:** The exceedance shift value calculated in step iii was then divided by the average annual June to September shift value. This calculated a shift factor that was used in the final temperature shift calculations.
- **Step 5:** The average June to September shift value for each schedule number was then calculated. For example, schedule number 11 was the schedule for eight years over the simulation period and the average June to September shift was 4.6^0F.
- **Step 6:** The average June to September shift value calculated in Step v was plotted versus its temperature schedule number, as shown in Figure 6B.C.58.
- **Step 7:** Average June to September shifts for each schedule number were then calculated using the regression equation in Figure 6B.C.58.
- **Step 8:** The shift values calculated in step vii were then multiplied by the shift factor calculated in step vii and was subtracted from the temperature target value in Table 6B.C.27. This created the Folsom Dam release temperature target schedules.
- **Step 9:** An iterative process where the Folsom Dam temperature target schedules developed using the initial temperature target schedules described in step 1 were then used in the next HEC5Q model run and then reloaded into the spreadsheet. The process was repeated until the Folsom Dam release temperature target schedules were deemed acceptable based on modeled temperature results. The final Folsom Dam release temperature target schedules are shown in Table 6B.C.28.

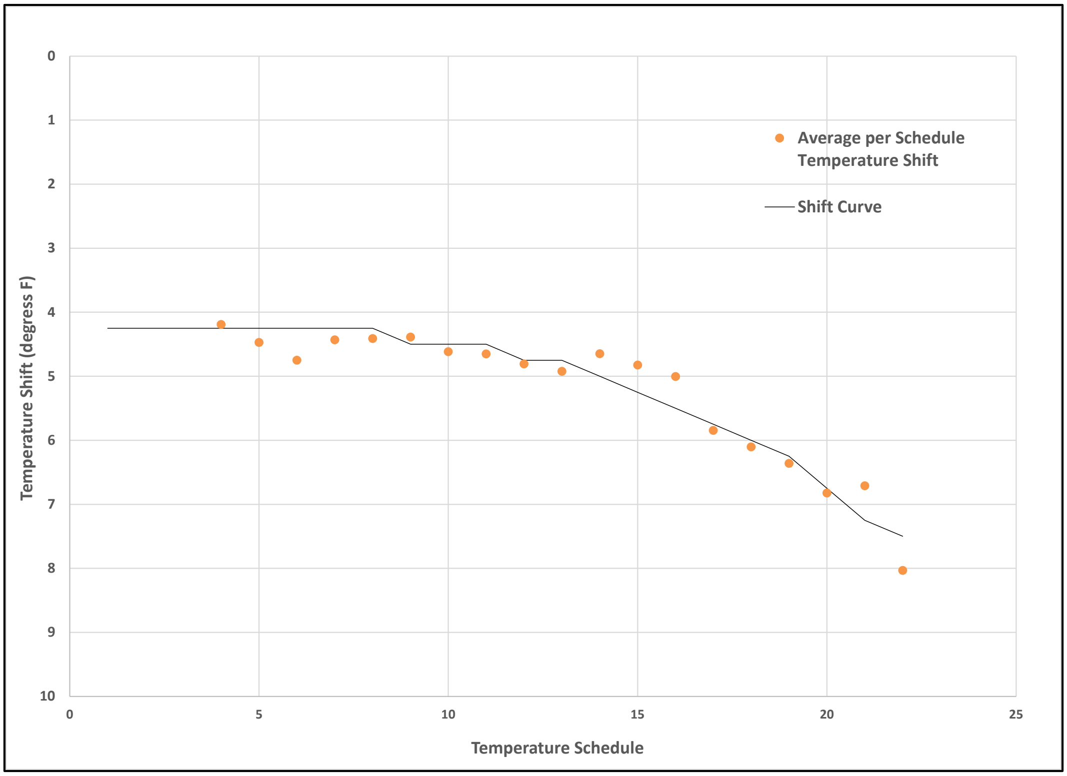

Figure 6B.C.58 Average Temperature Shift between Modeled Folsom Lake Release Temperatures and Watt Avenue Temperatures for each Schedule Number after Multiple Iterations

The shift curve shown in the plot was used to calculate the final temperature shifts used in the spreadsheet.

Table 6B.C.28 Final Folsom Dam Lake Release Temperature Targets in the Spreadsheet (Yellow highlighted cells indicate a change from the previous schedule)

January through April were not given shift factors and instead were given a constant 4^{0}F shift as a default for the same reason described for those months for the Watt Avenue temperature target schedules.

6B.C.12.3 Temperature Performance

Figure 6B.C.59 shows box and whisker plots of modeled temperatures at Watt Avenue in the completed spreadsheet.

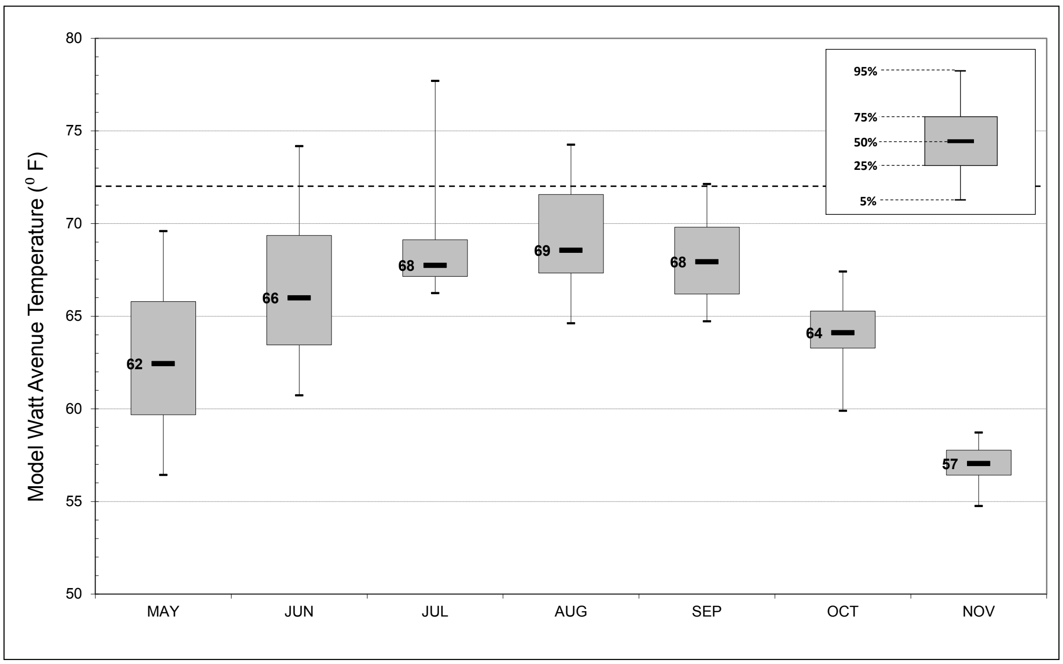

Figure 6B.C.59 Modeled Watt Avenue temperatures in Final Spreadsheet

The figure shows the expected pattern where temperatures are higher in the summer but the Watt Avenue target temperature for each month were met in majority of the years. The maximum temperature target (72^{0}F) was not exceeded in approximately 75 percent of years for all months. The years where the temperatures exceeded the maximum 72^{0}F target were during dry periods, when meeting the Watt Avenue temperature targets are not possible to meet due to low storage in Folsom Lake.

Appendix 6C

Methylmercury Model Documentation

This appendix provides information about the methods, modeling tools, and assumptions used for the Coordinated Long-term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS) analysis. It also provides information pertaining to the development of the analytical tools and the use of input data as well as model result processing and interpretation methods used for the impacts analysis and descriptions.

This appendix is organized into three main sections that are briefly described below:

- **Section 6C.1: Modeling Methodology.** The methylmercury impacts analysis used CalSim II, the Delta Simulation Model II (DSM2), and the Central Valley Regional Water Quality Control Board (Central Valley RWQCB) Total Maximum Daily Load (TMDL) model (RWQCB Model) to assess and quantify effects of the alternatives on the long-term operations of the CVP and SWP and on the environment. This section provides information about the overall analytical framework and how some of the model input information obtained from other models was processed through the use of analytical tools.
- **Section 6C.2: Modeling Simulations and Assumptions.** This section provides a brief description of the assumptions for the RWQCB Model simulations of the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5.
- **Section 6C.3: Modeling Results.** This section provides a description of the model simulation output formats used in the analysis and interpretation of modeling results for the alternatives impacts assessment.

6C.1 Modeling Methodology

This section summarizes the methylmercury modeling methodology used for the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5. It describes the overall analytical framework and contains descriptions of the key analytical and numerical tools and approaches used in the quantitative evaluation of the alternatives. The alternatives include several major components that will have significant effects on SWP and CVP operations and minor effects on the water quality of the system.

6C.1.1 Overview of the Modeling Approach and Objectives

Modeling of physical and biological methylmercury processes in the Delta is necessary to evaluate changes related to the implementation of alternatives that could affect the health of humans and wildlife consuming fish in the Delta. It has been recognized that fish tissue concentrations are the best indicator of mercury contamination in the Delta as described in the RWQCB Model (Central Valley RWQCB 2011). The RWQCB Model, an empirical tissue concentration model, was based on the concentration averages of fish mercury and water concentrations of methylmercury over broad areas of the Delta (Wood 2010). The RWQCB Model is used to estimate fish tissue mercury concentrations from concentrations of dissolved methylmercury in water.

CalSim II, DSM2 (water), and the RWQCB Model (fish tissue) were used in sequence to estimate the effects of CVP and SWP operations on water and fish tissue quality in the Delta. CalSim II simulates flow in the waterways, and DSM2 simulates one-dimensional hydrodynamics in the Delta, as discussed in Chapter 5, Surface Water Resources and Water Supplies. One of the three DSM2 modules, QUAL, simulates one-dimensional source tracking in the Delta. Results from DSM2 proportioned by source area were multiplied by average source concentrations and added to determine annual average aqueous methylmercury concentrations in the Delta for all year types and dry years for specific model nodes. The RWQCB Model is based on a power curve that uses the DSM2 output to simulate aqueous methylmercury concentrations to estimate total mercury concentrations in the fish fillets of standard 350-mm-long Largemouth Bass.

Figure 6C.1 shows the modeling tools applied in the methylmercury impacts assessment and the relationship between these tools. Each model included in Figure 6C.1 provides information to the next "downstream" model in order to provide various results to support the impacts analysis.

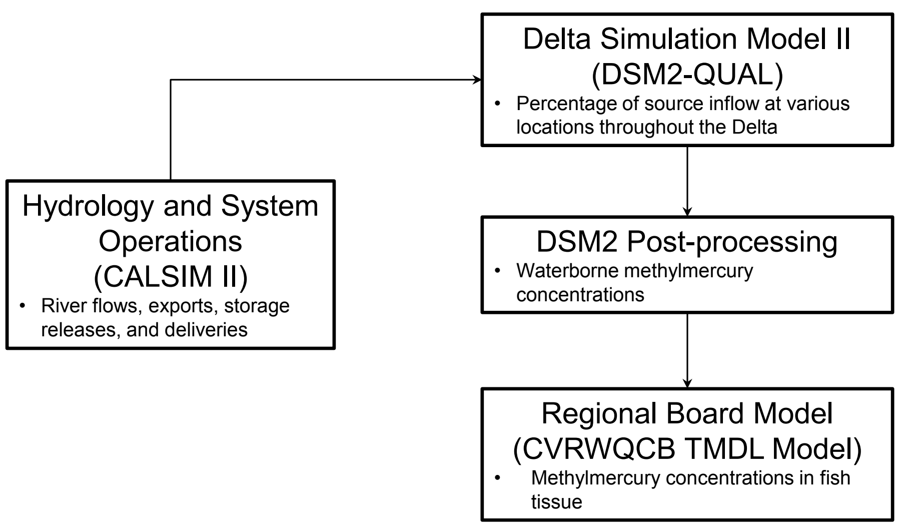

Figure 6C.1. Relationships among the Different Predictive Modeling Tools

6C.1.1.1 Modeling Objectives

Impacts on methylmercury resources in the Delta SWP and CVP Service Areas were evaluated for each alternative as part of the EIS development. Modeling objectives included the evaluation of the following:

- Percent changes in fish tissue mercury concentrations
- Exceedances of human and fish and wildlife thresholds

6C.1.2 Key Components of the Methylmercury Modeling

A calibrated regional flow model was used to provide a regional framework to be used for modeling of waterborne methylmercury concentrations. An additional model was used to translate waterborne methylmercury concentrations to total mercury concentrations in fish tissue.

6C.1.2.1 DSM2 Postprocessing

Dissolved methylmercury data were available for six inflow locations to the Delta (Table 6C.1):

- Sacramento River at Freeport (mainstem flow to Delta)
- San Joaquin River at Vernalis (mainstem flow to Delta)
- Mokelumne and Calaveras rivers (for Eastside tributaries)
- Various Delta locations (for Delta agriculture)
- Suisun Bay (for San Francisco Bay)

Table 6C.1. Modeled Methylmercury Concentrations in Water

	Drought	0.14	0.13	0.14	0.14

Notes:

ng/L = nanogram per liter

* “All” water years 1922-2003 represent the 82-year period modeled using DSM2; “drought” represents a 5-consecutive-year (water years 1987-1991) drought period consisting of dry and critical water year types (as defined by the Sacramento Valley 40-30-30 water year hydrologic classification index).

Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore model results for Second Basis of Comparison and Alternative 4 are not presented separately.

Model results for Alternative 2 and No Action Alternative are the same, therefore model results for Alternative 2 are not presented separately.

For DSM2 output locations, the geometric mean methylmercury concentrations from the inflow locations were combined with the modeled daily average percent inflow for each DSM2 output location to estimate waterborne methylmercury concentrations at those locations. The annual average mix of water from the six inflow sources (Table 6C.1) was calculated from daily percent inflows provided by the DSM2-QUAL model output. The daily waterborne methylmercury concentrations at DSM2 locations were calculated using the following equation:

$$C_{water\ quarterly} = [(I_1 * C_1)+(I_2 * C_2)+ (I_3 * C_3)+ (I_4 * C_4)+ (I_5 * C_5)+ (I_6 * C_6)]/100$$

Where:

- $C_{water\ daily}$ = daily average methylmercury concentration in water (micrograms/liter [µg/L]) at a DSM2 output location
- $I_{1\text{-}6}$ = modeled daily inflow from each of the six sources of water to the Delta for each DSM2 output location (percentage)
- $C_{1\text{-}6}$ = methylmercury concentration in water (µg/L) from each of the six inflow sources to the Delta (1-6)

The annual average waterborne methylmercury concentrations for the DSM2 output locations are shown in Table 6C.1.

6C.1.2.2 Regional Board Fish Tissue Model

The RWQCB Model predicts methylmercury concentration in 350-millimeter normalized Largemouth Bass fillet tissue from methylmercury in water. The Central Valley RWQCB developed an empirical power curve model based on measured Largemouth Bass fillet concentrations as averaged over large areas of the Delta compared to average methylmercury concentrations in water for those same areas and time periods (Central Valley RWQCB 2011):

Fish mercury (milligrams/kilogram, wet weight) = 20.365×(methylmercury in water, ng/L) $^{1.6374}$
(with r^2*=0.910, and P less than 0.05)*

The goal of the RWQCB Model was to establish the linkage between the 0.24 milligram per kilogram (mg/kg) tissue mercury TMDL target to a waterborne goal of 0.066 ng methylmercury/L. The RWQCB Model results are presented with the recognition of the imprecision of predicting fish tissue concentrations from estimates of methylmercury concentrations for specific Delta locations, but with the knowledge that Largemouth Bass are probably the best indicator of fish tissue contamination (see Section 6C.1.2.3). Results provide an estimated mean tissue concentration as would be expected by location and alternative. The model provides a Delta-specific, empirical estimate of the relationship between waterborne methylmercury and bioaccumulated fish tissue mercury.

The overall construction and calibration of the RWQCB Model were unchanged for this EIS analysis.

6C.1.2.3 Model Development

The RWQCB Model is based on unfiltered aqueous methylmercury data from March to October 2000 and Largemouth Bass fillet concentration data from September/October 2000. Largemouth Bass samples were chosen close in time and space to water collections. The paired samples, averaged over broad Delta areas, provided the framework for the nonlinear empirical model. Data were grouped by subareas of the Delta such as Sacramento River, Mokelumne River, Central Delta, San Joaquin River, and West Delta.

Largemouth Bass are excellent indicators of mercury contamination because they have a relatively high level of mercury compared to other species, are piscivorous, are abundantly distributed throughout the Delta, are popular gamefish, and have high site fidelity. Largemouth Bass are therefore representative of spatial patterns of tissue mercury concentrations throughout the aquatic food web, including exposure to humans.

The RWQCB Model was used to convert DSM2 estimated waterborne methylmercury concentrations to fish tissue mercury concentrations. The toxicity benchmark used to assess impacts of alternatives was the Central Valley RWQCB TMDL tissue concentration goal of 0.24 mg/kg wet weight (ww) of mercury for normalized 350-mm total length Largemouth Bass tissue (Central Valley RWQCB 2011).

6C.2 Modeling Simulations and Assumptions

This section describes the assumptions for the RWQCB Model simulations of the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5. Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore model results for Second Basis of Comparison and 4 are not presented separately. Model results for Alternative 2 and No Action Alternative are the same, therefore model results for Alternative 2 are not presented separately. A description of DSM2 model assumptions is presented in Appendix 5A.

6C.2.1 Location Assumptions

The Central Valley RWQCB developed a nonlinear model based on Largemouth Bass as grouped in large regions of the Delta (rather than specific locations) compared to average methylmercury concentrations in water for those same, general regions (Central Valley RWQCB 2011). As such, the model provides a Delta-specific, general, long-term average relationship between co-located waterborne methylmercury concentrations and total mercury concentrations in Largemouth Bass fillets.

6C.2.2 Normalization and Tissue Type Assumptions

As discussed above, Largemouth Bass are excellent indicators of long-term average mercury exposure, risk, and the spatial pattern for both ecological and human health effects. A fish tissue mercury dataset was available for Largemouth Bass from locations across the Delta. However, the Largemouth Bass tissue mercury concentrations were presented as edible fillet concentrations for fish normalized to 350 mm in total length (SFEI 2010). It is important to standardize concentrations to the same length fish for establishment of the model and for model predictions because of the well-established positive relationship between fish length and age and tissue mercury concentrations (e.g., Alpers et al. 2008). This same normalization technique was used by the Regional Board for their model (Central Valley RWQCB 2011). The 350-mm size fish is an appropriate size representative of human health consumption and risk. The standardized size allows the best comparison among locations and alternatives. The fillet concentrations predicted by the model are expected to be slightly different from whole-body fish concentrations as consumed by wildlife, but comparisons among locations and alternatives and to the Regional Board benchmark will allow an evaluation of relative impacts to fish and wildlife as well as most accurately estimating impacts to human consumers.

6C.2.3 Model Application Methodology

To evaluate differences between the No Action Alternative, Second Basis of Comparison, and other alternatives for impact assessment, modeled methylmercury concentrations were compared directly (for percent change) and to the 0.24-mg/kg wet weight tissue threshold benchmark.

Results of comparisons to these benchmarks are expressed as exceedance quotients (EQs) in some of the tables and figures. Annual average methylmercury concentrations in water did not exceed the unfiltered aqueous methylmercury goal (0.06 µg/L) or the California Toxic Rule criterion for the consumption of water at the organism (0.050 µg/L) and of the organism only (0.051 µg/L), so no EQs were calculated for waterborne concentrations.

6C.2.3.1 No Action Alternative and Second Basis of Comparison Model Runs

The overall purpose of the models is to provide a set of conditions for the No Action Alternative and the Second Basis of Comparison to be used for comparison with the forecasts of the alternatives to determine whether the implementation of the alternatives is likely to result in substantial impacts to methylmercury, thereby affecting biological resources. Modeling for the No Action Alternative and the Second Basis of Comparison was completed for five Delta interior locations, three western Delta locations, and four locations near major water diversions. DSM2 postprocessing output provided estimates of the waterborne methylmercury concentration at each of those 12 locations (Table 6C.1). The RWQCB Model was then used to estimate methylmercury tissue concentrations in 350-mm Largemouth Bass. The modeled tissue methylmercury concentrations and the EQs (based on comparisons to thresholds) both served as a basis for comparison of other alternatives to identify potential impacts.

6C.2.3.2 Alternatives 1 through 5 Model Runs

For model simulations of Alternatives 1 through 5, the same procedure as described for the No Action Alternative and the Second Basis of Comparison was used with similar assumptions.

6C.3 Modeling Results

The postprocessing tool that presents the results from the RWQCB Model is an Excel-based spreadsheet tool. The general preprocessing and input files development are described in the modeling data assumptions sections above. This section focuses on data analysis and results interpretation for the impacts descriptions.

6C.3.1 Postprocessing and Results Analysis: Delta-wide Model

Output data resulting from the RWQCB Model simulations for each alternative were processed to provide a tabular depiction of potential impacts to methylmercury resources (Tables 6C.2 – 6C.4). As discussed previously, outputs from the RWQCB Model used in this analysis are annual average fish tissue mercury concentrations for all year types and separately presented for the subset of dry years.

All annual average concentrations exceed the TMDL target goal of 0.24 mg/kg tissue mercury at all locations modeled in the Delta for all years both as measured and modeled. Results are shown in Tables 6C.2 – 6C.4 and Figures 6C.2 and 6C.3. Table 6C.1 presents the period-average waterborne methylmercury concentrations by location and water year type as used to model fish tissue concentrations (Tables 6C.2 – 6C.4).

The differences in fish tissue mercury concentrations over long-term average conditions were reduced or similar (5 percent or less) under Alternatives 1 through 5 as compared to the No Action Alternative, and under the No Action Alterantive and Alternatives 1 through 4 as compared to the Second Basis of Comparison , as shown in Tables 6C.2 – 6C.4. Fish tissue mercury concentrations over long-term average conditions are greater than 5 percent under Alternative 5 as compared to the Second Basis of Comparison in the Suisun Marsh (Montezuma Slough at Hunter Cut/Beldon's Landing), and near Delta water intakes (San Joaquin River at Antioch, Contra Costa Pumping Plant Number 1, Banks Pumping Plant, and Jones Pumping Plant).

Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore model results for Alternative 4 are not presented separately. Model results for Alternative 2 and No Action Alternative are the same, therefore model results for Alternative 2 are not presented separately.

6C.3.2 Model Limitations and Applicability

Although it is impossible to predict future hydrology, land use, and water use with certainty, the RWQCB Model and DSM2 were used to forecast impacts on fish that could result from implementation of the alternatives. Mathematical models like DSM2 can only approximate processes of physical systems. Models are inherently inexact because the mathematical description of the physical system is imperfect and the understanding of interrelated physical processes is incomplete. However, the RWQCB Model is a powerful tool that, when used carefully, can provide useful insight into processes of the physical system. Methylmercury concentrations for inflow sources to the Delta (e.g., agriculture in the Delta, Yolo Bypass, Eastside Tributaries) also caused uncertainty in the modeling because of limited data. For the Sacramento River and the San Joaquin River, about 90 data points (Chapter 6, Table 6.58; Table 6D.1) were used to estimate the mean methylmercury concentrations for these inflow sources, whereas the mean methylmercury concentrations for other inflow sources to the Delta had many fewer data points, ranging from 14 to no data points (concentrations for the Eastside Tributaries were assumed).

Appendix 6D

Selenium Model Documentation

This appendix provides information about the methods, modeling tools, and assumptions used for the Coordinated Long Term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS) analysis. This appendix also provides information pertaining to the development of the analytical tools and the use of input data as well as model result processing and interpretation methods used for the impacts analysis and descriptions.

This appendix is organized into three main sections:

- Section 6D.1: Modeling Methodology
  - The selenium impacts analysis uses CalSim II, the Delta Simulation Model II (DSM2), and Delta-specific selenium bioaccumulation modeling to assess and quantify effects of the alternatives on the long-term operation and the environment. This section provides information about the development and calibration of a Delta-wide bioaccumulation model for selenium in fish, use of outputs from that model to estimate bioaccumulation in bird eggs and fish fillets, and modeling of selenium bioaccumulation in sturgeon living in the western Delta using inputs from other models.
- Section 6D.2: Modeling Simulations and Assumptions
  - This section provides a brief description of the assumptions for the selenium model simulations of the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5.
- Section 6D.3: Modeling Results
  - This section provides a description of the model simulation output formats used in the analysis and interpretation of modeling results for the alternatives impacts assessment.

6D.1 Modeling Methodology

This section summarizes the selenium modeling methodology used for the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5. It describes the overall analytical framework and development and use of bioaccumulation models. This section also contains descriptions of the key analytical and numerical tools and approaches used in the quantitative evaluation of the alternatives. The project alternatives include changes to CVP and SWP operation that would cause subsequent effects on the water quality of the system relative to selenium. Those changes in waterborne selenium concentrations would propagate to changes in selenium concentrations in fish and bird eggs throughout the Delta.

6D.1.1 Overview of the Modeling Approach and Objectives

Modeling of flows, hydrodynamics, and selenium bioaccumulation in the Delta is necessary to support the selenium impact analysis of alternatives. Impact analysis focuses on evaluation of changes to selenium concentrations in tissues that affect the health of fish as well as wildlife and humans consuming fish in the Delta.

CalSim II, DSM2, and bioaccumulation modeling were used in sequence to estimate the effects of CVP and SWP operations on water quality relative to selenium in the Delta. CalSim II, which simulates flow in California's waterways, and DSM2, which simulates one-dimensional hydrodynamics in California's Delta, are discussed in detail in Appendix 5A. One of the three DSM2 modules, QUAL, simulates one-dimensional source tracking in the Delta. Results from DSM2 were multiplied by source concentrations (shown in Table 6D.1) to determine annual average waterborne selenium concentrations in the Delta for all year types and drought years.

Operations-related changes in waterborne selenium concentrations in the Delta may result in increased selenium bioaccumulation or toxicity (or both) to aquatic and semi-aquatic receptors using the Delta. Historical fish tissue data from 2000, 2005, and 2007 (Foe 2010a) and measured (for Sacramento River below Knights Landing and for San Joaquin River at Vernalis) or DSM2-modeled (other locations) waterborne selenium concentrations for selected locations in 2000, 2005, and 2007 were used to model water-to-tissue relationships. This modeling generally followed procedures described by Presser and Luoma (2010a, 2010b). Implementation of the Grassland Bypass Project (GBP) has led to a 60 percent decrease in selenium loads from the Grassland Drainage Area compared to pre-project conditions (San Francisco Bay Regional Water Quality Control Board 2008). These changes are reflected in data for the San Joaquin River at Vernalis, where water quality is monitored frequently because the river is a primary source of selenium to the Delta. Vernalis water data for 2 years (1999-2000, 2004-2005, and 2006-2007) were used for each year when fish data were available because of the GBP-related changes and because the lag time for selenium bioaccumulation in the piscivorous Largemouth Bass (*Micropterus salmoides*, the species for which the Delta-wide bioaccumulation model was calibrated) may be more than 1 year (Beckon 2014).

Output from the DSM2-QUAL model (expressed as percentage of inflow from different sources) was used in combination with the available measured waterborne selenium concentrations (Table 6D.1) to model concentrations of selenium at locations throughout the Delta. These modeled waterborne selenium concentrations were used in the relationship model to estimate bioaccumulation of selenium in whole-body fish and in bird eggs. Selenium concentrations in fish fillets were then estimated from those in whole-body fish. The following sections provide detailed information about the modeling approach for selenium.

Table 6D.1 Selenium Concentrations in Water at Inflow Sources to the Delta

Delta Sources	Representative Inflow Site	GM Se Concentration in Water (µg/L)[a]	Years	Source
Delta Agriculture	Mildred Island, Center	0.11	2000	Lucas and Stewart 2007
East Delta Tributaries	Mokelumne, Calaveras, and Cosumnes Rivers	0.10[b]	None	None
Martinez/Suisun Bay	San Joaquin River near Mallard Island	0.10	02/2000–08/2008	SFEI 2014
Sacramento River	Sacramento River at Freeport	0.09	11/2007–07/2014	USGS 2014
San Joaquin River	San Joaquin River at Vernalis (Airport Way)	0.45 [c]	11/2007-08/2014	USGS 2014
San Joaquin River	San Joaquin River at Vernalis (Airport Way)	0.83 [d]	1999-2000	SWAMP 2009
		0.85	2004-2005	SWAMP 2009
		0.58	2006-2007	SWAMP 2009
Yolo Bypass	Sacramento River below Knights Landing	0.23[e]	2004, 2007, 2008	DWR 2009

Notes:
a. Selenium concentrations are in dissolved fraction unless otherwise noted.
b. Dissolved selenium concentration is assumed to be 0.1 µg/L due to lack of available data and lack of sources that would be expected to result in concentrations greater than 0.1 µg/L.
c. Data used to represent conditions for comparison of alternatives.
d. Not specified whether total or dissolved selenium; data for 1999-2000 used for bioaccumulation by bass in 2000; data for 2004-2005 for bass in 2005; and data for 2006-2007 for bass in 2007.
e. Total selenium concentration in water.

µg/L = microgram(s) per liter
GM = geometric mean
Se = selenium

In addition to the Delta-wide modeling for fish and birds (calibrated with data for Largemouth Bass), selenium uptake and food-chain transfer information from the ecosystem-scale selenium model for the San Francisco Bay-Delta Regional Ecosystem Restoration Implementation Plan (Presser and Luoma 2013) informed the selenium bioaccumulation model for the western Delta. The Largemouth Bass has lower selenium bioaccumulation rates than those observed for sturgeon (Green Sturgeon [*Acipenser medirostris]* and White Sturgeon, [*A. transmontanus]*) and is not an appropriate model species that would be protective of sturgeon. Sturgeon differ by feeding, in part, on Overbite Clams (*Corbula* [*Potamocorbula*] *amurensis*) in Suisun Bay and may do so in the western portion of the Delta under future conditions. Therefore, DSM2-modeled waterborne selenium concentrations from three western-most locations in the Delta (Sacramento River at Emmaton, San Joaquin River at Antioch, and

Montezuma Slough at Hunter Cut/Beldon's Landing) were used to model selenium bioaccumulation for sturgeon at those three locations to supplement the modeling done for Largemouth Bass.

The results from this suite of physical and biological models are used to inform the understanding of effects of each alternative considered in this EIS on selenium. Modeling objectives included evaluation of the following:

- Percent changes in waterborne selenium concentrations under the alternatives as compared to the No Action Alternative and the Second Basis of Comparison
- Exceedances of fish, wildlife, or human thresholds for selenium effects

6D.1.2 Key Components of the Selenium Modeling

To fulfill the objectives of the selenium modeling effort, DSM2 output data were used in combination with source water concentrations to estimate waterborne selenium concentrations at representative locations throughout the Delta (Tables 6D.2 through 6D.4, located at end of this appendix). Waterborne selenium concentrations were then used to estimate tissue selenium concentrations in Largemouth Bass (as a representative higher trophic-level fish) throughout the Delta and in sturgeon in the western Delta. Estimation of concentrations in Largemouth Bass throughout the Delta included the development and calibration of a bioaccumulation model using measured concentrations in bass (Foe 2010a). In contrast, modeling for sturgeon in the western Delta relied on literature-based model parameters (Presser and Luoma 2013), because data were not available to further calibrate the model.

6D.1.2.1 DSM2 Post-processing

Dissolved or total selenium data were available for six inflow locations to the Delta (Table 6D.1):

- Sacramento River below Knights Landing (just upstream of Yolo Bypass, representing the Bypass source)
- Sacramento River at Freeport (mainstem flow to Delta)
- San Joaquin River at Vernalis (Airport Way) (mainstem flow to Delta)
- Mokelumne, Calaveras, and Cosumnes Rivers (for East Delta tributaries)
- Mildred Island, Center (for Delta Agriculture)
- San Joaquin River near Mallard Island (for Martinez/Suisun Bay)

Both dissolved and total selenium data were considered suitable for purposes of the modeling conducted for the Delta, because they typically do not differ greatly. Statements related to waterborne selenium concentrations in this appendix would be applicable to either dissolved or total concentrations.

Whole-body Largemouth Bass data for selenium were available from the following DSM2 output locations:

- Big Break
- Cache Slough Ryer
- Franks Tract
- Middle River Bullfrog
- Old River Near Paradise Cut
- Sacramento River Mile (RM) 44
- San Joaquin River Potato Slough

Largemouth Bass data also were available from the Veterans Bridge on the Sacramento River and from Vernalis on the San Joaquin River, but DSM2 data were not available for those locations; therefore, historical data for selenium concentrations in water collected nearby (Table 6D.1) were used to represent quarterly averages. The geometric mean of total selenium concentrations in water collected from the Sacramento River below Knights Landing in 2004, 2007, and 2008 (DWR 2009) were used to represent quarterly averages of selenium concentrations in water for Veterans Bridge in all years. The geometric means of selenium concentrations (total or dissolved was not specified) in water collected from 1999–2000, 2004-2005, and 2006-2007 (SWAMP 2009) were used to represent quarterly averages for selenium concentrations in water at Vernalis during 2000, 2005, and 2007, respectively.

For DSM2 output locations, the geometric mean selenium concentrations from the inflow locations were combined with the modeled quarterly average percent inflow for each DSM2 output location to estimate waterborne selenium concentrations at those locations. The quarterly average mix of water from the six inflow sources (Table 6D.1) was calculated from daily percent inflows provided by the DSM2 model output for the DSM2 output locations for which fish data were available. The quarterly waterborne selenium concentrations at DSM2 locations were calculated using Equation 1:

$$C_{water\ quarterly} = ([I_1*C_1] + [I_2*C_2] + [I_3*C_3] + [I_4*C_4] + [I_5*C_5] + [I_6*C_6])/100$$

Where:

- $C_{water\ quarterly}$ = quarterly average selenium concentration in water (micrograms/liter [µg/L]) at a DSM2 output location
- $I_{1\text{-}6}$ = modeled quarterly inflow from each of the six sources of water to the Delta for each DSM2 output location (percentage)
- $C_{1\text{-}6}$ = selenium concentration in water (µg/L) from each of the six inflow sources to the Delta (1-6)

Example Calculation: Modeled Selenium Concentration at Franks Tract Year 2000, First Quarter:

(43.94 [% inflow from Sacramento River water source at Franks Tract] × 0.09 µg/L [selenium concentration at Sacramento River at Freeport]) + (11.56 [% inflow from East Delta Tributaries water source at Franks Tract] × 0.10 µg/L [selenium concentration at Mokelumne, Calaveras, and Cosumnes Rivers]) + (15.79 [% inflow from San Joaquin River water source at Franks Tract] × 0.83 µg/L [selenium concentration at San Joaquin River at Vernalis]) + (0.02 [% inflow from Martinez/Suisun Bay water source at Franks Tract] × 0.10 µg/L [selenium concentration at San Joaquin River near Mallard Island]) + (0.32 [% inflow from Yolo Bypass water source at Franks Tract] × 0.23 µg/L [selenium concentration at Sacramento River below Knights Landing]) + (5.06 [% inflow from Delta Agriculture water source at Franks Tract] × 0.11 µg/L [selenium concentration at Mildred Island, Center])/100 = 0.19 µg/L

The quarterly and average annual waterborne selenium concentrations for the DSM2 output locations are shown in Table 6D.2 (Year 2000), Table 6D.3 (Year 2005), and Table 6D.4 (Year 2007).

6D.1.2.2 Delta-wide Selenium Model Development

Selenium concentrations in whole-body fish and in bird eggs were calculated using ecosystem-scale models developed by Presser and Luoma (2010a, 2010b, 2013). The models were based on biogeochemical and physiological factors from laboratory and field studies; loading rates, chemical speciation, and transformation to particulate material; bioavailability; bioaccumulation in invertebrates; and trophic transfer to predators. Important components of the methodology included (1) empirically determined environmental partitioning factors between water and particulate material that quantify the effects of dissolved speciation and phase transformation; (2) concentrations of selenium in living and non-living particulates at the base of the food web that determine selenium bioavailability to invertebrates; and (3) selenium biodynamic food web transfer factors that quantify the physiological potential for bioaccumulation from particulate matter to consumer organisms and from prey to their predators.

6D.1.2.2.1 Selenium Concentration in Particulates

Phase transformation reactions from dissolved to particulate selenium are the primary form by which selenium enters the food web. Presser and Luoma (2010a, 2010b, 2013) used field observations to quantify the relationship between particulate material and dissolved selenium as indicated in Equation 2.

$$C_{particulate} = K_d * C_{water\ column}$$

Where:

- $C_{particulate}$ = selenium concentration in particulate material (micrograms/kilogram, dry weight [µg/kg dw])
- K_d = particulate/water ratio
- $C_{water\ column}$ = selenium concentration in water column (µg/L)

The K_d (also called an "enrichment factor") describes the particulate/water ratio at the moment the sample was taken and should not be interpreted as an equilibrium constant (as it sometimes is mistaken to be). It can vary widely among hydrologic environments and potentially among seasons (Presser and Luoma 2010a, 2010b, 2013; Young et al. 2010). In addition, other factors such as selenium speciation, water residence time, and particle type affect K_d. Selenium typically enters a stream primarily as selenate. If the stream flows into a wetland and the water is retained there with sufficient residence time, recycling of selenium may occur. This results in generation of particulate selenium and conversion to more bioaccumulative selenite and organo-selenium from the less-bioaccumulative dissolved selenate. Residence time of water containing selenium is usually the most influential factor on the conditions in the receiving aquatic environment. Short water residence times (such as in streams and rivers) limit partitioning of selenium into particulate material. Conversely, longer residence times (such as in sloughs, lakes, and estuaries) allow greater uptake by plants, algae, and microorganisms. Furthermore, environments in downstream portions of a watershed can receive cumulative contributions of upstream recycling in a hydrologic system. Because of its high variability, K_d is a large source of uncertainty in any selenium model where extrapolations from selenium concentrations in the water column to those in aquatic organism tissues, or from tissue to waterborne concentrations, are necessary.

In developing the Delta-wide bioaccumulation model for bass, the particulate selenium concentration initially was estimated using Equation 2 and a default K_d of 1,000 (Presser and Luoma 2010a). Because the K_d is typically much more variable than other steps in the bioaccumulation model, the K_d was then adjusted to calibrate the model so that the modeled concentrations for fish approximated the measured concentrations in bass for normal and wet years (2000 and 2005) and for drought years (2007), as described in more detail in Section 6D.1.2.3.

6D.1.2.2.2 Selenium Concentrations in Invertebrates

Trophic transfer factors (TTFs) for transfer of selenium from particulates to prey and to predators were developed using data from laboratory experiments and field studies (Presser and Luoma 2010a, 2010b, 2013). TTFs are species-specific, but the range of TTFs for freshwater invertebrates was found to be similar to TTFs for marine invertebrates determined in laboratory experiments.

TTFs for estimating selenium concentrations in invertebrates were calculated using Equation 3:

$$TTF_{invertebrate} = (C_{invertebrate})/(C_{particulate})$$

Where:

- $TTF_{invertebrate}$ = trophic transfer factor from particulate material to invertebrate
- $C_{invertebrate}$ = concentration of selenium in invertebrate (µg/g dw)
- $C_{particulate}$ = concentration of selenium in particulate material (µg/g dw)

An average aquatic insect TTF was calculated from TTFs for aquatic insect species with similar bioaccumulative potential, including Mayfly (*Baetidae; Heptageniidae; Ephemerellidae*), Caddisfly (*Rhyacophilidae; Hydropsychidae*), Crane Fly (*Tipulidae*), Stonefly (*Perlodidae*/*Perlidae*; *Chloroperlidae*), Damselfly (*Coenagrionidae*), Corixid (*Cenocorixa* sp.), and Chironomid (*Chironomus* sp.) aquatic life stages. Species-specific TTFs ranged from 2.1 to 3.2; the average TTF of 2.8 was used in the Delta-wide model.

6D.1.2.2.3 Selenium Concentrations in Whole-body Fish

The mechanistic equation for modeling of selenium bioaccumulation in fish tissue is similar to that for invertebrates if whole-body concentrations are the endpoint (Presser and Luoma 2010a, 2010b, 2013), as shown in Equation 4:

$$TTF_{fish} = C_{fish} / C_{invertebrate}$$

where:

$$C_{invertebrate} = C_{particulate} * TTF_{invertebrate}$$

therefore:

$$C_{fish} = C_{particulate} * TTF_{invertebrate} * TTF_{fish}$$

Where:

- C_{fish} = concentration of selenium in fish (µg/g dw)
- $C_{particulate}$ = concentration of selenium in particulate material (µg/g dw)
- $C_{invertebrate}$ = *concentration of selenium in invertebrate (µg/g dw)*
- $TTF_{invertebrate}$ = trophic transfer factor from particulate material to invertebrate
- TTF_{fish} = trophic transfer factor from invertebrate to fish

Modeling selenium bioaccumulation into a particular fish species considers organism physiology and its preferred foods. However, variability in fish tissue selenium concentrations for present modeling purposes is driven more by dietary choices and their respective levels of bioaccumulation (that is, TTFinvertebrate) than by differences in fish physiology or the dietary transfer to the fish (TTFfish). A diet of mixed prey (including invertebrates or other fish) can be modeled as shown in Equation 5:

$$C_{fish} = TTF_{fish} * ([C_1 * F_1] + [C_2 * F_2] + [C_3 * F_3])$$

Where:

- C_{fish} = concentration of selenium in fish (µg/g dw)
- TTF_{fish} = trophic transfer factor for fish species
- $C_{1\text{-}3}$ = concentration of selenium in invertebrate or fish prey items 1, 2, and 3 (µg/g dw)
- $F_{1\text{-}3}$ = fraction of diet composed of prey items 1, 2, and 3

Modeling of selenium concentrations in longer food webs with higher trophic levels (for example, predator fish such as bass consuming forage fish) can be completed by incorporating additional TTFs, as shown in Equation 6:

$$C_{predatorfish} = C_{particulate} * TTF_{invertebrate} * TTF_{foragefish} * TTF_{predatorfish}$$

Where:

- $C_{predatorfish}$ = concentration of selenium in fish (µg/g dw)
- $C_{particulate}$ = concentration of selenium in particulate material (µg/g dw)
- $TTF_{invertebrate}$ = trophic transfer factor from particulate material to invertebrate
- $TTF_{foragefish}$ = trophic transfer factor for invertebrates to foraging fish species
- $TTF_{predatorfish}$ = trophic transfer factor for forage fish to predator species

The fish TTFs reported in Presser and Luoma (2010a) ranged from 0.5 to 1.6, so the average fish TTF of 1.1 was used for all trophic levels of fish in the Delta-wide model.

Modeled selenium concentrations in whole-body fish were used to estimate selenium concentrations in fish fillets, as described in Section 6D.1.2.2.5.

6D.1.2.2.4 Selenium Concentrations in Bird Eggs

Selenium concentrations in bird tissues can be estimated, but the transfer of selenium into bird eggs is more meaningful for evaluating reproductive endpoints (Presser and Luoma 2010a; Ohlendorf and Heinz 2011). Examples of models for selenium transfer to bird eggs are as shown in Equations 7 and 8:

$$C_{birdegg} = C_{particulate} * TTF_{invertebrate} * TTF_{birdegg}$$

(this equation is based on birds, such as shorebirds, eating invertebrates)

or:

$$C_{birdegg} = C_{particulate} * TTF_{invertebrate} * TTF_{fish} * TTF_{birdegg}$$

(this equation is based on birds, such as herons or terns, feeding on small fish)

Where:

- $C_{birdegg}$ = concentration of selenium in bird egg (µg/g dw)
- $C_{particulate}$ = concentration of selenium in particulate material (µg/g dw)
- $TTF_{invertebrate}$ = trophic transfer factor from particulate material to invertebrate
- TTF_{fish} = trophic transfer factor from invertebrate to fish
- $TTF_{birdegg}$ = trophic transfer factor from invertebrate or fish (depending on diet) to bird egg

Presser and Luoma (2010b, 2013) reviewed the available data for selenium bioaccumulation from diet to bird eggs and concluded that the mean $TTF_{birdegg}$ = 2.6 was most appropriate for modeling. This TTF was based on laboratory studies in which Mallards (*Anas platyrhynchos*) were fed selenium-fortified diets to evaluate reproductive effects. Mallards are considered a sensitive species to selenium based on reproductive endpoints. In their previous evaluation of those data, Presser and Luoma (2010a) concluded that a $TTF_{birdegg}$ = 1.8 was appropriate. The form of selenium included in the Mallard diet (selenomethionine) has been used as a surrogate in many laboratory studies to represent exposure of fish and birds under field conditions. Other laboratory studies were conducted with Black-crowned Night-herons (*Nycticorax*

nycticorax) by Smith et al (1988), for Eastern Screech-owls (*Otus asio)* by Wiemeyer and Hoffman (1996), and for American Kestrels (*Falco sparverius)* by Santolo et al. (1999). In each of these studies, the experimental groups also received supplemental selenium in the form of selenomethionine. Transfer factors for the selenium-supplemented birds varied from approximately 1.0 to 2.2, with a mean of 1.5.

In field studies conducted at Kesterson Reservoir and the Volta Wildlife Area reference site, extensive sampling of food-chain biota and bird eggs was conducted from 1983 through 1985, and birds were collected to determine qualitatively the kinds of aquatic organisms they had eaten (Saiki and Lowe 1987; Hothem and Ohlendorf 1989; Schuler et al. 1990; Ohlendorf and Hothem 1995). Based on the kinds of food items found in each of the sampled species and the mean selenium concentrations in those kinds of organisms, a mean selenium concentration was estimated for each species at each site during each nesting season. In contrast to the findings with selenomethionine-supplemented diets in the laboratory, TTFs from diet to eggs were almost always less than 2.0. At the Volta Wildlife Area, where diet and egg selenium concentrations were representative of "background" conditions, transfer factors ranged from 0.63 to 2.0, with a mean of 1.35. At Kesterson, the transfer factors ranged from less than 0.2 to 0.48.

Because selenomethionine in the Mallard diet is probably more readily transferred to eggs than are the selenium forms in field-collected food-chain biota, the $TTF_{birdegg}$ = 1.8 value from Presser and Luoma (2010a) was used in the bioaccumulation model.

6D.1.2.2.5 Selenium Concentrations in Fish Fillets

Selenium concentrations in whole-body fish from the bioaccumulation model were converted to selenium concentrations in skinless fish fillets for evaluation of potential human health effects. The regression equation provided in Saiki et al. (1991) for Largemouth Bass from the San Joaquin River system was considered to be the most representative of fish in the Delta and was used for the conversion of these selenium concentrations as shown in Equation 9:

$$SF = (-0.388) + (1.322 * WB)$$

Where:

- SF = selenium concentration in skinless fish fillet (µg/g dw)
- WB = selenium concentration in whole-body fish (µg/g dw)

For the impact assessment in this EIS, fish fillet data were compared to the Advisory Tissue Level (2.5 micrograms per gram [µg/g]) in wet weight (ww) (OEHHA 2008); therefore, wet-weight concentrations were estimated from dry-weight concentrations using the equation provided by Saiki et al. (1991) as shown in Equation 10:

$$WW = DW * (100 – Moist)/100$$

Where:

- *WW* = selenium concentration in wet weight (µg/g ww)
- *DW* = selenium concentration in dry weight (µg/g dw)
- *Moist* = mean moisture content of the species

Because moisture content in fish varies among species, sample handling, and locations, the mean moisture content of 70 percent used by Foe (2010b) was used as an assumed approximation for fish in the Delta. The final equation used to estimate selenium concentration in skinless fish fillets (wet weight) from selenium concentration in whole-body fish (dry weight) is as shown in Equation 11:

$$SF = ([-0.388] + [1.322 * WB]) * 0.3$$

Where:

- *SF* = selenium concentrations in skinless fish fillet (µg/g ww)
- *WB* = selenium concentration in whole-body fish (µg/g dw)

6D.1.2.3 Delta-wide Selenium Model Calibration

Several models were evaluated and refined to estimate selenium uptake in fish and in bird eggs from waters in the Delta. Input parameters to the model (K_ds and the number of trophic levels) were varied among the models as refinements were made. Data for Largemouth Bass collected in the Delta from areas near DSM2 output locations were used to calculate the geometric mean selenium concentration in whole-body fish (Foe 2010a). The ratio of the estimated (modeled) selenium concentration in fish to measured selenium in whole-body bass was used to evaluate each fish model and to focus refinements of the model. These Delta-wide models are presented in the following subsections.

Characteristics of water flow in the Delta affect selenium bioaccumulation and the model refinements, because longer residence time for the water can be expected to increase bioaccumulation by increasing K_d. Foe (2010a) reported the water year type for 2000 as “above normal” for both the Sacramento River and San Joaquin River watersheds. It came after “wet” water years and was followed by “dry” water years. Year 2005 was wetter than 2000, was reported as “above normal” for the Sacramento River watershed and “wet” for the San Joaquin River watershed. Year 2005 occurred between periods of wet water years. Water Year 2007 was reported as “dry” (Sacramento River watershed) and “critically dry” (San Joaquin River watershed). It came after wet water years and was followed by critically dry water years.

There was no difference in bass selenium concentrations in the Sacramento River at Rio Vista in comparison to the San Joaquin River at Vernalis in 2000, 2005, and 2007 (Foe 2010a). The lack of a difference in bioaccumulated selenium between the two river systems was unexpected because the San Joaquin River is considered a significant source of selenium to the Delta. There were differences among years, however, that were related to hydrology and water flow through the Delta. Year 2005 selenium concentrations in bass were comparatively lower than those estimated for Year 2000. As expected in a wet water year, the water residence time was shorter, resulting in less selenium recycling, lower K_d values, and lower concentrations of selenium entering the food web. The dry water year (2007) resulted in a longer water residence time, higher K_d values, greater selenium recycling, and higher concentrations of bioavailable selenium entering the food web. These differences among years were considered when refining the selenium bioaccumulation model.

6D.1.2.3.1 Bioaccumulation in Whole-body Fish

Models estimating whole-body selenium concentrations in fish were refined by modifying dietary composition and input parameters to closely represent measured conditions in the Delta. Each model is described in this section.

Model 1 was a basic representative of uptake by a forage fish, while Model 2 calculated sequential bioaccumulation in a more complex food web that included predatory fish eating forage fish, as shown below:

Model 1: Trophic level 3 (TL-3) fish eating invertebrates (Equation 12):

$$C_{fish} = C_{particulate} * TTF_{invertebrate} * TTF_{fish}$$

Model 2: Trophic level 4 (TL-4) fish eating TL-3 fish (Equation 13):

$$C_{predatorfish} = C_{particulate} * TTF_{invertebrate} * TTF_{foragefish} * TTF_{predatorfish}$$

Where:

- C_{fish} = concentration of selenium in fish (µg/g dw)
- $C_{particulate}$ = concentration of selenium in particulate material (µg/g dw)
- $TTF_{invertebrate}$ = Trophic transfer factor from particulate material to invertebrate
- TTF_{fish} = Trophic transfer factor from invertebrate to forage fish or forage fish to predator fish

Equation 12 is the same as Equation 4 and Equation 13 is the same as Equation 6 that were described previously for the generalized model. In both Models 1 and 2, the particulate selenium concentration was estimated using Equation 2 and a default K_d of 1,000. The average TTFs for invertebrates (2.8) and fish (1.1) were used in each model. The outputs of estimated selenium concentrations and the ratios of predicted-to-observed bass selenium concentrations for Models 1 and 2 are presented in Table 6D.5 and Figure 6D.1 (all figures are provided at the end of this appendix).

Models 1 and 2 tended to substantially underestimate the whole-body selenium concentrations in fish compared to bass data reported in Foe (2010a). This was partly because Model 1 was estimating selenium concentration in a forage fish (TL-3), whereas bass are a predatory fish with expected higher dietary exposure. Consequently, Model 1 was not further developed as the selenium bioaccumulation model to represent fish in the Delta.

Model 2 is representative of predatory fish, but Model 2 was very similar to Model 1 in distribution of data and in underestimating bass data, even though an additional trophic-level transfer was included in the model. As noted in Section 6D.1.2.2.1 and described in much greater detail by Presser and Luoma (2010a, 2010b, 2013), the K_d values for uptake from water are far more variable than the

TTFs for invertebrates or fish. Models 1 and 2 also apparently reflect the tendency of selenium (as an essential nutrient) to be more bioaccumulative when waterborne concentrations are low (as described by Stewart et al. [2010]), which they were for the DSM2-modeled concentrations (that is, 0.09 to 0.85 µg/L). Available K_d values from various sampling efforts in the Delta provided by Presser and Luoma (2010b) were reviewed for potential applicability in the modeling effort. Those values varied on the basis of locations within the Delta and Suisun Bay and also by water year and flow characteristics (often greater than 5,000 and sometimes exceeding 10,000). However, efforts to incorporate various selected K_d values (for example, 2,000 or 3,000) into the model uniformly for different DSM2 locations failed to produce ratios of modeled-to-measured fish selenium concentrations that approximated 1 (they either over- or underestimated fish selenium concentrations because of variability in site conditions).

The available bass data and the assumed TTFs for invertebrates (2.8) and fish (1.1) were used to back-calculate a location and sample-specific K_d. It is recognized that some of the variability in bioaccumulation may be associated with the TTFs, but there were no reasonable assumptions for selection of alternative values to plug into the model.

When TTFs were held constant, back-calculation of K_d values revealed a concentration-related influence on the values. For waterborne selenium concentrations in the range of 0.09 to 0.13 µg/L (N = 50), the median was 5,575; when waterborne selenium concentrations were in the range of 0.14 to 0.40 µg/L (N = 19), the median K_d was 2,431; for waterborne selenium concentrations in the range of 0.41 to 0.85 µg/L (N = 19), the median K_d was 748. These observations are consistent with an inverse relationship between waterborne selenium concentrations and bioaccumulation in aquatic organisms (Stewart et al. 2010).

Figure 6D.2 shows the log-log regression relation of K_d to waterborne selenium concentration when all years are included and the TTFs are held constant, while Figure 6D.3 shows the relationship for normal/wet years (2000 and 2005) and Figure 6D.4 shows the regression for dry years (2007), when the K_ds were generally higher.

Model 3 is based on Model 2 (with TTFs as described previously) but includes the K_d estimated from the log-log regression relation for all years (Figure 6D.2). This produced a median ratio of predicted-to-observed whole-body selenium in bass that slightly exceeded 1 (Figure 6D.1); details are provided in Table 6D.6. Because of the noticeable differences between 2007 (the dry year) and the other 2 years, the next step in modeling was to evaluate 2007 separately from 2000 and 2005.

Model 4 was developed using the log-log relationship between K_d and water selenium concentrations for 2000 and 2005 (Figure 6D.3). Model 5 was developed using log-log relationship between K_d and water selenium concentrations for 2007 (Figure 6D.4 and Table 6D.7). These two models produced ratios of predicted-to-observed whole-body selenium in bass approximating 1, as shown in Figure 6D.1.

As expected in a large, complex, and diverse ecological habitat such as the Delta, variations in the data distribution and in the outputs of the models are not surprising. However, it should be noted that the estimated K_d values for Model 3 (674-6,060; Table 6D.6), Model 4 (651-4,997; Table 6D.7), and Model 5 (1,206-8,064; Table 6D.7) are consistent with those summarized by Presser and Luoma (2010b) for the Delta.

Figures 6D.5 and 6D.6 illustrate the distribution of data for selenium concentrations in Largemouth Bass (Foe 2010a) relative to the measured or DSM2-modeled waterborne selenium concentrations (Tables 6D.1 through 6D.4) and Models 3, 4, and 5 to complement the boxplots shown in Figure 6D.1. There is notably more variability in selenium concentrations in bass between 0.09 and 0.13 µg/L than at higher waterborne selenium concentrations (as shown in both Figures 6D.5 and 6D.6); most of the higher values are from 2007 and most of the lower ones are from 2005.

Figure 6D.5 shows the available data for 2000, 2005, and 2007 plotted with the Model 3 prediction of selenium concentrations. As noted previously in text and in Figure 6D.1, the model slightly over-predicts the median concentrations in fish on the basis of waterborne selenium concentrations. This effect is reflected in Figure 6D.1 by the outliers above the 90th percentile bar (that is, the higher over-predictions for fish, which are those from 2000 and 2005). However, overall, the model is within 1 µg/g for all values less than the prediction, and within approximately 1.2 µg/g for the values greater than the prediction (Figure 6D.5).

Because of the notable differences between data for 2007 compared to combined 2000 and 2005 data, Model 4 was developed for 2000 and 2005 and Model 5 was developed for 2007, Figure 6D.6 shows those model predictions compared to the data. These two models improved the predictions; although the figure shows more differences between data and the models at the lower waterborne concentrations (that is, less than 0.30 µg/L) than at higher ones, the divergence is generally less than 0.5 µg/g at the higher waterborne concentrations. The outliers for Model 4 are mostly above the 90th percentile (that is, over-predicting concentrations in fish), rather than below, as shown in Figure 6D.1. For Model 5, the predictions are "tighter" with just a few outliers above or below the 90th percentile.

Evaluation of water-year effects on selenium concentration in bass concluded that Model 4 was relatively predictive of selenium concentration in whole-body bass during normal to wet water years. Model 5 was considered predictive for dry water years (such as 2007). Model 3 incorporates the varying bioaccumulation when all years are considered (that is, 2000, 2005, and 2007). Although Model 3 tends to slightly overestimate selenium bioaccumulation (Table 6D.6 and Figure 6D.1), it was used for estimating selenium concentrations in whole-body fish in the impact assessment for "All" years, and Model 5 was used for "Drought" years.

6D.1.2.3.2 Selenium Bioaccumulation in Bird Eggs

The K_d, invertebrate TTF, and fish TTFs developed for use in fish bioaccumulation Models 4 and 5 were also used to estimate selenium uptake into bird eggs using the following two bird egg models (Table 6D.8):

Bird Egg: Uptake from invertebrates (Equation 14):

$$C_{birdegg} = C_{particulate} * TTF_{invertebrate} * TTF_{birdegg}$$

where:

$$C_{particulate} = K_d * C_{water}$$

Bird Egg: Uptake from fish (Equation 15):

$$C_{birdegg} = C_{particulate} * TTF_{invertebrate} * TTF_{fish} * TTF_{fish} * TTF_{birdegg}$$

where:

$$C_{particulate} = K_d * C_{water}$$

Where:

- $C_{birdegg}$ = concentration of selenium in bird egg (µg/g dw)
- $C_{particulate}$ = concentration of selenium in particulate material (µg/g dw)
- C_{water} = selenium concentration in water column (µg/L)
- K_d = particulate/water ratio
- $TTF_{invertebrate}$ = trophic transfer factor from particulate material to invertebrate
- TTF_{fish} = trophic transfer factor from invertebrate or fish to fish
- $TTF_{birdegg}$ = trophic transfer factor from invertebrate or fish (depending on diet) to bird egg

Equation 14 is the same as Equation 7, but Equation 15 differs from Equation 8 in that it assumes birds are eating larger predatory fish such as bass.

6D.1.2.4 Western Delta Sturgeon Model

Presser and Luoma (2013) determined K_d values for San Francisco Bay (including Carquinez Strait – Suisun Bay) during “low flow” conditions (5,986) and “average” conditions (3,317). These values were used to model selenium concentrations in particulates in bioaccumulation modeling for sturgeon under “Drought” and “All” year conditions at the three locations in the western Delta. (By comparison, calibration of the Delta-wide model for two western-most location from which bass had been collected [Big Break] resulted in an average K_d = 3,736 for 2000/2005 [Model 4, normal/wet years] and average K_d = 7,166 for 2007 [Model 5, dry year].)

Sturgeon in the western Delta, Carquinez Strait, and Suisun Bay typically prey on a mix of clams including *Corbula amurensis*, which is known to be an efficient bioaccumulator of selenium (Stewart et al. 2010) and crustaceans. Presser and Luoma (2013) assumed a sturgeon diet of 50 percent clams and 50 percent amphipods and other crustaceans in their model. Based on this diet, the authors reported a TTF of 9.2 (identified as TTF_{prey} in Table 1 of Presser and Luoma [2013]). This TTF was used to calculate concentrations in sturgeon invertebrate prey for the Sacramento River at Emmaton, San Joaquin River at Antioch, and Montezuma Slough at Hunter Cut/Beldon's Landing locations under the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5.

A TTF of 1.3 from diet to fish (identified as $TTF_{predator}$) was reported for sturgeon in Presser and Luoma (2013) and was used to calculate concentrations of selenium in sturgeon for the three western Delta locations.

Modeling for sturgeon at the three western Delta locations did not require refinement because it relied on recent data provided by Presser and Luoma [2013]) and because data to refine the model were not available.

6D.2 Modeling Simulations and Assumptions

As described in Section 6D.1, selenium modeling was performed for evaluation of the alternatives. This section describes the assumptions for the selenium model simulations of the No Action Alternative, Second Basis of Comparison, and other alternatives. A description of DSM2 model assumptions is in Appendix 5A.

The following model simulations were used as the basis of evaluating the impacts of Alternatives 1 through 5 as compared to the No Action Alternative, and the No Action Alternative and Alternatives 1 through 5 as compared to the Second Basis of Comparison:

- No Action Alternative
- Second Basis of Comparison

The following selenium model simulations of other alternatives were performed:

- Alternative 1 – for selenium simulation purposes, considered the same as Second Basis of Comparison
- Alternative 2 – for selenium simulation purposes, considered the same as No Action Alternative
- Alternative 3
- Alternative 4 – for selenium simulation purposes, considered the same as Second Basis of Comparison.
- Alternative 5

The general selenium modeling assumptions described in the following subsection pertain to all the model runs.

6D.2.1 Delta-wide Assumptions

The calibrated Delta-wide selenium bioaccumulation models (Models 3, 4, and 5) are considered representative of conditions in the Delta under current and likely future conditions, because they incorporate realistic concentrations of waterborne selenium and they predict selenium concentrations in predatory fish that approximate measured concentrations in Largemouth Bass. The calibrated models take into account the variable nature of selenium bioaccumulation in relation to waterborne concentrations, which is reflected in the generally inverse relationship between the K_d and waterborne selenium concentration.

Models are not available to quantitatively estimate the level of changes in selenium bioaccumulation as related to residence time, but the effects of residence time are incorporated in the bioaccumulation modeling for selenium that was based on higher K_d values for drought years in comparison to wet, normal, or all years. If increases in fish tissue or bird egg selenium were to occur, the increases would likely be of concern only where fish tissues or bird eggs are already elevated in selenium to near or above thresholds of concern. That is, where biota concentrations are currently low and not approaching thresholds of concern (which is the case throughout the Delta, except for sturgeon in the western Delta), changes in residence time alone would not be expected to cause them to then approach or exceed thresholds of concern. In consideration of this factor, although the Delta as a whole is a Clean Water Act (CWA) Section 303(d)-listed waterbody for selenium (SWRCB 2011), and although monitoring data of fish tissue or bird eggs in the Delta are sparse, the most likely areas in which biota tissue selenium concentrations would be high enough that additional bioaccumulation due to increased residence time from restoration areas would be a concern are the western Delta and Suisun Bay (discussed below for sturgeon), and the south Delta in areas that receive San Joaquin River water.

The South Delta receives elevated selenium loads from the San Joaquin River. In contrast to Suisun Bay and possibly the western Delta in the future, the south Delta lacks the Overbite Clam (*Corbula* [*Potamocorbula*] *amurensis*), which is considered a key driver of selenium bioaccumulation in Suisun Bay because of its high bioaccumulation of selenium and its role in the benthic food web that includes long-lived sturgeon. The south Delta does have *Corbicula fluminea*, another bivalve that bioaccumulates selenium, but it is not as invasive as the Overbite Clam and thus likely makes up a smaller fraction of sturgeon diet. Also, nonpoint sources of selenium in the San Joaquin Valley that contribute selenium to the Delta will be controlled through a Total Maximum Daily Load (TMDL) developed by the Central Valley Regional Water Quality Control Board (Central ValleyRWQCB) for the lower San Joaquin River, established limits for the Grassland Bypass Project, and Basin Plan objectives (Central Valley RWQCB 2001, 2010; SWRCB 2010a, 2010b) that are expected to result in decreasing discharges of selenium from the San Joaquin River to the Delta. Further, if selenium levels in the San Joaquin River are not sufficiently reduced by these efforts, it is expected that the SWRCB and Central Valley RWQCB would initiate additional TMDLs to further control nonpoint sources of selenium.

6D.2.2 Western Delta Sturgeon Assumptions

Modeling for selenium bioaccumulation by sturgeon in the western Delta is considered to be based on the most appropriate uptake factors available, which were published recently by Presser and Luoma (2013) specifically for sturgeon in northern San Francisco Bay estuary. The disparity between larger estimated changes for sturgeon and smaller changes for other biota (that is, whole-body fish, bird eggs, and fish fillets) is attributable largely to differences in modeling approaches, as described previously. The model for most biota was calibrated to encompass the varying concentration-dependent uptake from waterborne selenium concentrations (expressed as the K_d, which is the ratio of selenium concentrations in particulates [as the lowest level of the food chain] relative to the waterborne concentration) that was exhibited in data for Largemouth Bass in 2000, 2005, and 2007 at various locations across the Delta. In contrast, the modeling for sturgeon could not be similarly calibrated at the three western Delta locations and used literature-derived uptake factors and TTFs for the estuary from Presser and Luoma (2013). There was a significant negative log-log relationship of K_d to waterborne selenium concentration that reflected the greater bioaccumulation rates for bass at low waterborne selenium than at higher concentrations. There was no difference in bass selenium concentrations in the Sacramento River at Rio Vista compared to the San Joaquin River at Vernalis in 2000, 2005, and 2007 (Foe 2010a), despite a nearly 10-fold difference in waterborne selenium concentrations. It is unknown whether this might also occur in the sturgeon food web. Thus, there is more confidence in the site-specific modeling based on the Delta-wide model that was calibrated for bass data than in the estimates for sturgeon based on "fixed" K_d values for all years and for drought years without regard to waterborne selenium concentration at the three locations in different time periods.

The western Delta and Suisun Bay receive elevated selenium loads from North San Francisco Bay (including San Pablo Bay, Carquinez Strait, and Suisun Bay) and from the San Joaquin River. Point sources of selenium in North San Francisco Bay (that is, refineries) that contribute selenium to Suisun Bay are expected to be reduced through a TMDL under development by the San Francisco Bay Regional Water Quality Control Board (San Francisco Bay RWQCB 2012) that is expected to result in decreasing discharges of selenium. Nonpoint sources of selenium in the San Joaquin Valley that contribute selenium to the San Joaquin River, and thus the Delta and Suisun Bay, will be controlled through a TMDL developed by the Central Valley RWQCB (2001) for the lower San Joaquin River, established limits for the GBP, and Basin Plan objectives (Central Valley RWQCB 2010; SWRCB 2010a, 2010b) that are expected to result in decreasing discharges of selenium from the San Joaquin River to the Delta. If selenium levels are not sufficiently reduced via these efforts, it is expected that the SWRCB and the San Francisco Bay and Central Valley regional Water Quality Control Boards would initiate additional actions to further control sources of selenium.

6D.2.3 Model Application Methodology

To evaluate differences in the impact assessment, modeled whole-body fish, bird egg or fish fillet data were compared directly (for percent change) and to the following threshold effect benchmarks:

- Whole-body fish for the Delta-wide model were compared to the Level of Concern (4 milligrams per kilogram [mg/kg] dw; Beckon et al. 2008) and the Toxicity Level (8.1 mg/kg dw; USEPA 2014) for fish tissue.

- Modeled bird egg selenium concentrations were compared to Level of Concern (6 mg/kg dw) and Toxicity Level (10 mg/kg dw) values from Beckon et al. (2008).
- Fish fillet data were compared to the Advisory Tissue Level (2.5 µg/g ww) for human consumption of fish (OEHHA 2008).
- Whole-body selenium concentrations in sturgeon were compared to Low Effect (5 mg/kg dw) and High Effect (8 mg/kg dw) guidelines from Presser and Luoma (2013).

Results of comparisons to these benchmarks are expressed as Exceedance Quotients (EQs) in some of the tables and figures. Annual average selenium concentrations in water did not exceed the 5.0 µg/L(4-day average) or 20 µg/L (1-hour average) criterion, so no EQs were calculated.

6D.2.3.1 No Action Alternative and Second Basis of Comparison Models

The purpose of the No Action Alternative and the Second Basis of Comparison for comparison with the forecasts of the alternative models was to determine whether the implementation of the proposed alternatives is likely to result in substantial impacts to selenium, thereby affecting biological resources. The No Action Alternative and the Second Basis of Comparison models were completed for five Delta interior, three western Delta, and four major Delta diversion locations. DSM2 post-processing output provided estimates of the waterborne selenium concentration at each of those 12 locations (Table 6D.9). The Delta-specific selenium bioaccumulation model that was calibrated using Largemouth Bass data from the Delta was then used to estimate selenium concentrations in whole-body fish and then in bird eggs and fish fillets. Selenium concentrations in sturgeon inhabiting the western Delta (represented by three locations) were estimated using recently published literature parameters. Modeled selenium concentrations in whole-body fish (predatory fish throughout the Delta or sturgeon in the western Delta), bird egg or fish fillet data were compared to the threshold effect benchmarks listed previously. The modeled tissue selenium concentrations themselves and the EQs (based on comparisons to thresholds) both served as a basis for comparison of other alternatives to identify potential impacts.

6D.2.3.2 Alternative Models

For each of the alternative model simulations, the same procedure as described for the No Action Alternative and the Second Basis of Comparison models was used, with similar assumptions, to estimate waterborne selenium concentrations and selenium concentrations in fish and bird eggs. Each alternative model simulation for each type of biota (whole-body fish [either using the Delta-wide model for bass or the western Delta sturgeon model], bird eggs, or fish fillets) was compared to both the No Action Alternative and the Second Basis of Comparison to determine potentially significant impacts.

6D.3 Modeling Results

The post-processing tool is Excel-based. The general pre-processing and input files development are described in the modeling data assumptions sections above. This section focuses on data analysis and results interpretation for the impact assessment.

6D.3.1 Post-processing and Results Analysis: Delta-wide Model

Output data resulting from the model simulations for each alternative are processed to provide a tabular depiction of potential impacts to fish and wildlife (Tables 6D.13 through 6D.15). As discussed previously, outputs from the post-processing model used in this analysis are annual average selenium fish tissue concentrations for all year types and separately presented for the subset of drought years.

The variation in concentrations between the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5 was less than 5 percent (Tables 6D.13 through 6D.15). Annual average concentrations do not exceed the selenium thresholds at all locations modeled in the Delta for all years and drought years both as measured and as modeled. Results are shown in Tables 6D.9 through 6D.15 and Figures 6D.7 through 6D.10. Table 6D.9 presents the period-average waterborne selenium concentrations by location and water year type that were used to model fish tissue (whole-body and fillet) and bird egg concentrations (Tables 6D.10 through 6D.12).

All estimated selenium concentrations in water and biota (whole-body fish, bird eggs, and fish fillets) were below the benchmarks used for evaluation (presented in Section 6D.2.4). The highest estimated selenium concentrations were for Alternative 1 in the San Joaquin River at San Andreas Landing and Sacramento River at Emmaton, and Alternative 3 in the North Bay Aqueduct at Barker Slough in drought years (Tables 6D.10 through 6D.12). Changes in estimated selenium concentrations for Alternatives 3 and 5 compared to the No Action Alternative and Alternative 1 were less than 4 percent (Tables 6D.14 and 6D.15).

6D.3.2 Post-processing and Results Analysis: Western Delta Sturgeon Model

Output data resulting from the sturgeon model simulations for each alternative at the three western Delta locations were processed to provide a tabular depiction of potential impacts to sturgeon. Table 6D.16 presents the period-average waterborne selenium concentrations by location and water year type that were used to model fish tissue concentrations (Table 6D.17). As discussed previously, outputs from the post-processing model used in this analysis are annual average selenium concentrations in whole-body sturgeon for all year types and separately presented for the subset of drought years.

The expected variations in whole-body sturgeon selenium concentrations between the No Action Alternative, the Second Basis of Comparison, and Alternatives 1 through 5 were less than 1 mg/kg dw (Table 6D.17). The highest estimated selenium concentrations were for drought years at all three locations with little difference among alternatives. Annual average sturgeon concentrations slightly exceeded the low selenium thresholds for all locations and alternatives for drought years, but not for all years. Results of comparisons to the thresholds are shown in Table 6D.18 and Figure 6D.11. Estimated selenium concentrations did not exceed high thresholds.

Changes in estimated selenium concentrations compared to the No Action Alternative and Second Basis of Comparison are less than 5 percent for all years and for drought years (Table 6D.19). The largest predicted changes were a small decrease under Alternative 3 relative to the No Action Alternative for the San Joaquin River at Antioch in all years and a small increase predicted for Alternative 5 relative to Second Basis of Comparison at that location in all years. Both of these predicted changes were less than 5 percent. However, as noted previously, even the expected changes for the San Joaquin River at Antioch for Alternatives 3 and 5 as compared to the No Action Alternative or the Second Basis of Comparison were less than 1 mg/kg dw. It is not likely that such small changes in whole-body selenium concentrations would be detectable under field conditions.

6D.3.3 Model Limitations and Applicability

Although it is impossible to predict future hydrology, land use, and water use with certainty, the selenium model and DSM2 were used to forecast impacts to fish and wildlife that could result from implementation of the alternatives. The selenium model for sturgeon has greater uncertainty than the selenium model for bass because the sturgeon model was not as finely calibrated for varying K_d relative to waterborne selenium concentrations throughout the Delta, as discussed in Section 6D.2.2. Mathematical models like DSM2 can only approximate processes of physical systems. Models are inherently inexact because the mathematical description of the physical system is imperfect and the understanding of interrelated physical processes is incomplete. However, the selenium models are powerful tools that, when used carefully, can provide useful insight into processes of the physical system. Selenium concentrations for inflow sources to the Delta (for example, agriculture in the Delta, Yolo Bypass, Eastside Tributaries) also caused uncertainty in the modeling because of limited data. For the Sacramento River and the San Joaquin River, approximately 90 data points (Chapter 6, Table 6.58; Table 6D.1) were used to estimate the mean selenium concentrations for these inflow sources, whereas the mean selenium concentrations for other inflow sources to the Delta had many fewer (0 to 14) data points (concentrations for the Eastside Tributaries were assumed).

Notes:

Equations from Presser and Luoma (2010a, 2010b) were used to calculate selenium concentrations for fish. Models 1 and 2 used the default K_d (1000) and the average selenium trophic transfer factors to aquatic insects (2.8) and fish (1.1 for all trophic levels).

Model 1 = TL-3 Fish Eating Invertebrates

Model 2 = TL-4 Fish Eating TL-3 Fish

Invert. = invertebrate

K_d = particulate concentration/water concentration ratio

µg/g, dw = micrograms per gram, dry weight

NA = not available; bass not collected here

RM = river mile

TL = trophic level

a. Geometric mean calculated from whole-body largemouth bass data presented in Foe (2010a).

b. Fish data collected at Rio Vista (Foe 2010a) were used to calculate geometric mean whole-body largemouth bass and ratios.

c. Fish data collected at Old River near Tracy (Foe 2010a) were used to calculate geometric mean whole-body largemouth bass and ratios.

d. Geometric mean of total selenium concentrations in water collected from years 2004, 2007, and 2008 (DWR Website 2009) was used to estimate selenium concentrations in particulates and biota (DSM2 data were not available). Fish data collected from Sacramento River at Veterans Bridge (Foe 2010a) were used to calcula mean whole-body largemouth bass and ratios.

e. Geometric mean of selenium concentrations (total or dissolved was not specified) in water collected from years 1999–2000 (SWAMP Website 2009) was used to estimate Year 2000 selenium concentrations in particulates and biota (DSM2 data were not available); years 2004-2005 were used for Year 2005 estimates; and ye 2007 were used for Year 2007 estimates.

Notes:

Equations from Presser and Luoma (2010a, 2010b) were used to calculate selenium concentrations for fish. Model 3 used the average selenium trophic transfer factors to aquatic insects (2.8) and fish (1.1 for all trophic levels).

Model 3 = Model 2 (TL-4 Fish Eating TL-3 Fish) with K_d estimated using all years regression (log K_d = 2.76-0.97(logDSM2))

Invert. = invertebrate

K_d = particulate concentration/water concentration ratio

µg/g, dw = micrograms per gram, dry weight

NA = not available; bass not collected here

RM = river mile

TL = trophic level

a. Geometric mean calculated from whole-body largemouth bass data presented in Foe (2010a).

b. Fish data collected at Rio Vista (Foe 2010a) were used to calculate geometric mean whole-body largemouth bass and ratios.

c. Fish data collected at Old River near Tracy (Foe 2010a) were used to calculate geometric mean whole-body largemouth bass and ratios.

d. Geometric mean of total selenium concentrations in water collected from years 2004, 2007, and 2008 (DWR Website 2009) was used to estimate selenium concentrations in particulates and biota (DSM2 data were not available). Fish data collected from Sacramento River at Veterans Bridge (Foe 2010a) were used to calc geometric mean whole-body largemouth bass and ratios.

e. Geometric mean of selenium concentrations (total or dissolved was not specified) in water collected from years 1999-2000 (SWAMP Website 2009) was used to estimate Year 2000 selenium concentrations in particulates and biota (DSM2 data were not available); years 2004-2005 were used for Year 2005 estimates; and years 200 2007 were used for Year 2007 estimates.

Table 6D.7 Selenium Bioaccumulation from Water (µg/L) to Particulates and Fish (µg/g, dw) Using Model 2 with Estimated K_d from Normal/Wet Years Regression for Model 4 and Dry Years Regression for Model 5

Notes:

Equations from Presser and Luoma (2010a, 2010b) were used to calculate selenium concentrations for fish. Models 4 and 5 used the average selenium trophic transfer factors to aquatic insects (2.8) and fish (1.1 for all trophic levels).

Model 4 = Model 2 (TL-4 Fish Eating TL-3 Fish) with K_d estimated using normal/wet years regression (log K_d = 2.75-0.90(logDSM2))

Model 5 = Model 2 (TL-4 Fish Eating TL-3 Fish) with K_d estimated using dry years (2007) regression (log K_d = 2.84-1.02(logDSM2))

Invert. = invertebrate

K_d = particulate concentration/water concentration ratio

µg/g, dw = micrograms per gram, dry weight

NA = not available; bass not collected here

RM = river mile

TL = trophic level

a. Geometric mean calculated from whole-body largemouth bass data presented in Foe (2010a).

b. Fish data collected at Rio Vista (Foe 2010a) were used to calculate geometric mean whole-body largemouth bass and ratios.

c. Fish data collected at Old River near Tracy (Foe 2010a) were used to calculate geometric mean whole-body largemouth bass and ratios.

d. Geometric mean of total selenium concentrations in water collected from years 2004, 2007, and 2008 (DWR Website 2009) was used to estimate selenium concentrations in particulates and biota (DSM2 data were not available). Fish data collected from Sacramento River at Veterans Bridge (Foe 2010a) were used to calc geometric mean whole-body largemouth bass and ratios.

e. Geometric mean of selenium concentrations (total or dissolved was not specified) in water collected from years 1999-2000 (SWAMP Website 2009) was used to estimate Year 2000 selenium concentrations in particulates and biota (DSM2 data were not available); years 2004-2005 were used for Year 2005 estimates; and years 200 2007 were used for Year 2007 estimates.

Table 6D.8 Selenium Bioaccumulation from Water (µg/L) to Particulates, Whole-body Fish (µg/g, dw), and Bird Eggs (µg/g, dw) Using Model 2 with Estimated K_d from Normal/Wet Years Regression for Model 4 and Dry Years Regression for Model 5

Notes:
a. All: Water years 1922-2003 represent the 82-year period modeled using DSM2. Drought: Represents a 5 consecutive year (water years 1987-1991) drought period consisting of dry and critical water year types (as defined by the Sacramento Valley 40-30-30 water year hydrologic classification index)
b. Dry weight, except as noted for fish fillets

Alt. = alternative
dw = dry weight
mg/kg = milligram per kilogram
NAA = No Action Alternative
SBC = Second Basis of Comparison
“Alt. 1 (SBC)” is the same as Second Basis of Comparison. This nomenclature was used in this appendix to be consistent with the model run output for the model run that represents both Second Basis of Comparison and Alternative 1.
Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 4 results are not presented separately. Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented separately.
ww = wet weight

Notes:

a. All: Water years 1922-2003 represent the 82-year period modeled using DSM2. Drought: Represents a 5 consecutive year (water years 1987-1991) drought period consisting of dry and critical water year types (as defined by the Sacramento Valley 40-30-30 water year hydrologic classification index).

b. Dry weight, except as noted for fish fillets.

c. Exceedance Quotient = tissue concentration/benchmark

d. Level of Concern for fish tissue (lower end of range) = 4 mg/kg dw (Beckon et al. 2008)

e. Toxicity Level for fish tissue = 8.1 mg/kg dw (USEPA 2014)

f. Level of Concern for bird eggs (lower end of range) = 6 mg/kg dw (Beckon et al. 2008)

g. Toxicity Level for bird eggs = 10 mg/kg dw (Beckon et al. 2008)

h. Advisory Tissue Level = 2.5 mg/kg ww (OEHHA 2008)

Alt. = Alternative

dw = dry weight

mg/kg = milligram per kilogram

NAA = No Action Alternative

SBC = Second Basis of Comparison

“Alt. 1 (SBC)” is the same as Second Basis of Comparison. This nomenclature was used in this appendix to be consistent with the model run output for the model run that represents both Second Basis of Comparison and Alternative 1.

Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 4 results are not presented separately. Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented separately.

ww = wet weight

SBC = Second Basis of Comparison

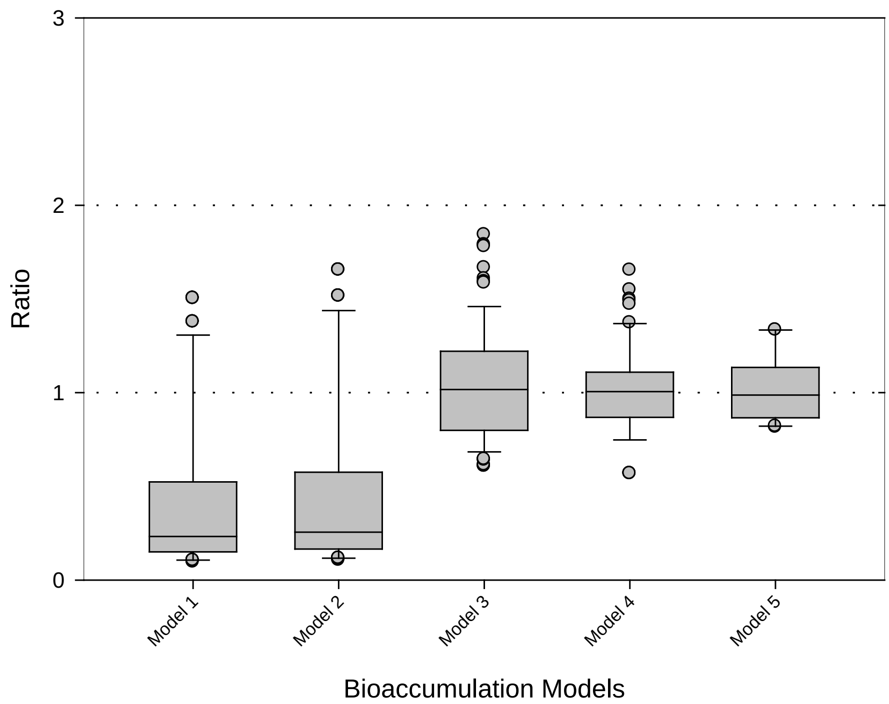
Table 6D.19 Percent Change in Selenium Concentrations Relative to No Action Alternative and Second Basis of Comparison

Location	Period *	Alternative 3 NAA	Alternative 3 Alt1 (SBC)	Alternative 5 NAA	Alternative 5 Alt 1 (SBC)
Sacramento River at Emmaton	ALL	-2.0	-0.7	0.9	2.2
	DROUGHT	-0.8	-0.1	1.8	2.5
San Joaquin River at Antioch	ALL	-4.7	-1.3	1.2	4.8
	DROUGHT	-1.2	-0.2	2.5	3.5
Montezuma Slough at Hunter Cut/Beldon's Landing	ALL	-2.2	-0.7	0.5	2.1
	DROUGHT	-0.5	-0.1	0.8	1.2

Notes:
* All: Water years 1922-2003 represent the 82-year period modeled using DSM2. Drought: Represents a 5-consecutive-year (Water Years 1987-1991) drought period consisting of dry and critical water-year types (as defined by the Sacramento Valley 40-30-30 water year hydrologic classification index).

"Alt. 1 (SBC)" is the same as Second Basis of Comparison. This nomenclature was used in this appendix to be consistent with the model run output for the model run that represents both Second Basis of Comparison and Alternative 1.
Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 4 results are not presented separately.
Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented separately.
dw = dry weight
mg/kg = milligram per kilogram
SBC = Second Basis of Comparison



For Models 1 and 2, default values (K_d = 1000, TTF_{invert} = 2.8, TTF_{fish} = 1.1) were used in calculations as follows:

Model 1=Trophic level 3 (TL-3) fish eating invertebrates

Model 2= TL-4 fish eating TL-3 fish

Model 3=Model 2 with K_d estimated using all years regression (log Kd = 2.76-0.97(logDSM2))

Model 4=Model 2 with K_d estimated using normal/wet years (2000/2005) regression (log Kd = 2.75-0.90(logDSM2))

Model 5=Model 2 with K_d estimated using dry years (2007) regression (logKd = 2.84-1.02(logDSM2))

Figure 6D.1 Ratios of Predicted Selenium Concentrations in Fish Models 1 through 5 to Observed Selenium Concentrations in Largemouth Bass

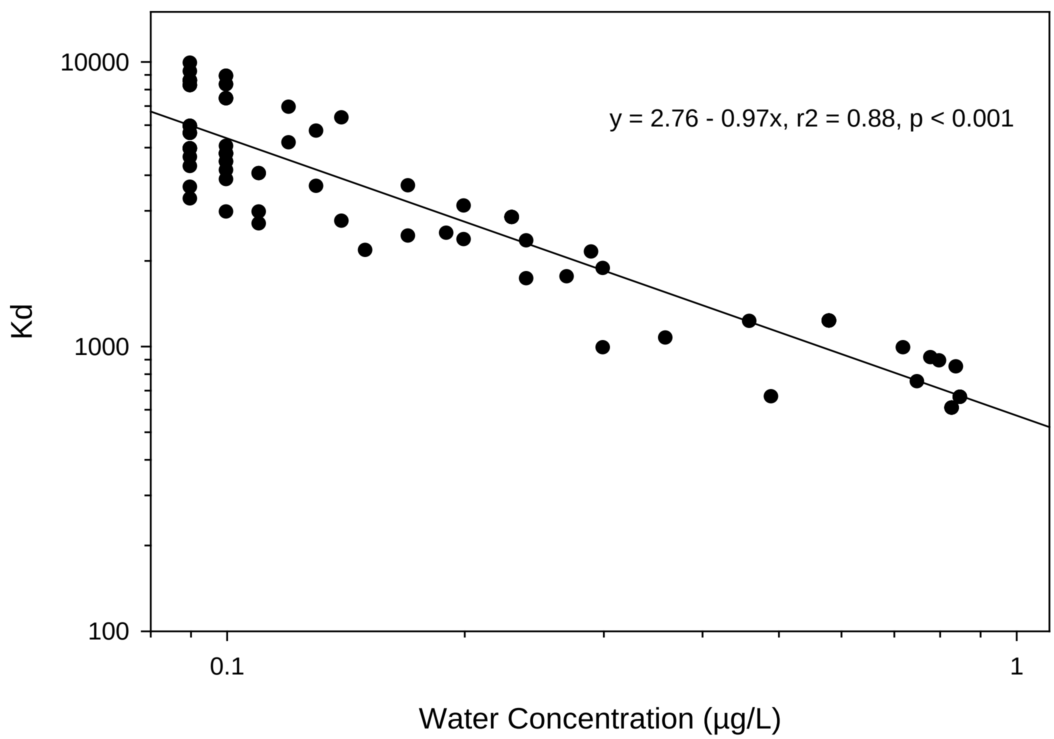


Figure 6D.2 Log-log Regression Relation of Estimated K_d to Waterborne Selenium Concentration for Model 3 in All Years (Based on Years 2000, 2005, and 2007)

To predict the K_d (y) from water concentrations using the regression equation, take the log of the water concentration (x), multiply it by the slope (-0.97), which gives a positive number for x<1 (i.e., waterborne selenium concentrations less than 1 µg/L); then add this number to the intercept (2.76) and take the antilog.

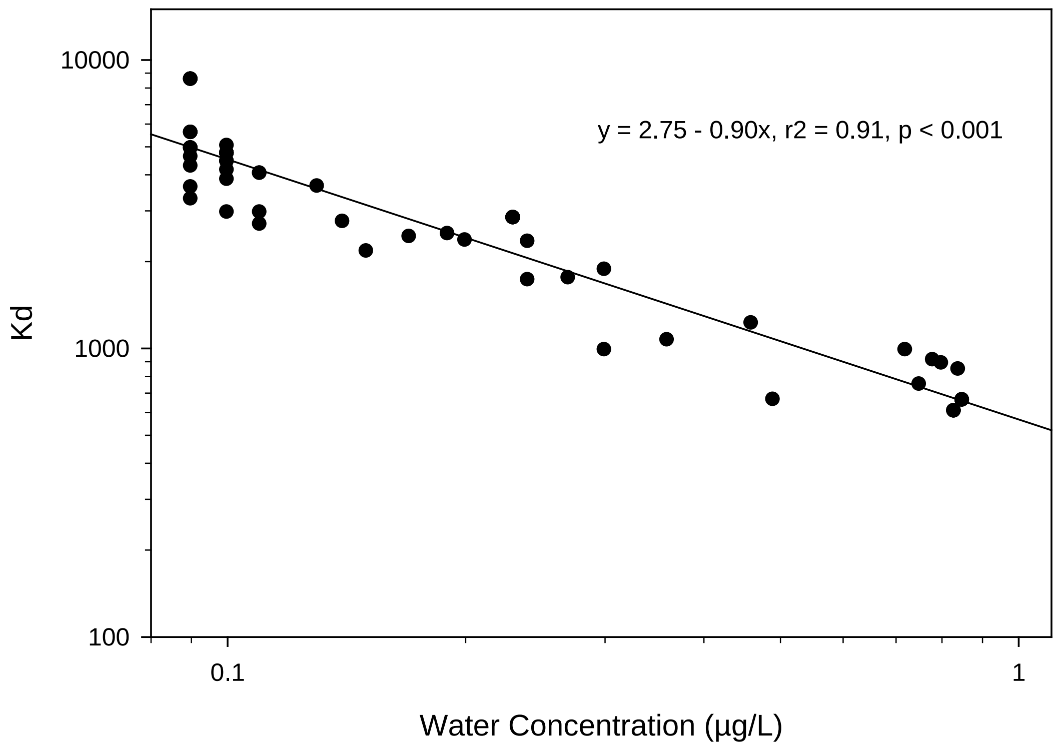

Figure 6D.3 Log-log Regression Relation of Estimated K_d to Waterborne Selenium Concentration for Model 4 in Normal/Wet Years (Based on Years 2000 and 2005)

To predict the K_d (y) from water concentrations using the regression equation, take the log of the water concentration (x), multiply it by the slope (-0.90), which gives a positive number for $x<1$ (i.e., waterborne selenium concentrations less than 1 µg/L); then add this number to the intercept (2.75) and take the antilog.

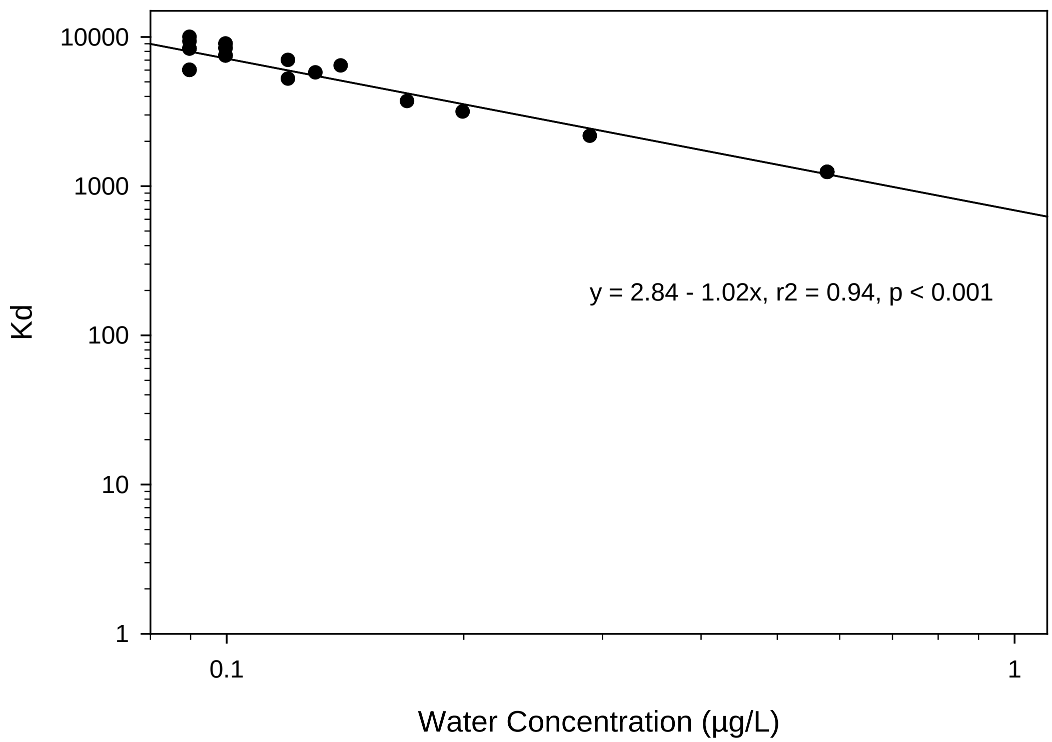

Figure 6D.4 Log-log Regression Relation of Estimated K_d to Waterborne Selenium Concentration for Model 5 in Dry Years (Based on Year 2007)

To predict the K_d (y) from water concentrations using the regression equation, take the log of the water concentration (x), multiply it by the slope (-1.02), which gives a positive number for x<1 (i.e., waterborne selenium concentrations less than 1 µg/L); then add this number to the intercept (2.84) and take the antilog.

Appendix 6E

Analysis of Delta Salinity Indicators

This appendix provides information about the methods and assumptions used for the Coordinated Long-Term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS) analysis for Delta salinity indicators. It is organized into two main sections that are briefly described below:

- Section 6E.1: Analysis of Delta Salinity Indicators Methodology and Assumptions
  - The impacts analysis for Delta salinity indicators uses the DSM2-QUAL model to quantify changes in salinity, chloride, and bromide concentrations. This section describes the overall analytical approach and assumptions for simulations of the No Action Alternative, Second Basis of Comparison, and the other alternatives.
- Section 6E.2: Analysis of Delta Salinity Indicators Results
  - This section presents the results for salinity, chloride concentration, and bromide concentration at different locations within in the Delta.

6E.1 Analysis of Delta Salinity Indicators Methodology and Assumptions

6E.1.1 Analysis Methodology

To evaluate the potential effects on water quality within the Delta, three different parameters were quantified: salinity (measured as Electrical Conductivity [EC]), chloride concentration, and bromide concentration. This section describes how these parameters were estimated for the analysis.

6E.1.1.1 Salinity

Monthly average salinity in the Delta was estimated at select locations within the Delta in terms of EC (in units of micromhos per centimeter [µmhos/cm]) using the DSM2-QUAL model for all the alternatives. Refer to Appendix 5A, Section A for a detailed description of the DSM2-QUAL model.

6E.1.1.2 Chloride Concentration

Monthly average chloride concentration at primarily diversion and export locations within the Delta was calculated based on the maximum of the following regression equations taken from CalSim II:

$$CCl- = EC*0.285-50$$

$$CCl- = EC*0.15-12$$

where: EC is the monthly average Electrical Conductivity value at the export location and CCl- is the monthly average chloride concentration in mg/L

The regression equations calculate chloride concentrations based on whether the location is riverine or seawater dominant. To be conservative, the maximum of chloride concentration calculated using the above two equations was used. The EC value in this equation is the salinity value described previously that is output from the DSM2-QUAL model.

6E.1.1.3 Bromide Concentration

Monthly average bromide concentration at diversion and export locations within the Delta was calculated based on the following regression equations from the California Department of Water Resources (DWR) 33rd Annual Progress Report (DWR 2012):

*if VolFpMartinez <0.4 then CBr- = EC*0.0004-0.0364*

*if VolFpMartinez >0.4 then CBr- = EC*0.0000827-0.1117*

where: VolFpMartinez is the monthly average Martinez Source Water (Volumetric) Fingerprinting value at the location, EC is the monthly average Electrical Conductivity (µmhos/cm) value at the export location and CBr- is the monthly average bromide concentration (mg/L)

The Volumetric Fingerprinting and EC values (the same salinity value used for the chloride calculation) in this equation are both outputs of the DSM2-QUAL model, and methodology for estimating these parameters is described in Appendix 5A, Section A.

6E.1.2 Analysis Scenario Assumptions

This section describes the assumptions for the Analysis of the Delta Salinity Indicators for the No Action Alternative, Second Basis of Comparison, and other alternatives.

The following CalSim II model simulations were performed as the basis of evaluating the impacts of Alternatives 1 through 5 as compared to the No Action Alternative, and the No Action Alternative and Alternatives 1 through 5 as compared to the Second Basis of Comparison:

- No Action Alternative
- Second Basis of Comparison

The following model simulations of other alternatives were performed:

- Alternative 1 – for simulation purposes, considered the same as Second Basis of Comparison
- Alternative 2 – for simulation purposes, considered the same as No Action Alternative
- Alternative 3

- Alternative 4 – for simulation purposes, considered the same as Second Basis of Comparison.
- Alternative 5

Assumptions for each of these alternatives were developed with the surface water modeling tools and are described in Appendix 5A, Section B.

Assumptions for each of these alternatives are reflected to monthly CalSim II flows that are input into the DSM2 model to generate the salinity results described in this section. The salinity (EC) results are then used to calculate the chloride and bromide concentrations based on the equations described in this section. The equations described above pertain to all alternatives.

6E.2 Analysis of Delta Salinity Indicators Results

Results are provided for each of the following runs separately:

- No Action Alternative
- Second Basis of Comparison
- Alternative 1
- Alternative 3
- Alternative 5

Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 4 results are not presented separately. Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented separately.

In addition, the same statistics are provided for the following comparisons to establish changes of the alternative with respect to one of the bases of comparison:

- Alternative 1 compared to No Action Alternative
- Alternative 3 compared to No Action Alternative
- Alternative 5 compared to No Action Alternative
- No Action Alternative compared to Second Basis of Comparison
- Alternative 3 compared to Second Basis of Comparison
- Alternative 5 compared to Second Basis of Comparison

The first set of results is provided as probability of exceedance curves of salinity (EC) for select locations within the Delta. For this analysis, exceedance plots for monthly average EC were generated based on the 82-year CalSim II time period for each of the alternatives and bases of comparison. Differences among alternatives were evaluated using the exceedance probability corresponding to varying levels of salinity. The first set of results is provided as the following figures:

- B.1. Sacramento River downstream of Steamboat Slough Salinity (Figures 6E.B.1.1. through 6E.B.1.12.)

- B.2. Sacramento River at Emmaton Salinity (Figures 6E.B.2.1. through 6E.B.2.12.)
- B.3. San Joaquin River at Jersey Point Salinity (Figures 6E.B.3.1. through 6E.B.3.12.)
- B.4. Sacramento River at Collinsville Salinity (Figures 6E.B.4.1. through 6E.B.4.12.)
- B.5. Sacramento River at Mallard Slough Salinity (Figures 6E.B.5.1. through 6E.B.5.12.)
- B.6. Sacramento River at Port Chicago Salinity (Figures 6E.B.6.1. through 6E.B.6.12.)
- B.7. Jones Pumping Plant Salinity (Figures 6E.B.7.1. through 6E.B.7.12.)
- B.8. Banks Pumping Plant Salinity (Figures 6E.B.8.1. through 6E.B.8.12.)
- B.9. Antioch Salinity (Figures 6E.B.9.1. through 6E.B.9.12.)
- B.10.1. Chipps Island North Channel Salinity (Figures 6E.B.10.1.1. through 6E.B.10.1.12.)
- B.10.2. Chipps Island South Channel Salinity (Figures 6E.B.10.2.1. through 6E.B.10.2.12.)
- B.11. Old River at Rock Slough Salinity (Figures 6E.B.11.1. through 6E.B.11.12.)
- B.12. Contra Costa Water District Old River Intake Salinity (Figures 6E.B.12.1. through 6E.B.12.12.)
- B.13. Contra Costa Water District Victoria Canal Intake Salinity (Figures 6E.B.13.1. through 6E.B.13.12.)
- B.14. Barker Slough North Bay Aqueduct Intake Salinity (Figures 6E.B.14.1. through 6E.B.14.12.)
- B.15. San Joaquin River at Vernalis Salinity (Figures 6E.B.15.1. through 6E.B.15.12.)

A discussion of results and impact assessment is provided in the Environmental Consequences section of Chapter 6.

The second set of results is provided as tables summarizing the EC as well as chloride and bromide concentrations at select locations within the Delta with long-term averages over the entire CalSim II simulation period. Averages are also provided by water year type.

As noted earlier, EC was used as surrogate for Delta salinity results.

The following results are presented in this section:

- B.1. Sacramento River downstream of Steamboat Slough Salinity (Tables 6E.B.1.1. through 6E.B.1.6.)

- B.2. Sacramento River at Emmaton Salinity (Tables 6E.B.2.1. through 6E.B.2.6.)
- B.3. San Joaquin River at Jersey Point Salinity (Tables 6E.B.3.1. through 6E.B.3.6.)
- B.4. Sacramento River at Collinsville Salinity (Tables 6E.B.4.1. through 6E.B.4.6.)
- B.5. Sacramento River at Mallard Slough Salinity (Tables 6E.B.5.1. through 6E.B.5.6.)
- B.6. Sacramento River at Port Chicago Salinity (Tables 6E.B.6.1. through 6E.B.6.6.)
- B.7. Jones Pumping Plant Salinity (Tables 6E.B.7.1. through 6E.B.7.6.)
- B.8. Banks Pumping Plant Salinity (Tables 6E.B.8.1. through 6E.B.8.6.)
- B.9. Antioch Salinity (Tables 6E.B.9.1. through 6E.B.9.6.)
- B.10.1. Chipps Island North Channel Salinity (Tables 6E.B.10.1.1. through 6E.B.10.1.6.)
- B.10.2. Chipps Island South Channel Salinity (Tables 6E.B.10.2.1. through 6E.B.10.2.6.)
- B.11. Old River at Rock Slough Salinity (Tables 6E.B.11.1. through 6E.B.11.6.)
- B.12. Contra Costa Water District Old River Intake Salinity (Tables 6E.B.12.1. through 6E.B.12.6.)
- B.13. Contra Costa Water District Victoria Canal Intake Salinity (Tables 6E.B.13.1. through 6E.B.13.6.)
- B.14. Barker Slough North Bay Aqueduct Intake Salinity (Tables 6E.B.14.1. through 6E.B.14.6.)
- B.15. San Joaquin River at Vernalis Salinity (Tables 6E.B.15.1. through 6E.B.15.6.)
- B.16. Sacramento River at Mallard Slough Chloride Concentration (Tables 6E.B.16.1. through 6E.B.16.6.)
- B.17. Jones Pumping Plant Chloride Concentration (Tables 6E.B.17.1. through 6E.B.17.6.)
- B.18. Banks Pumping Plant Chloride Concentration (Tables 6E.B.18.1. through 6E.B.18.6.)
- B.19. Old River at Rock Slough Chloride Concentration (Tables 6E.B.19.1. through 6E.B.19.6.)
- B.20. Contra Costa Water District Old River Intake Chloride Concentration (Tables 6E.B.20.1. through 6E.B.20.6.)

- B.21. Contra Costa Water District Victoria Canal Intake Chloride Concentration (Tables 6E.B.21.1. through 6E.B.21.6.)
- B.22. Antioch Chloride Concentration (Tables 6E.B.22.1. through 6E.B.22.6.)
- B.23. Jones Pumping Plant Bromide Concentration (Tables 6E.B.23.1. through 6E.B.23.6.)
- B.24. Banks Pumping Plant Bromide Concentration (Tables 6E.B.24.1. through 6E.B.24.6.)
- B.25. Old River at Rock Slough Bromide Concentration (Tables 6E.B.25.1. through 6E.B.25.6.)
- B.26. Contra Costa Water District Old River Intake Bromide Concentration (Tables 6E.B.26.1. through 6E.B.26.6.)
- B.27. Contra Costa Water District Victoria Canal Intake Bromide Concentration (Tables 6E.B.27.1. through 6E.B.27.6.)

The third set of results provided are probability of exceedance curves that present the differences between simulated salinity or chloride concentrations and the D-1641 agricultural salinity standards or M&I chloride concentration standards for select locations within the Delta. Each plot contains a dashed threshold line at the zero value on the Y-Axis. Values above this line indicate the percentage of years the applied D-1641 standard was exceeded. For this analysis, exceedance plots were generated based on the 82-year simulation period for each alternative.

As noted earlier, EC was used as surrogate for Delta salinity results.

The following results are presented in this section:

- B.28. Sacramento River at Emmaton Compliance with D-1641 Agricultural Salinity Standard
- B.29. San Joaquin River at Jersey Point Compliance with D-1641 Agricultural Salinity Standard
- B.30. Contra Costa Canal at Pumping Plant #1 Compliance with D-1641 M&I Chloride Standard
- B.31. San Joaquin River at Antioch Water Works Compliance with D-1641 M&I Chloride Standard
- B.32. West Canal at Mouth of Clifton Court Forebay Compliance with D-1641 M&I Chloride Standard
- B.33. Delta-Mendota Canal at Tracy Pumping Plant Compliance with D-1641 M&I Chloride Standard
- B.34. Barker Slough at North Bay Aqueduct Compliance with D-1641 M&I Chloride Standard
- B.35. Cache Slough at City of Vallejo Intake Compliance with D-1641 M&I Chloride Standard

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

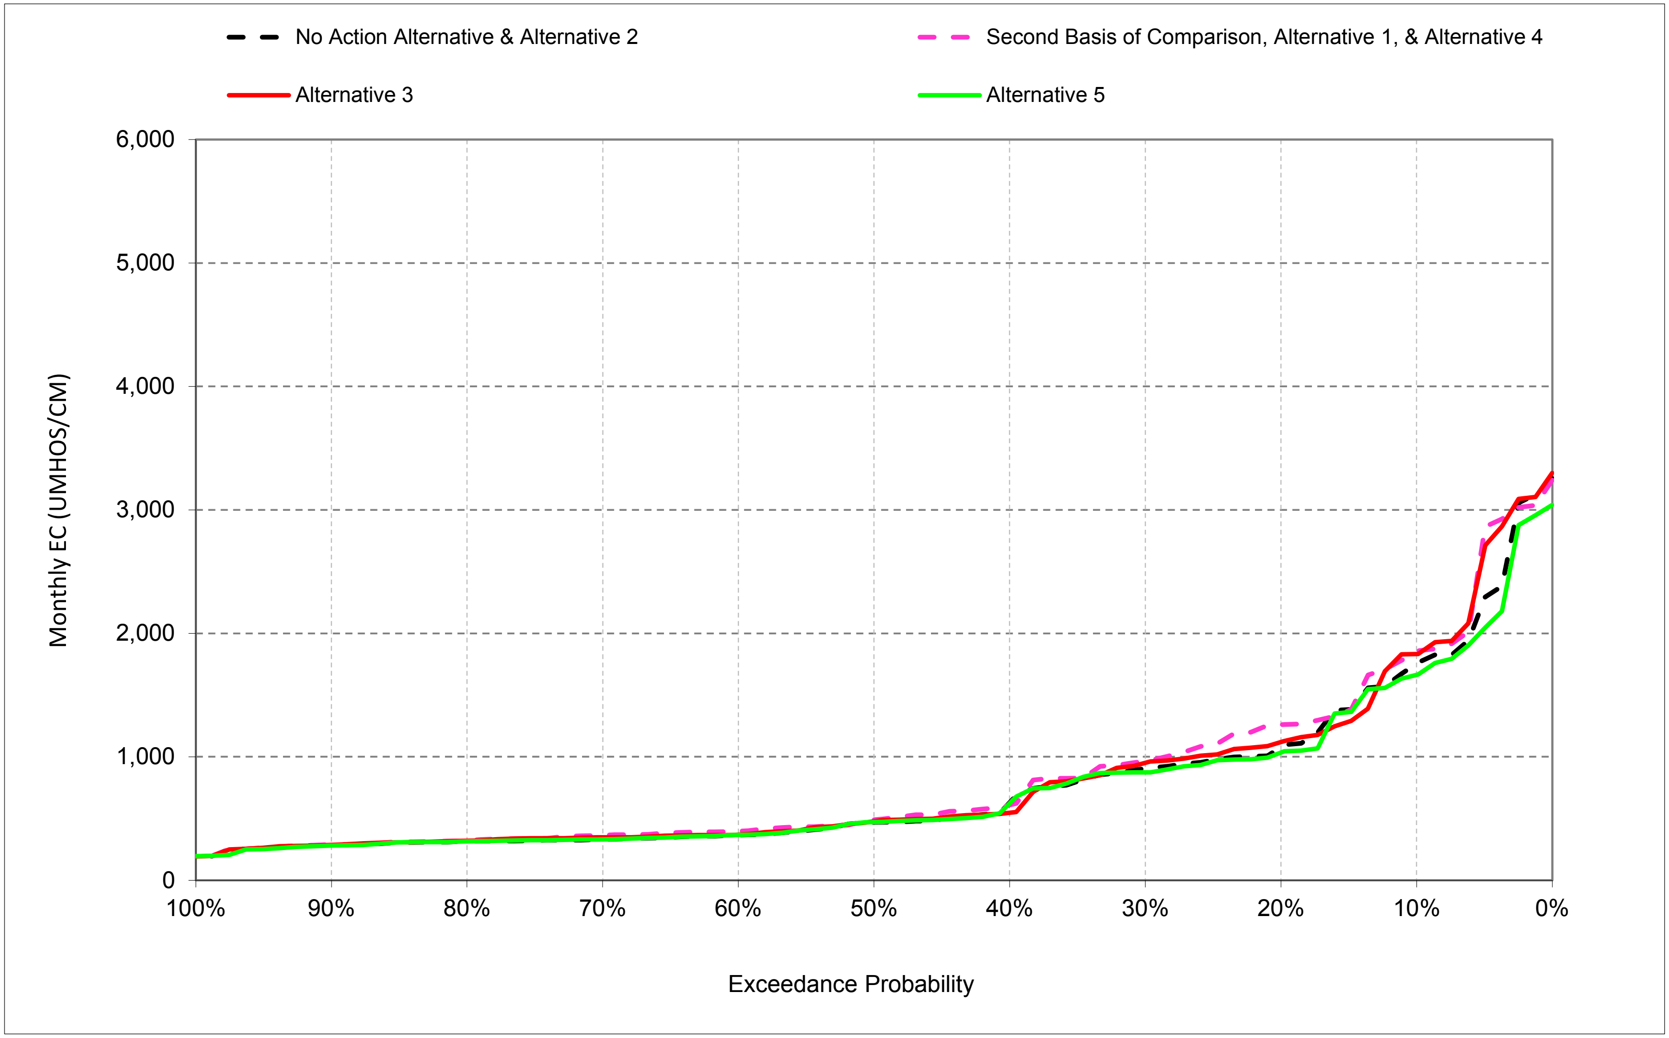
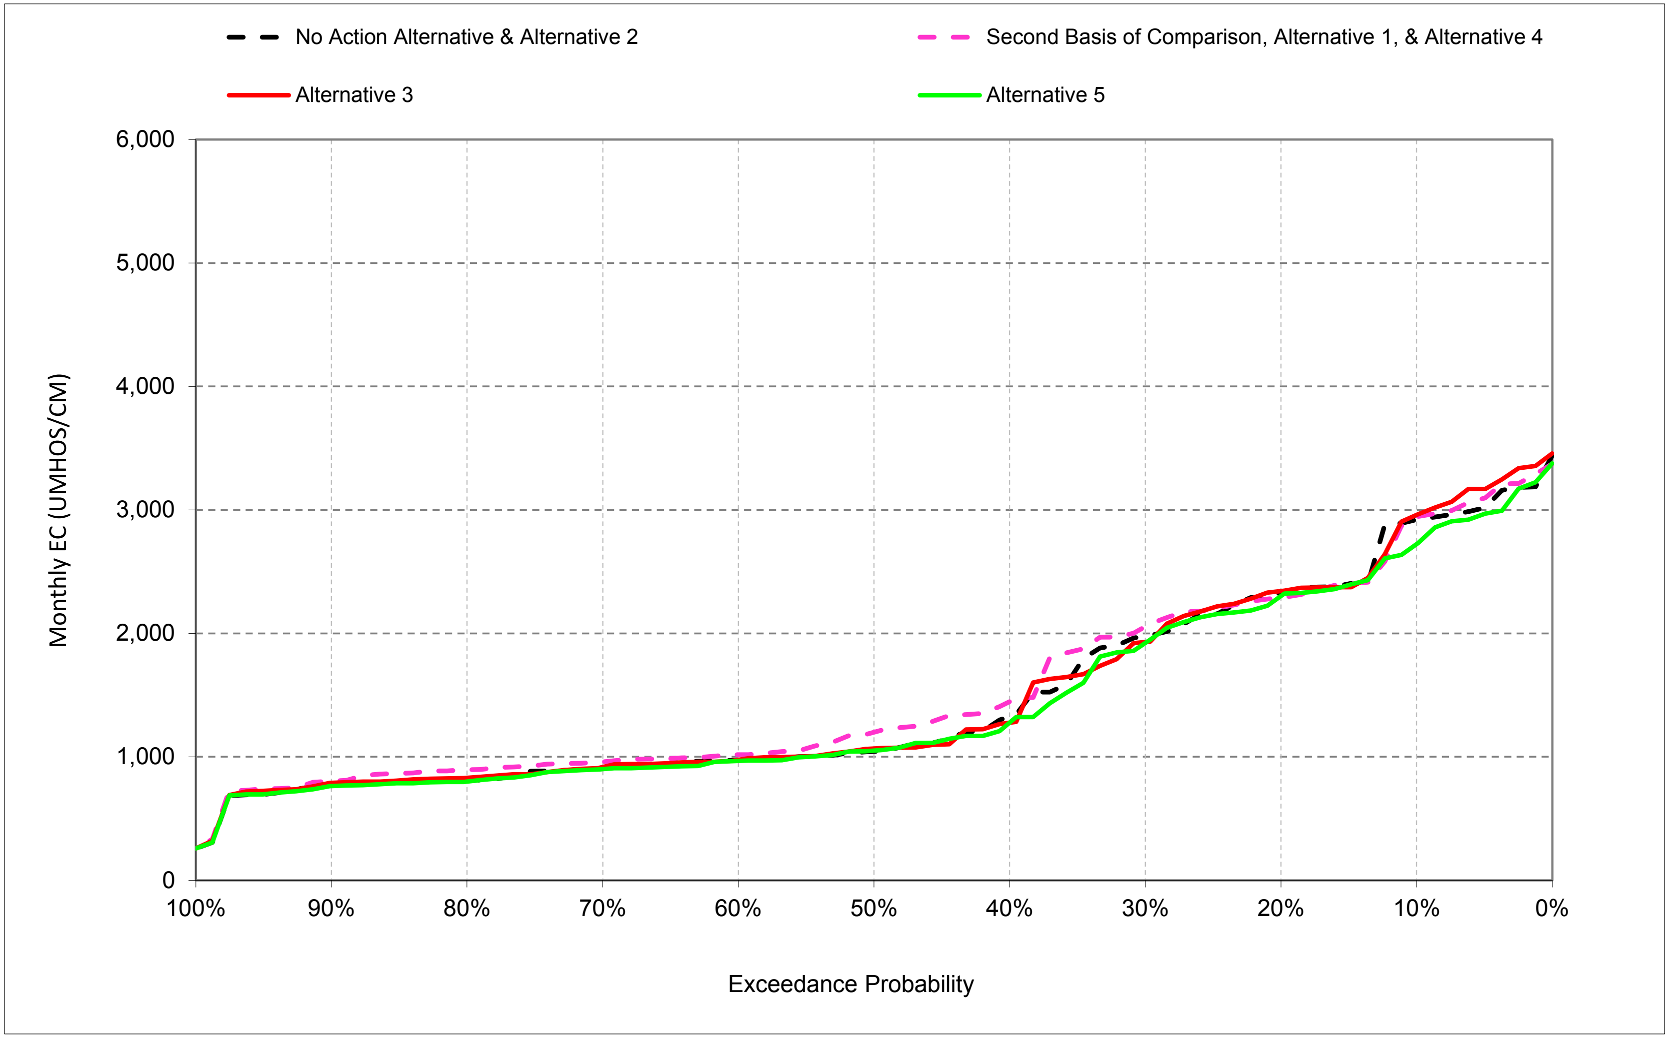
Figure 6E.B.2.10. Sacramento River at Emmaton Salinity, Electrical Conductivity, July



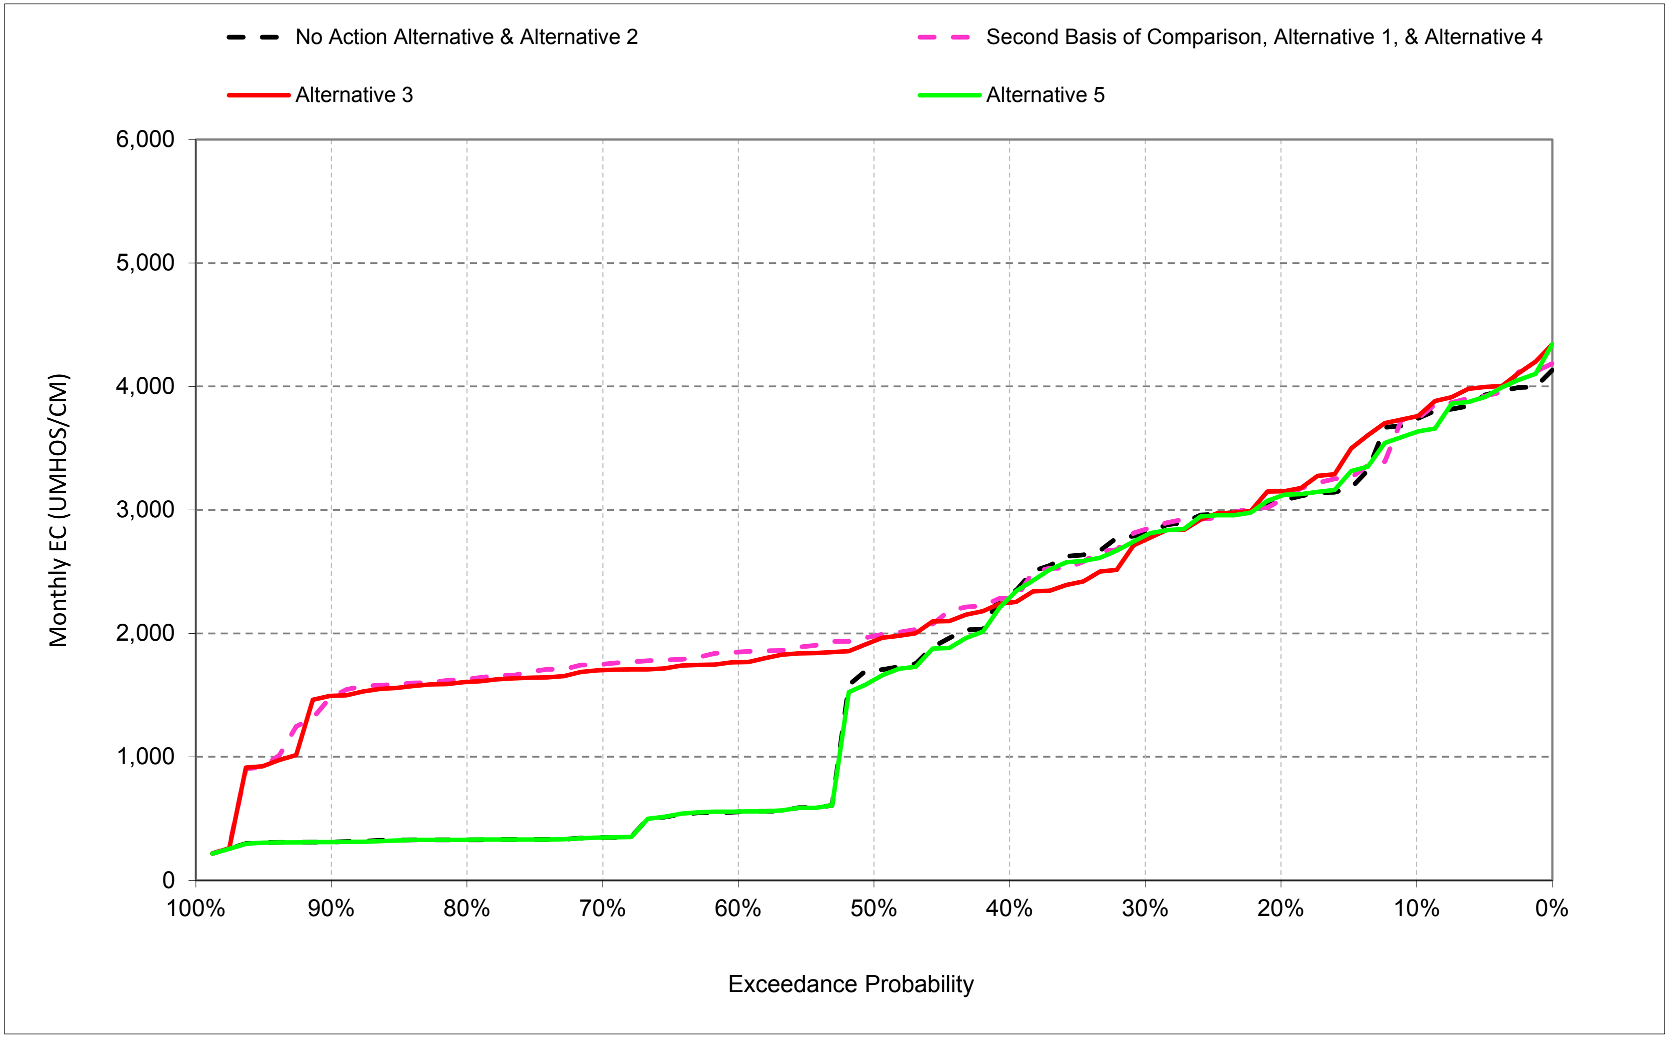
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.2.11. Sacramento River at Emmaton Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.2.12. Sacramento River at Emmaton Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

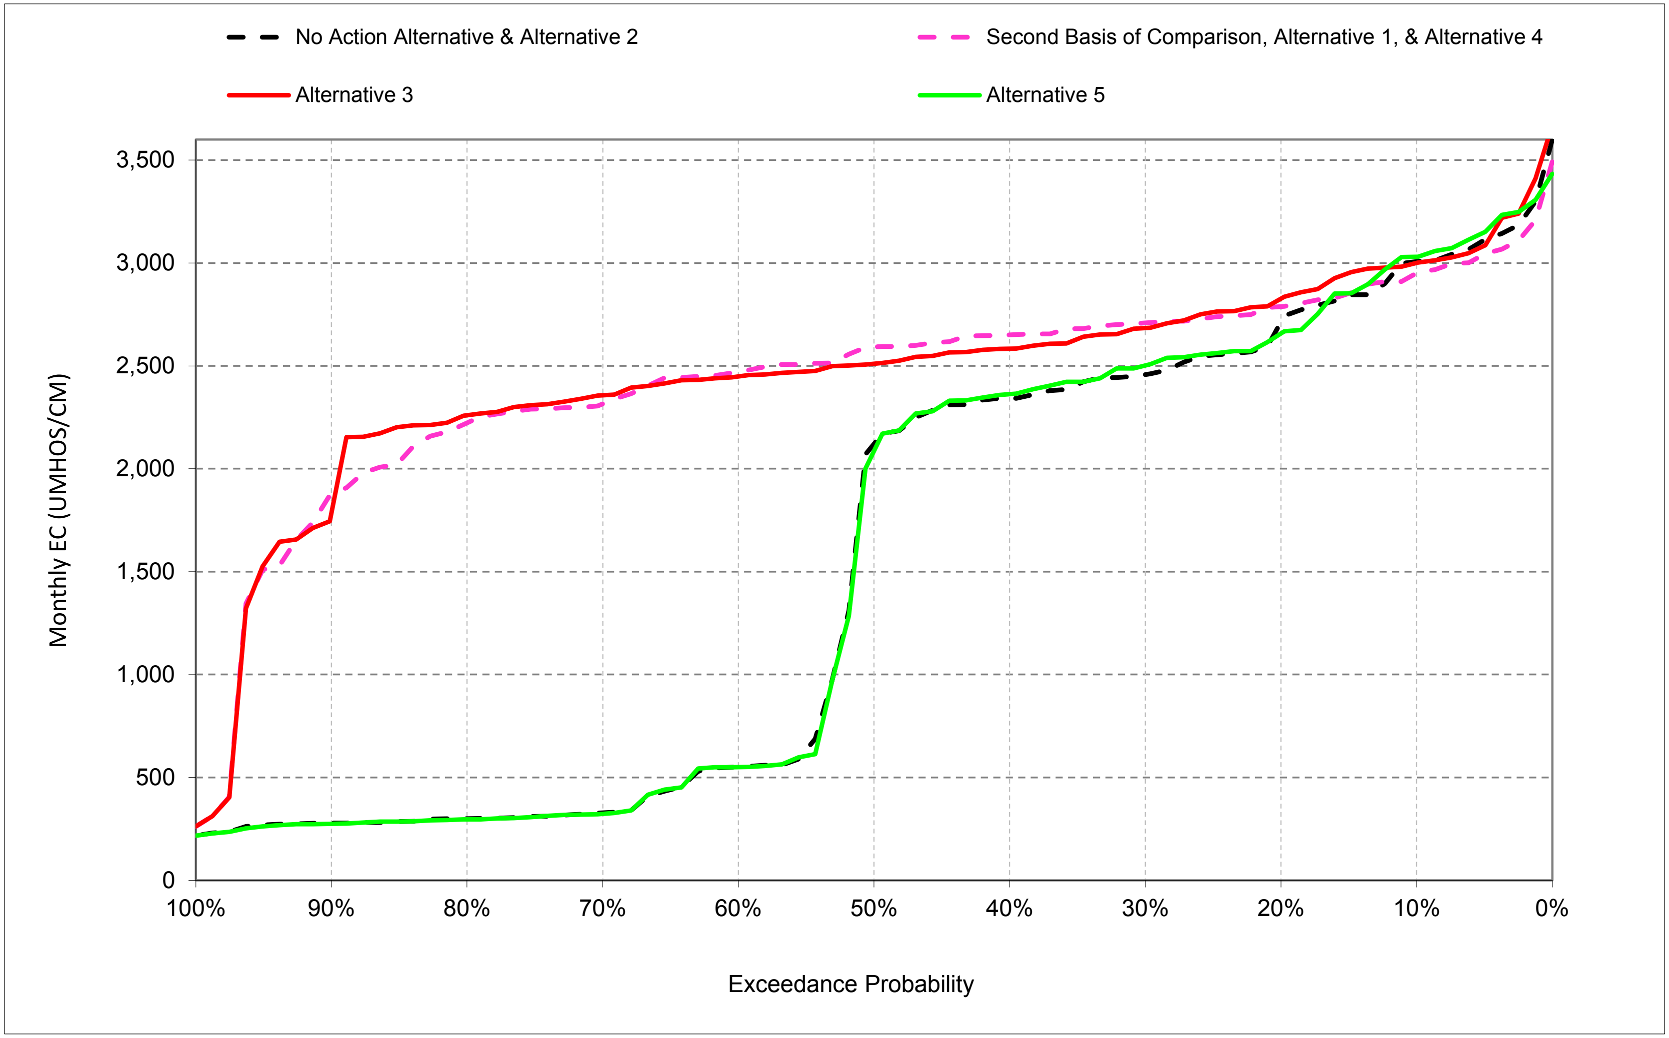
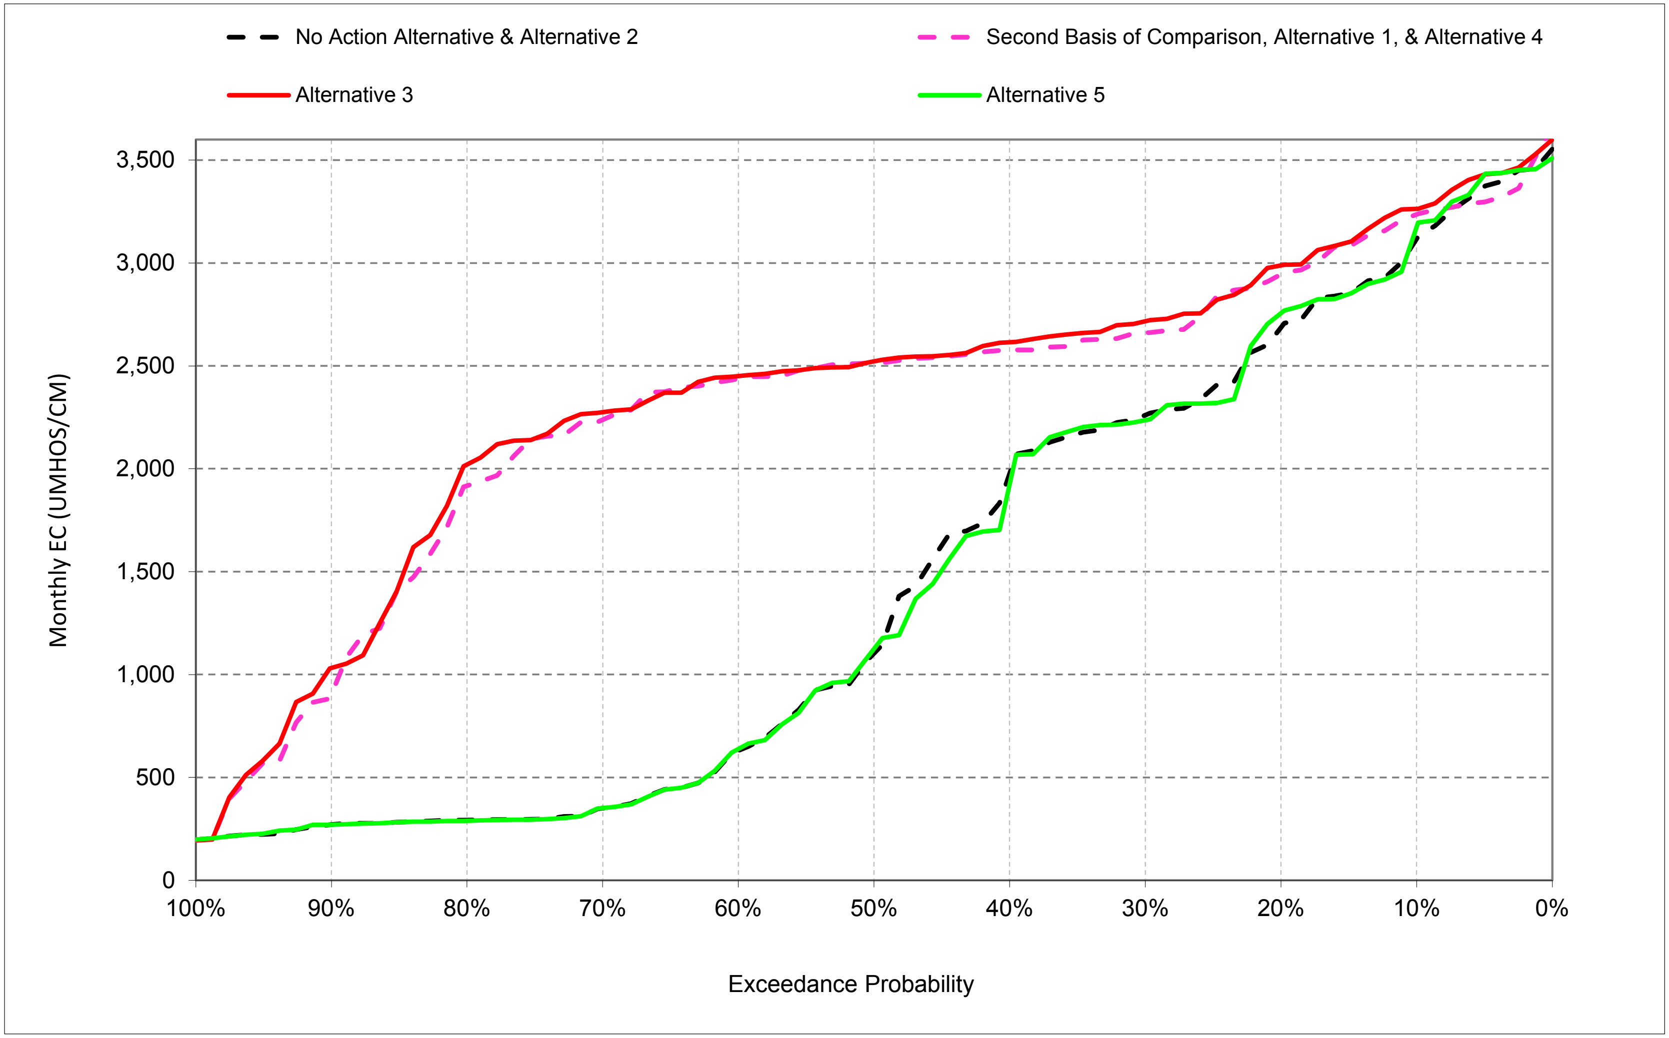
B.3. San Joaquin River at Jersey Point Salinity

Figure 6E.B.3.1. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, October



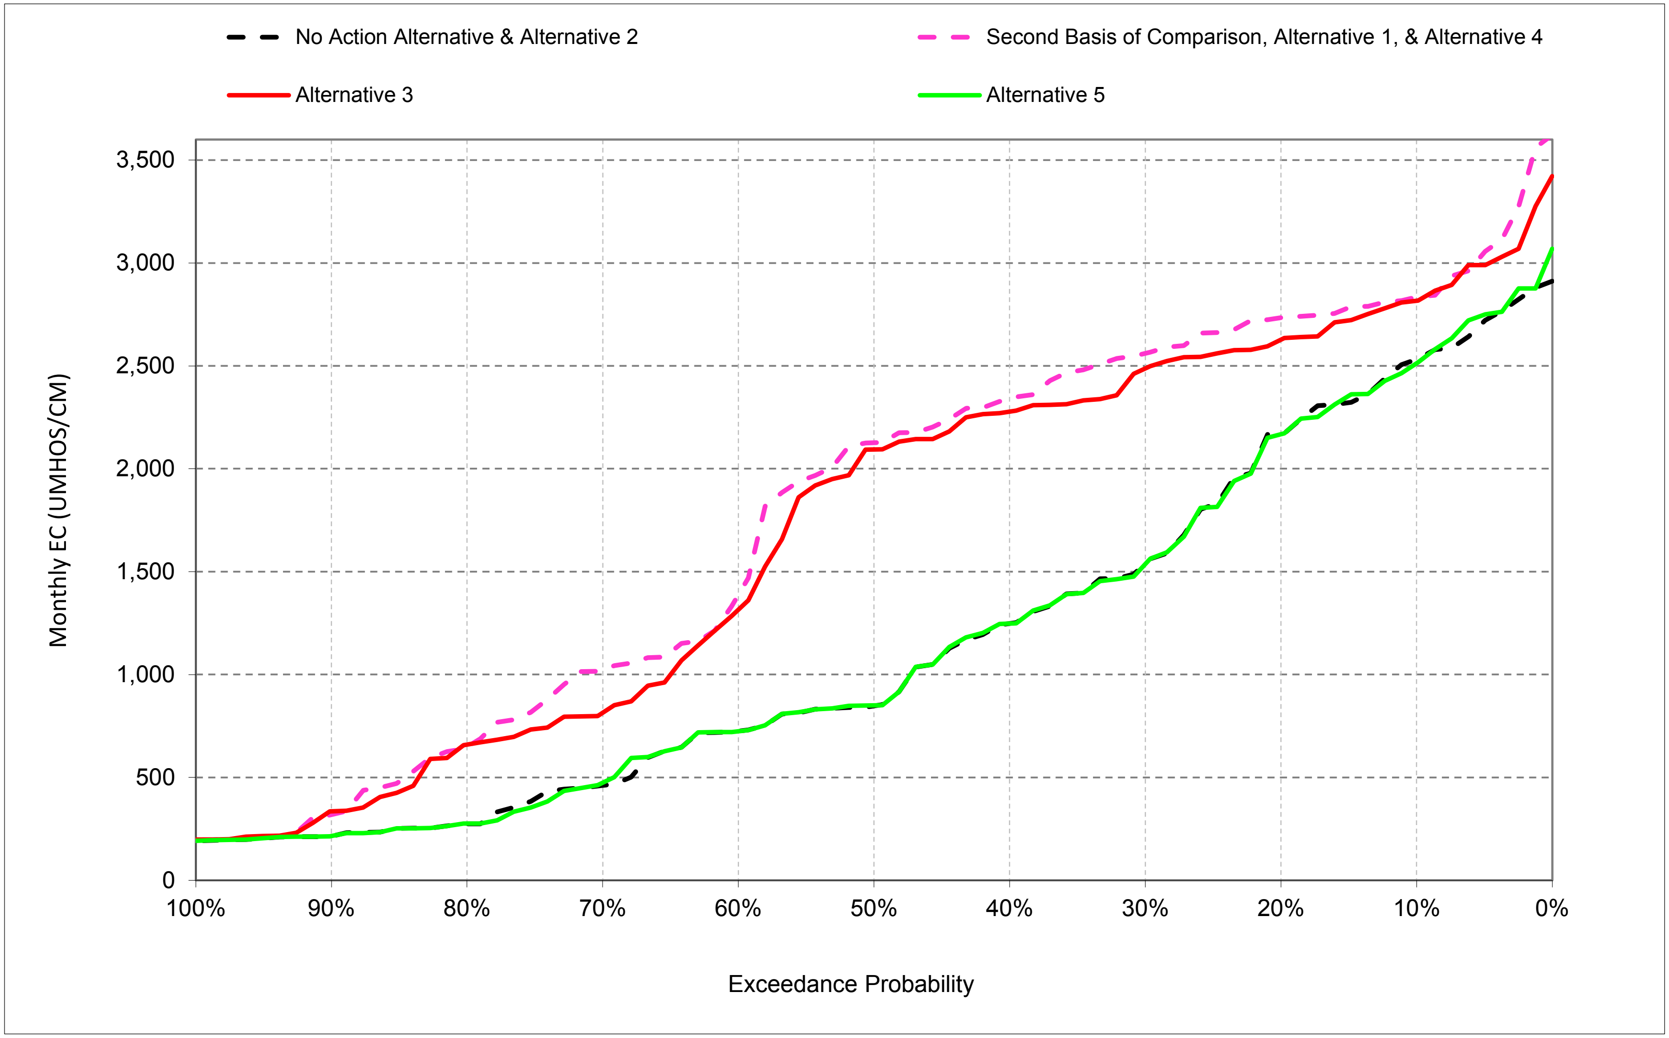
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.2. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, November



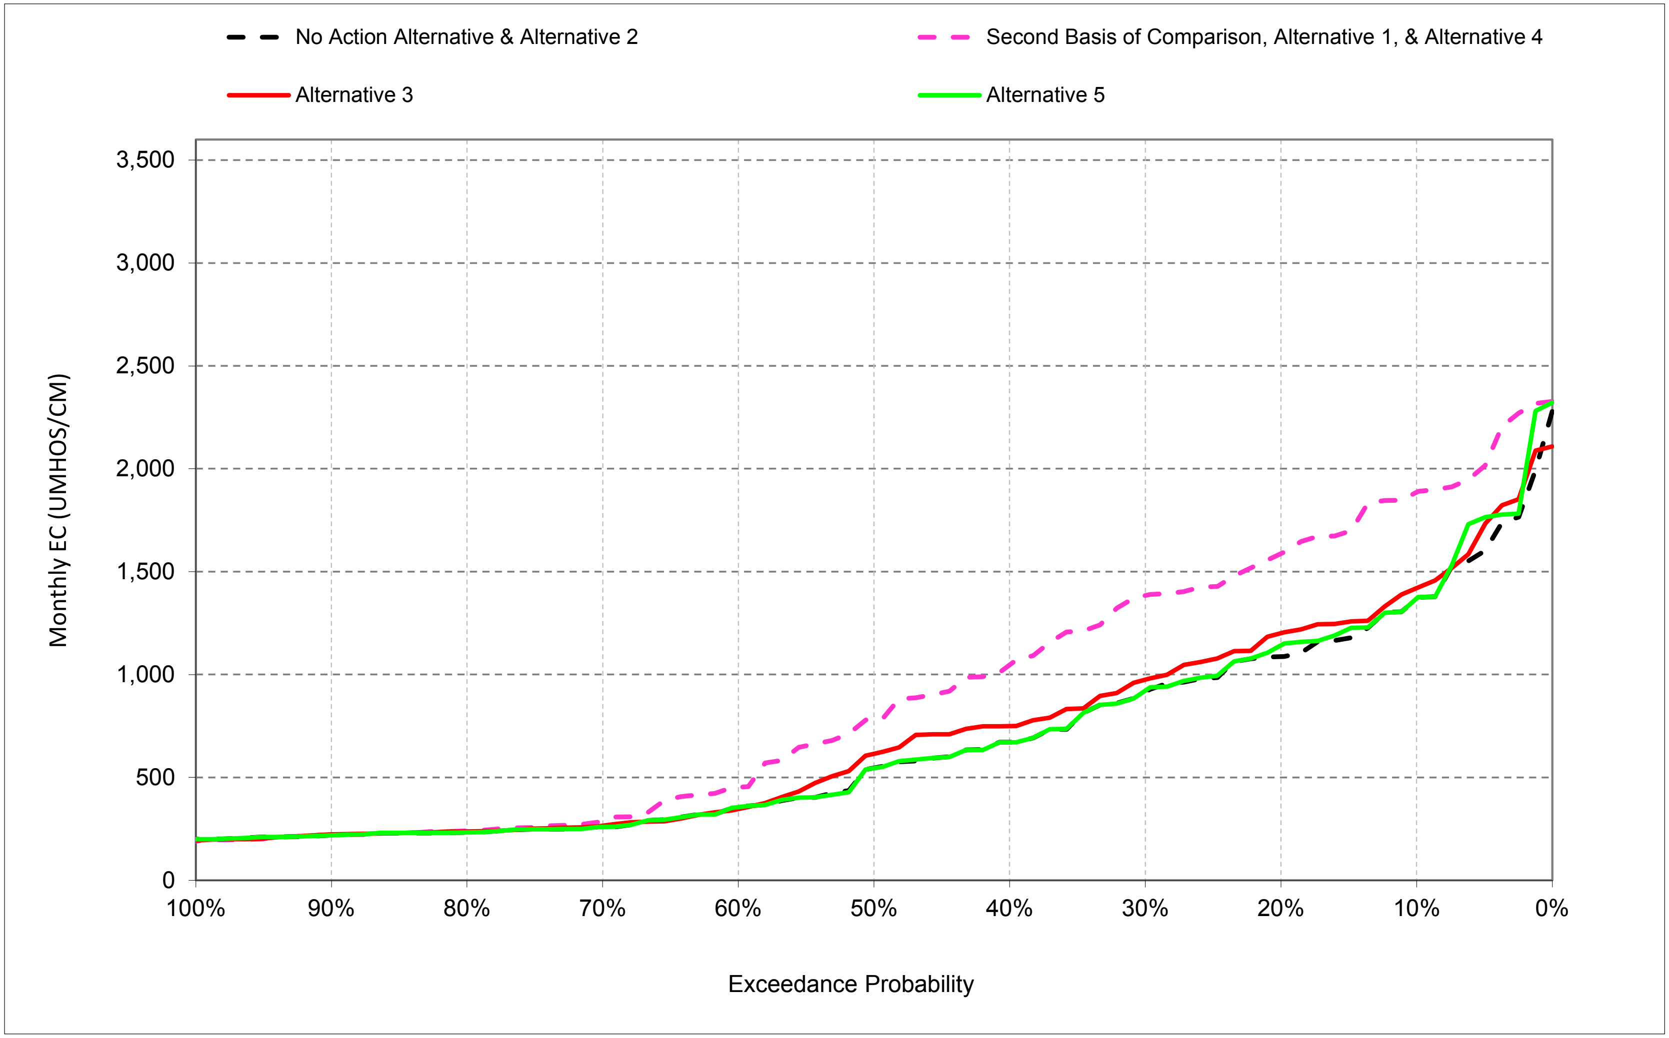
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.3. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, December



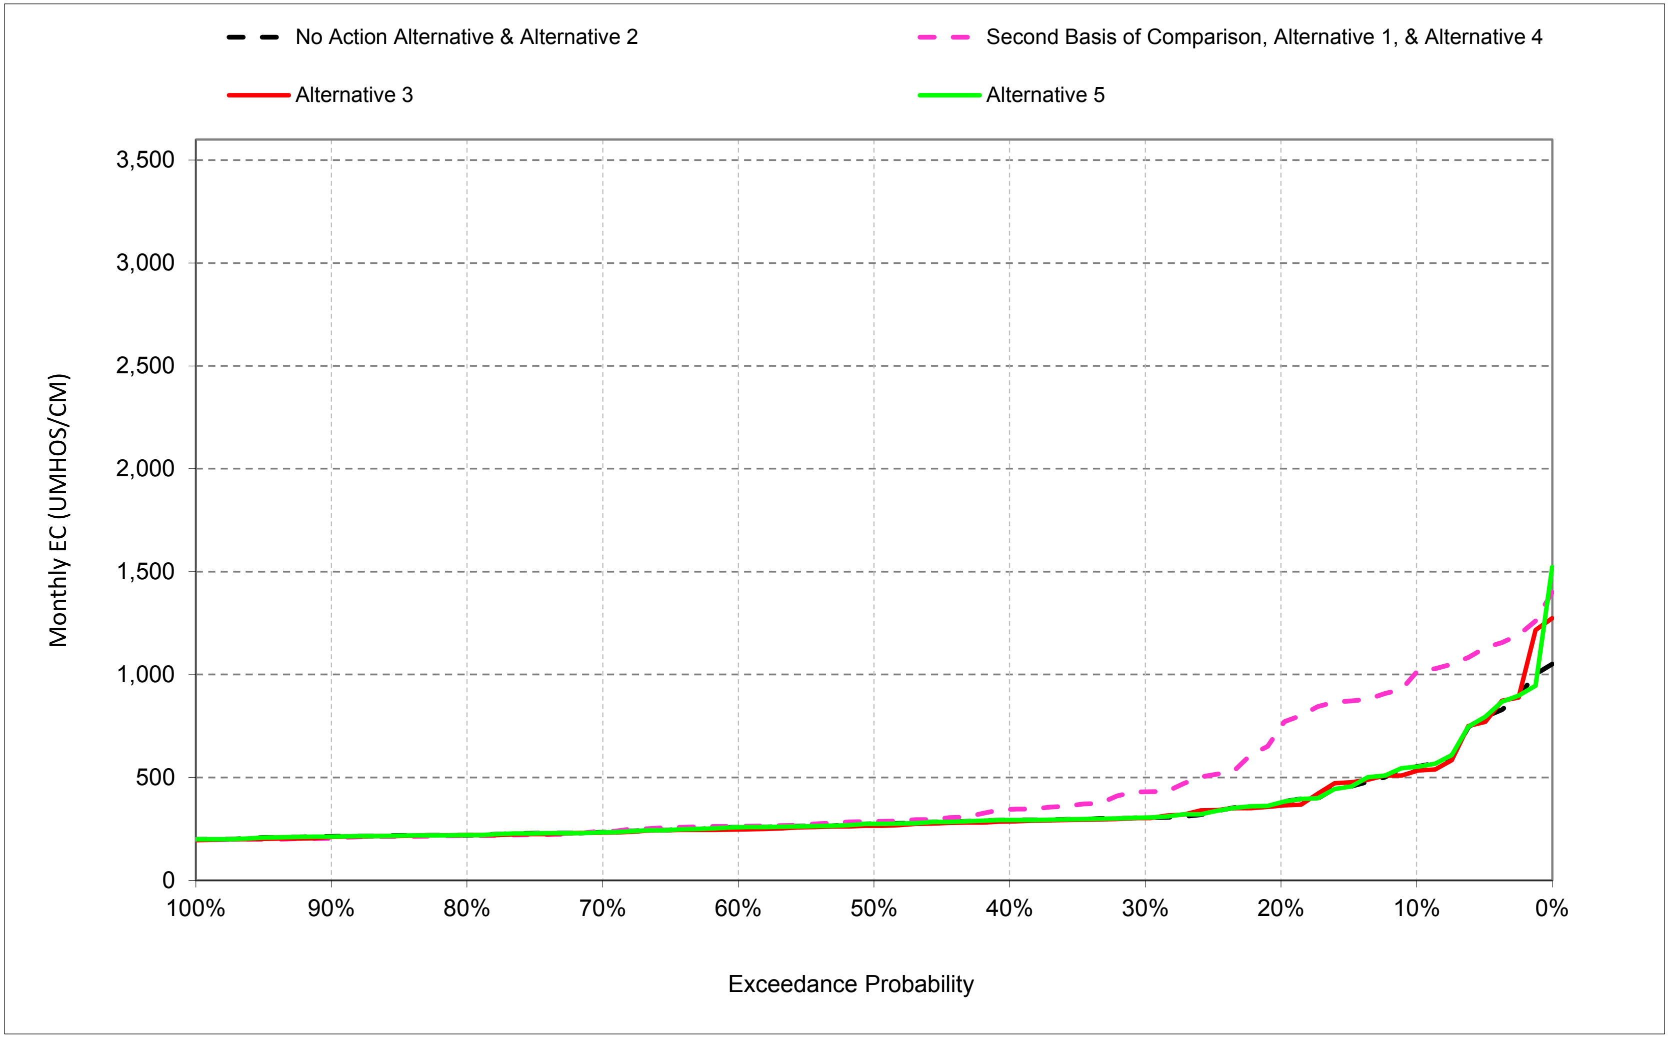
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.4. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, January



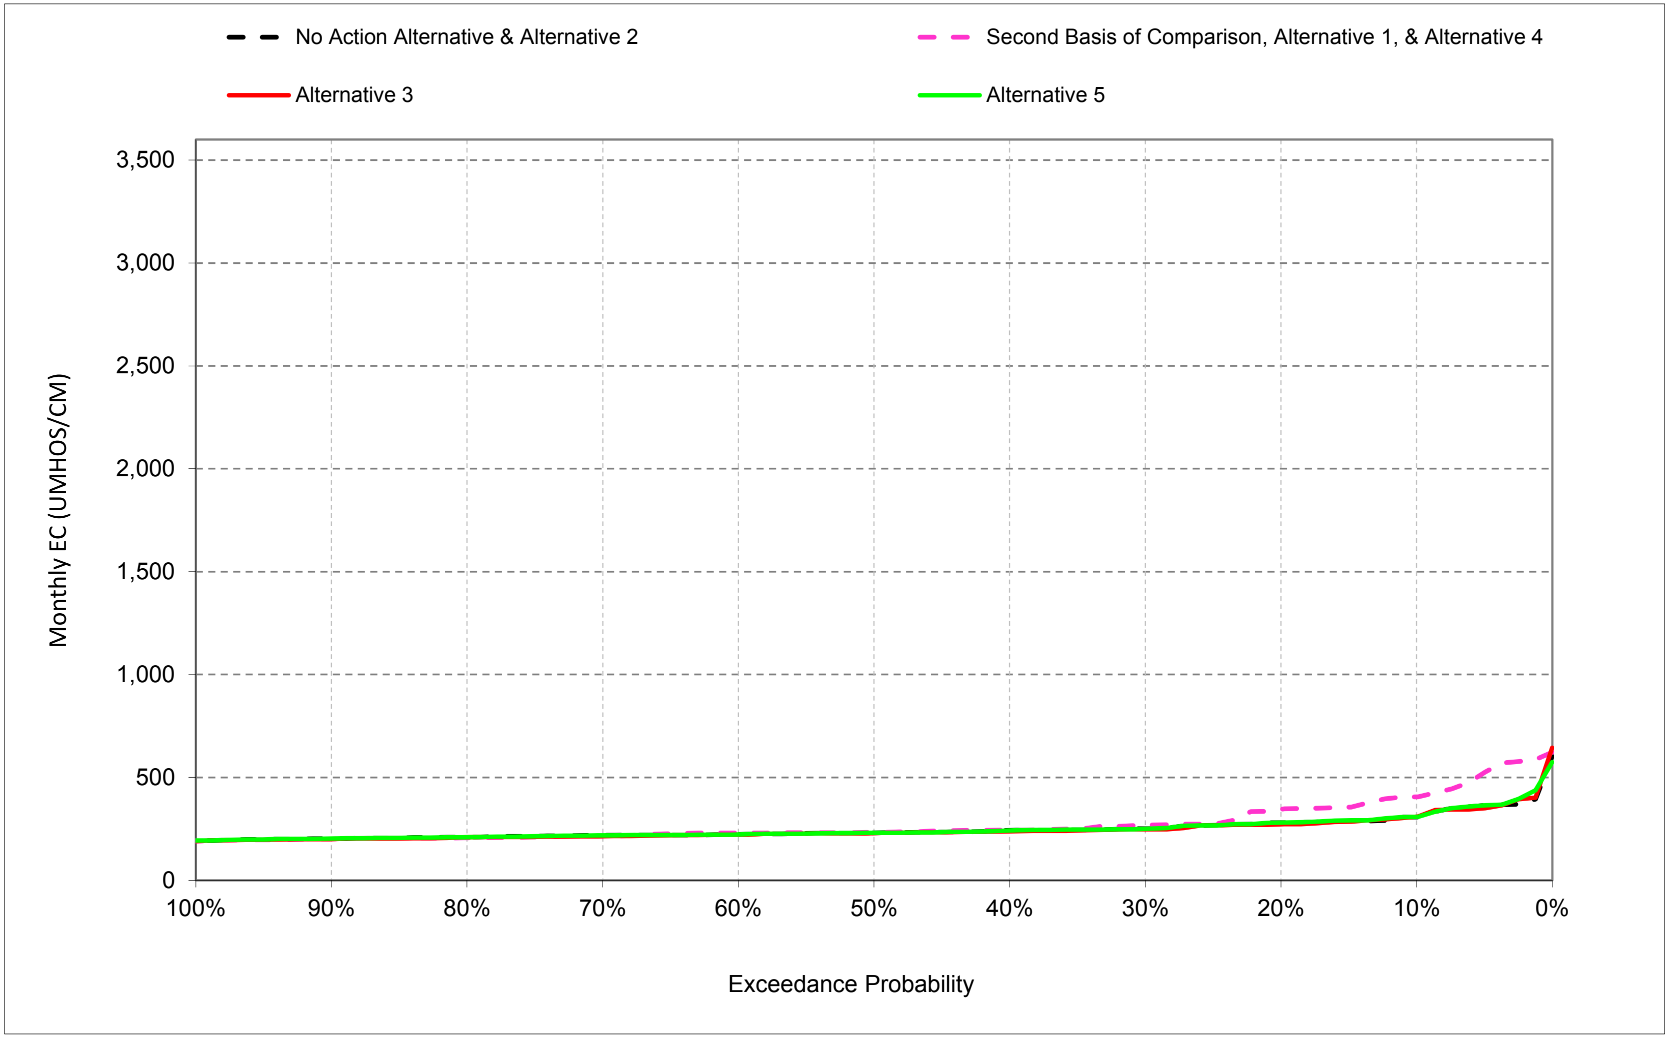
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.5. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, February



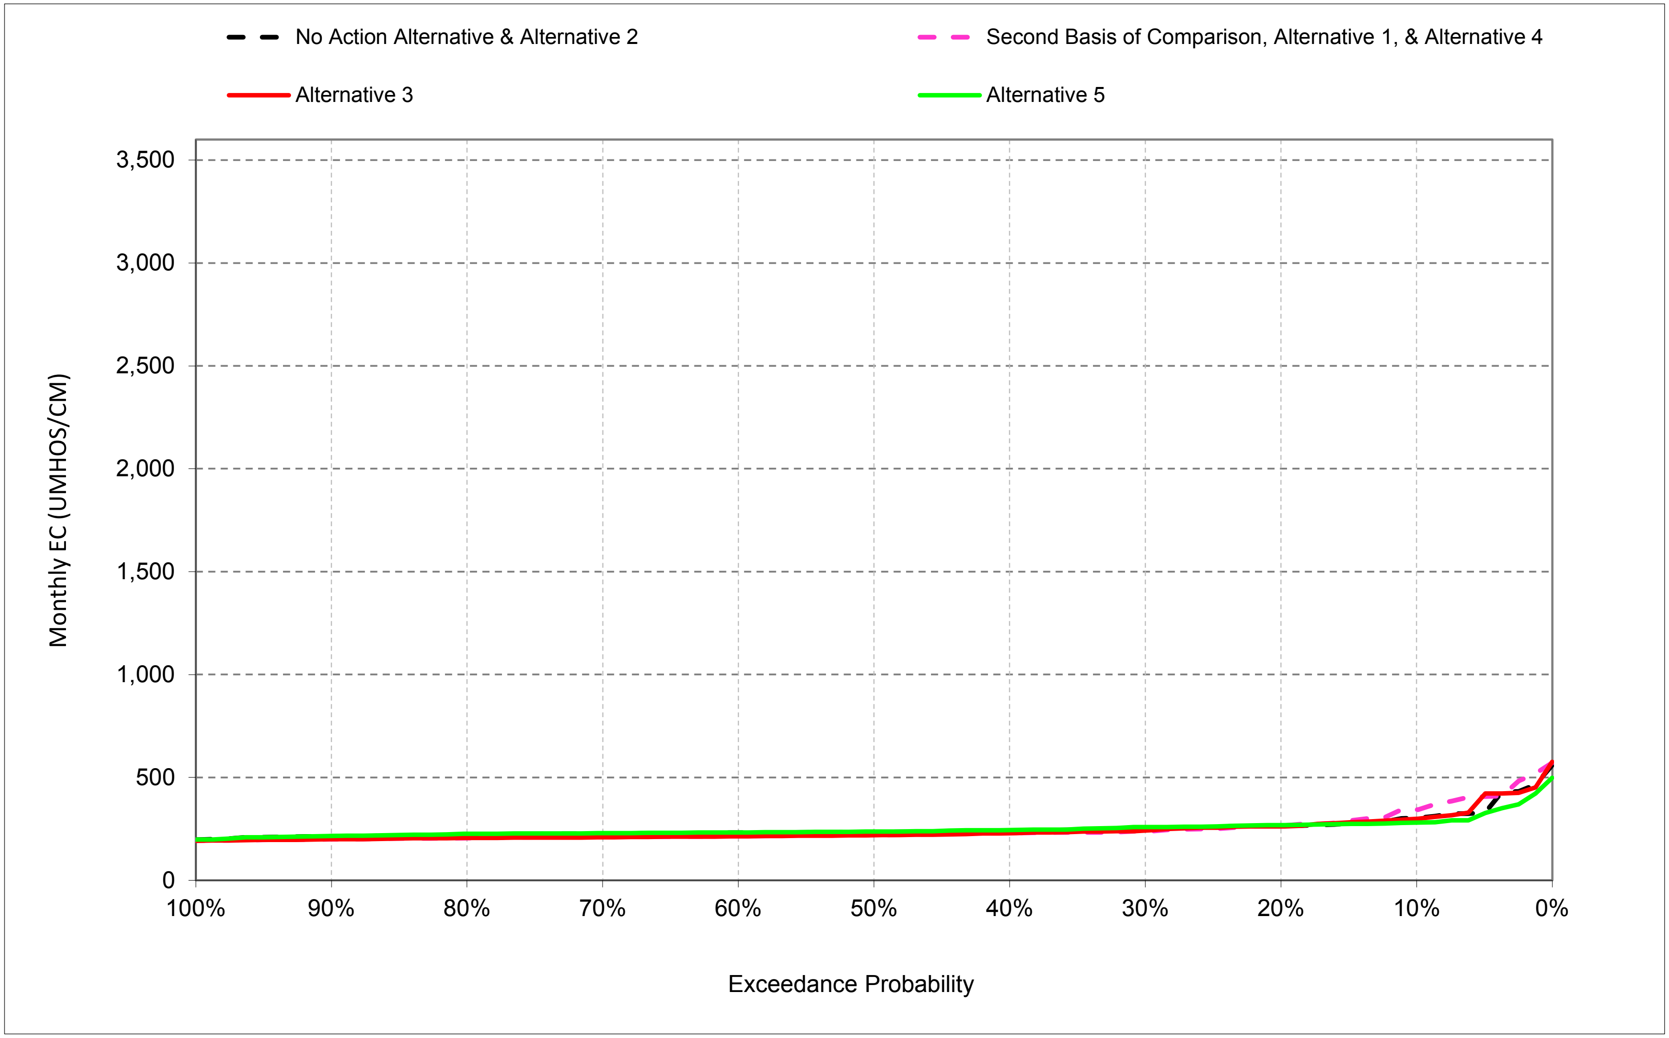
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.6. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, March



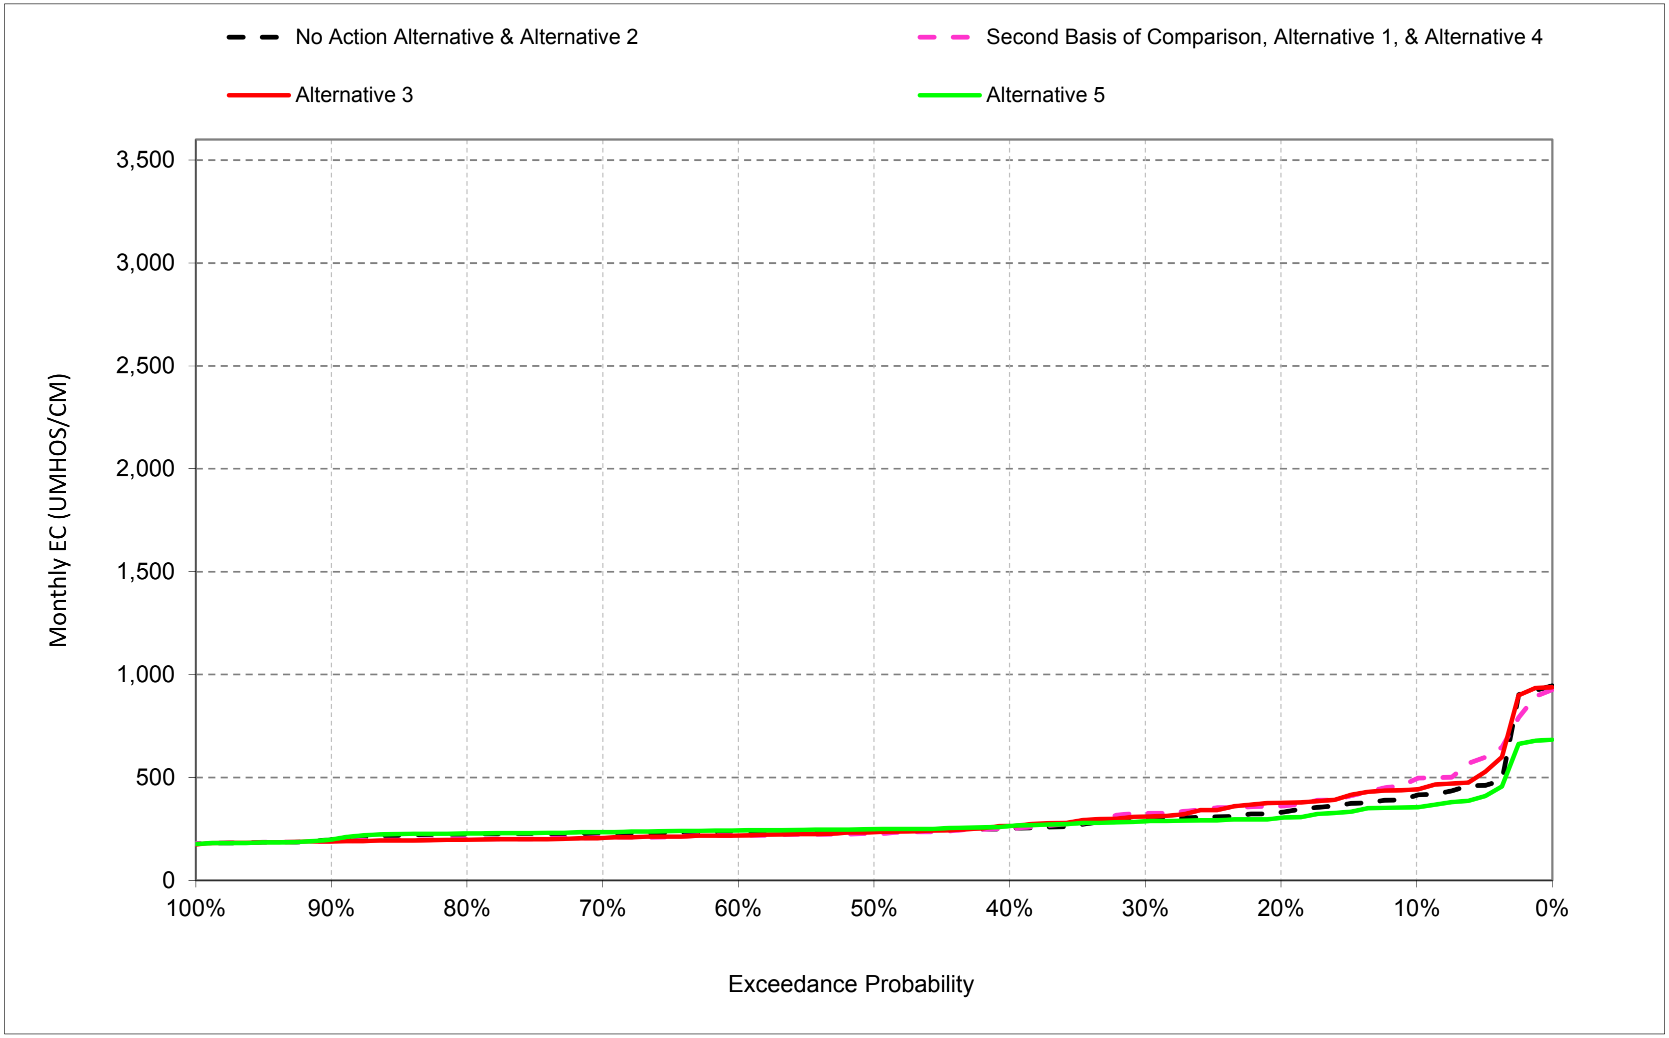
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.7. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, April



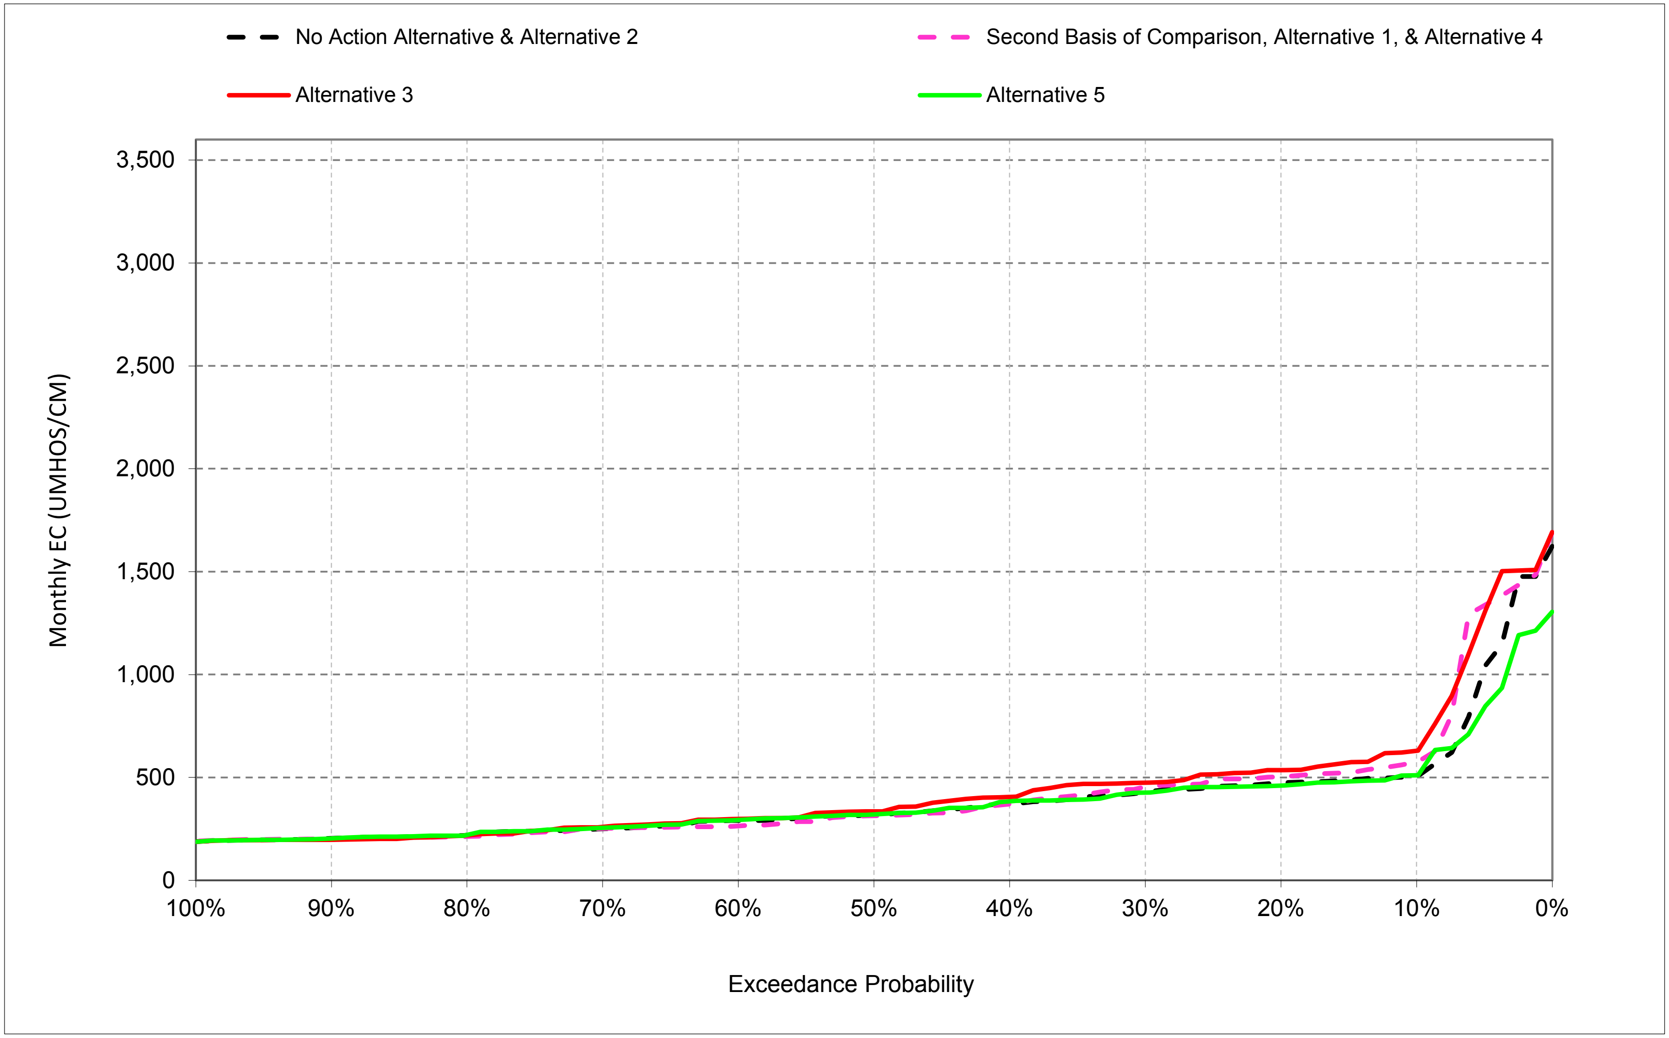
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.8. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, May



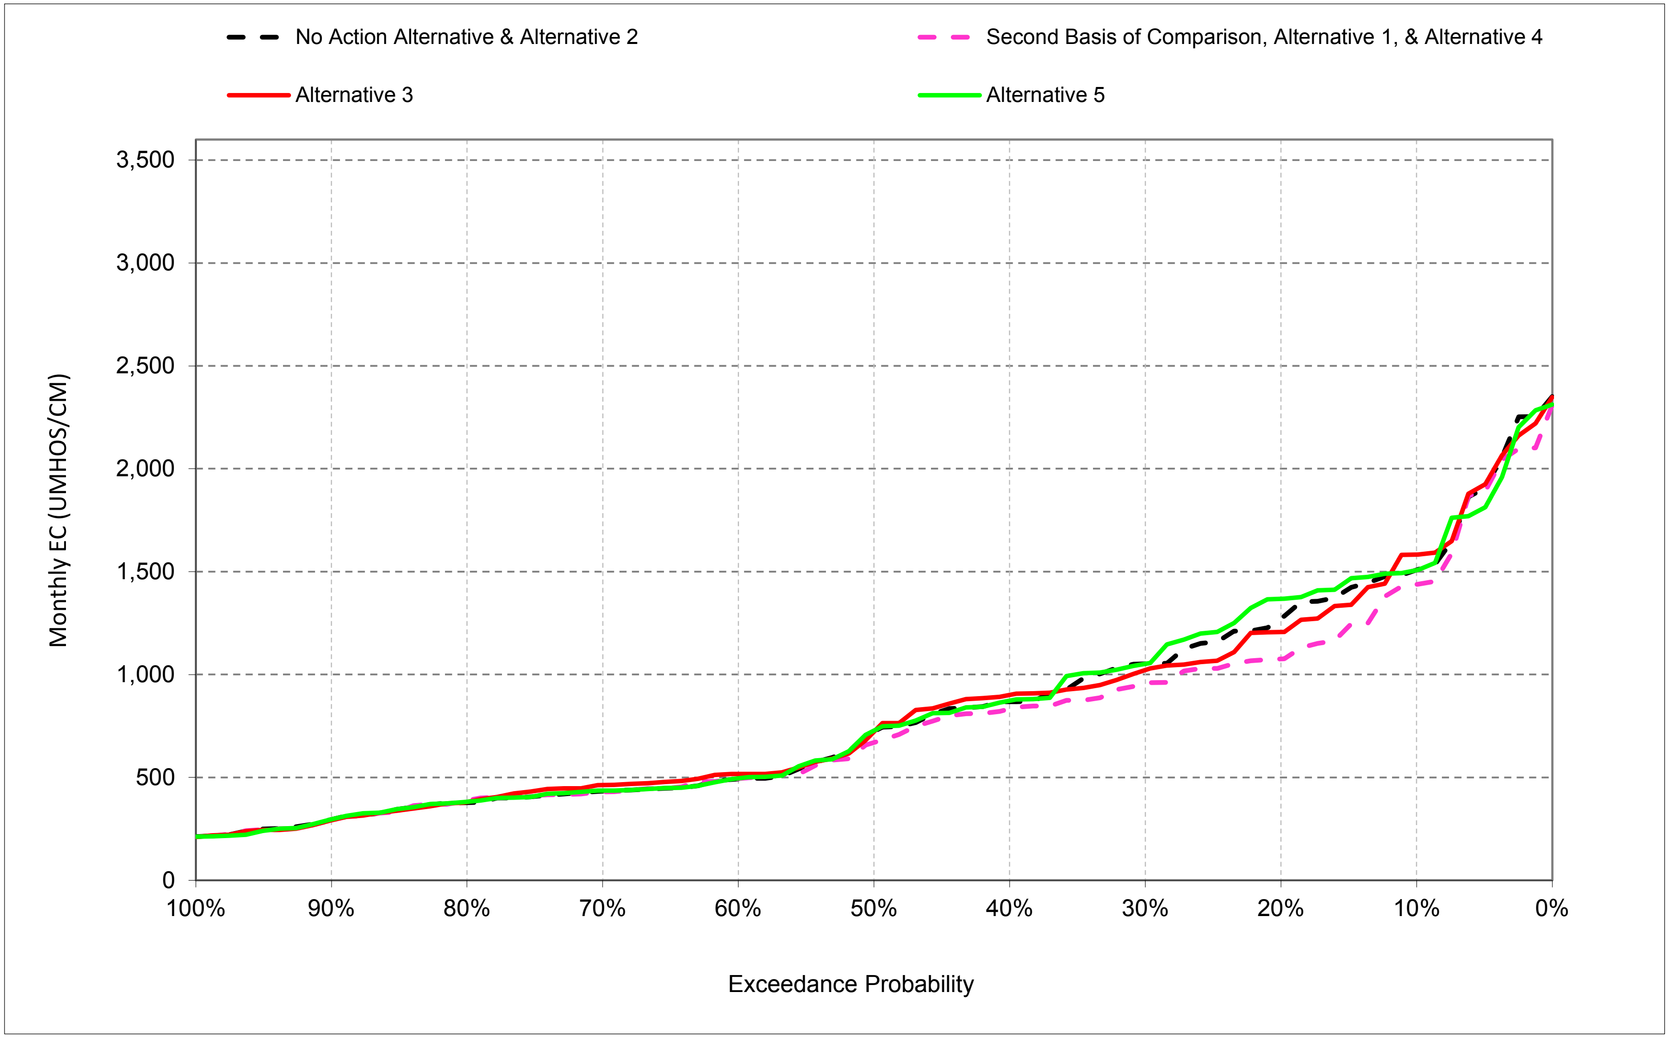
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.9. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, June



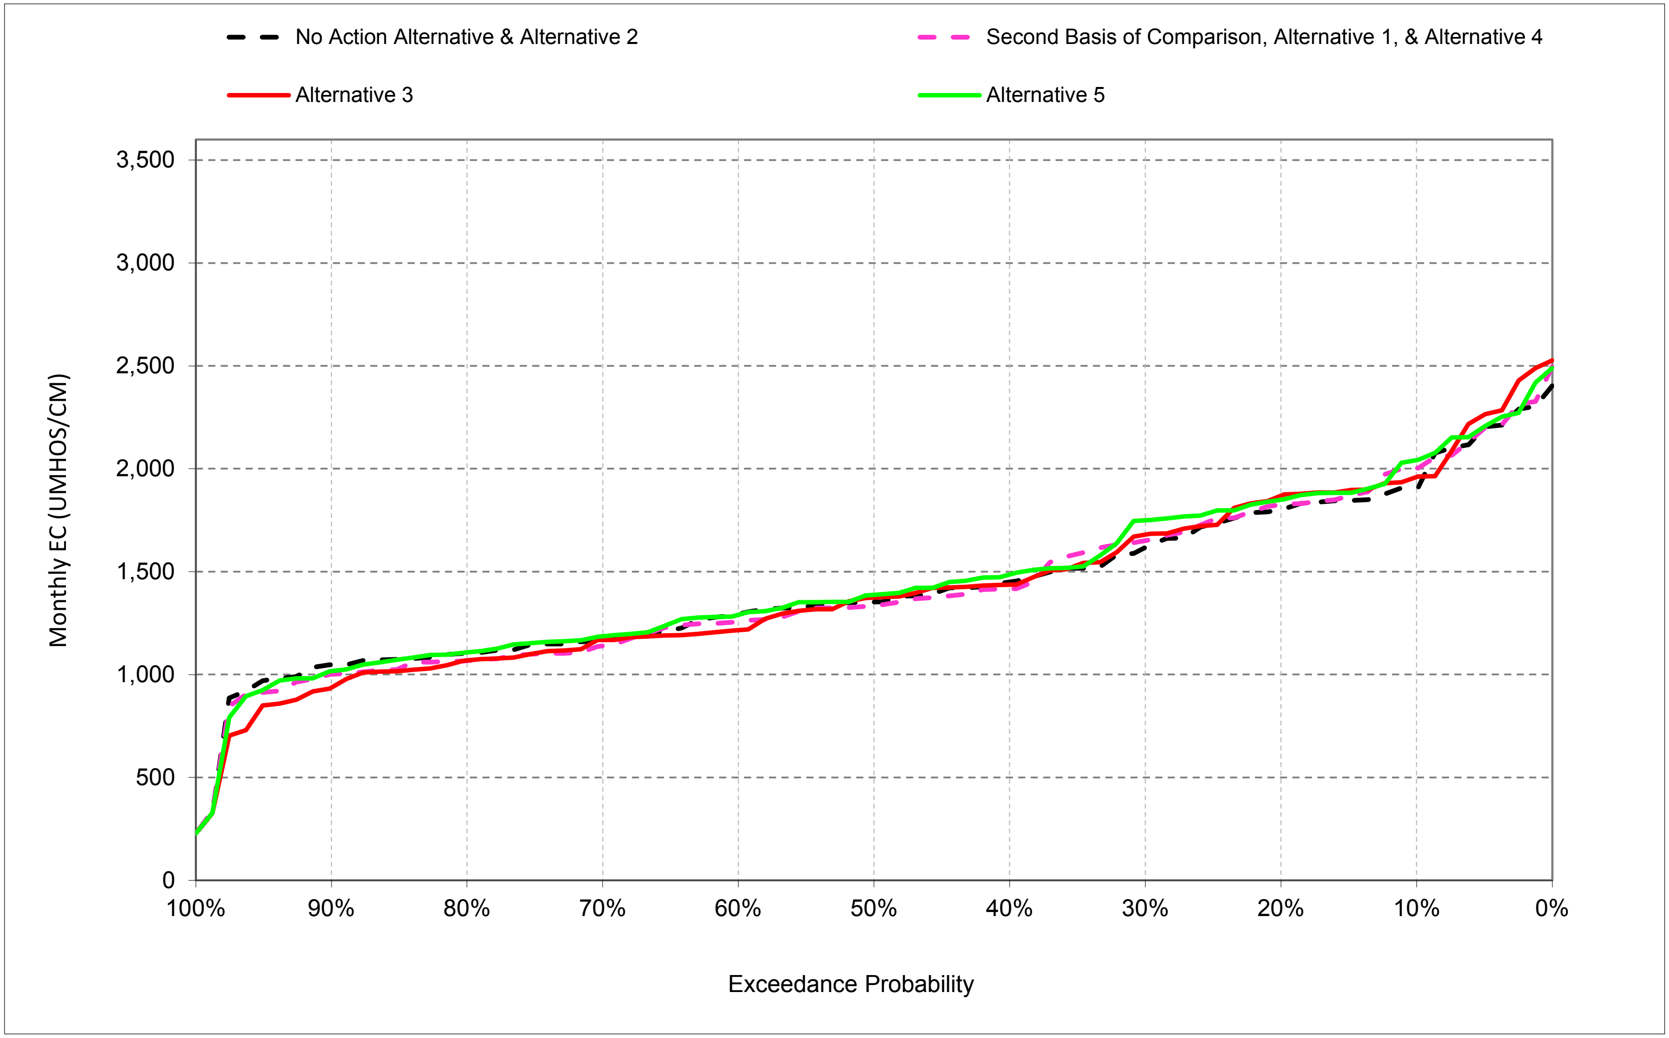
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.10. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, July



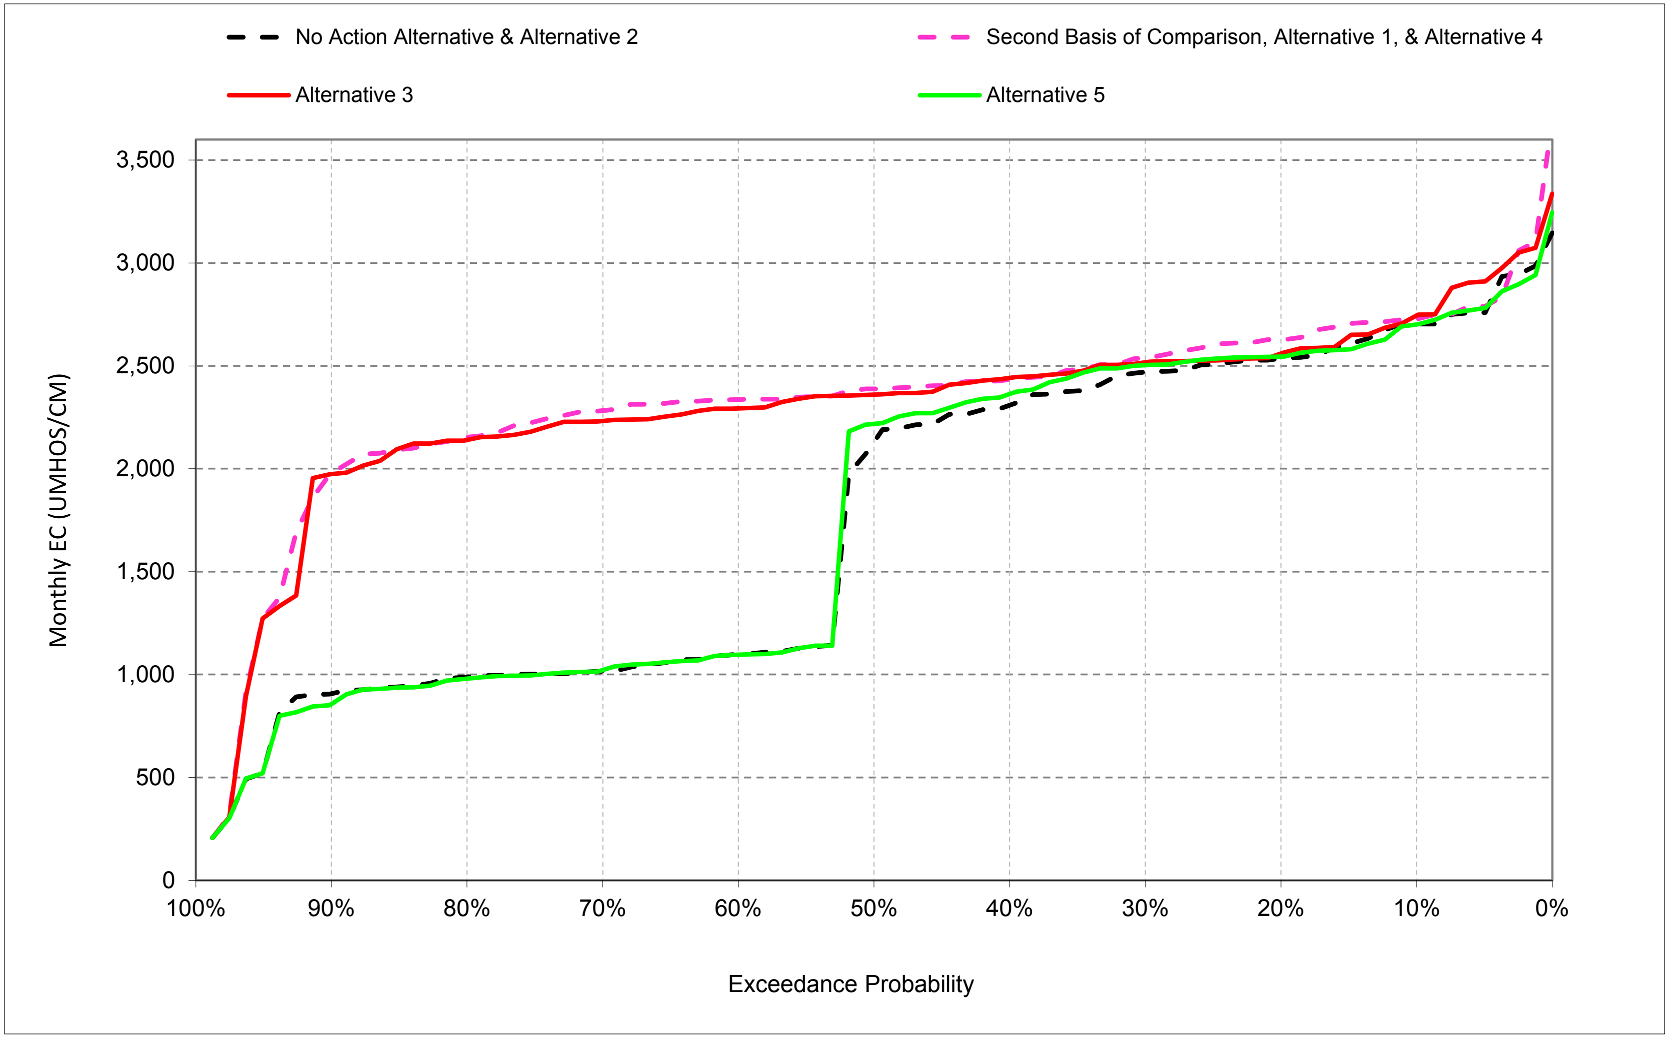
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.11. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.3.12. San Joaquin River at Jersey Point Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

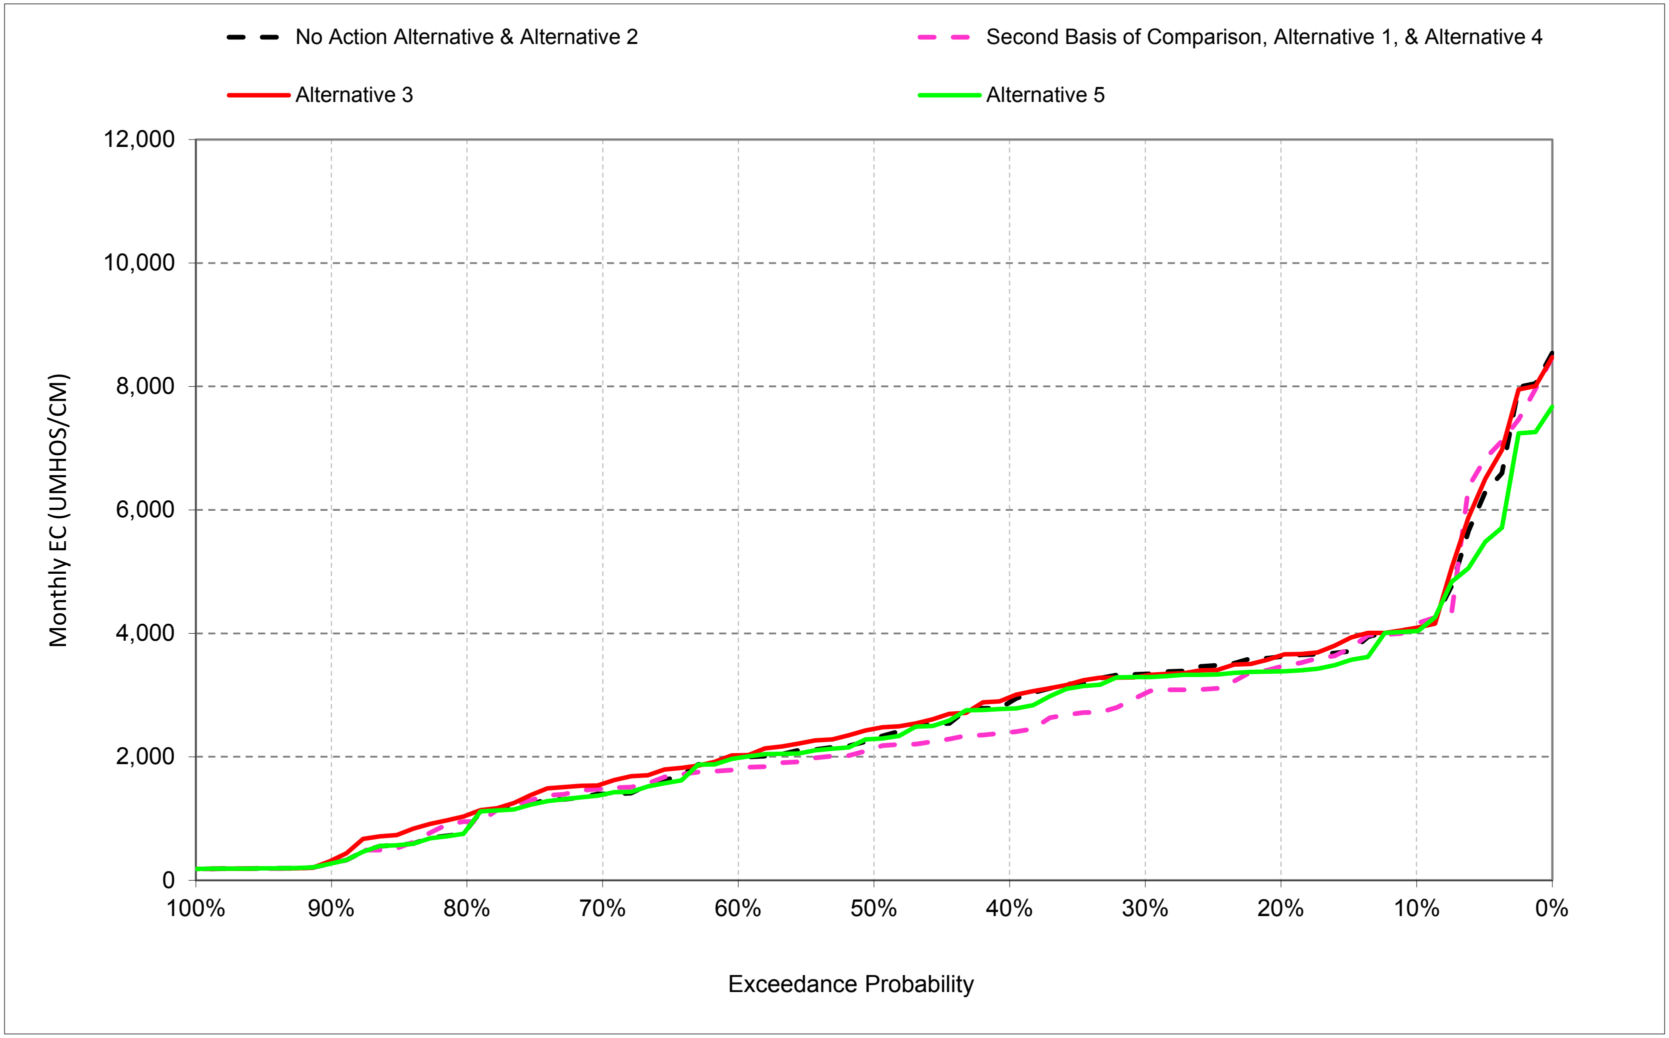
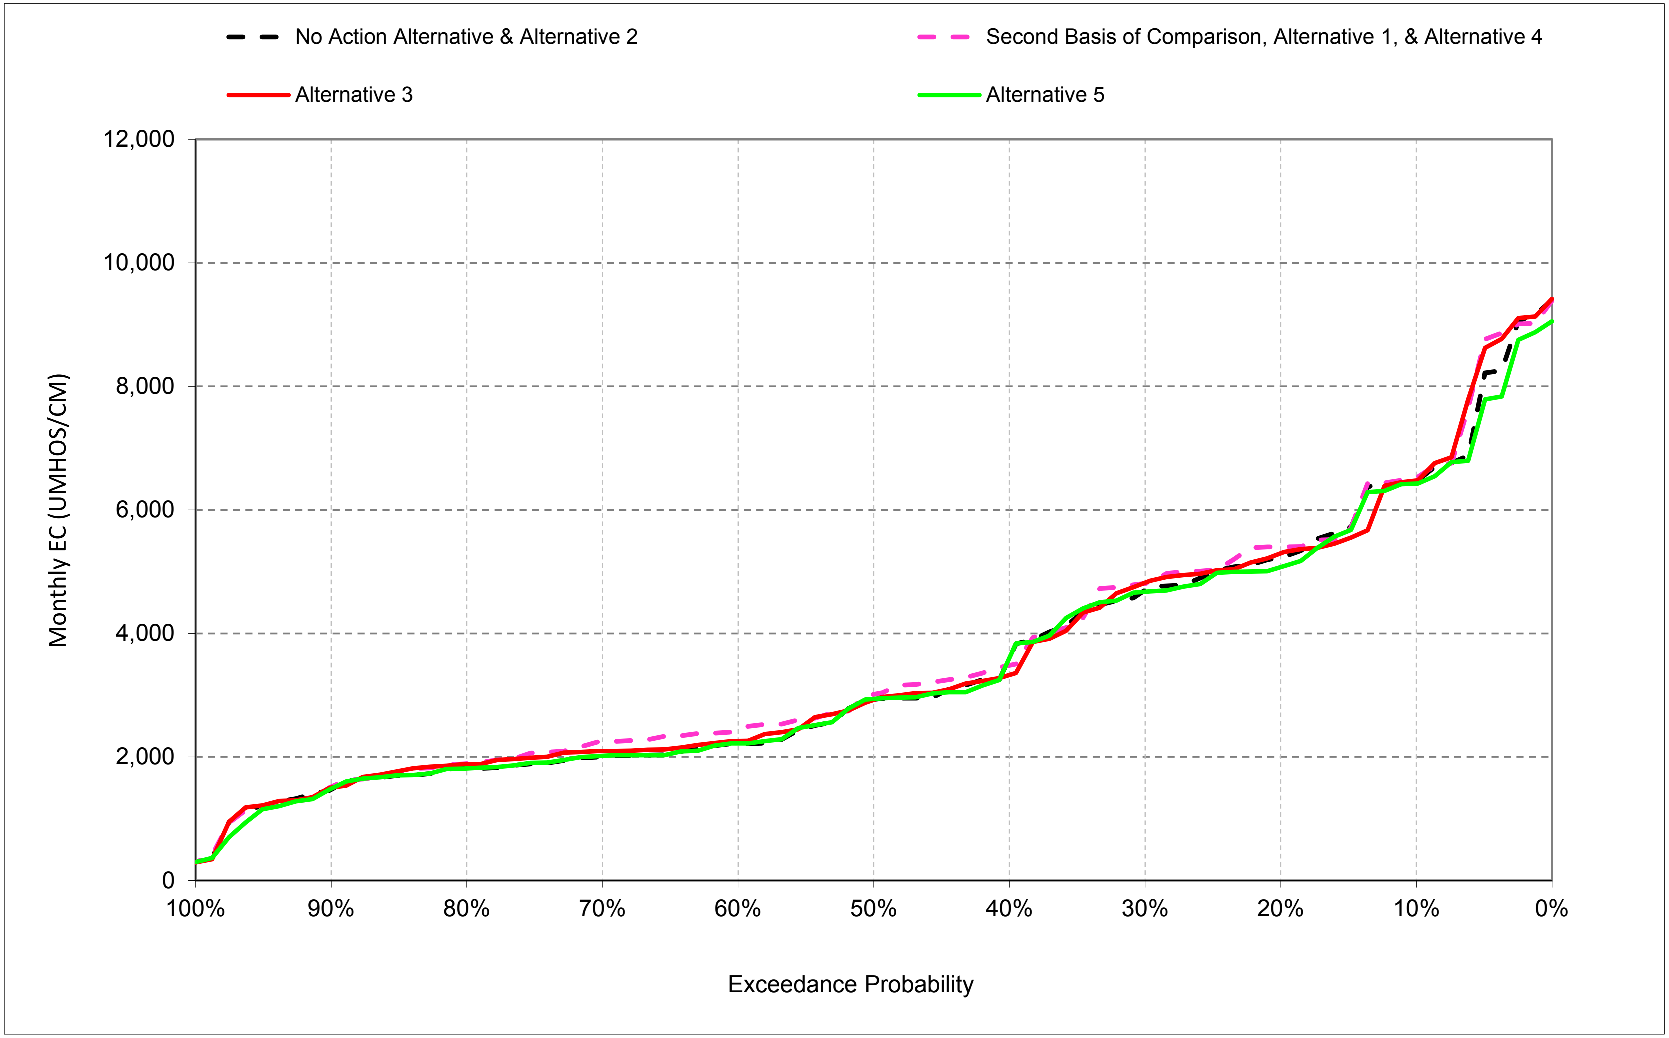
Figure 6E.B.4.9. Sacramento River at Collinsville Salinity, Electrical Conductivity, June



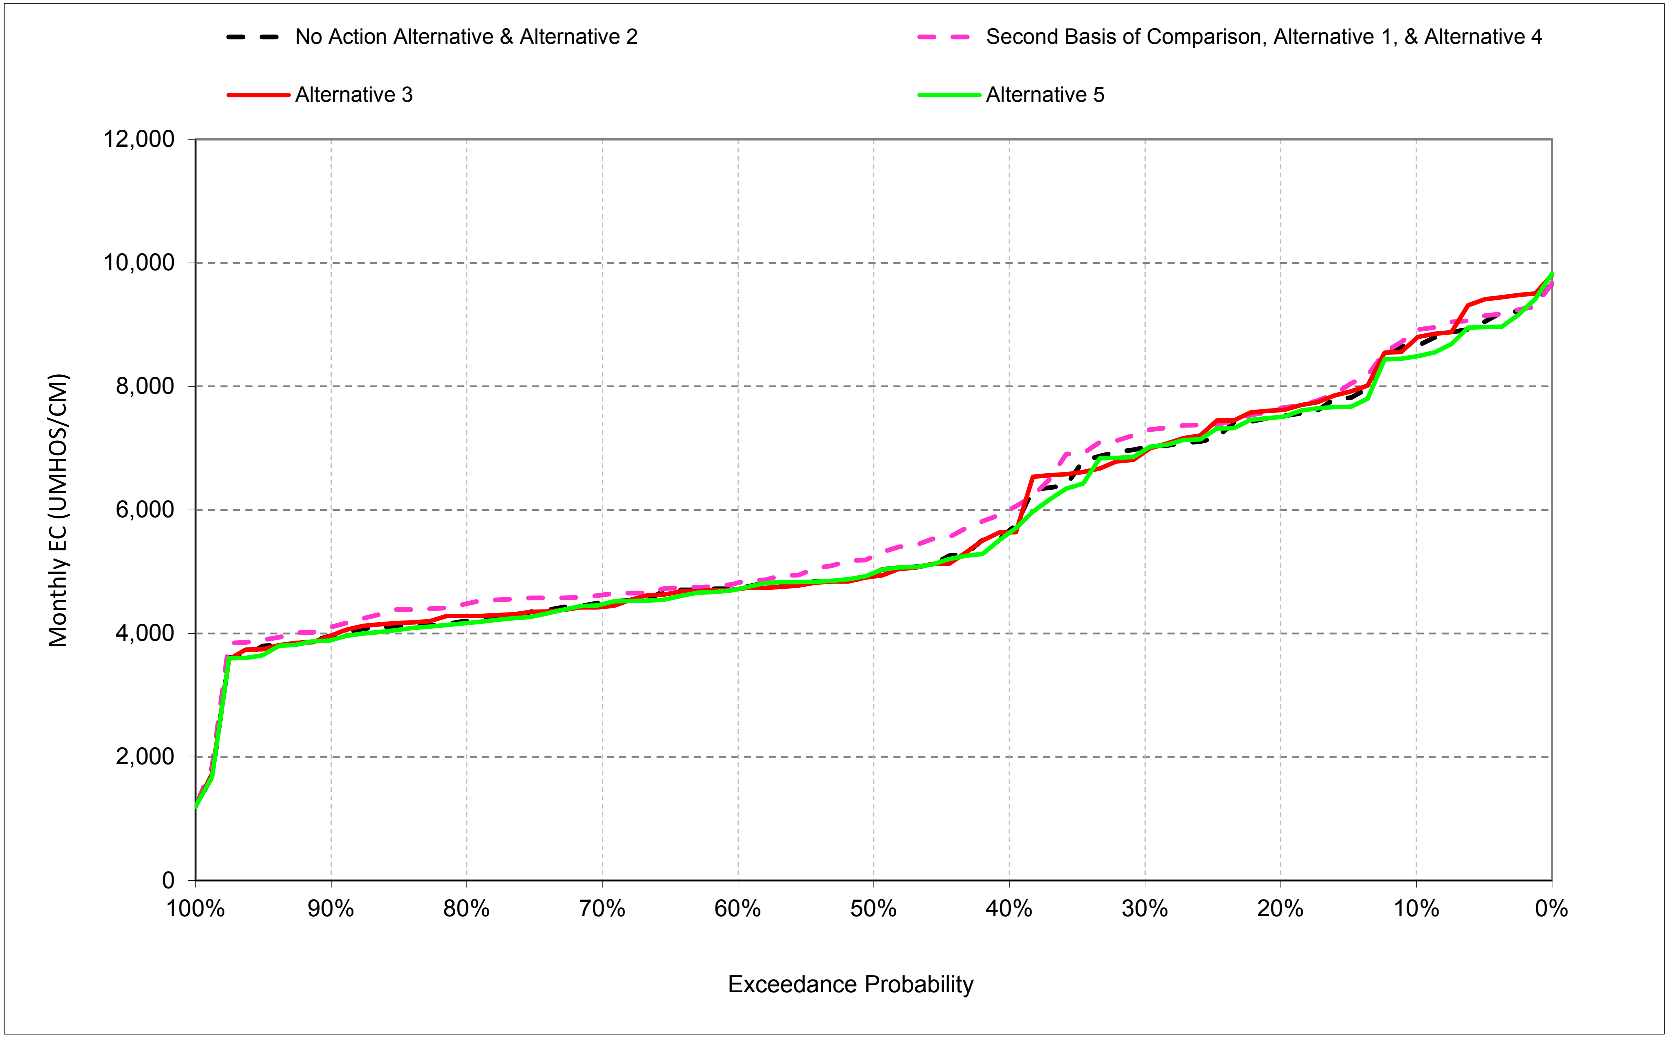
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.4.10. Sacramento River at Collinsville Salinity, Electrical Conductivity, July



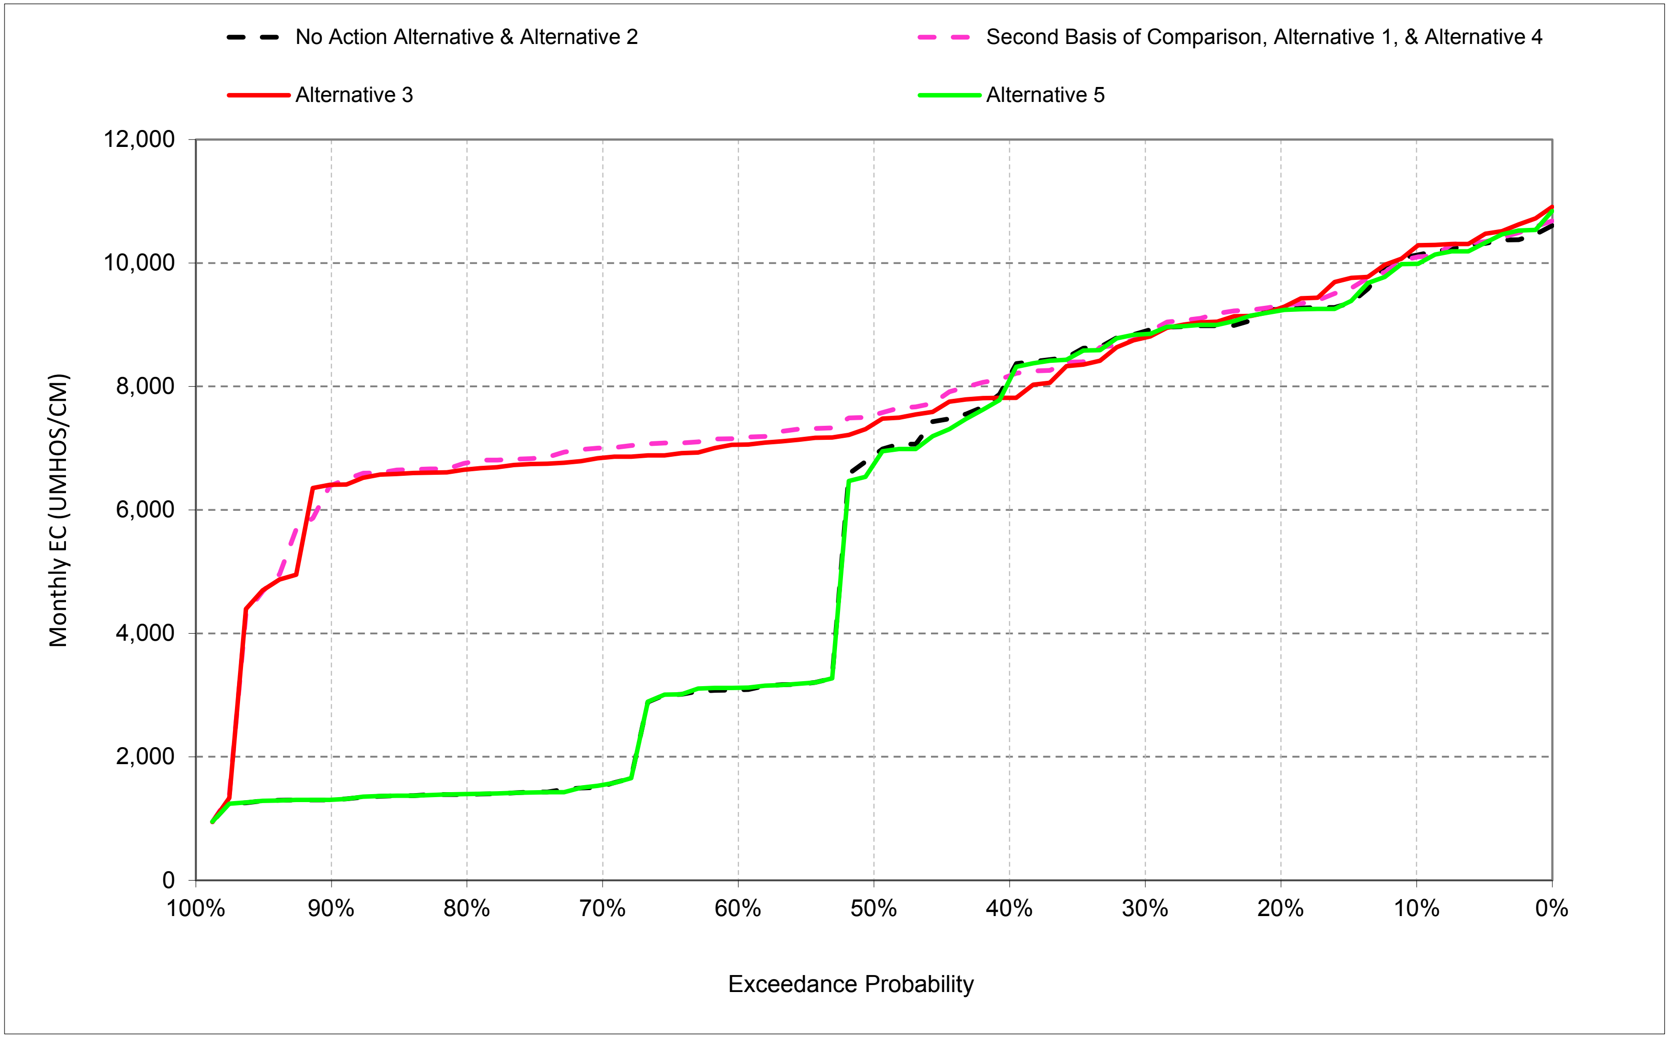
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.4.11. Sacramento River at Collinsville Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.4.12. Sacramento River at Collinsville Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

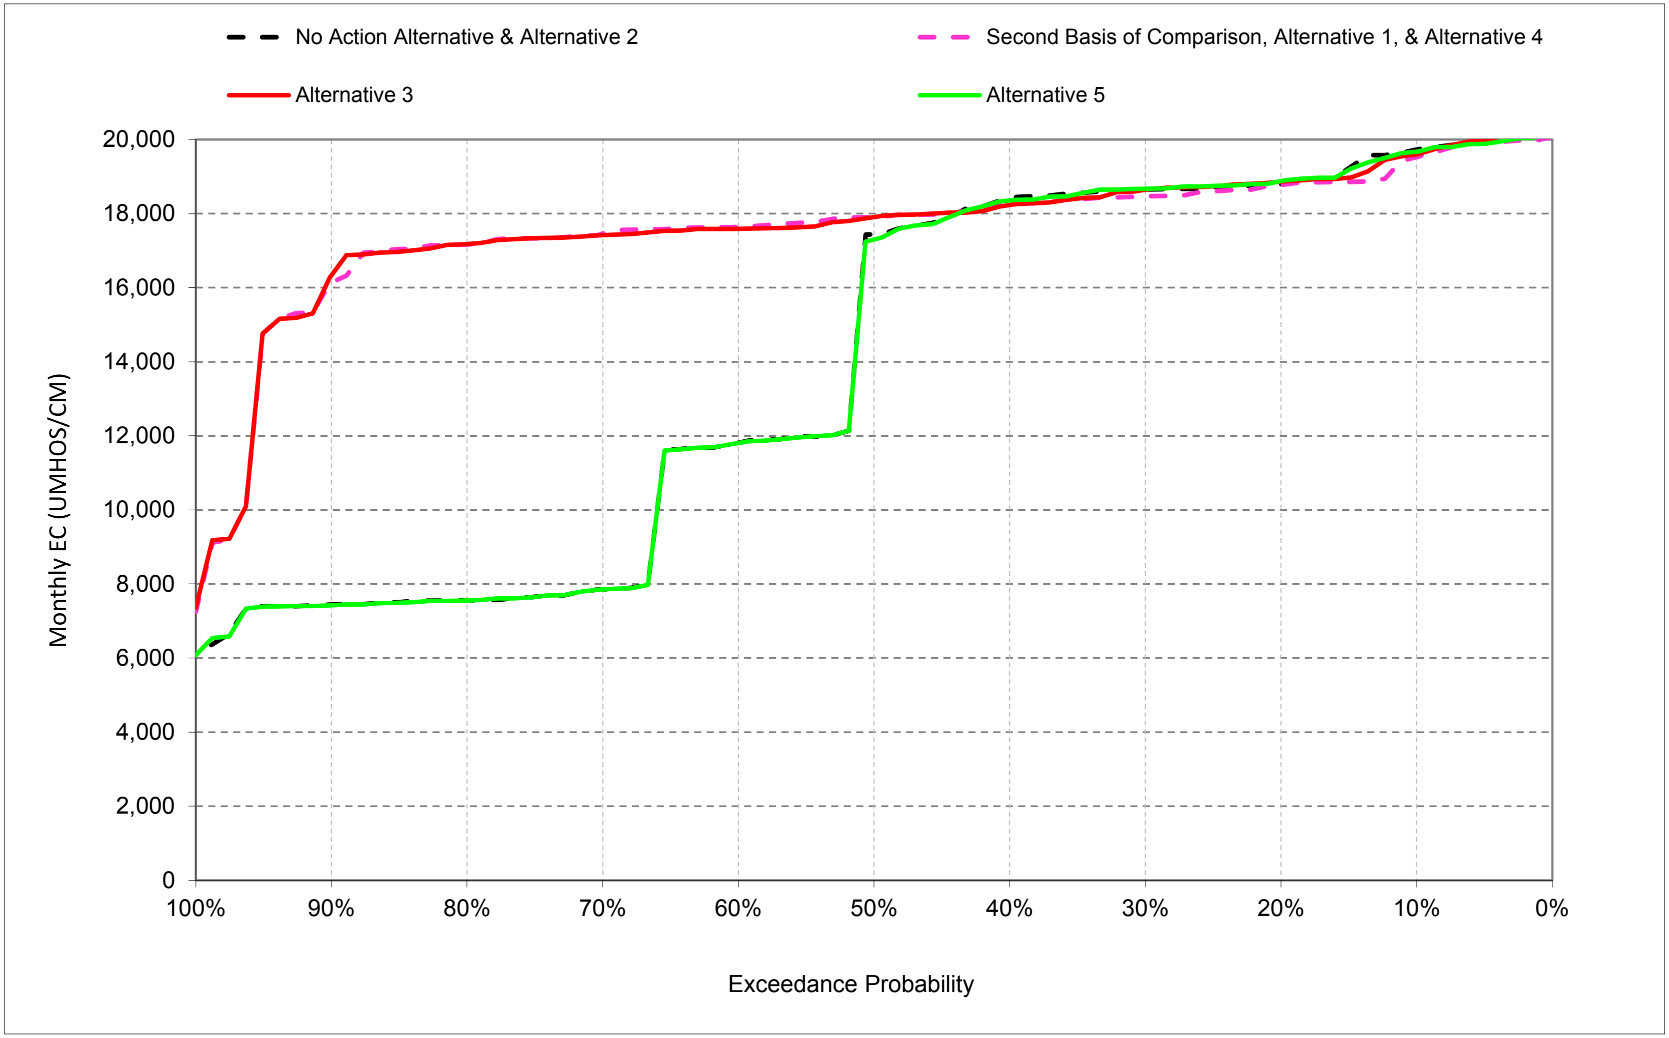
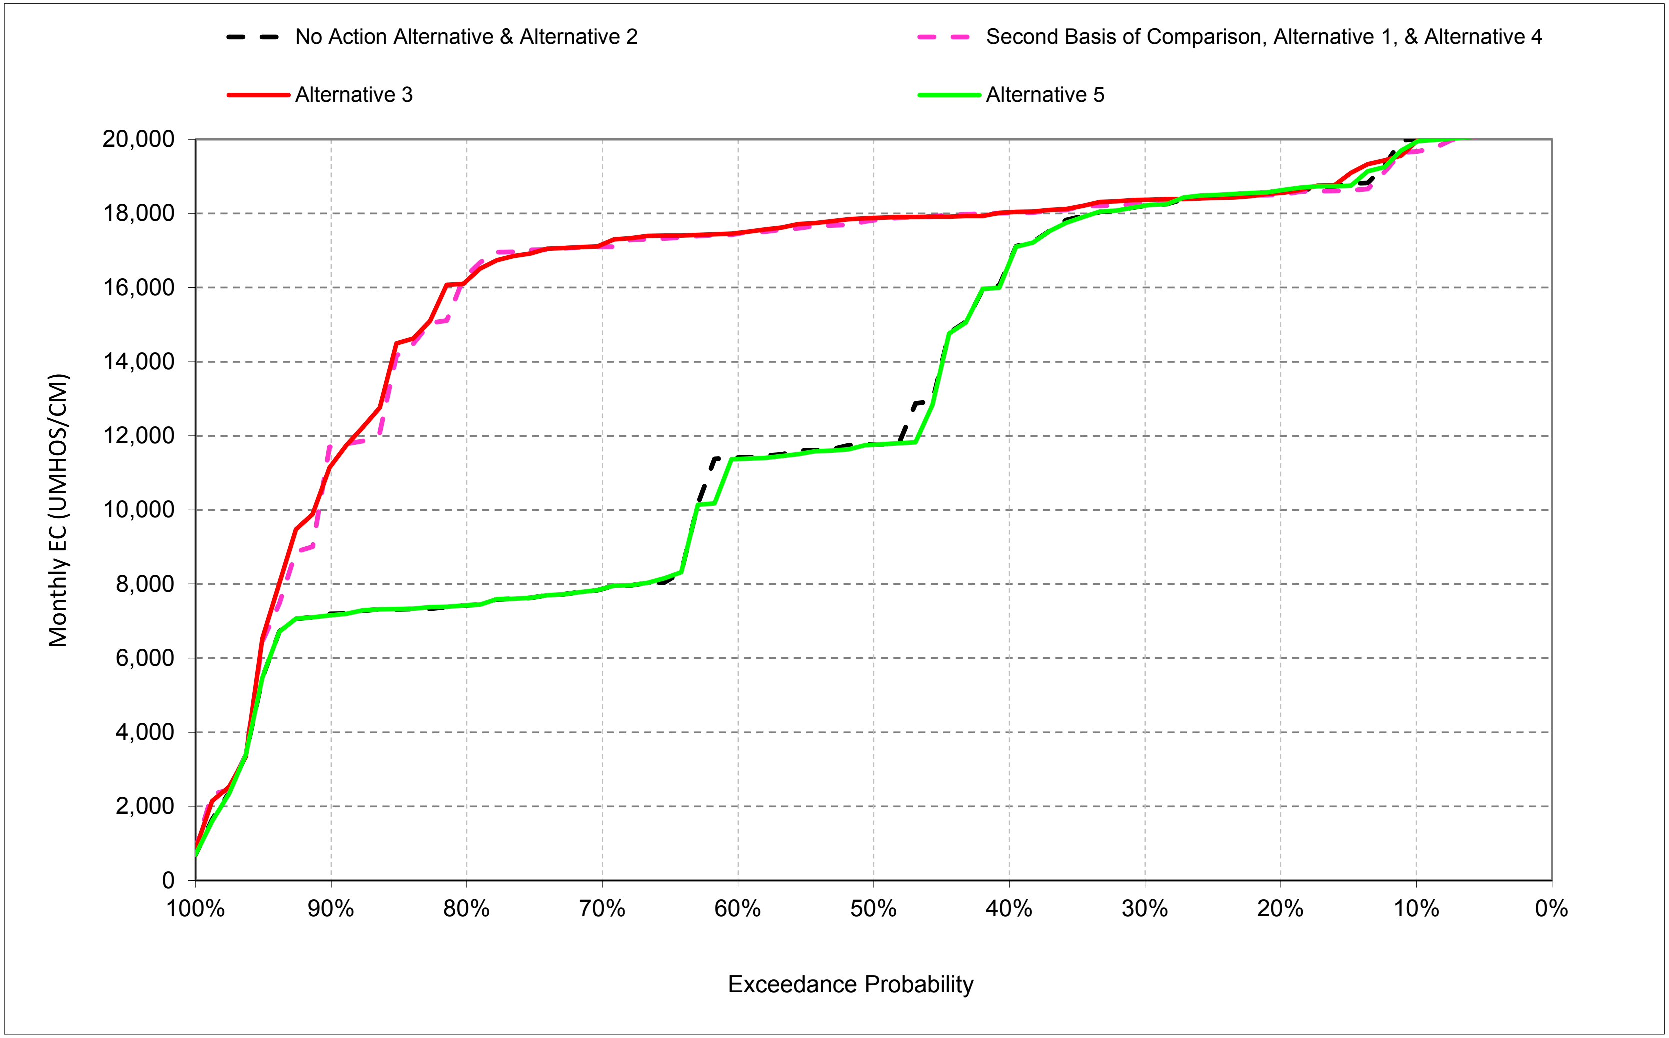
B.6. Sacramento River at Port Chicago Salinity

Figure 6E.B.6.1. Sacramento River at Port Chicago Salinity, Electrical Conductivity, October



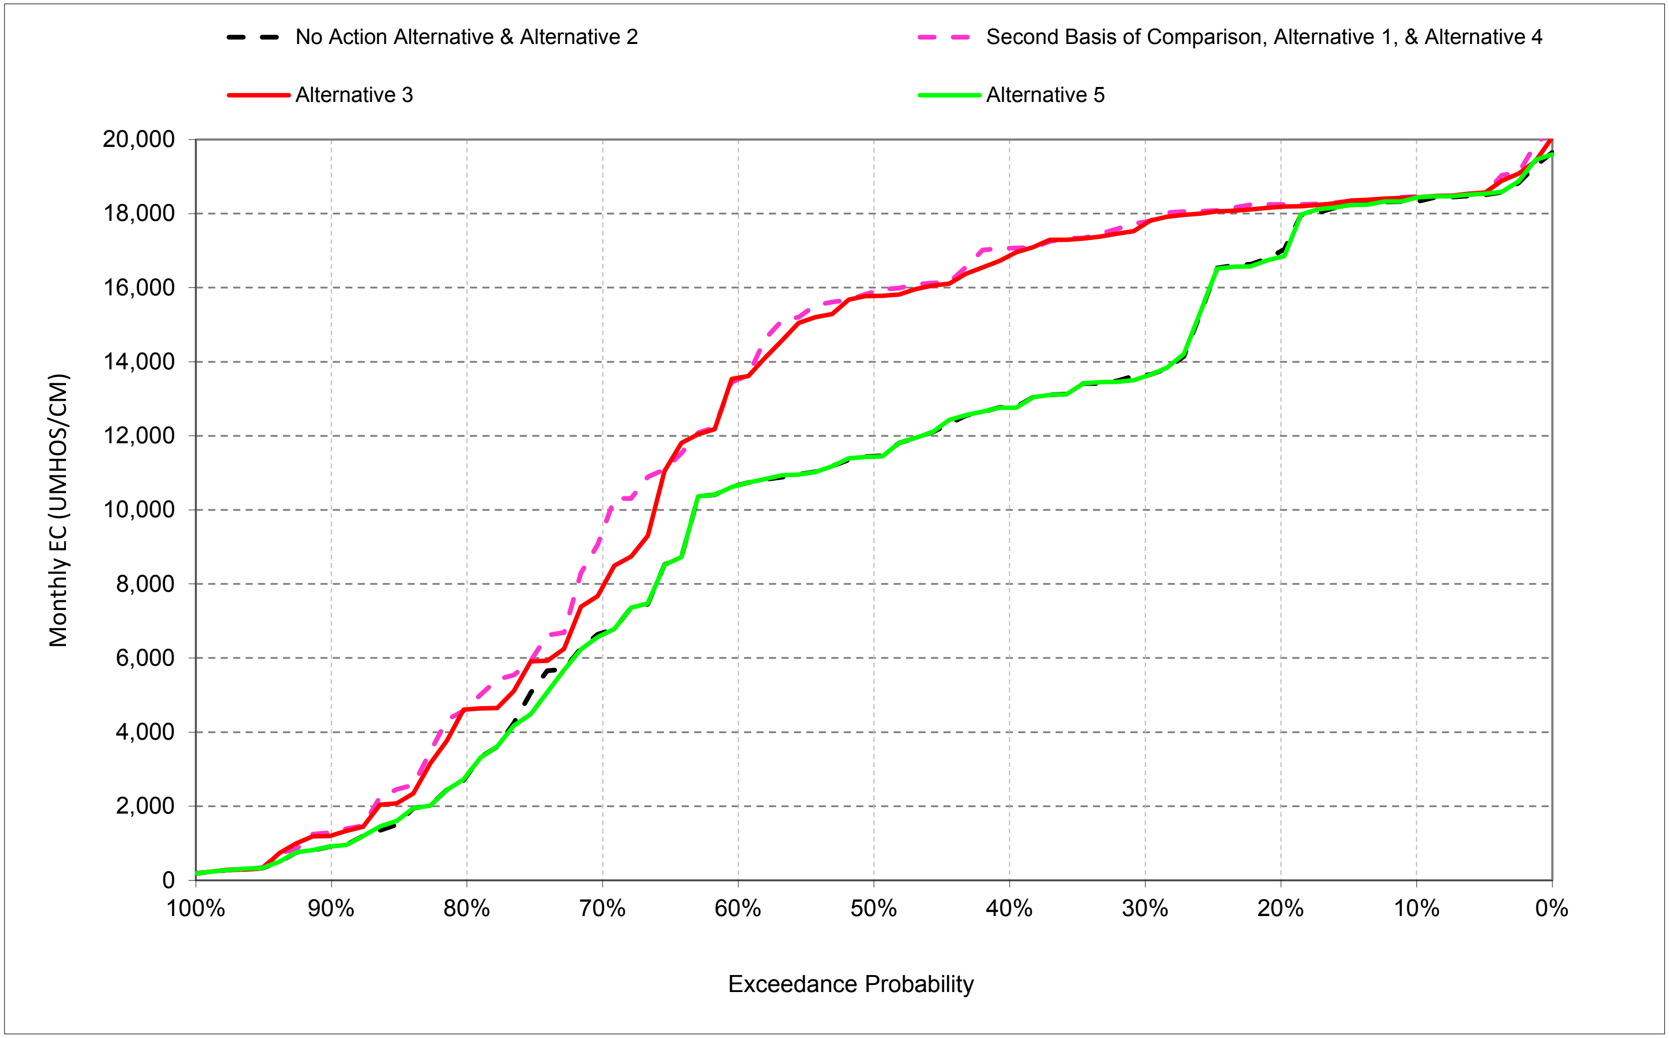
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.2. Sacramento River at Port Chicago Salinity, Electrical Conductivity, November



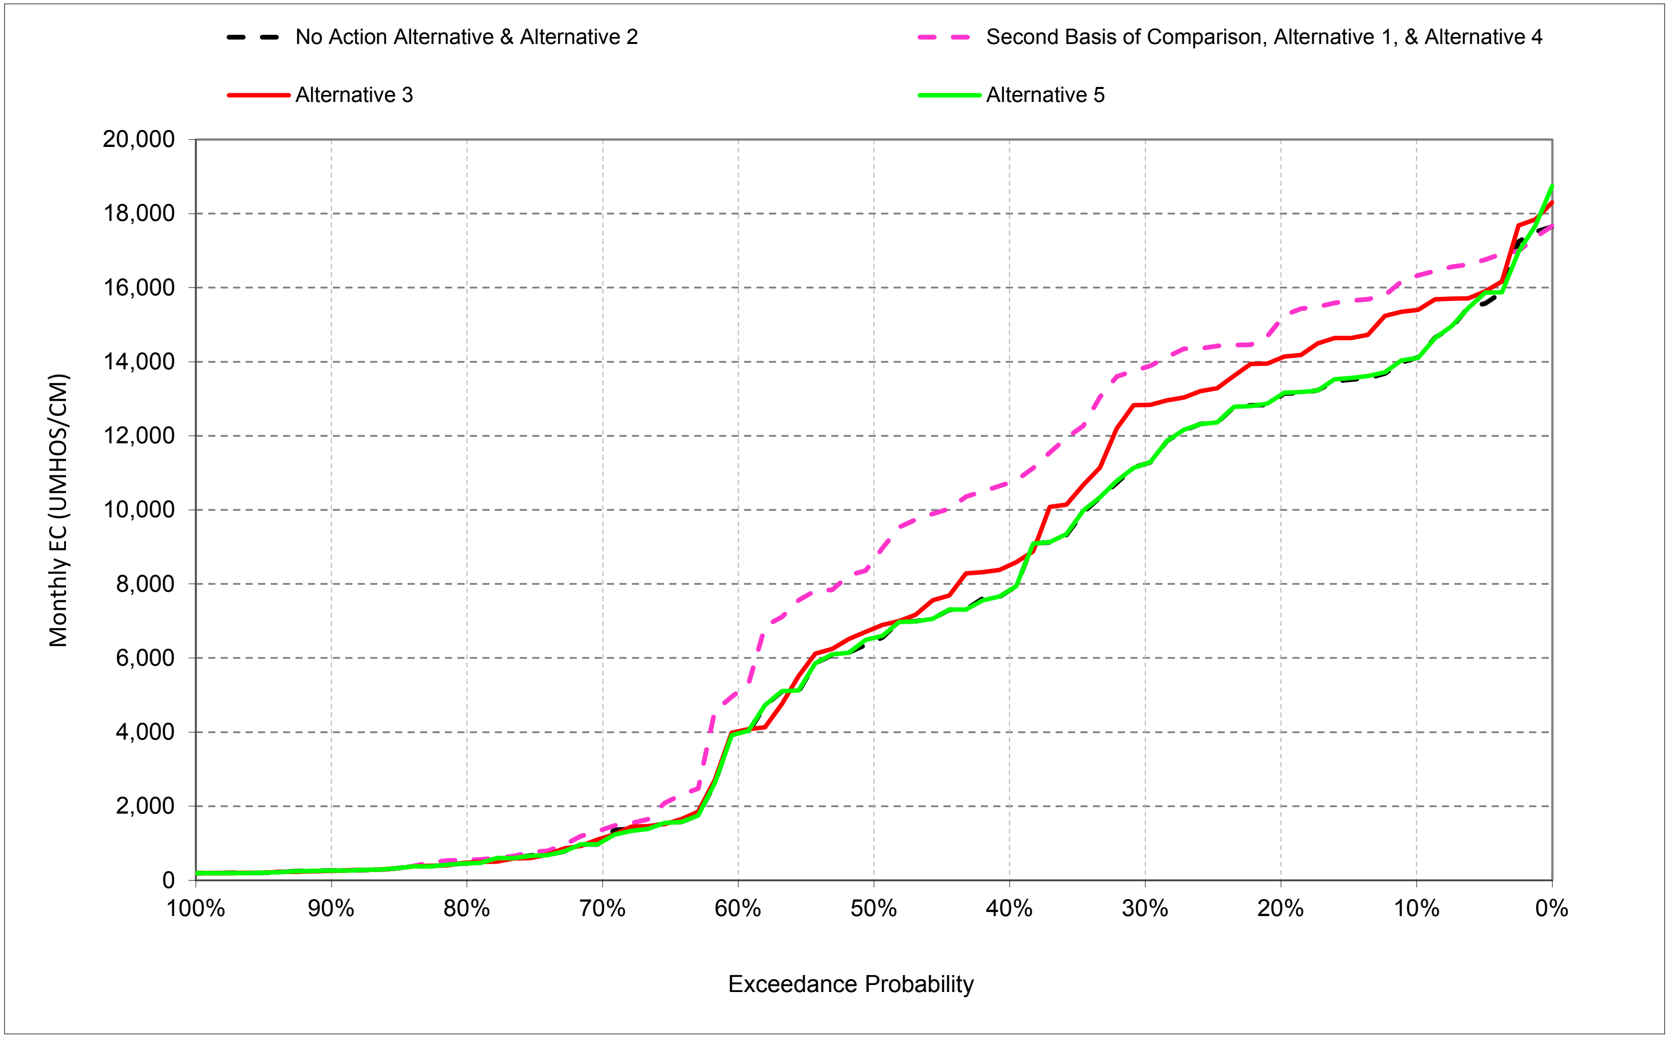
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.3. Sacramento River at Port Chicago Salinity, Electrical Conductivity, December



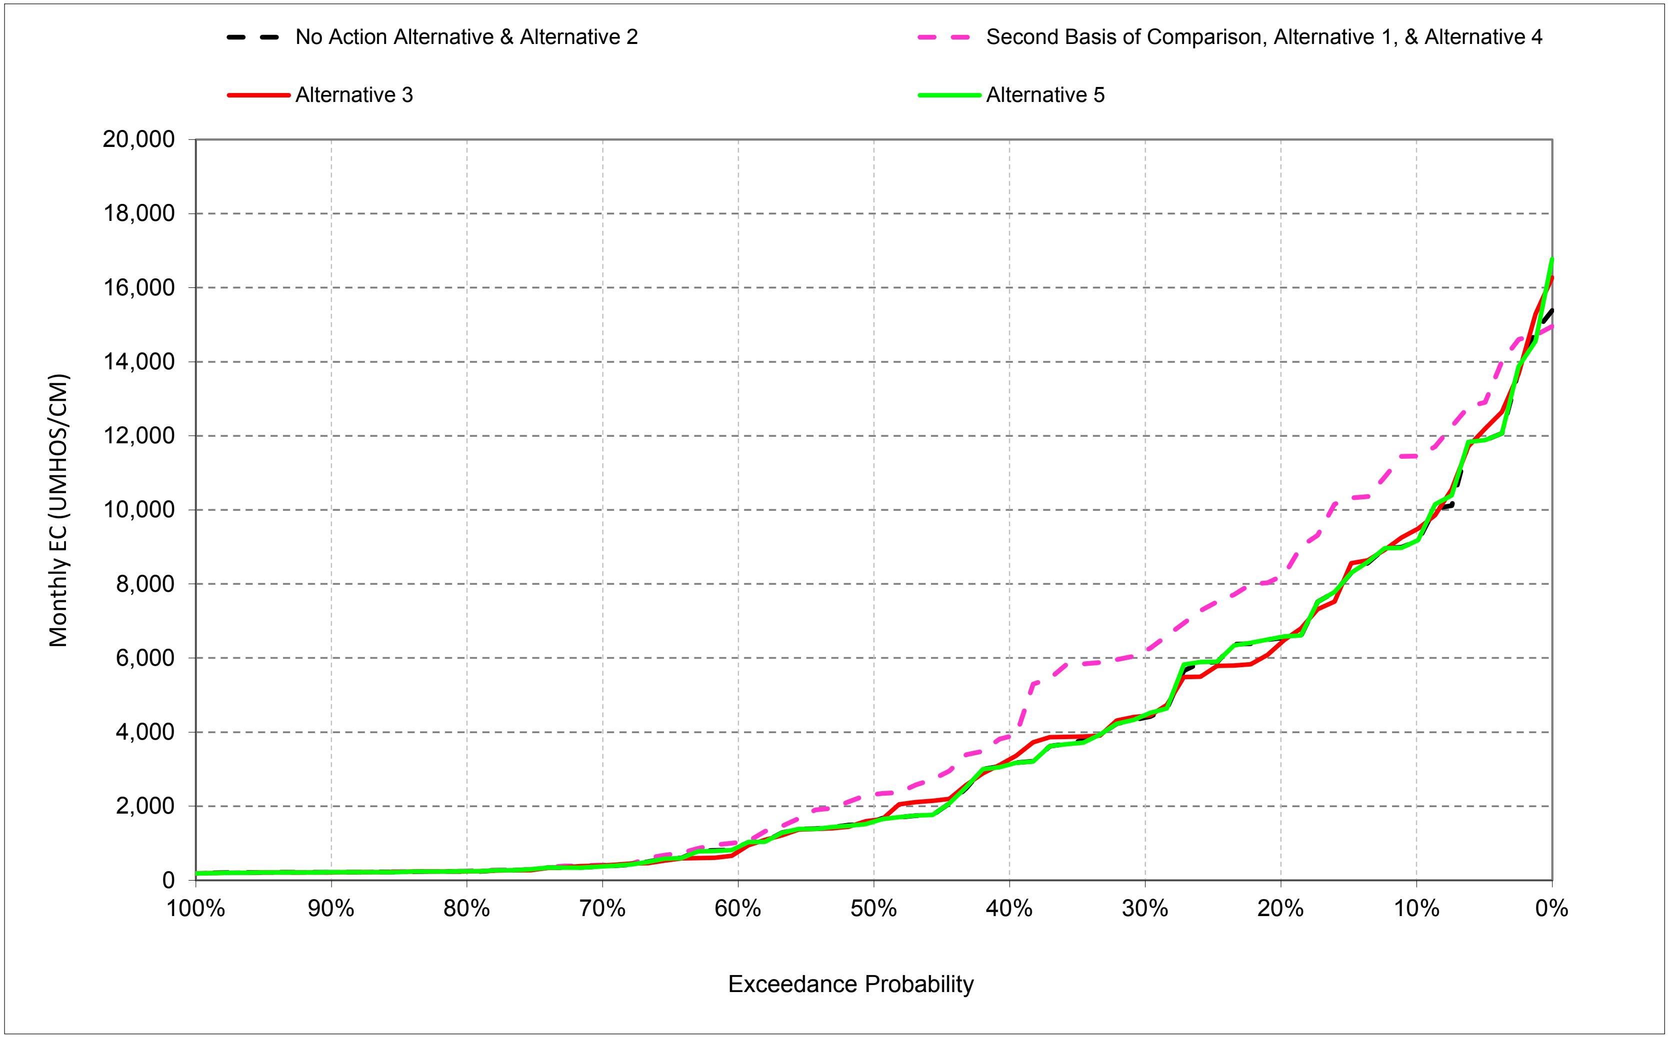
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.4. Sacramento River at Port Chicago Salinity, Electrical Conductivity, January



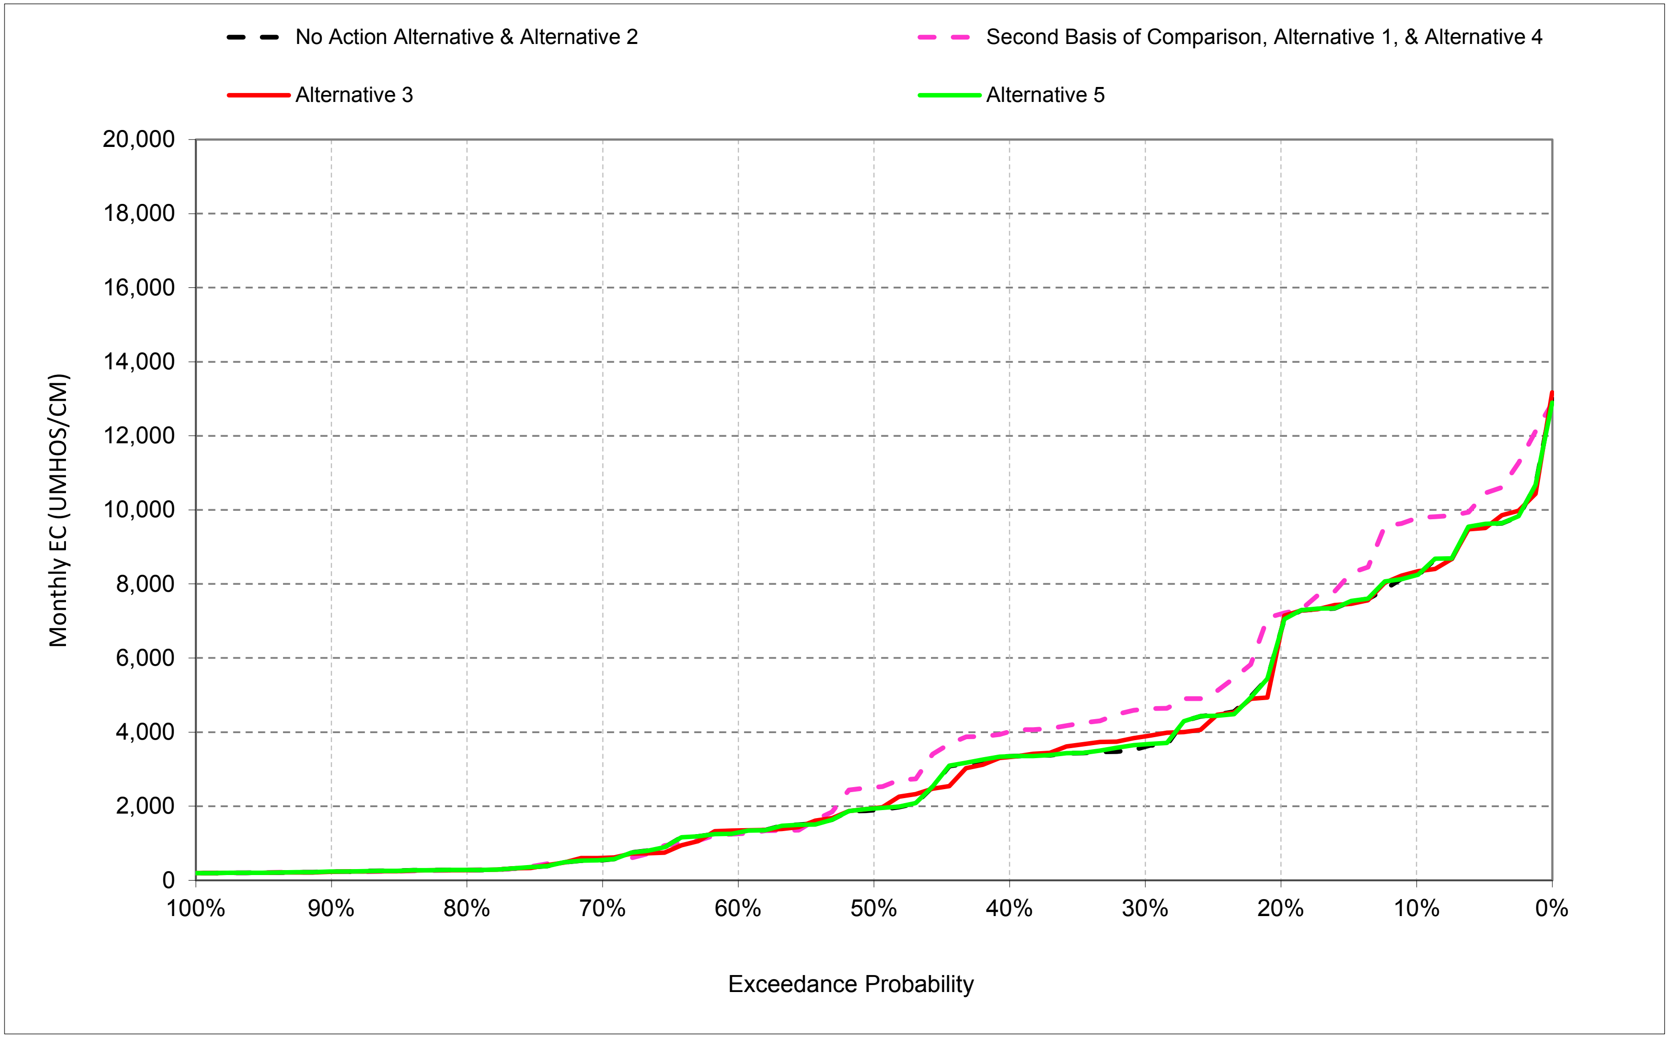
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.5. Sacramento River at Port Chicago Salinity, Electrical Conductivity, February



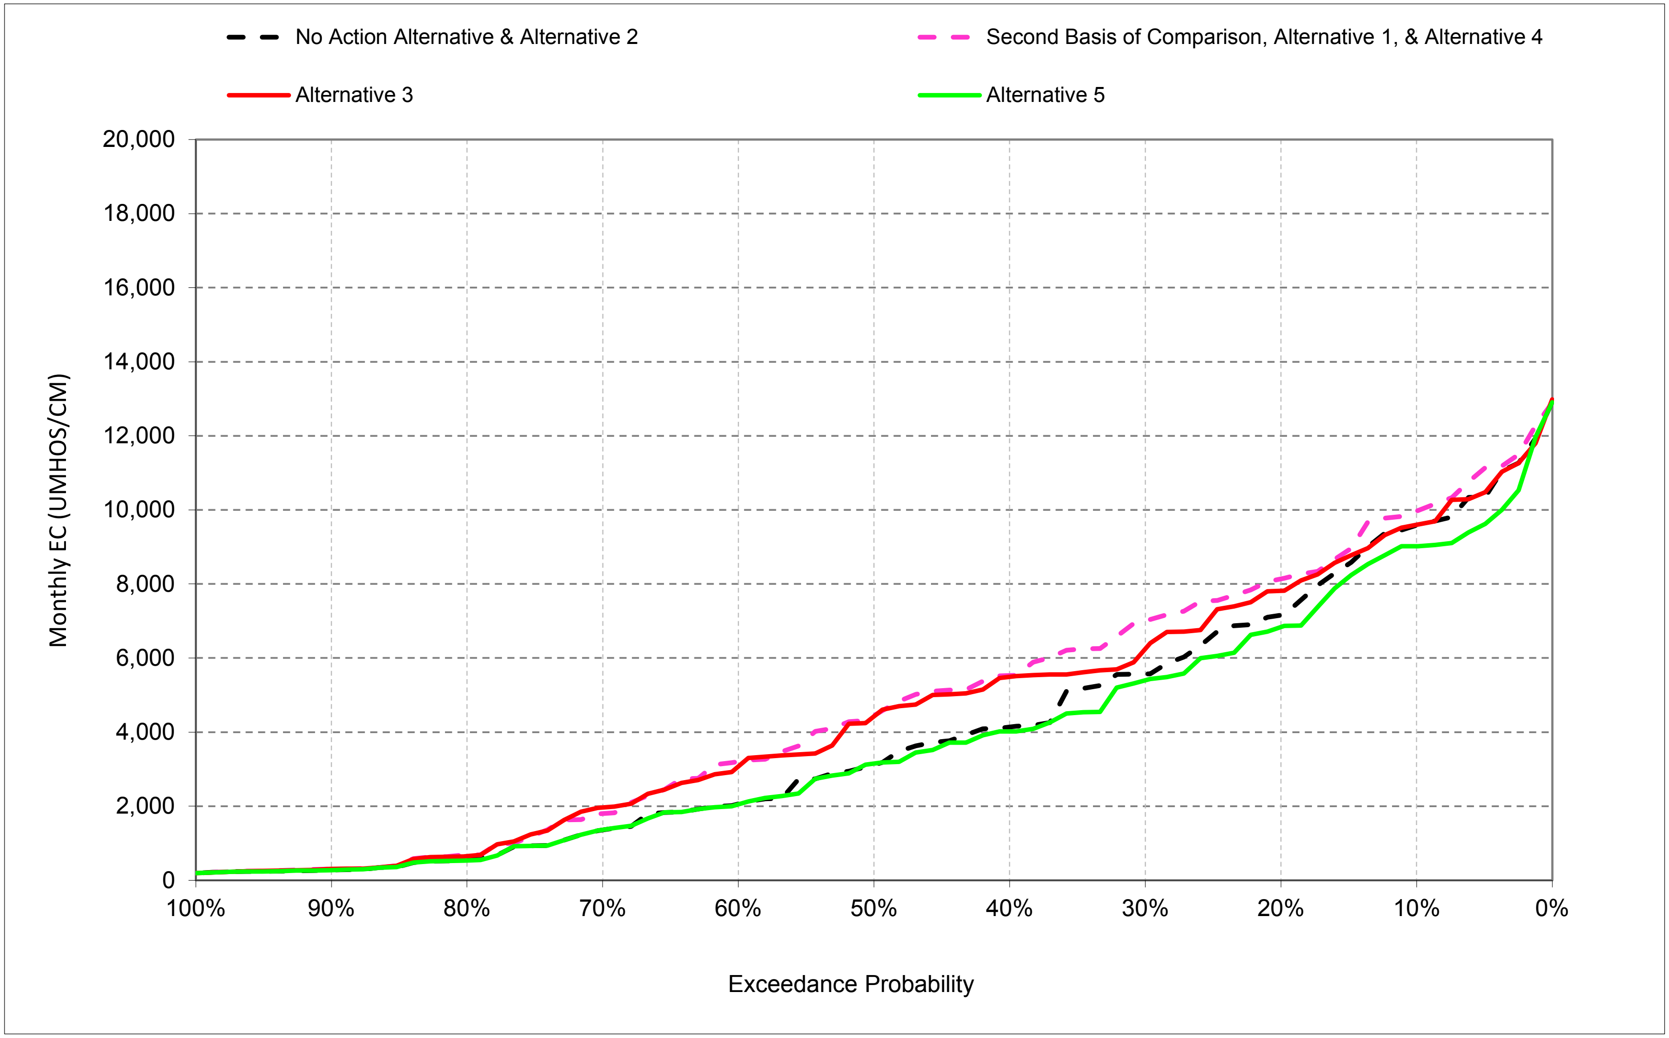
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.6. Sacramento River at Port Chicago Salinity, Electrical Conductivity, March



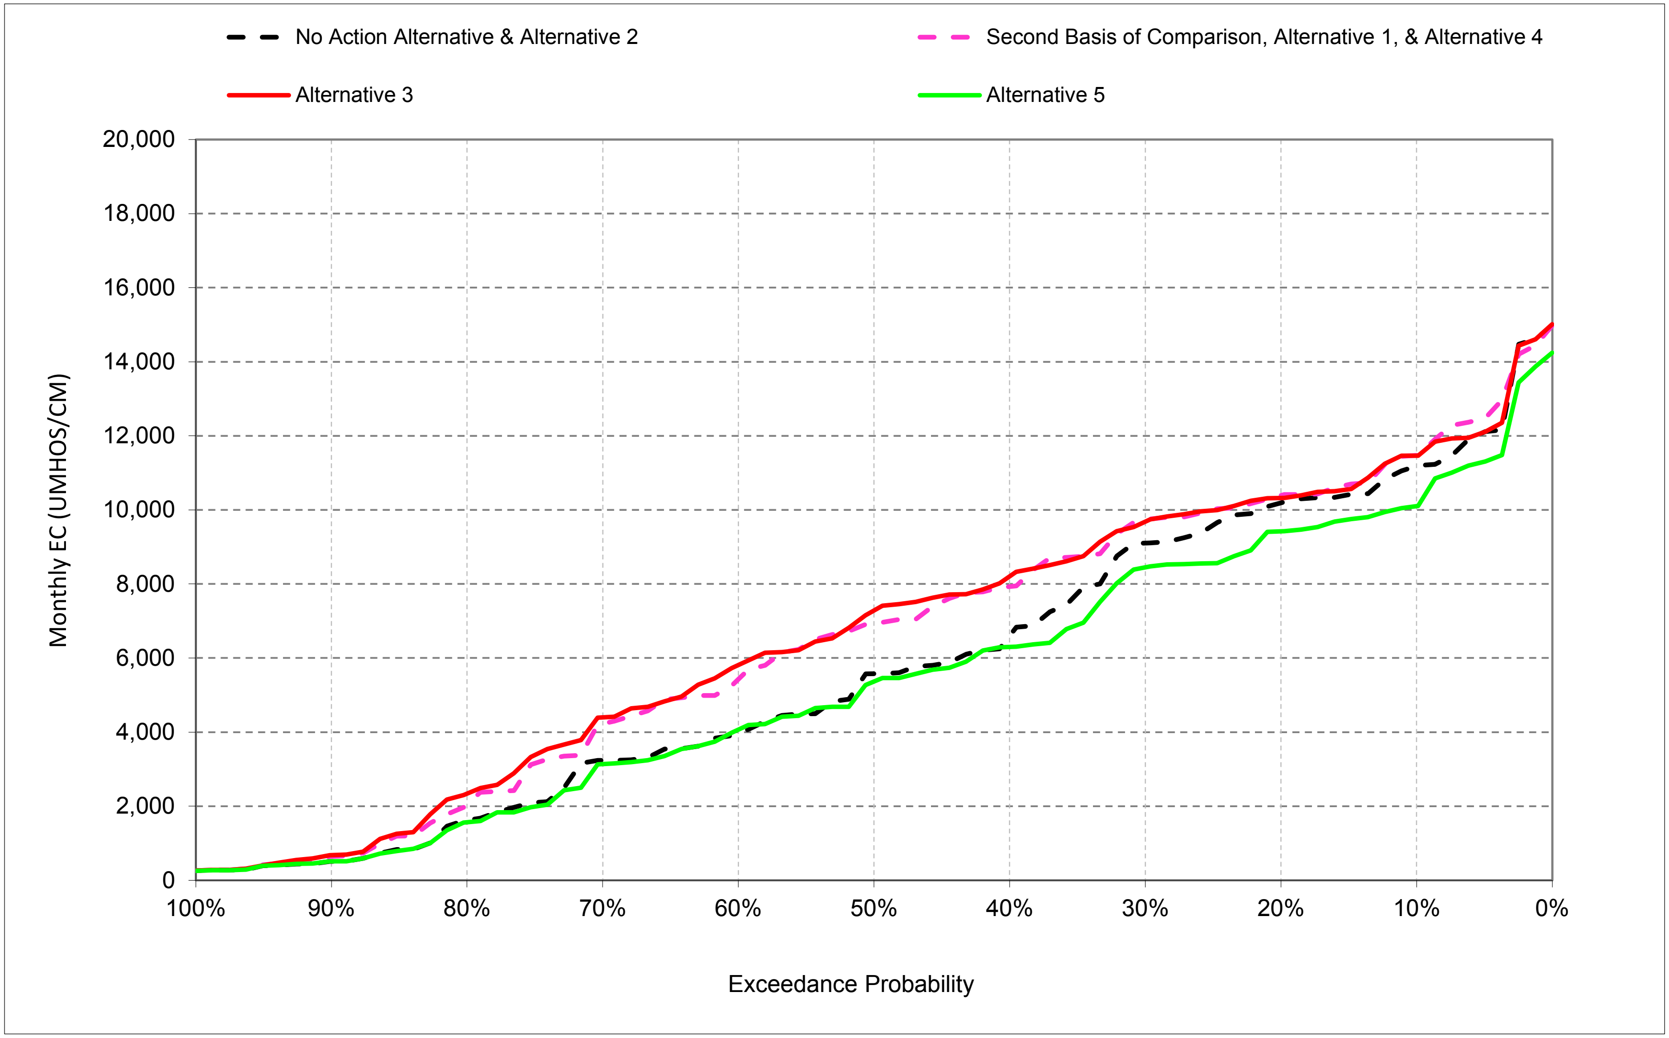
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.7. Sacramento River at Port Chicago Salinity, Electrical Conductivity, April



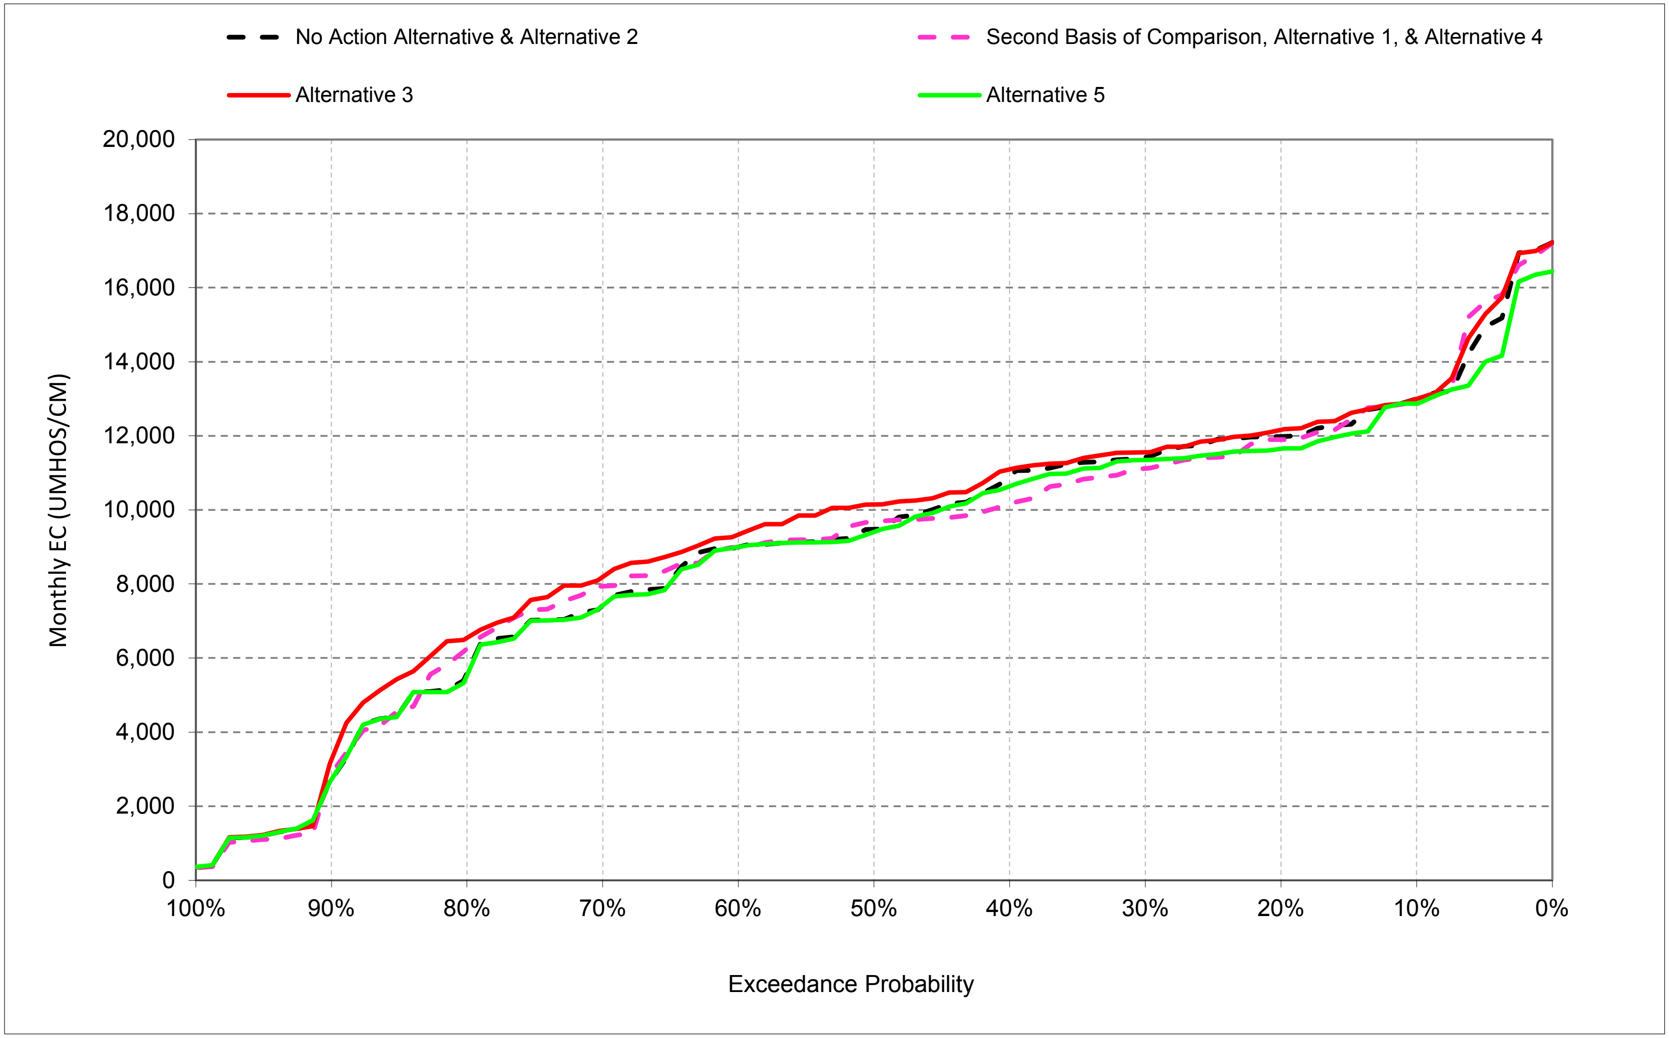
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.8. Sacramento River at Port Chicago Salinity, Electrical Conductivity, May



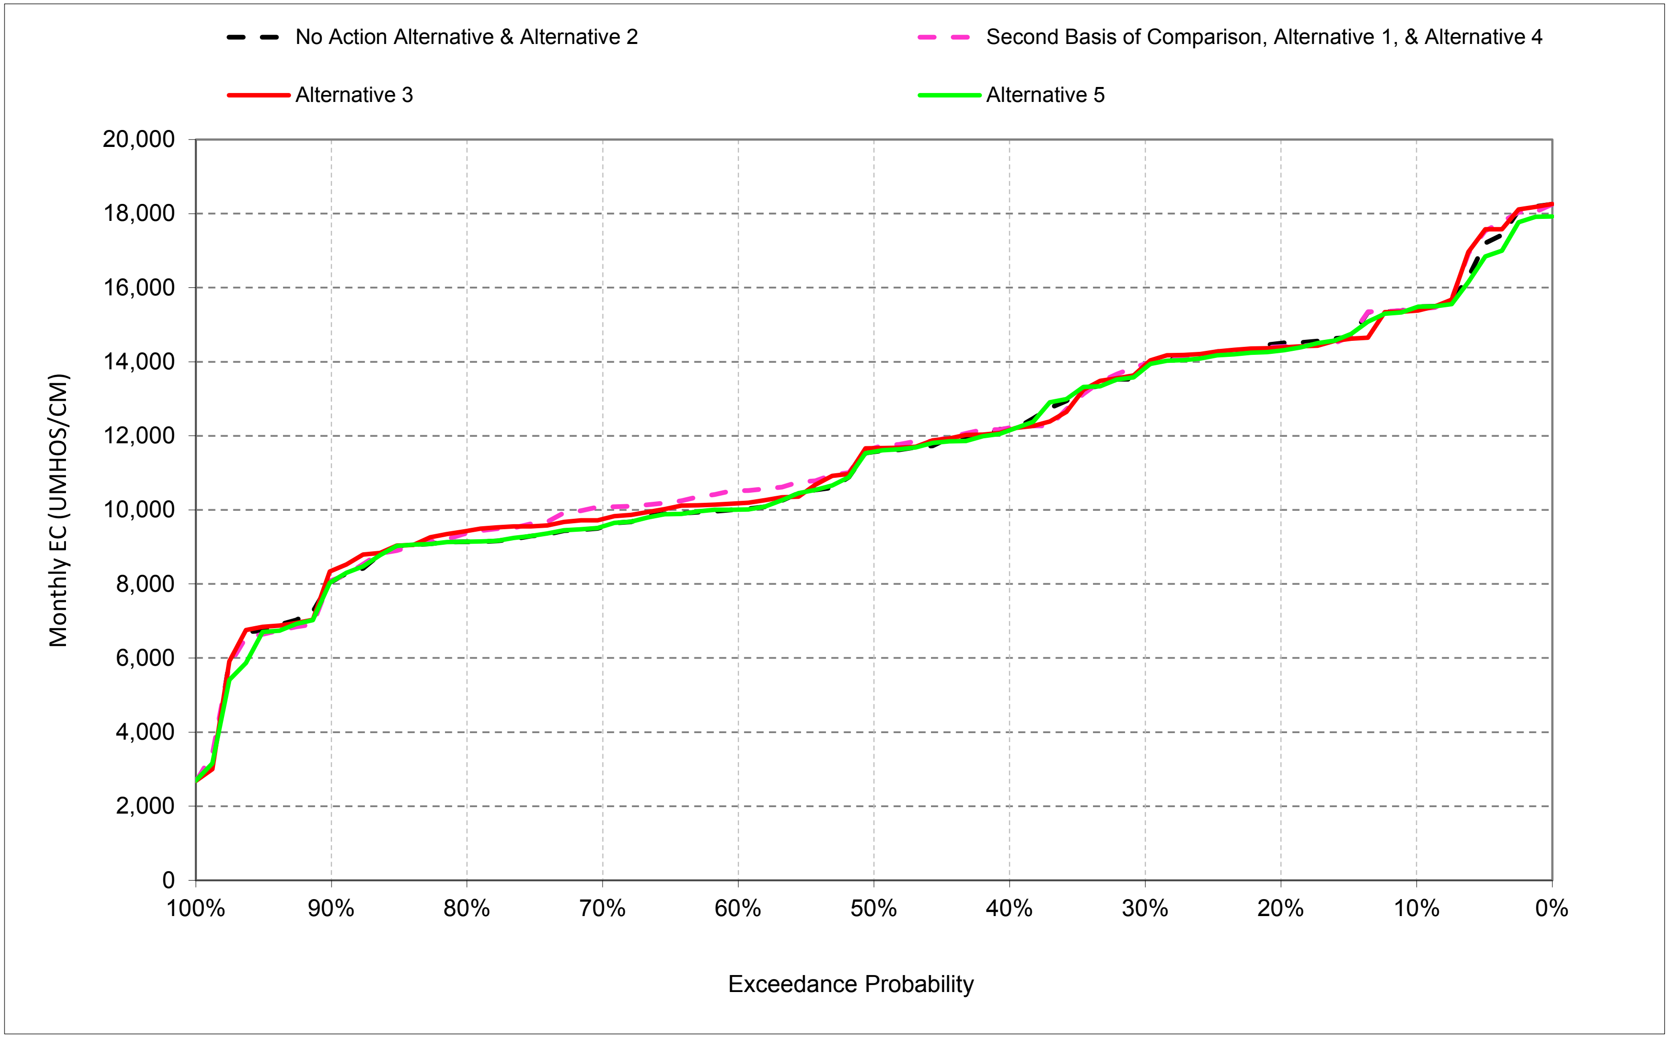
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.9. Sacramento River at Port Chicago Salinity, Electrical Conductivity, June



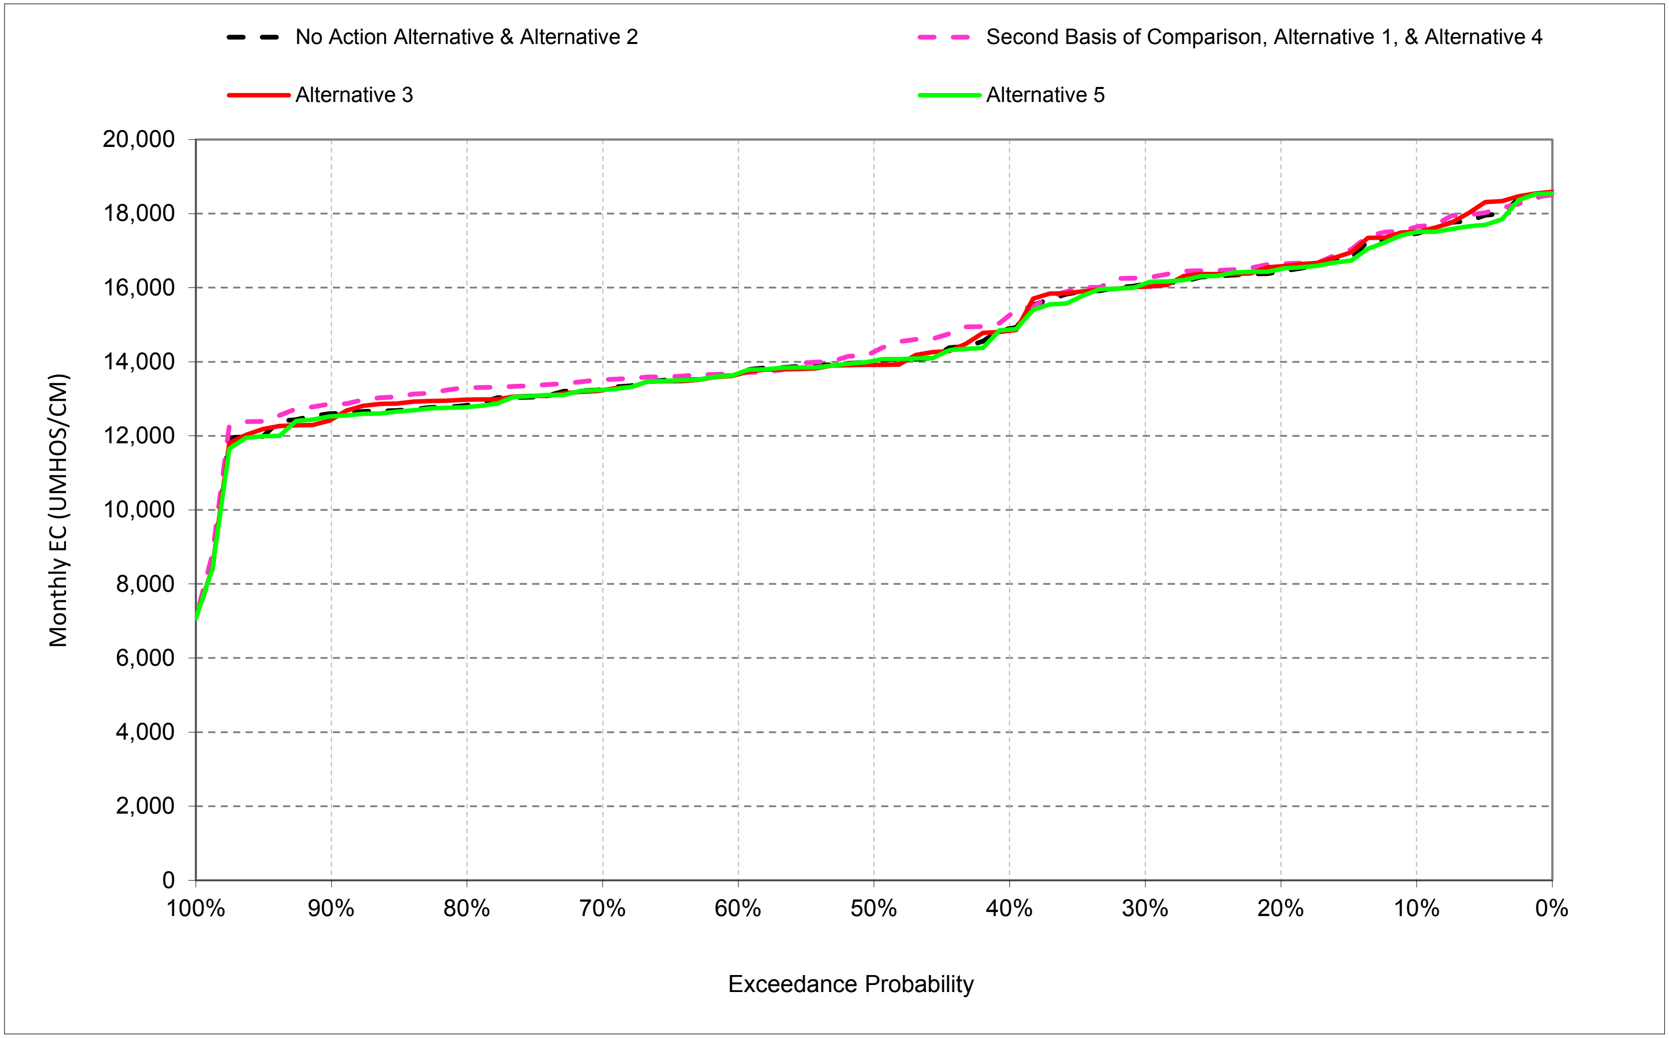
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.10. Sacramento River at Port Chicago Salinity, Electrical Conductivity, July



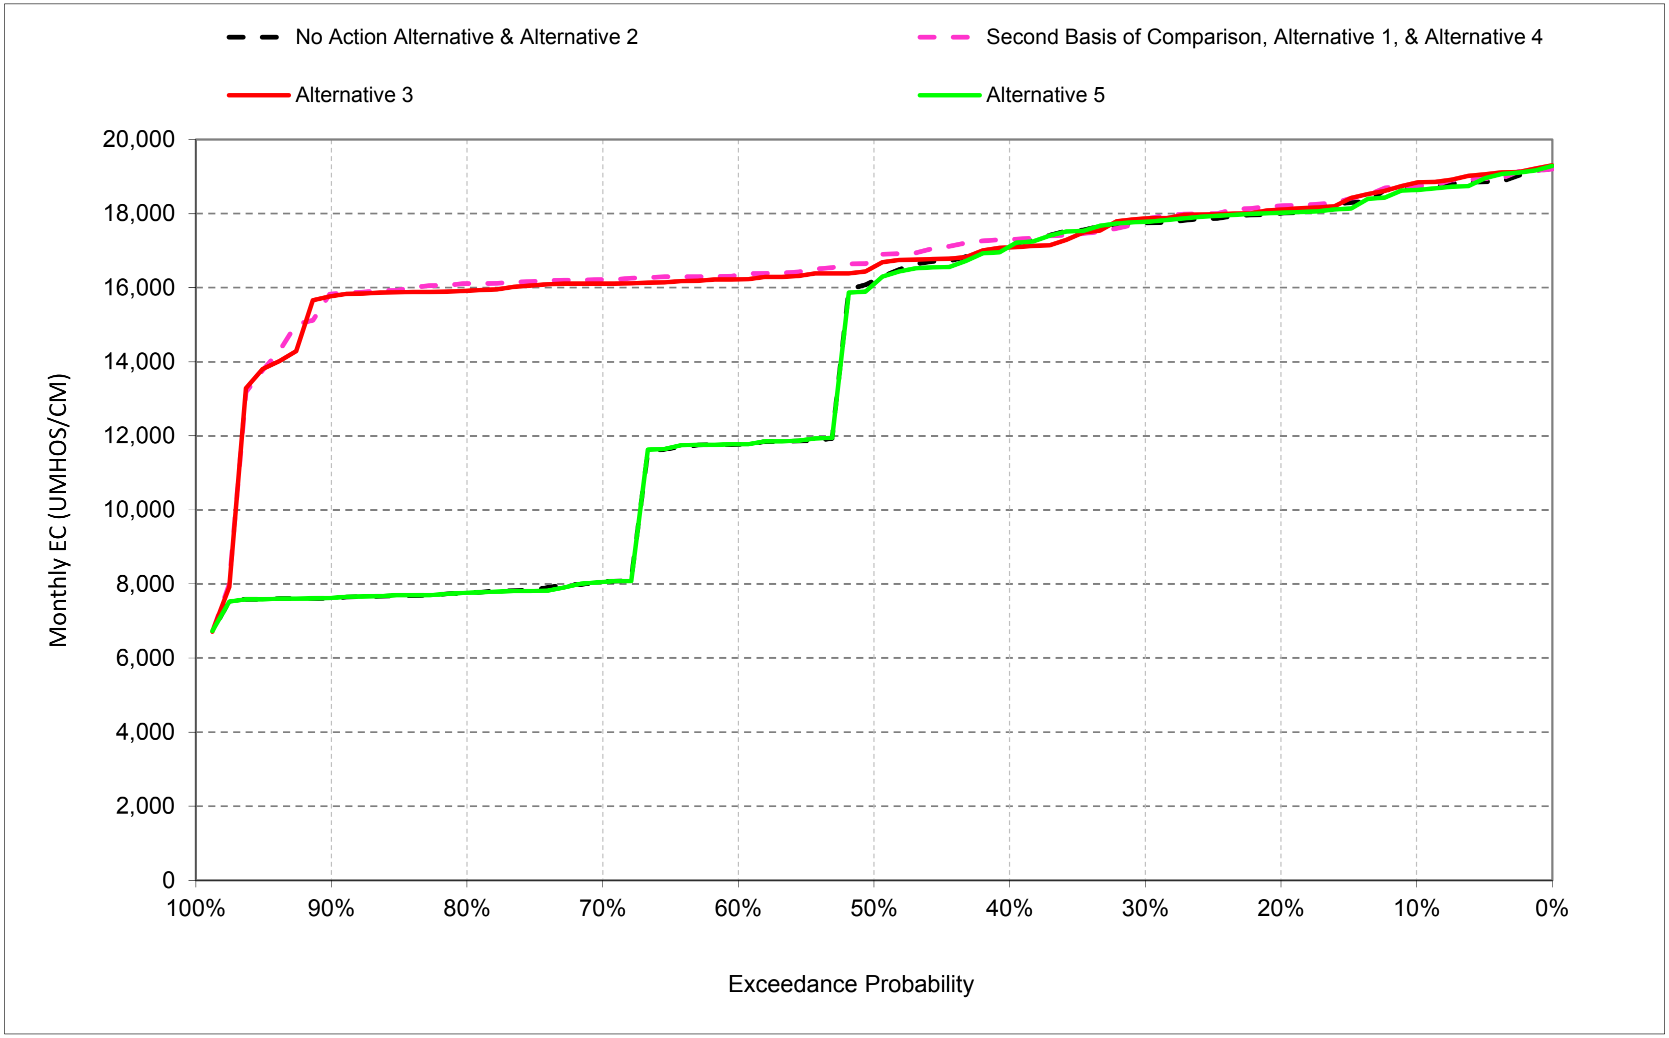
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.11. Sacramento River at Port Chicago Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.6.12. Sacramento River at Port Chicago Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

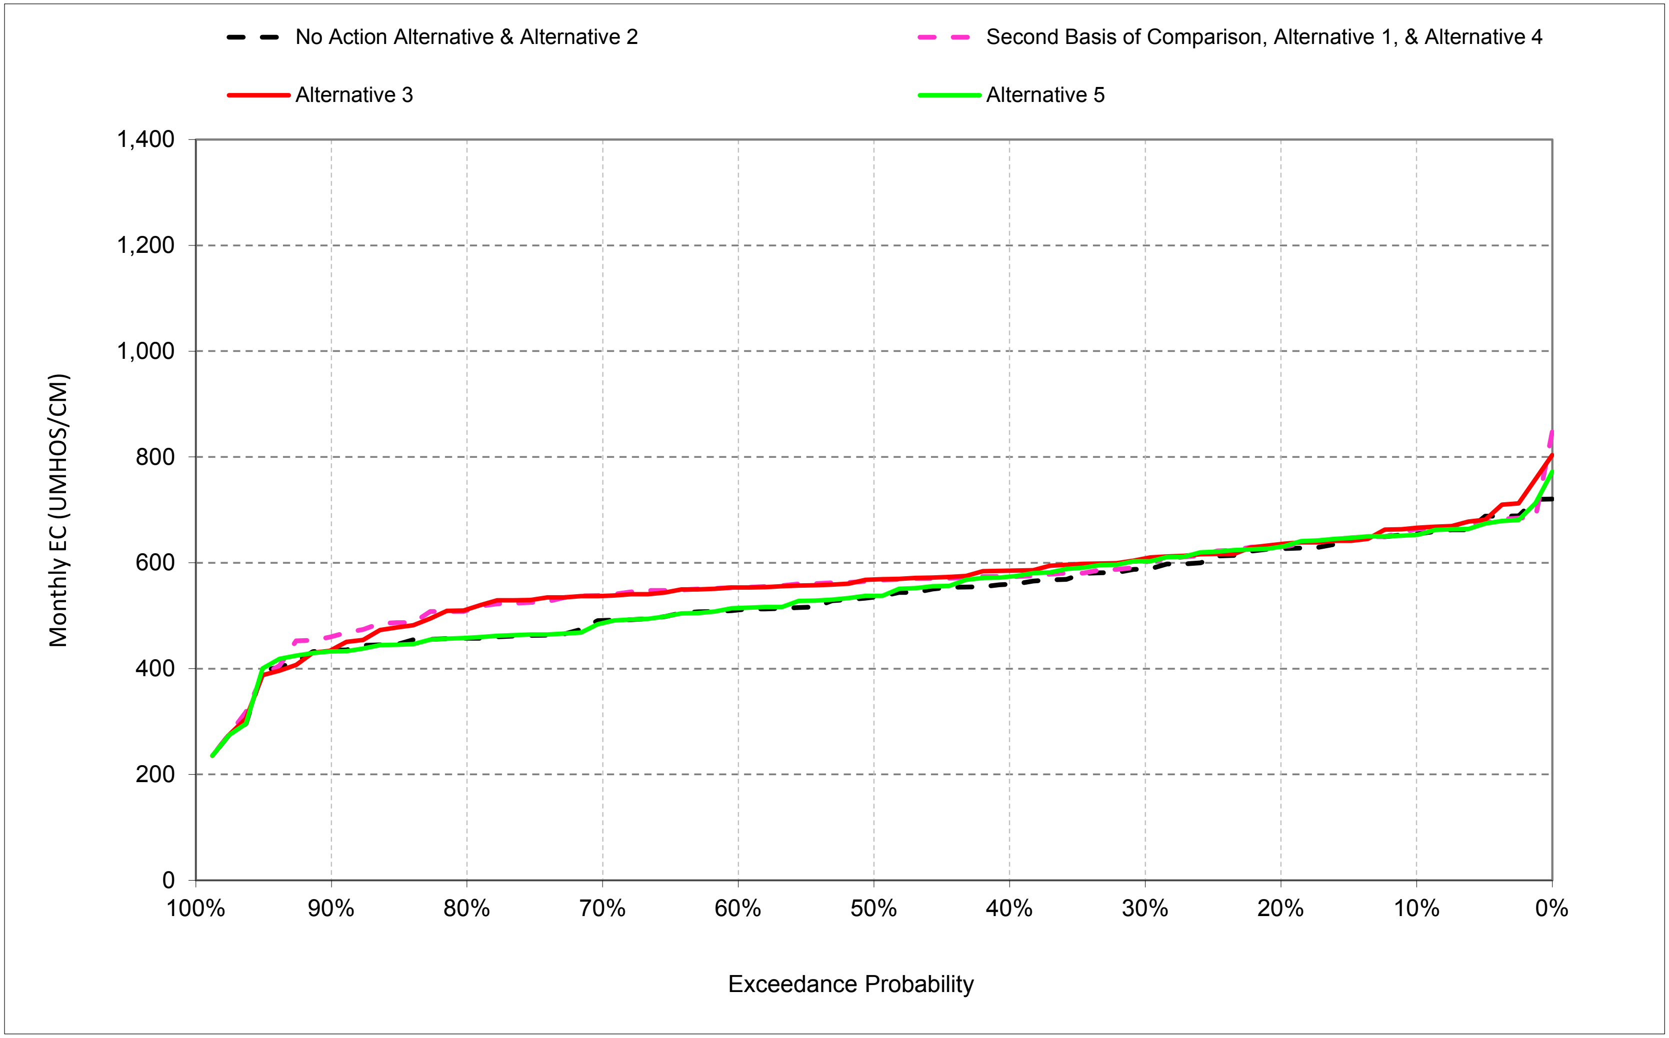
Figure 6E.B.7.12. Jones Pumping Plant Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

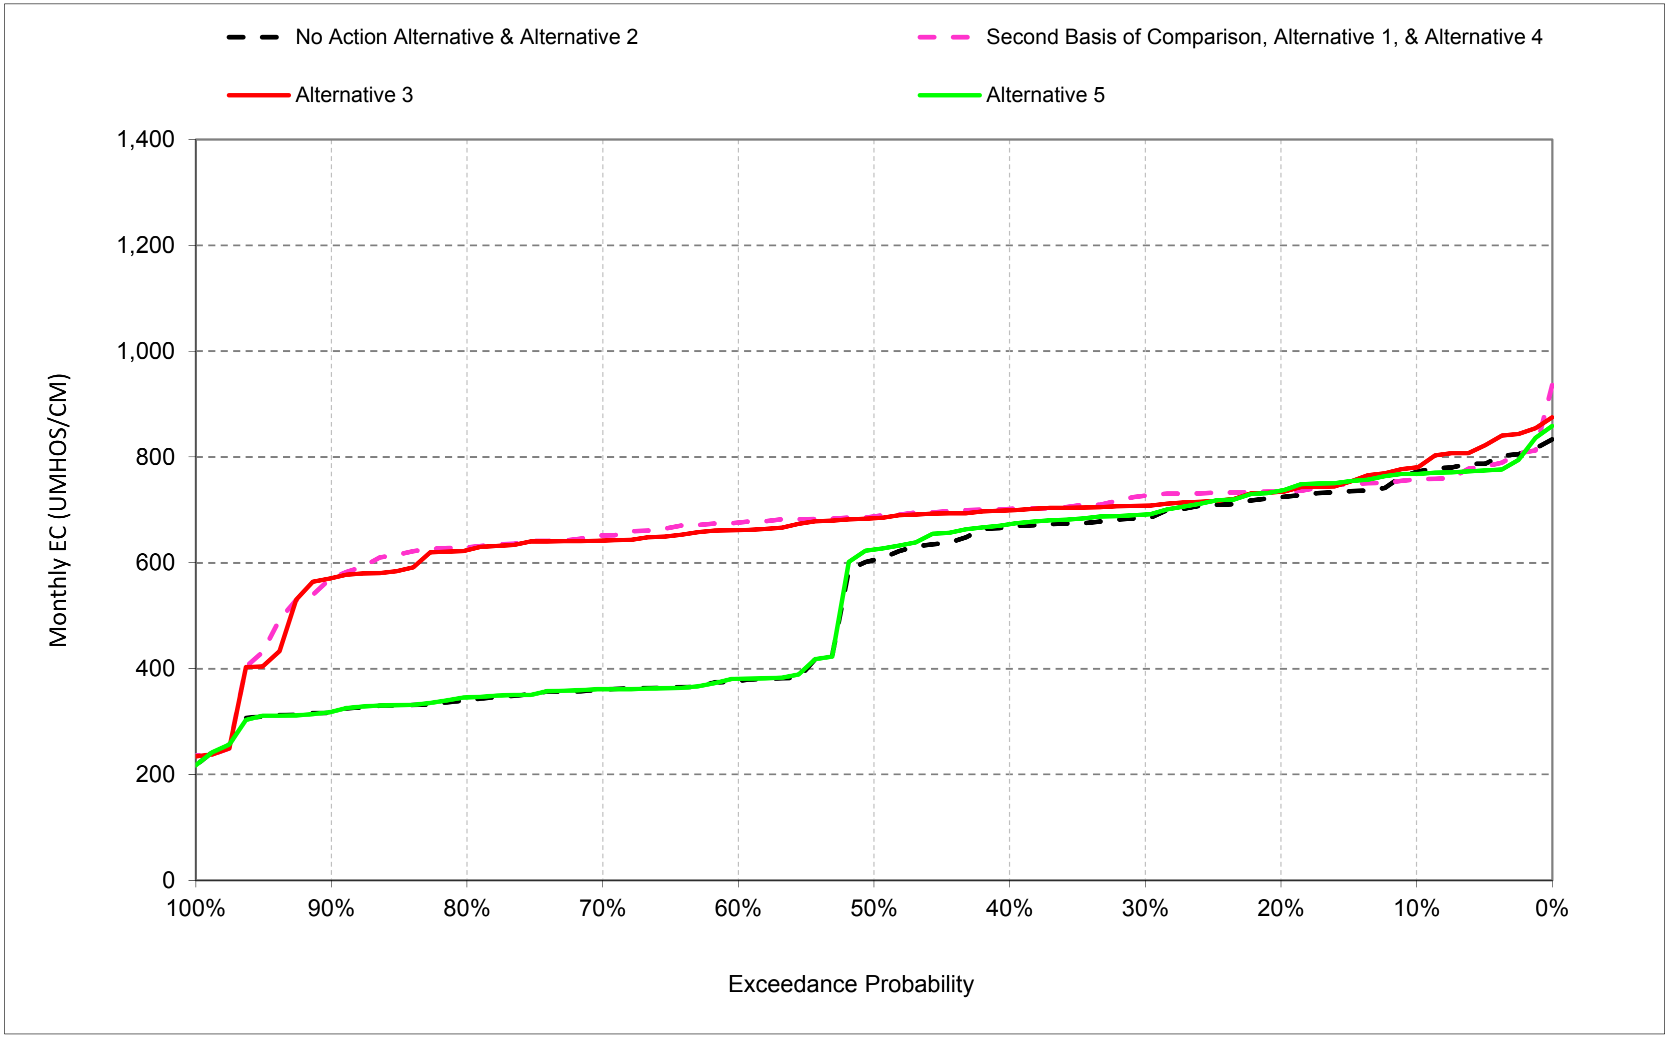
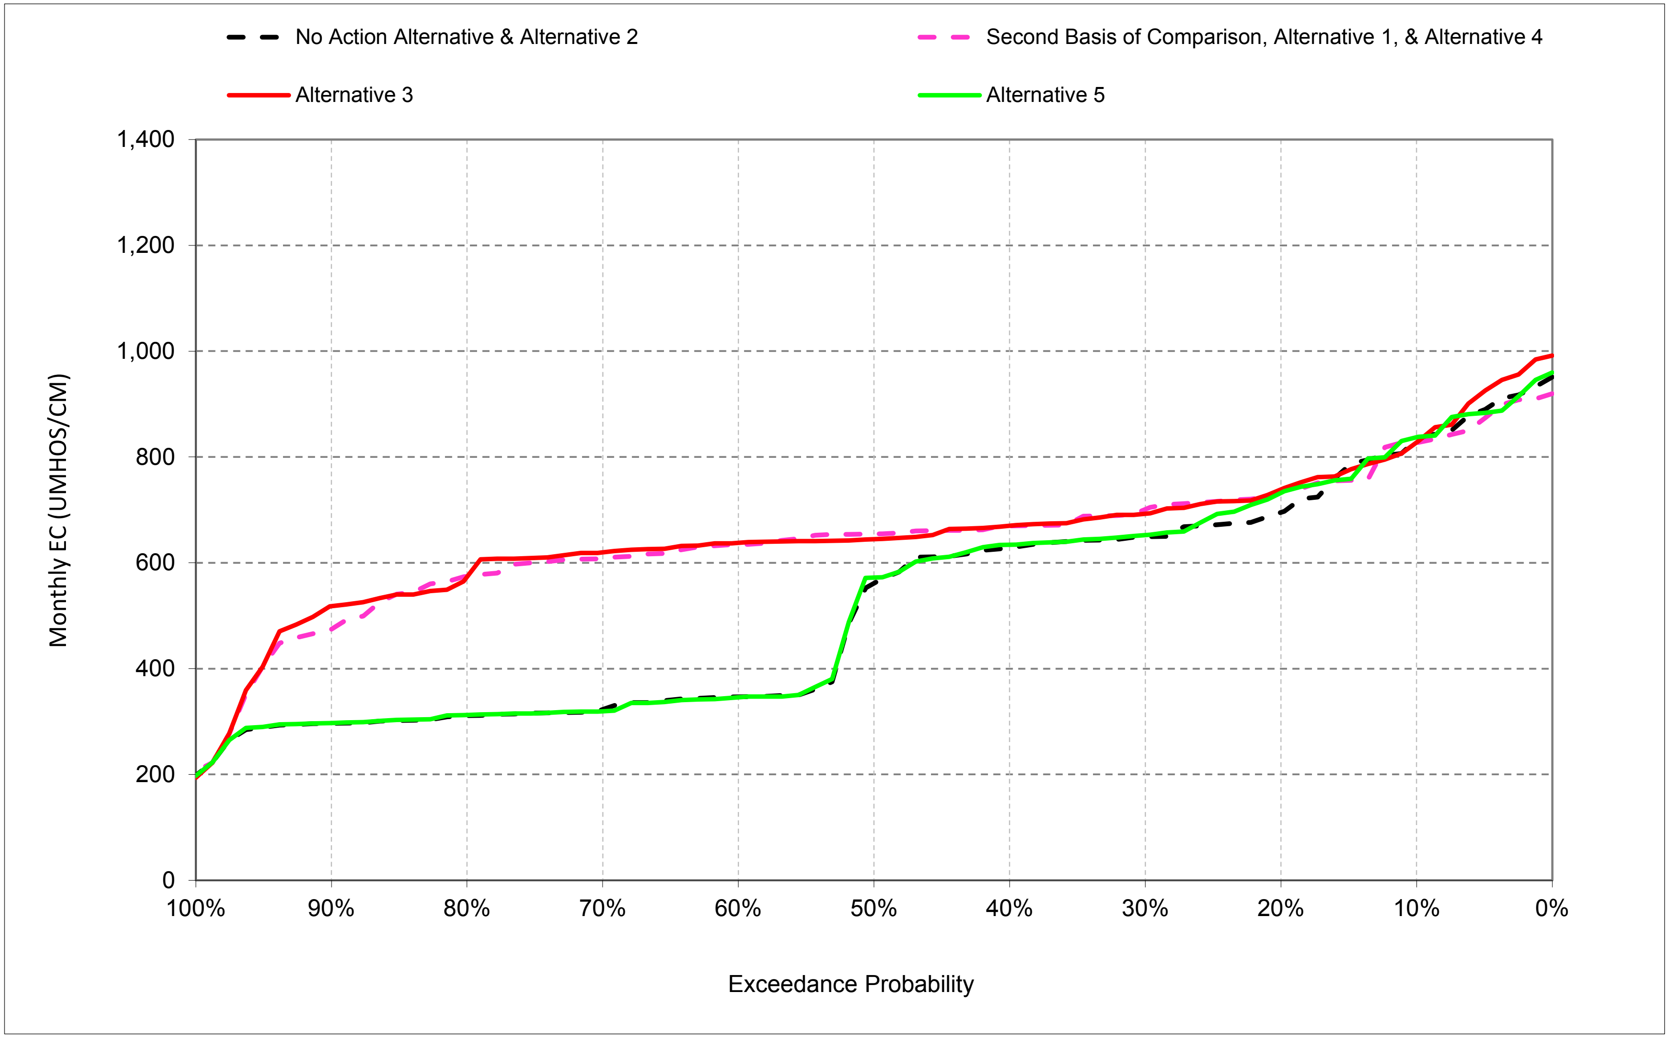
B.8. Banks Pumping Plant Salinity

Figure 6E.B.8.1. Banks Pumping Plant Salinity, Electrical Conductivity, October



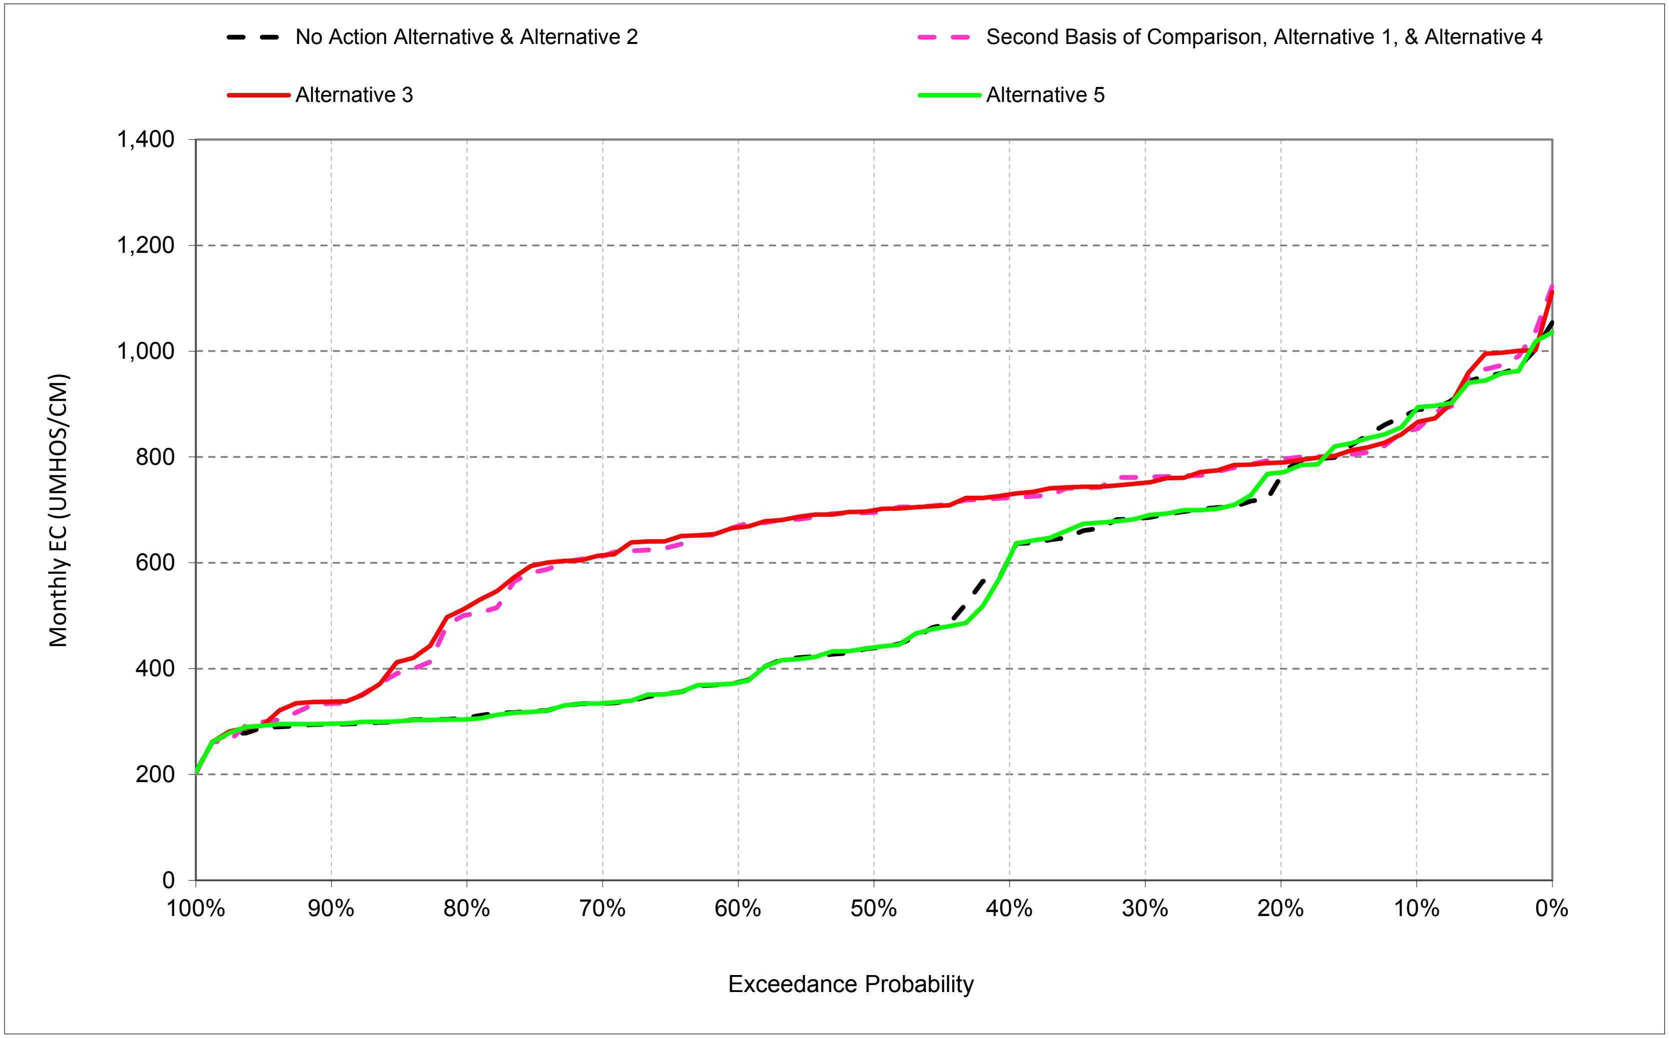
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.2. Banks Pumping Plant Salinity, Electrical Conductivity, November



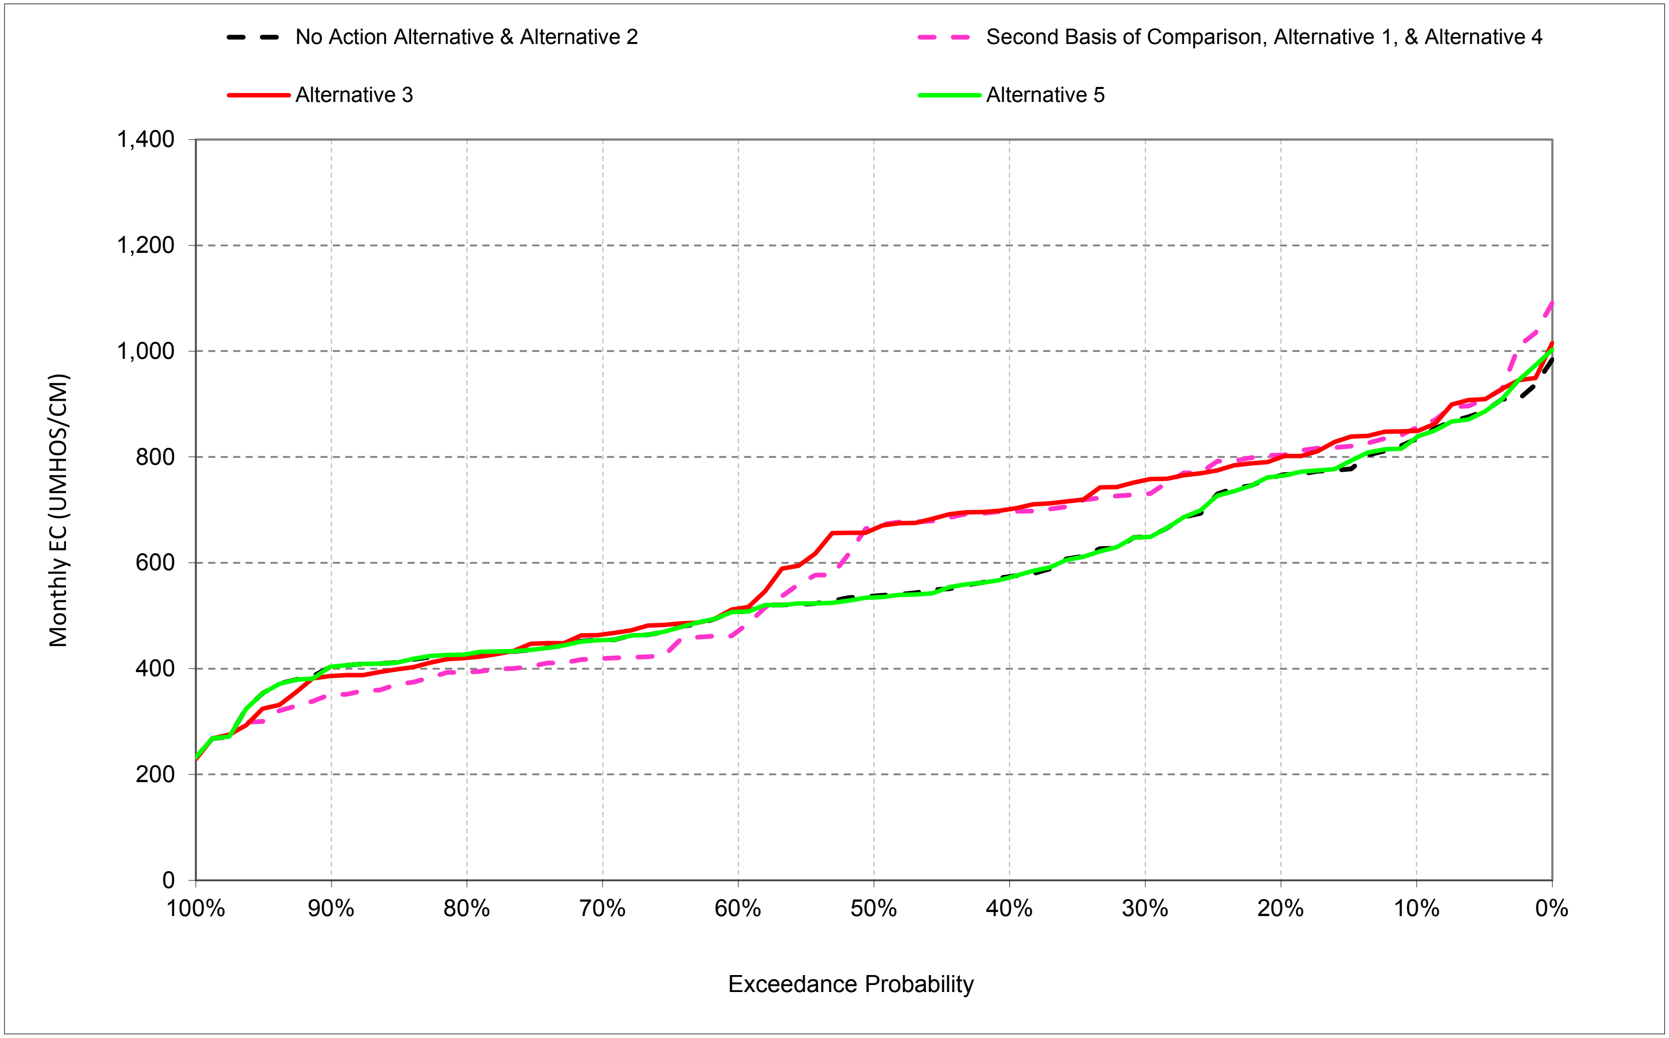
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.3. Banks Pumping Plant Salinity, Electrical Conductivity, December



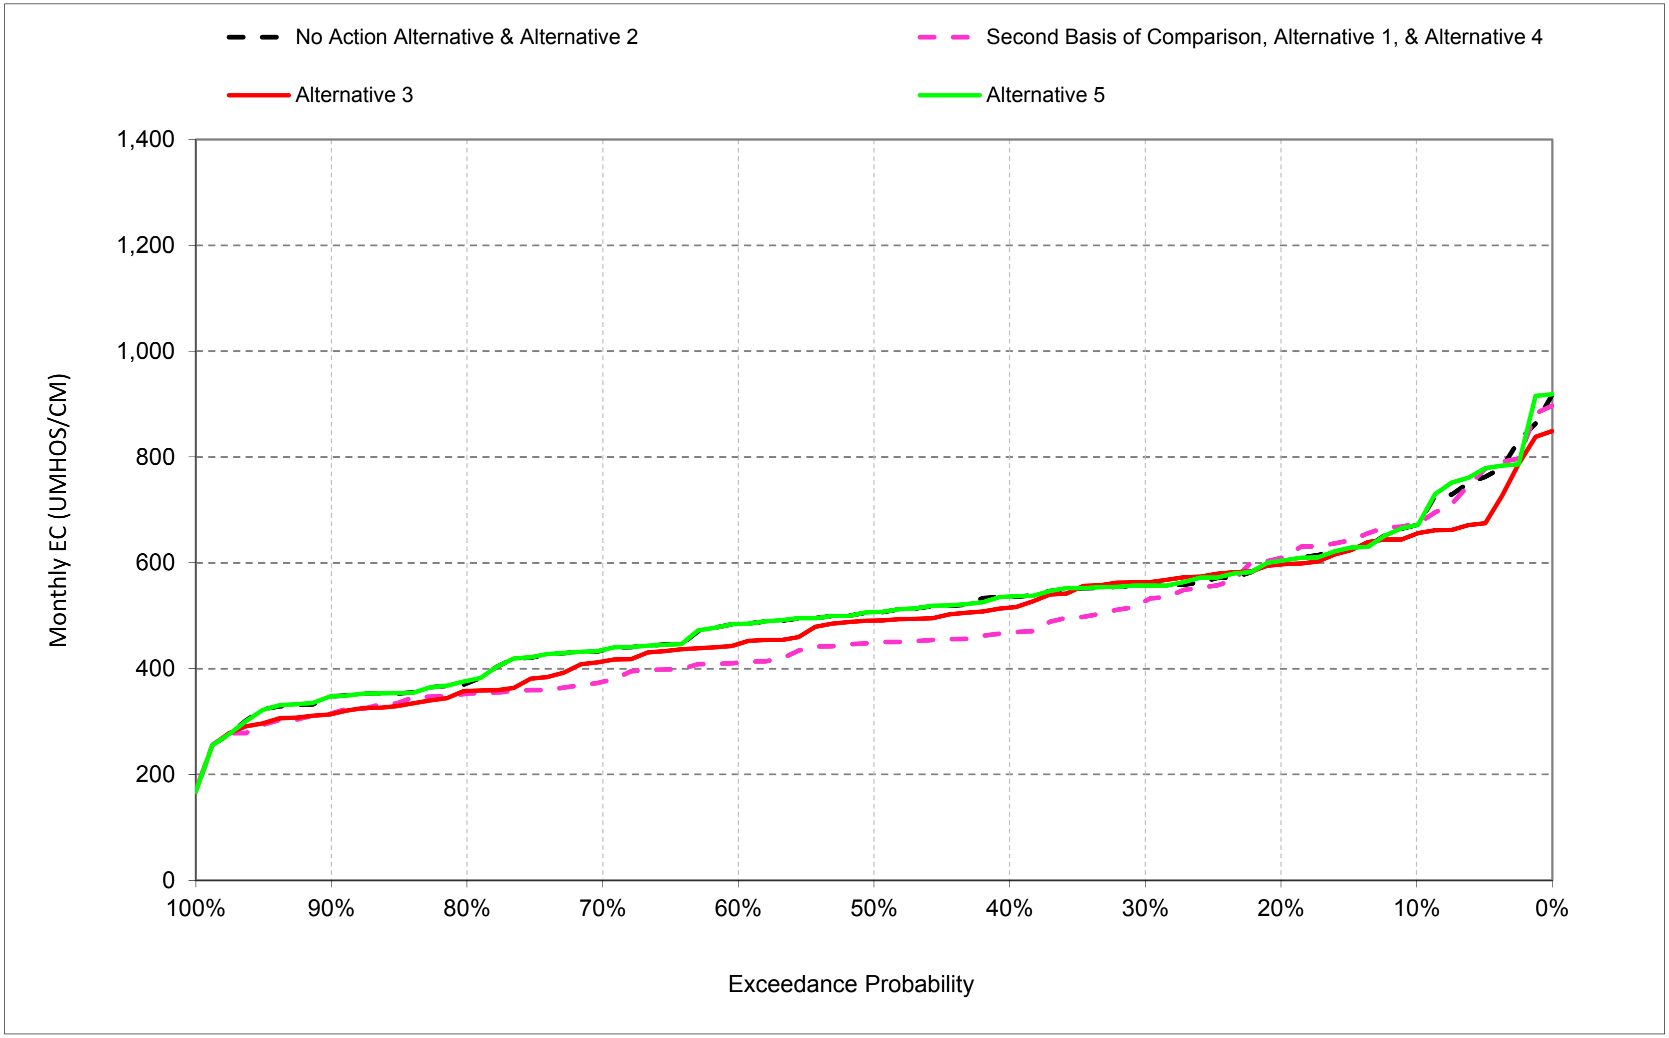
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.4. Banks Pumping Plant Salinity, Electrical Conductivity, January



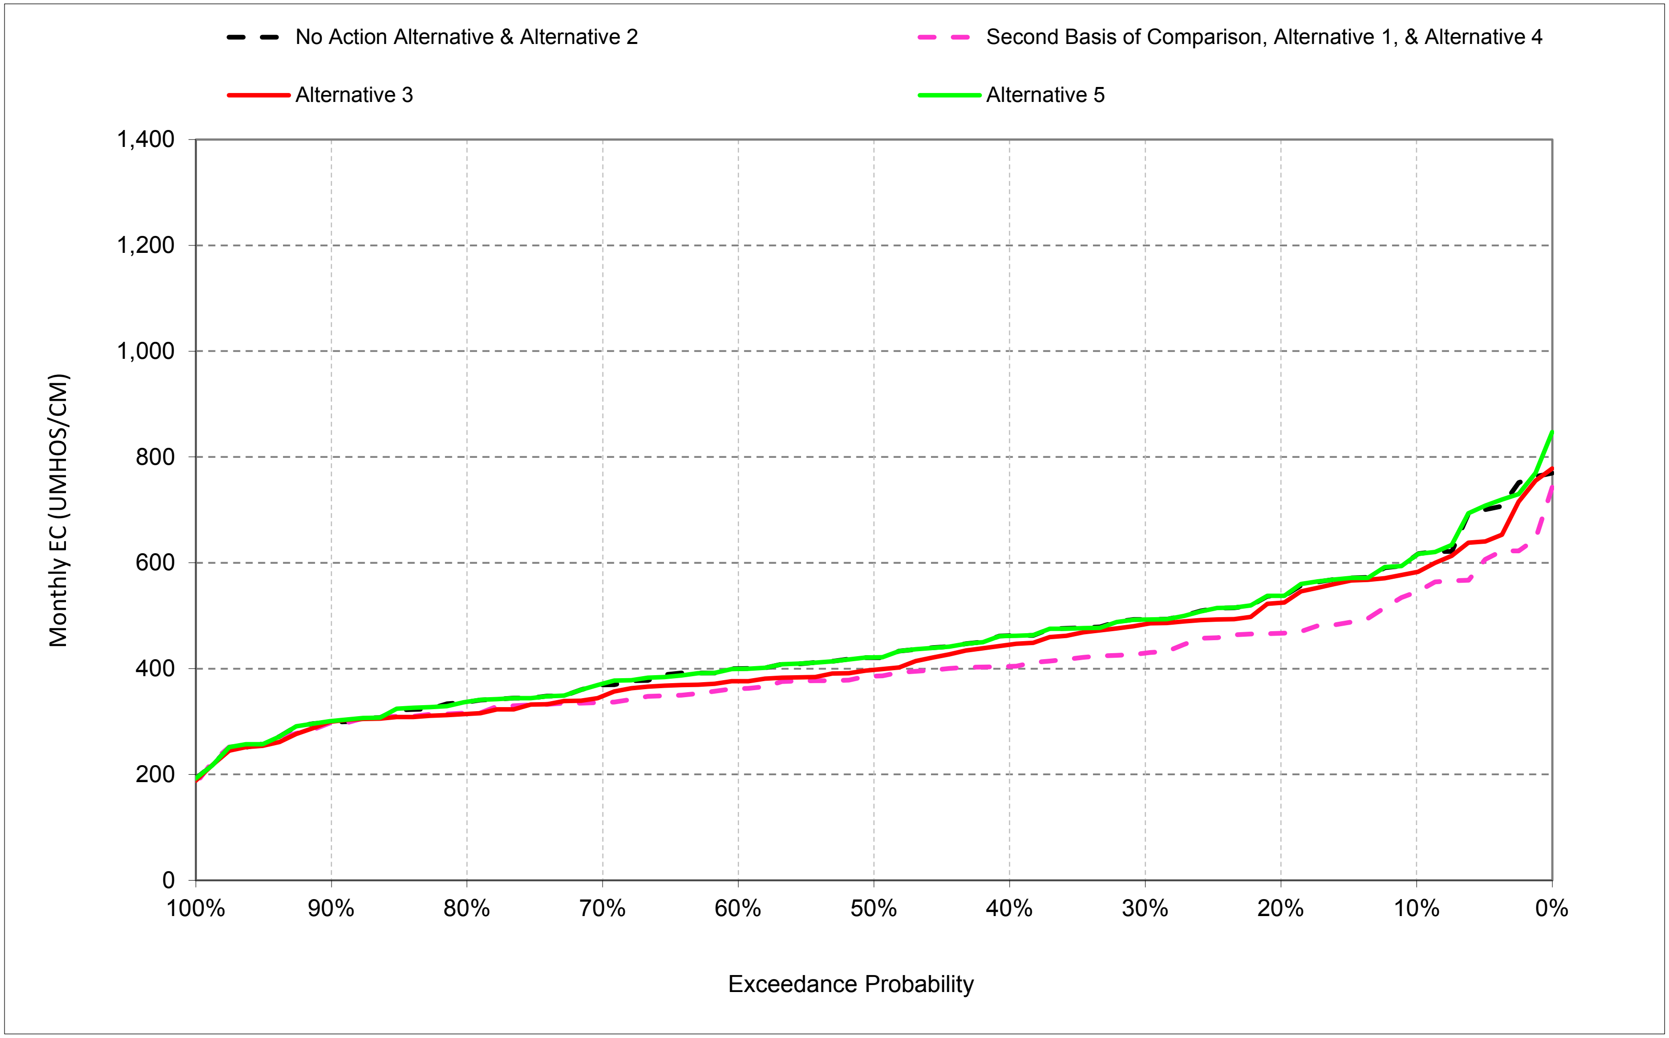
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.5. Banks Pumping Plant Salinity, Electrical Conductivity, February



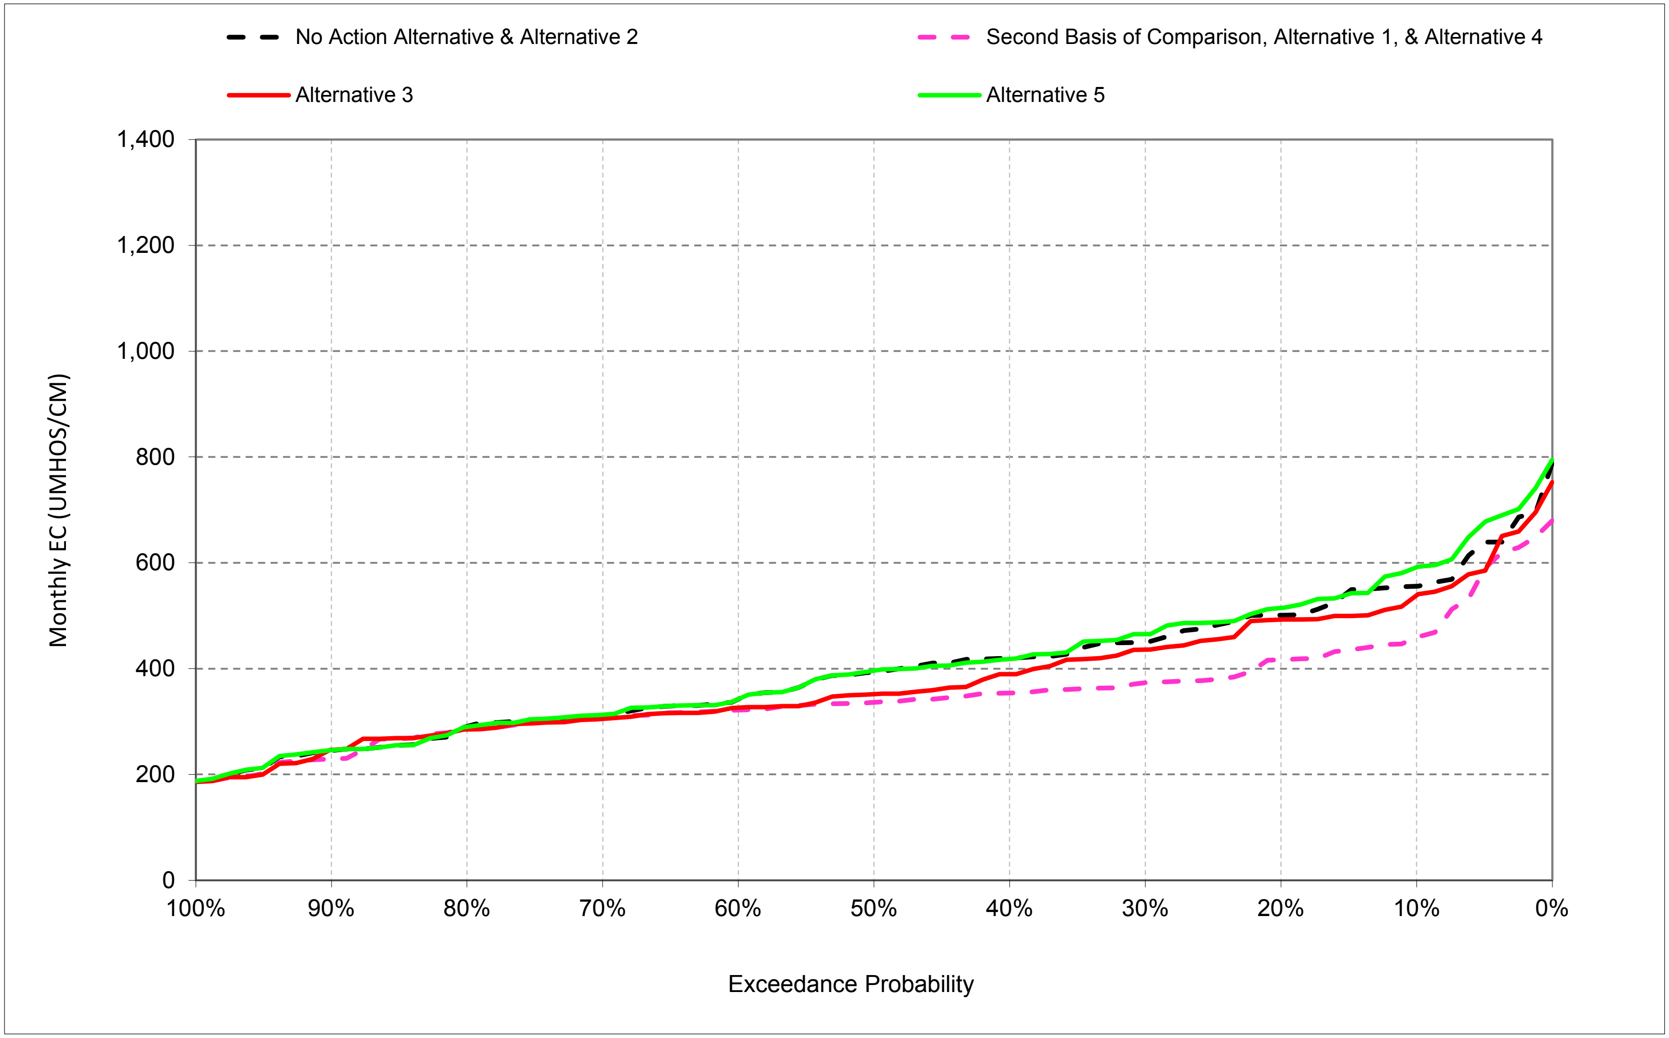
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.6. Banks Pumping Plant Salinity, Electrical Conductivity, March



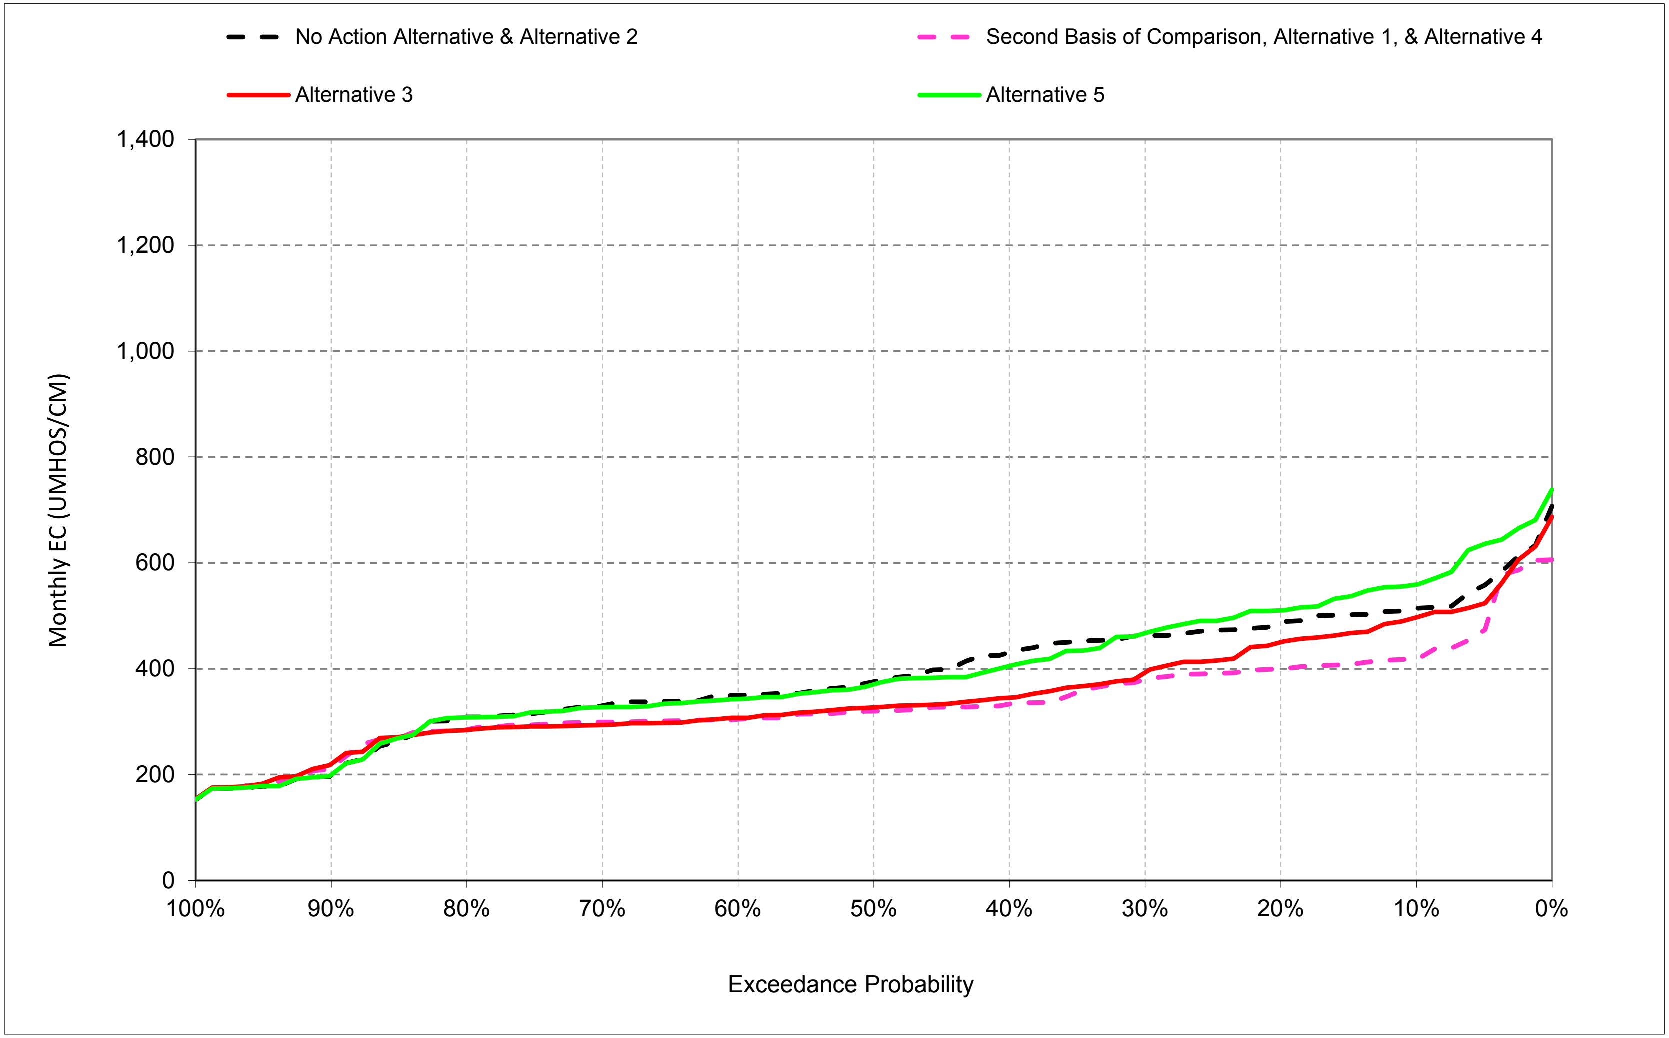
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.7. Banks Pumping Plant Salinity, Electrical Conductivity, April



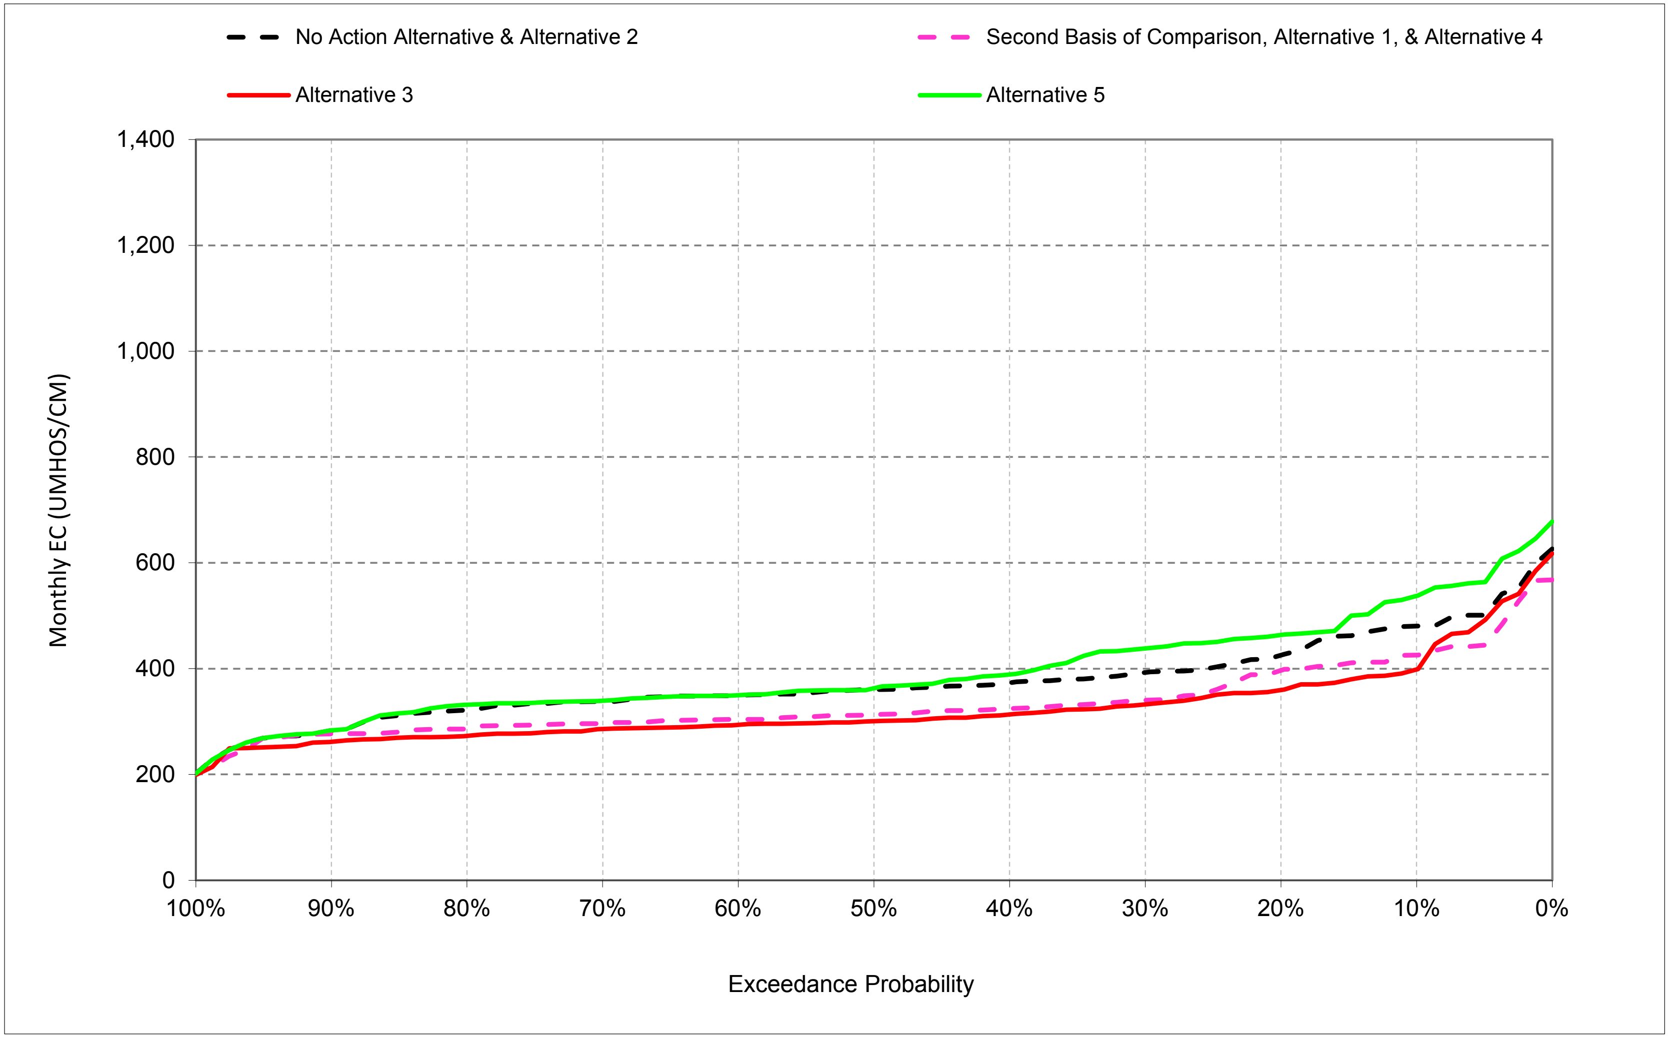
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.8. Banks Pumping Plant Salinity, Electrical Conductivity, May



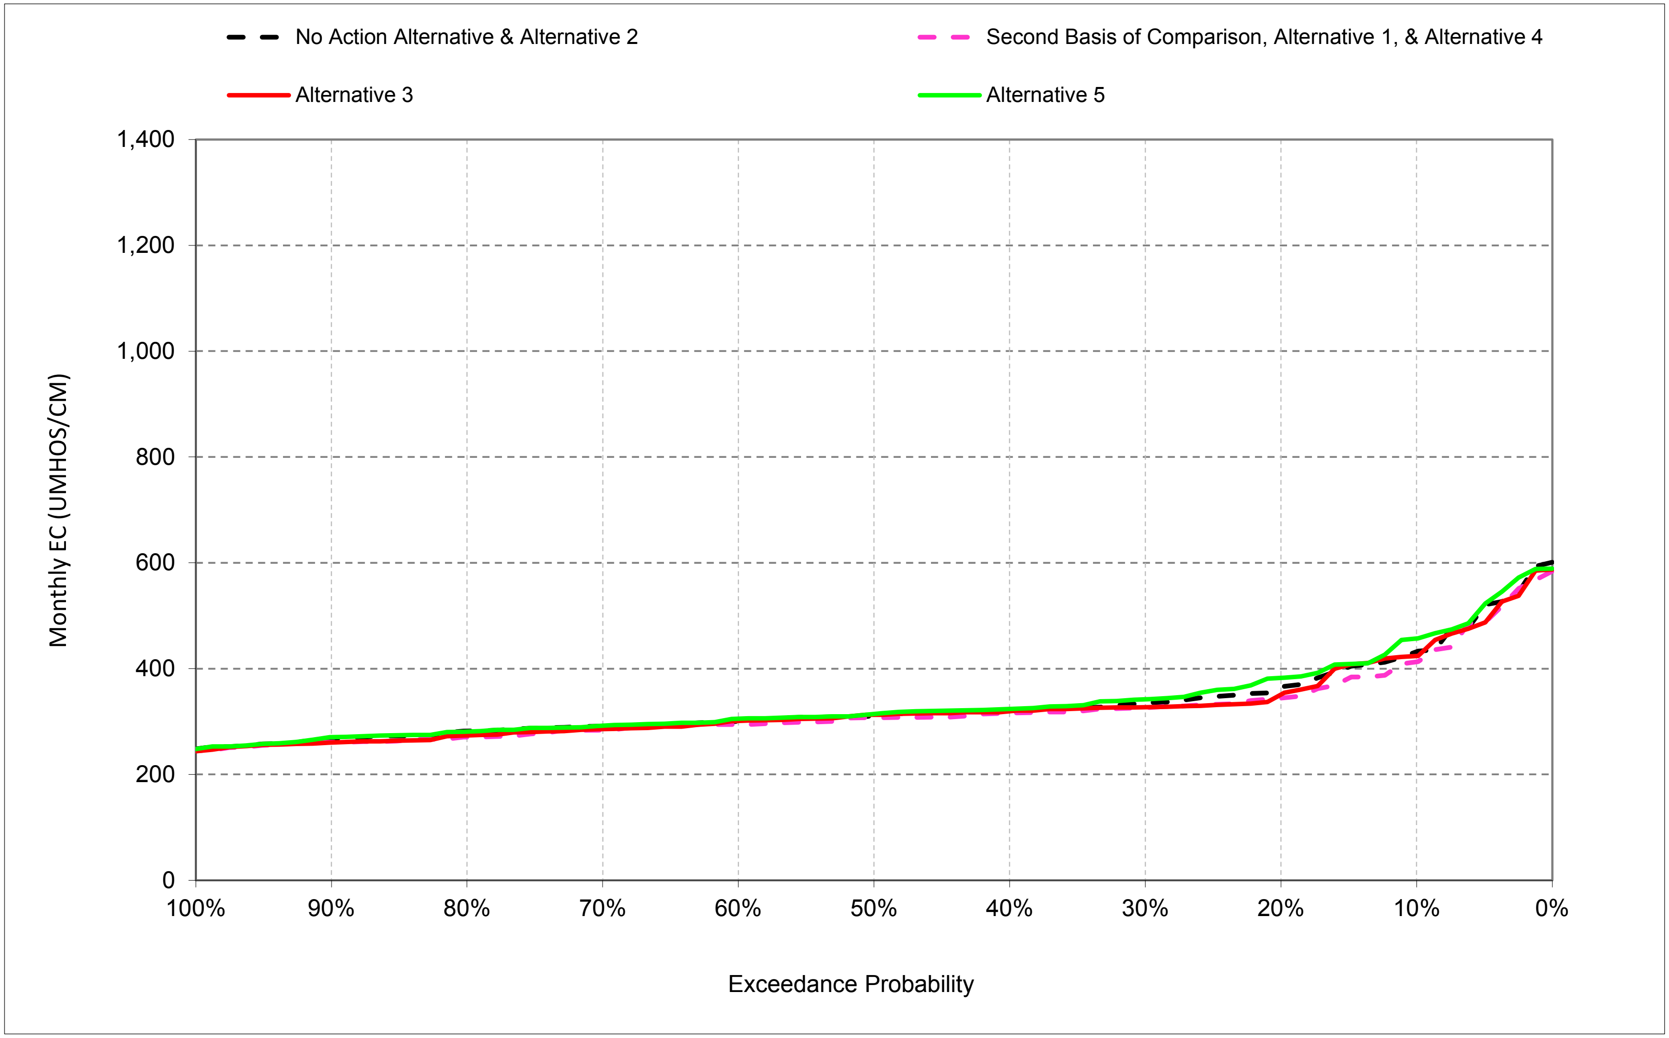
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.9. Banks Pumping Plant Salinity, Electrical Conductivity, June



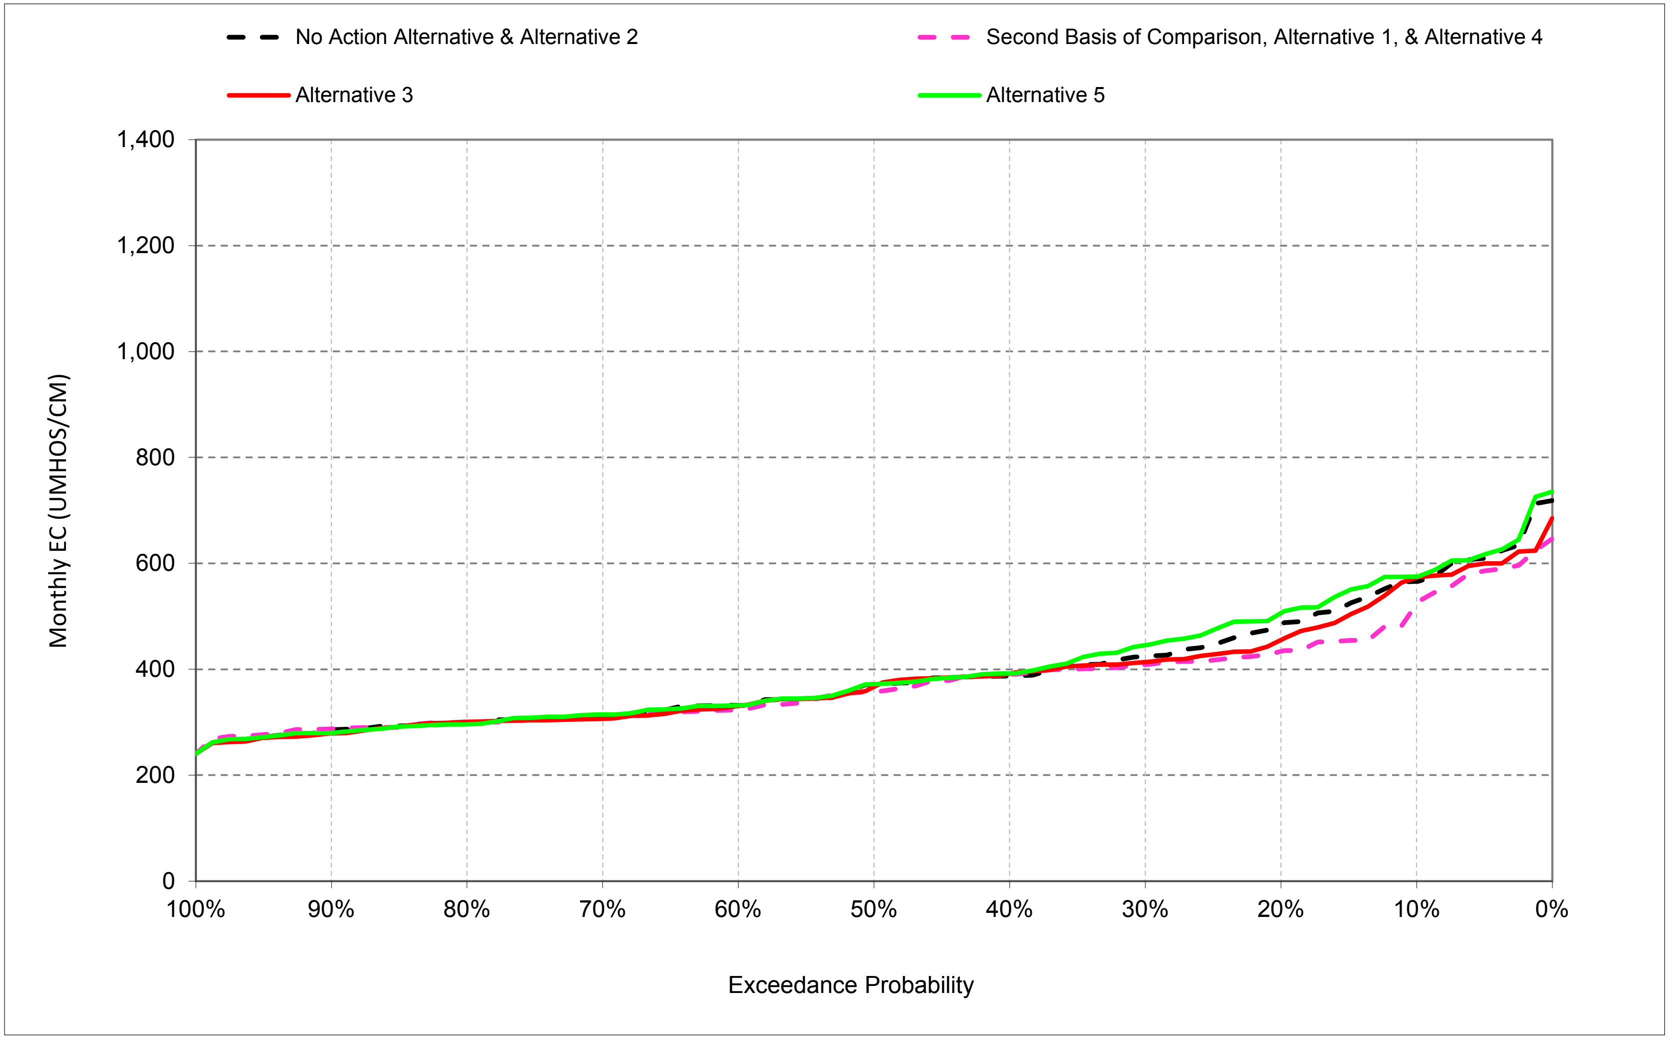
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.10. Banks Pumping Plant Salinity, Electrical Conductivity, July



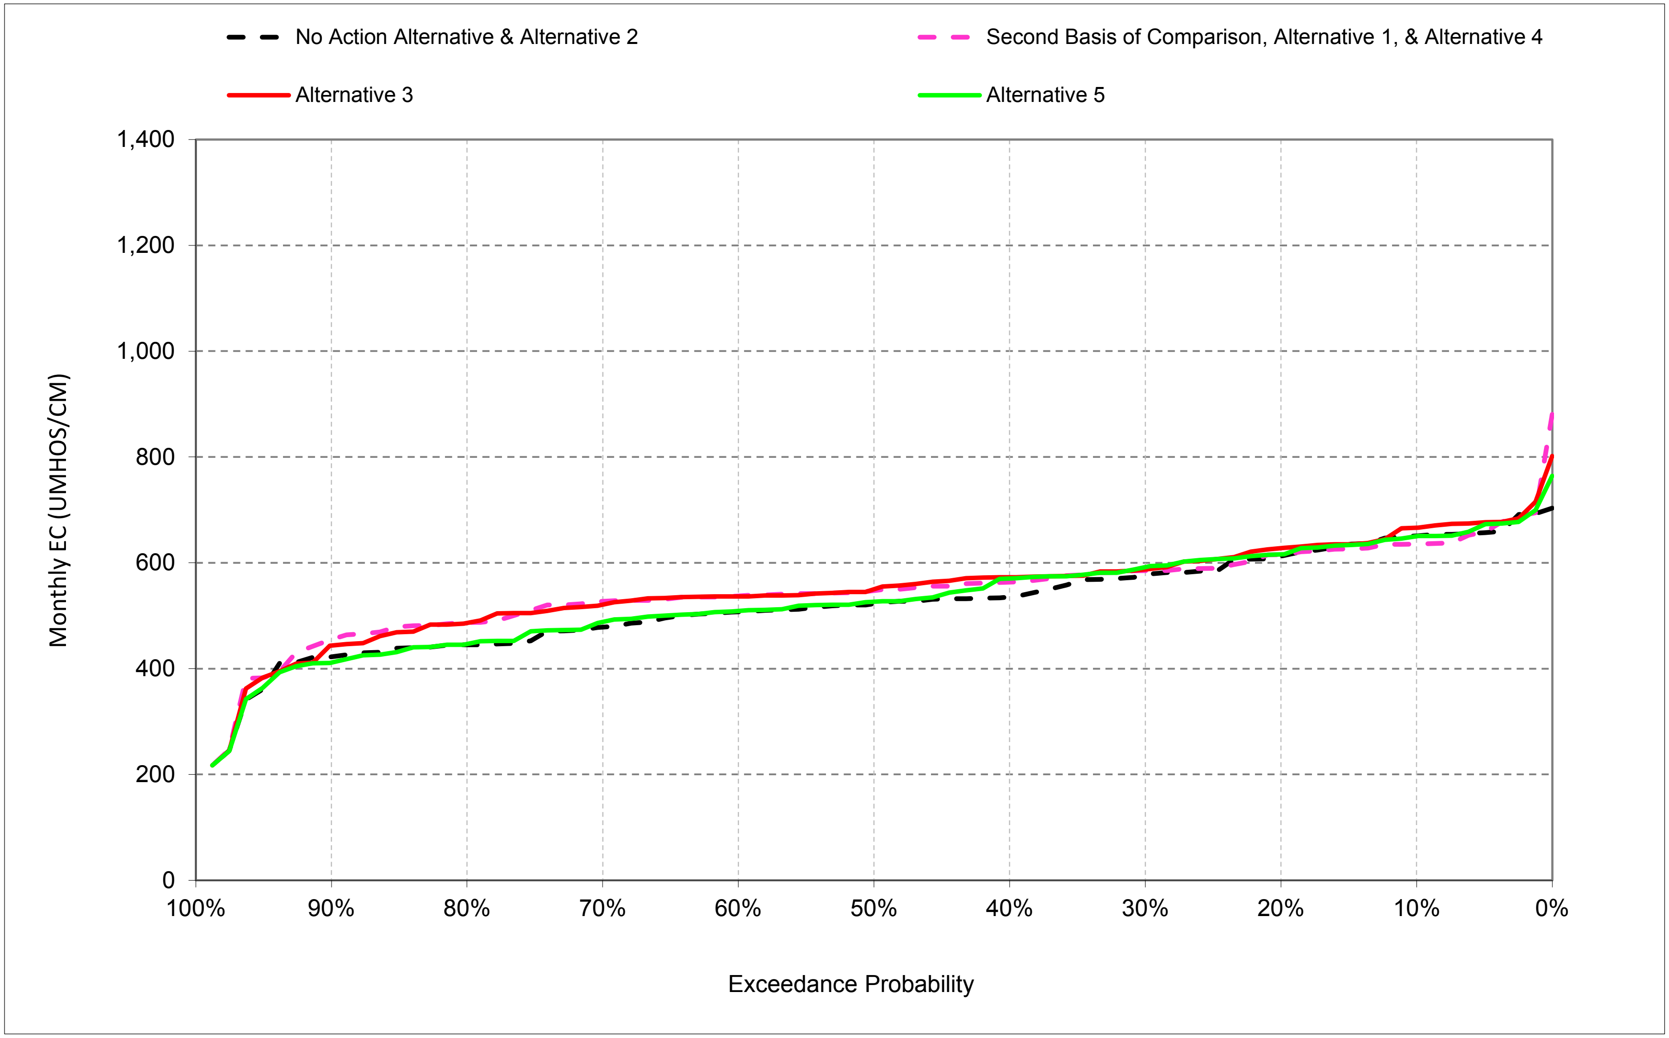
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.11. Banks Pumping Plant Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.8.12. Banks Pumping Plant Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

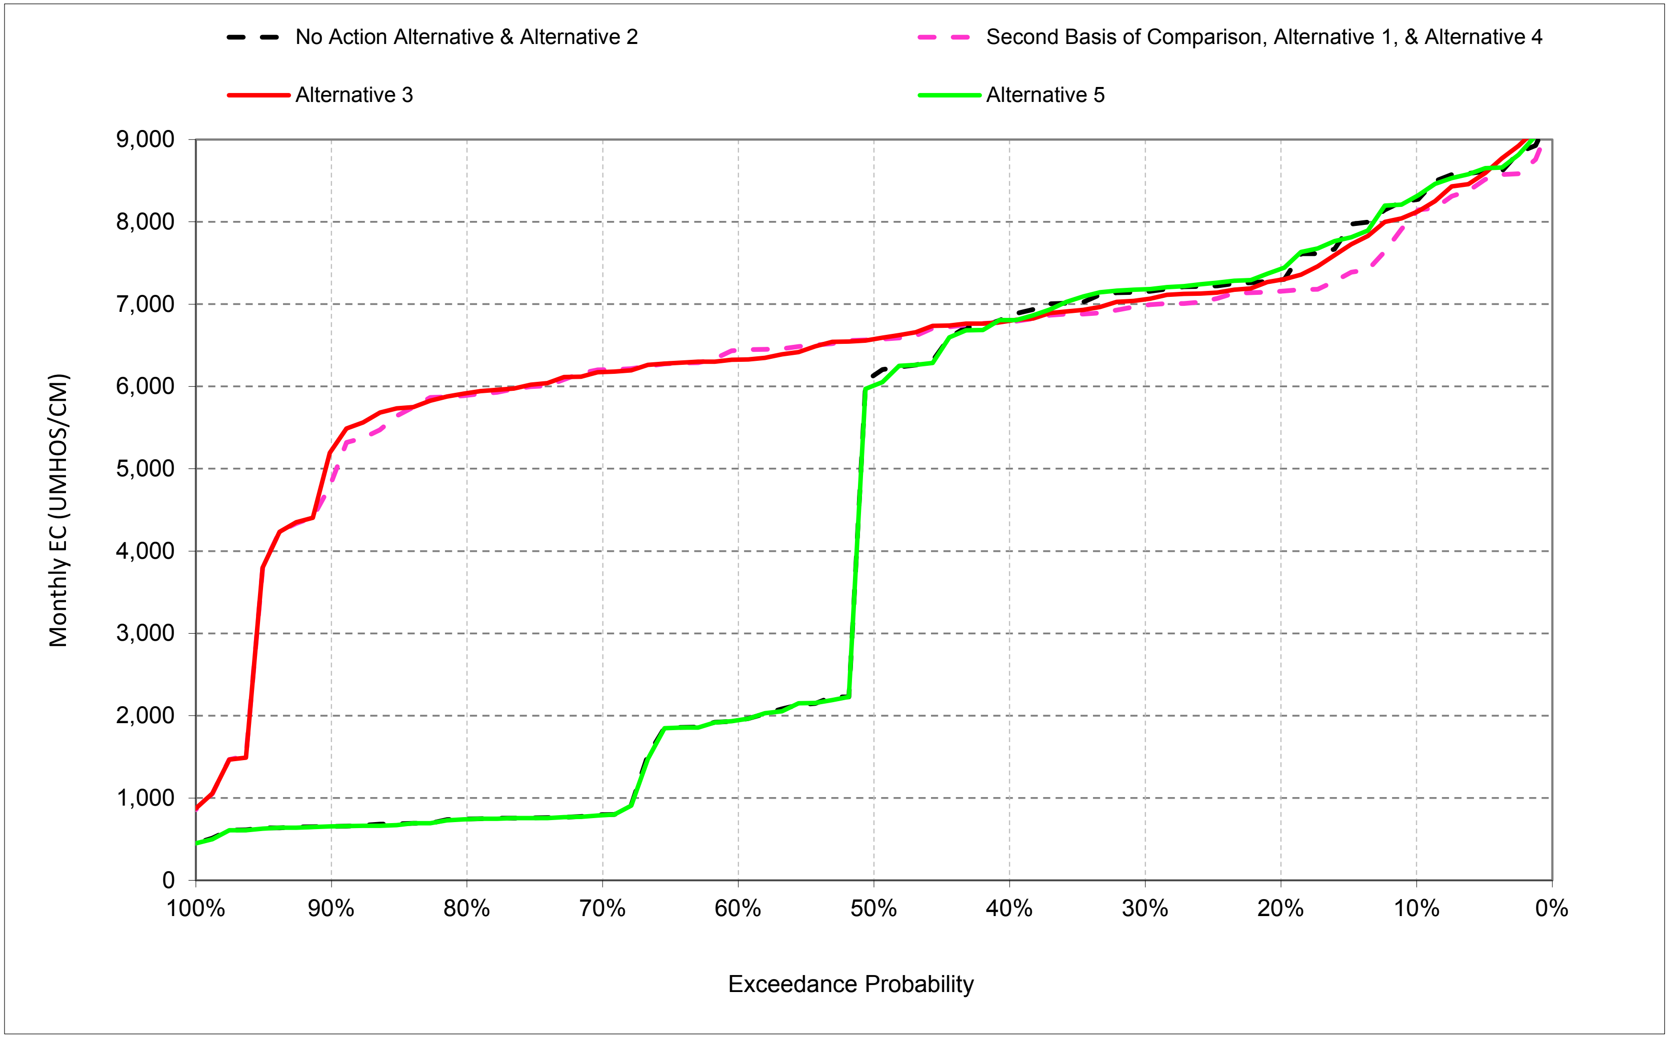
B.9. Antioch Salinity

Figure 6E.B.9.1. Antioch Salinity, Electrical Conductivity, October



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.9.2. Antioch Salinity, Electrical Conductivity, November

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

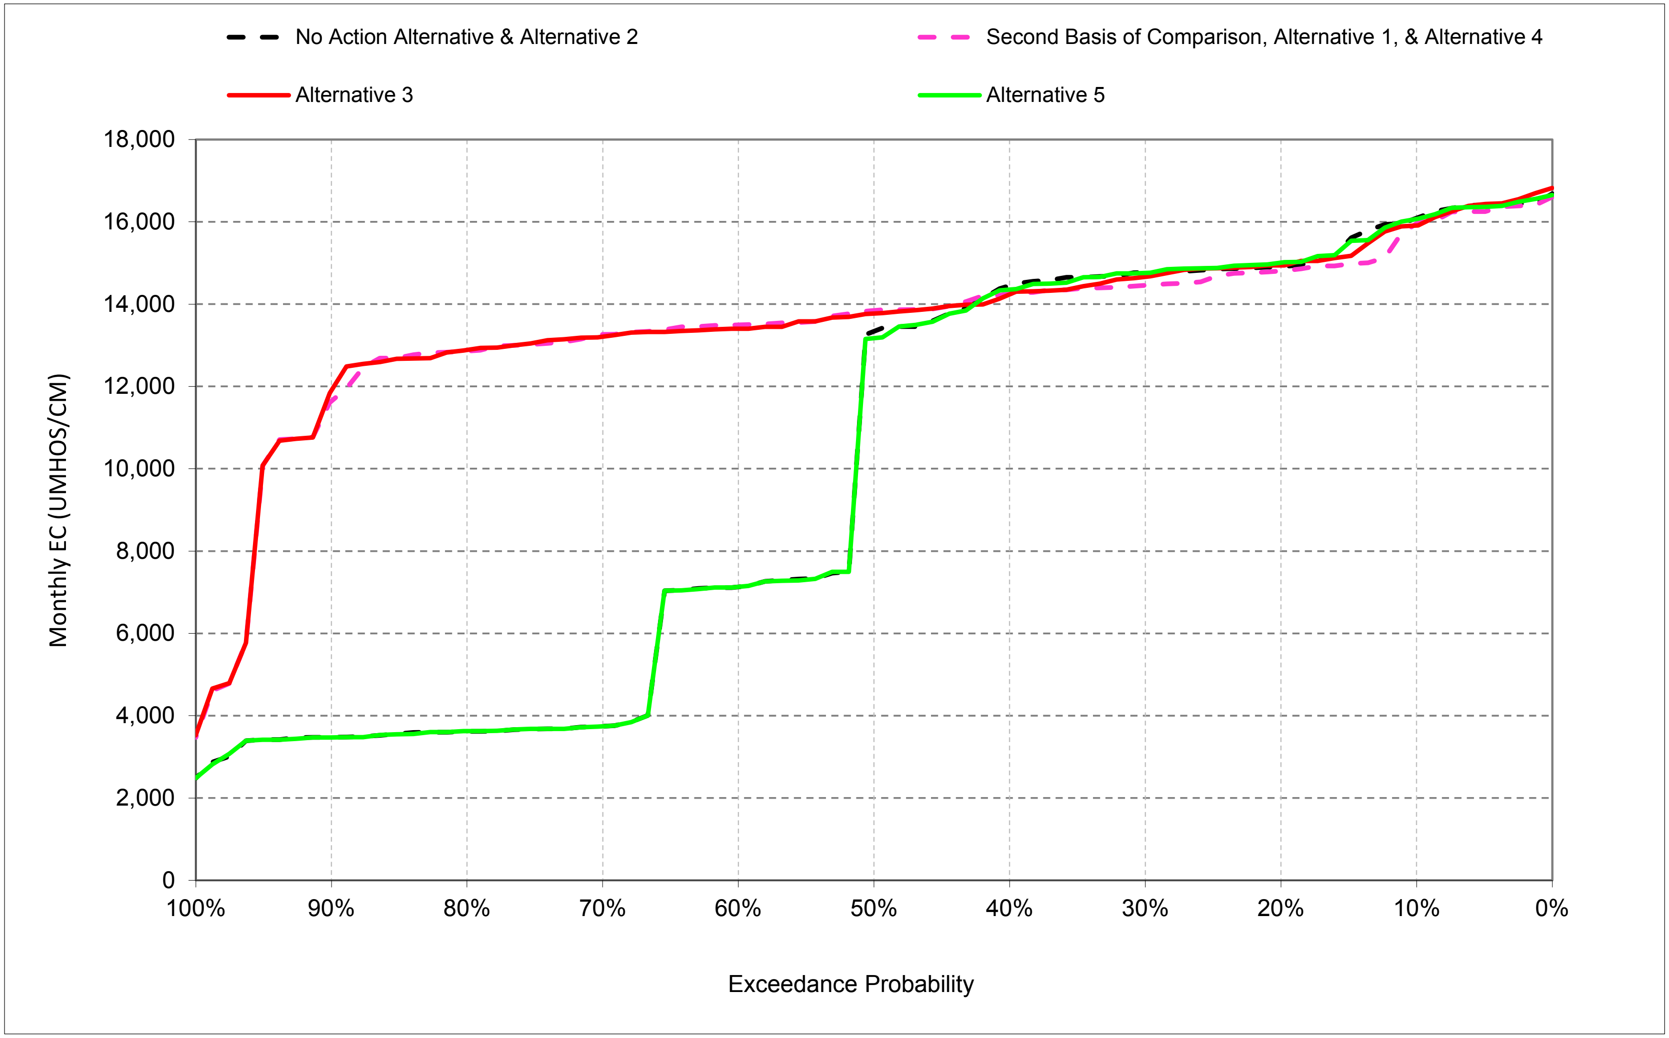
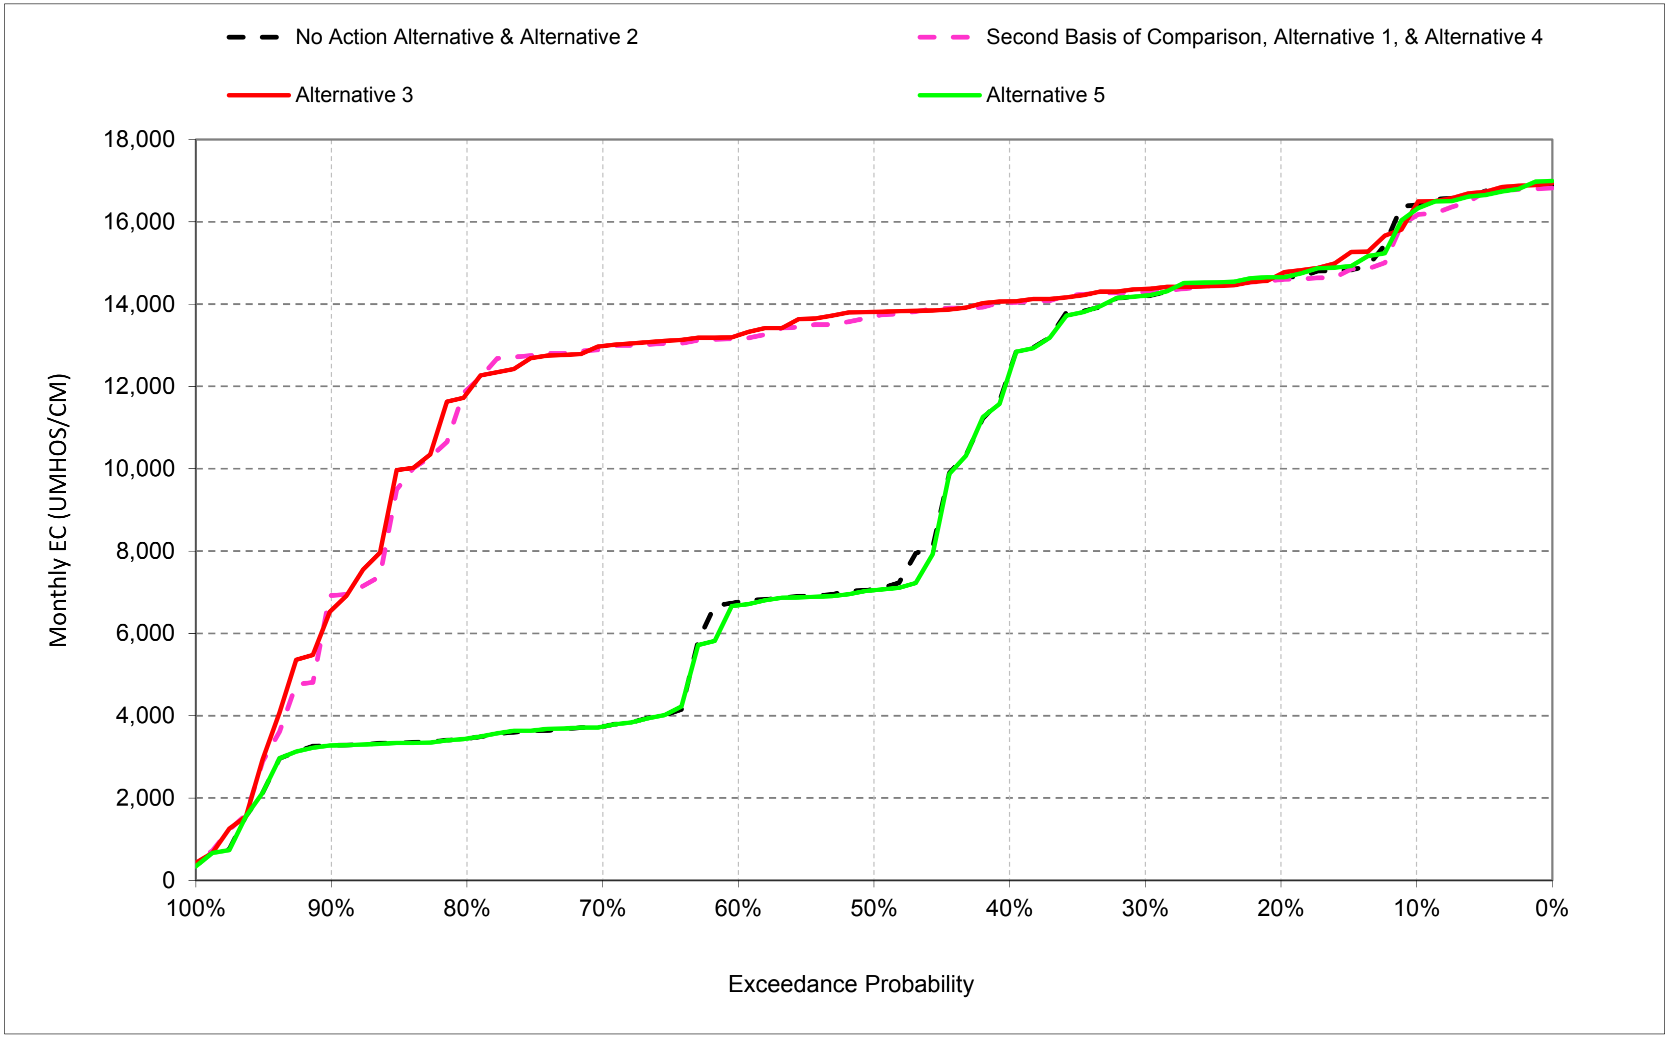
B.10.1 Chipps Island North Channel Salinity

Figure 6E.B.10.1.1. Chipps Island North Channel Salinity, Electrical Conductivity, October



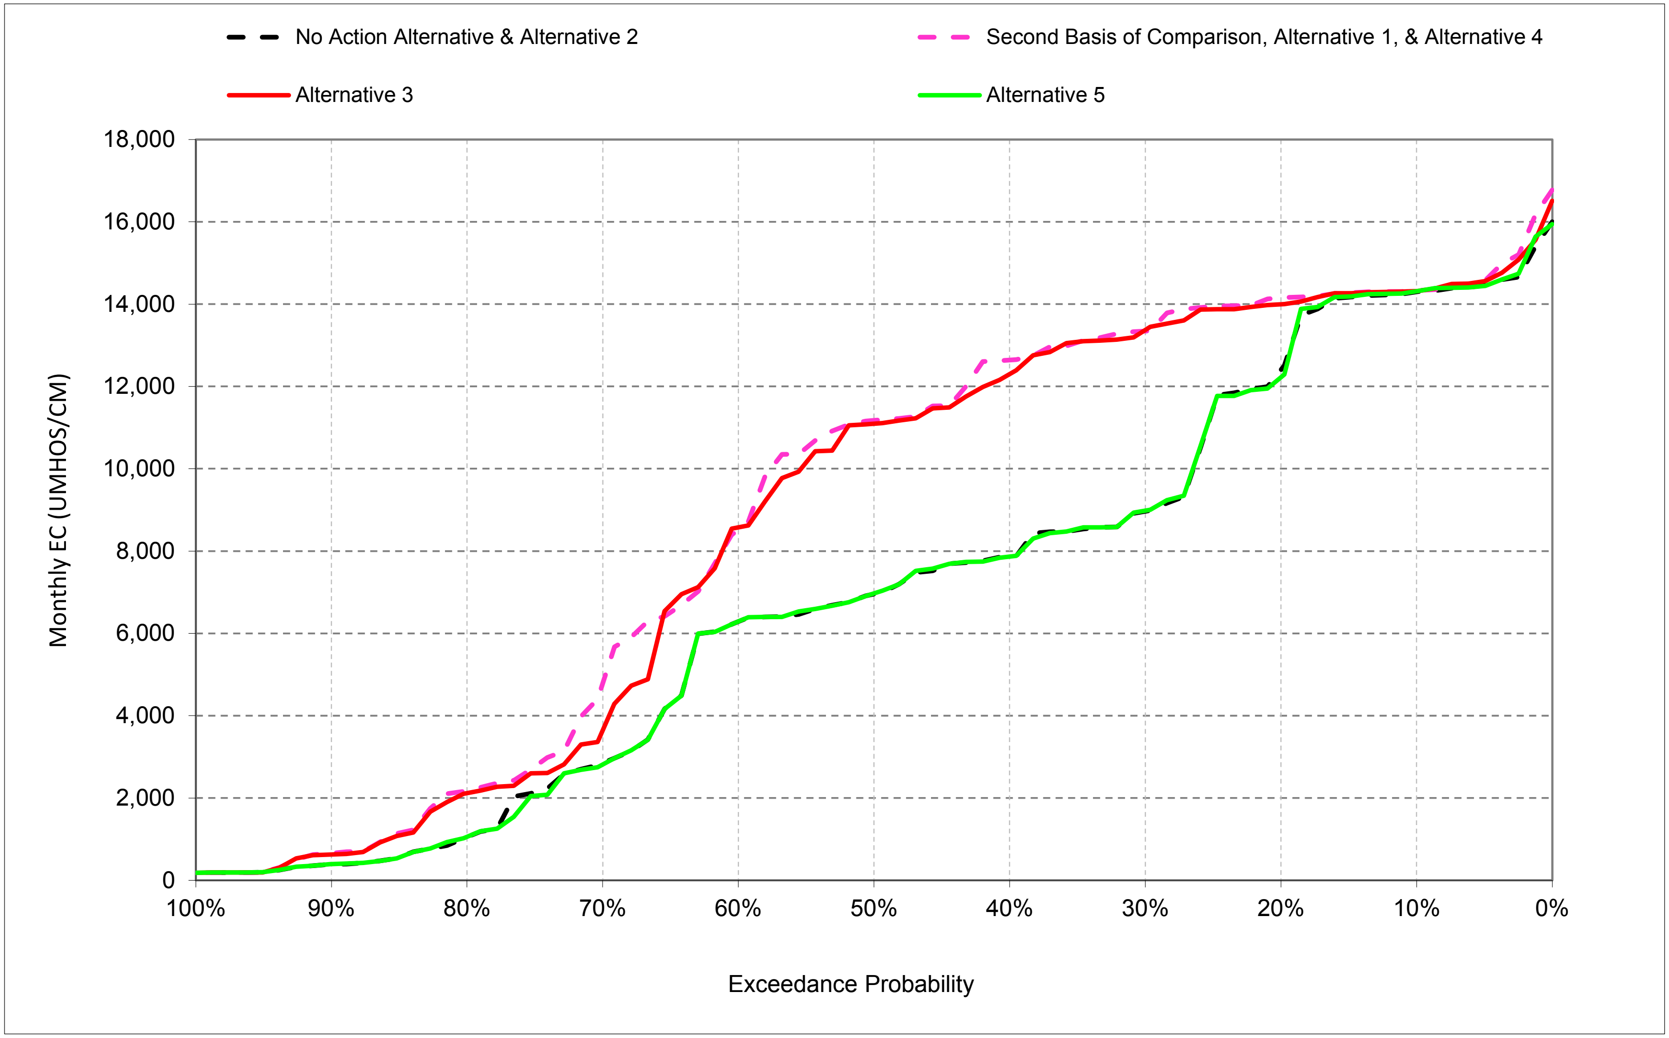
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.2. Chipps Island North Channel Salinity, Electrical Conductivity, November



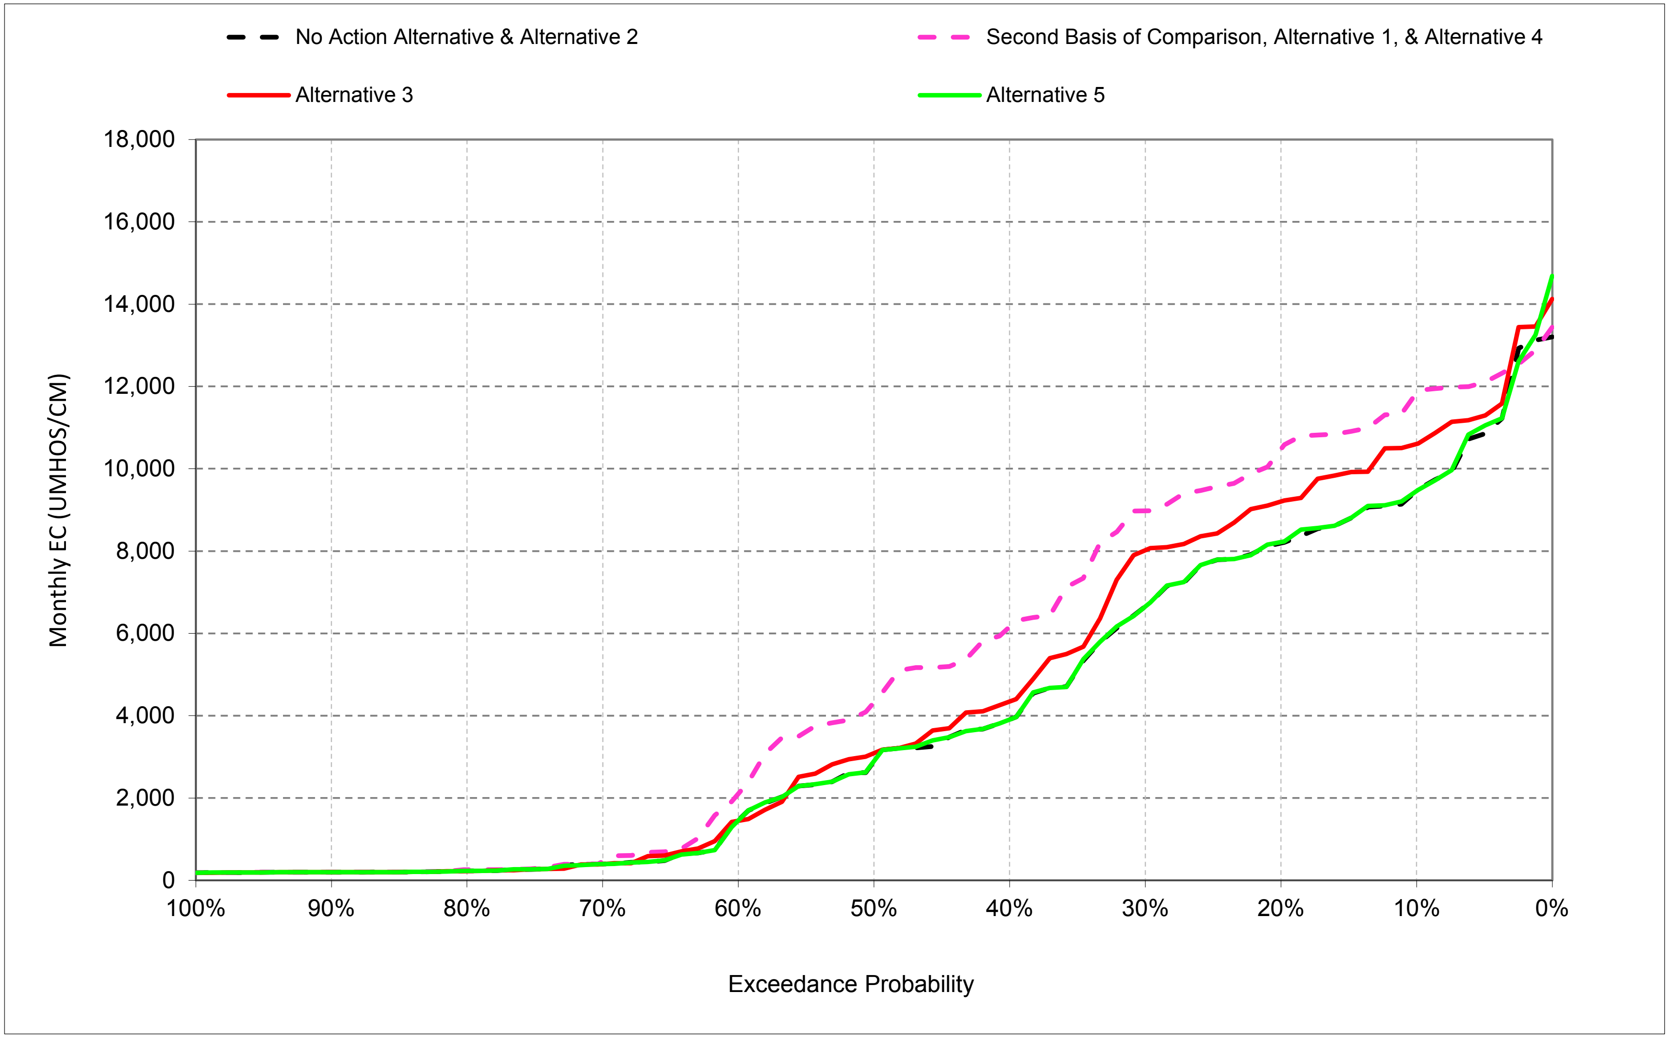
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.3. Chipps Island North Channel Salinity, Electrical Conductivity, December



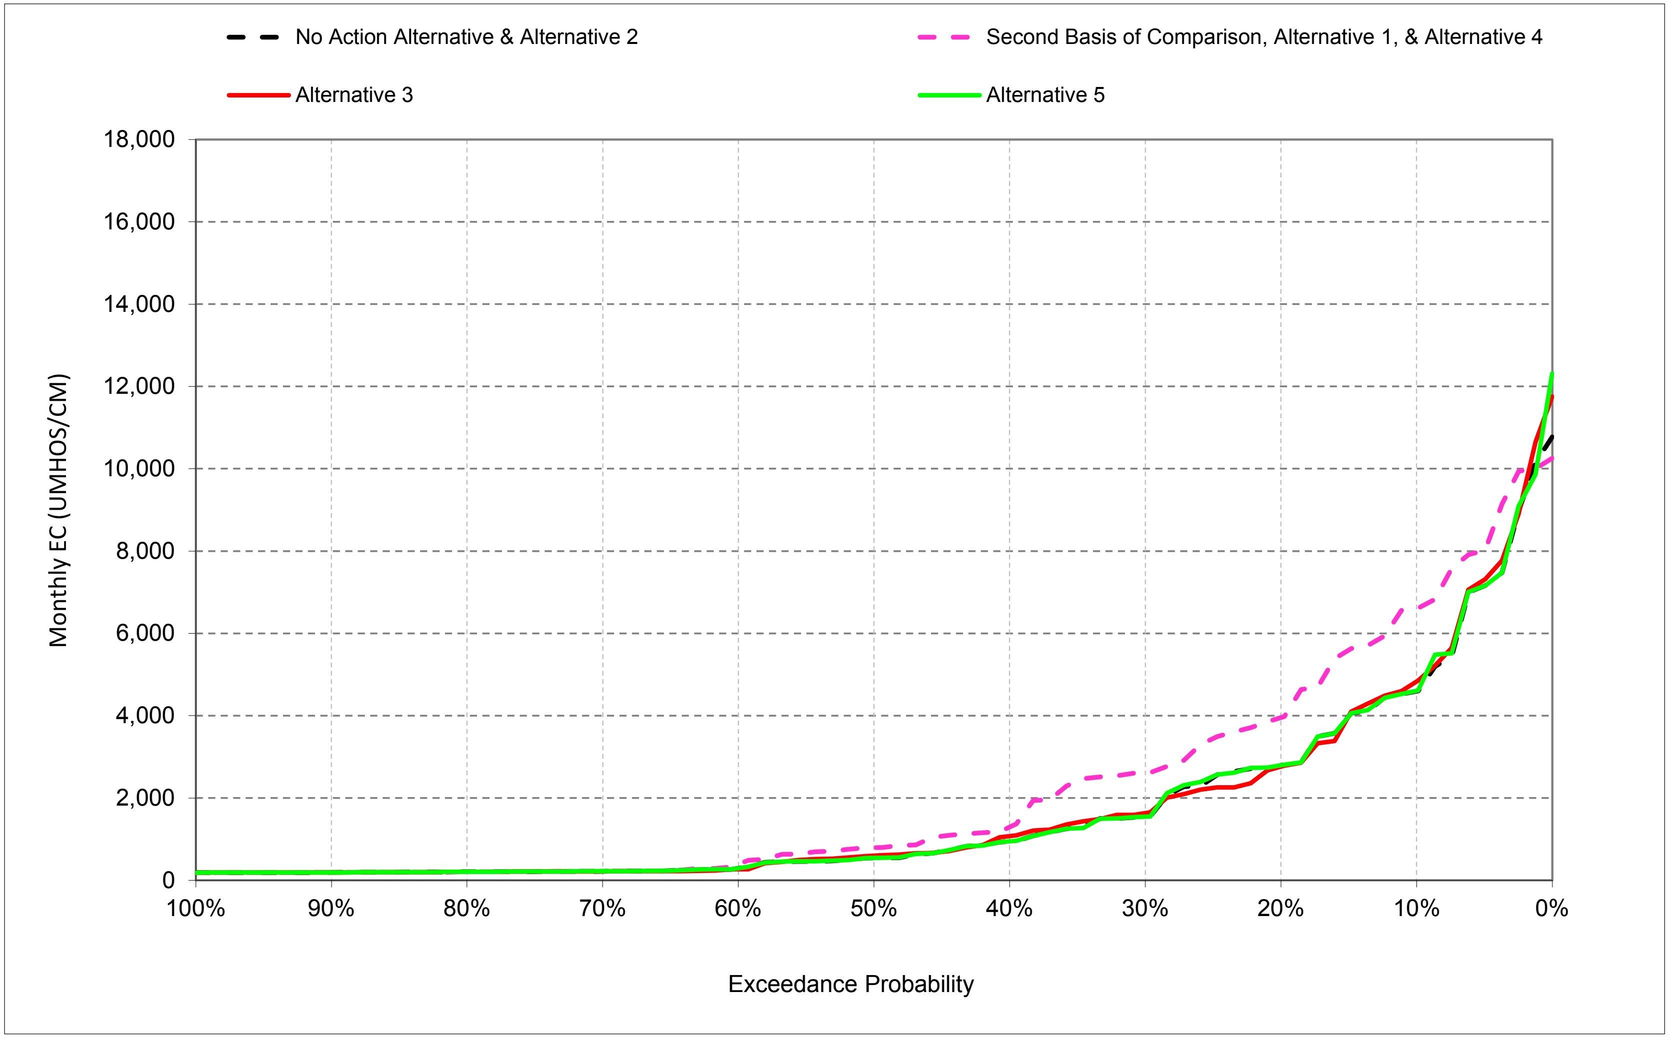
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.4. Chipps Island North Channel Salinity, Electrical Conductivity, January



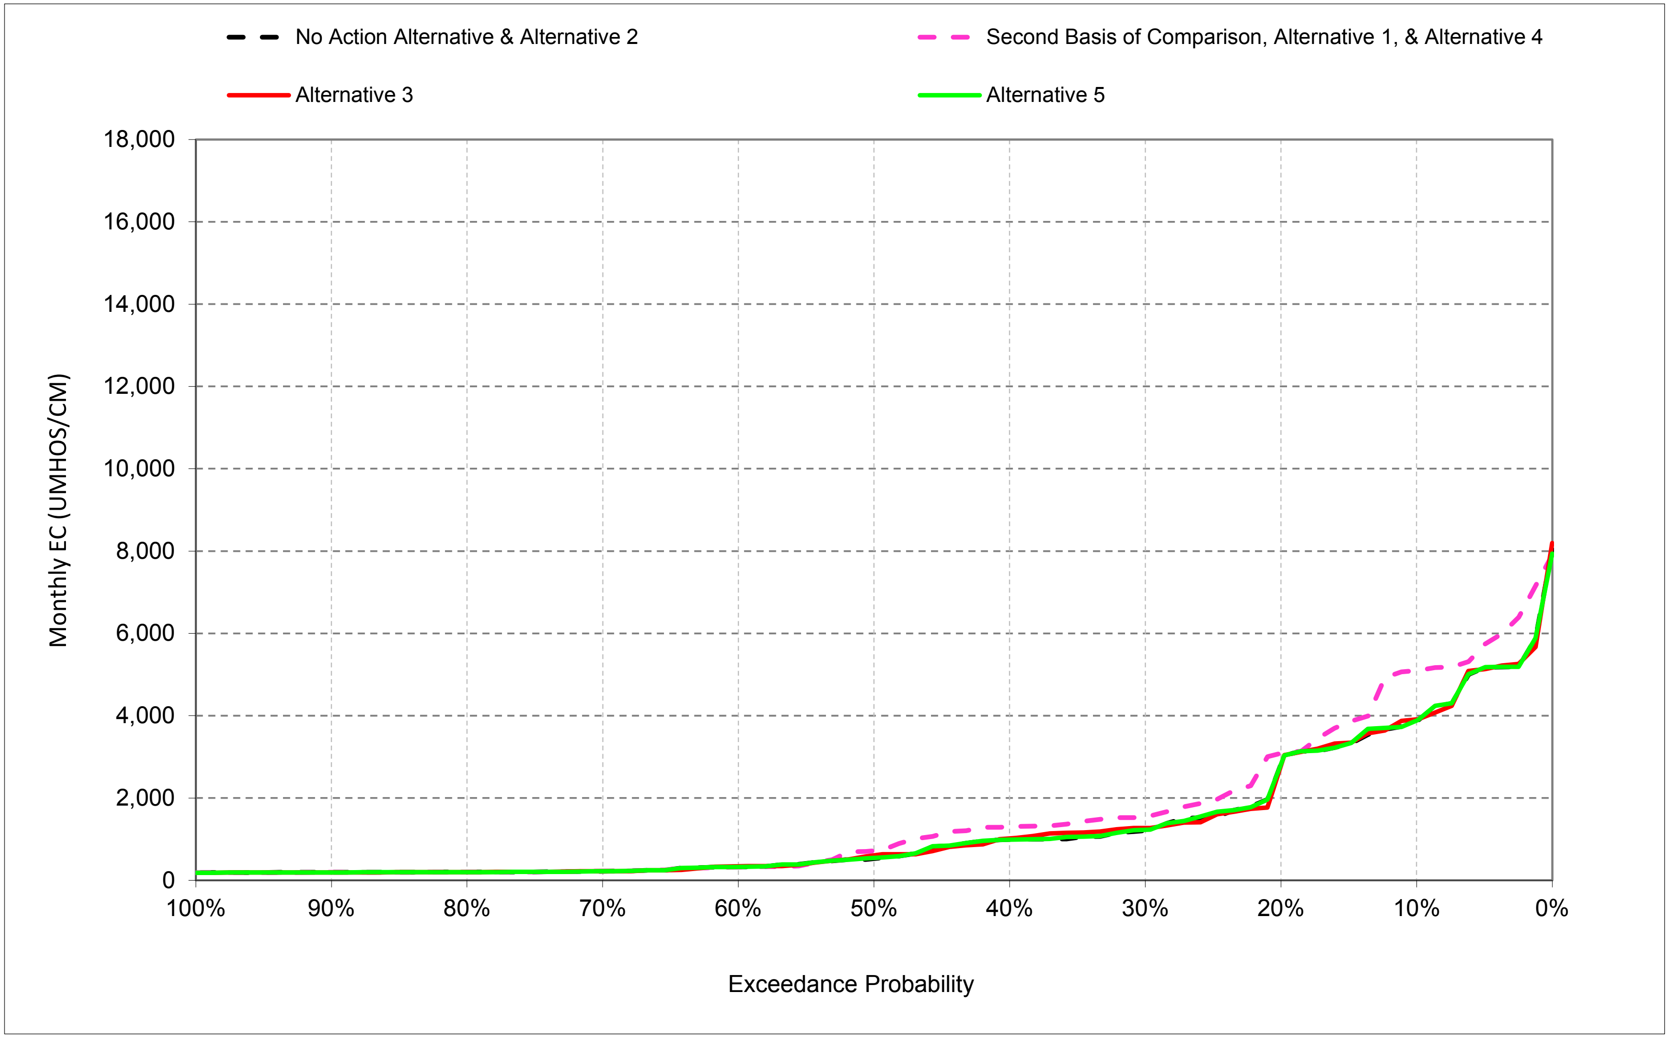
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.5. Chipps Island North Channel Salinity, Electrical Conductivity, February



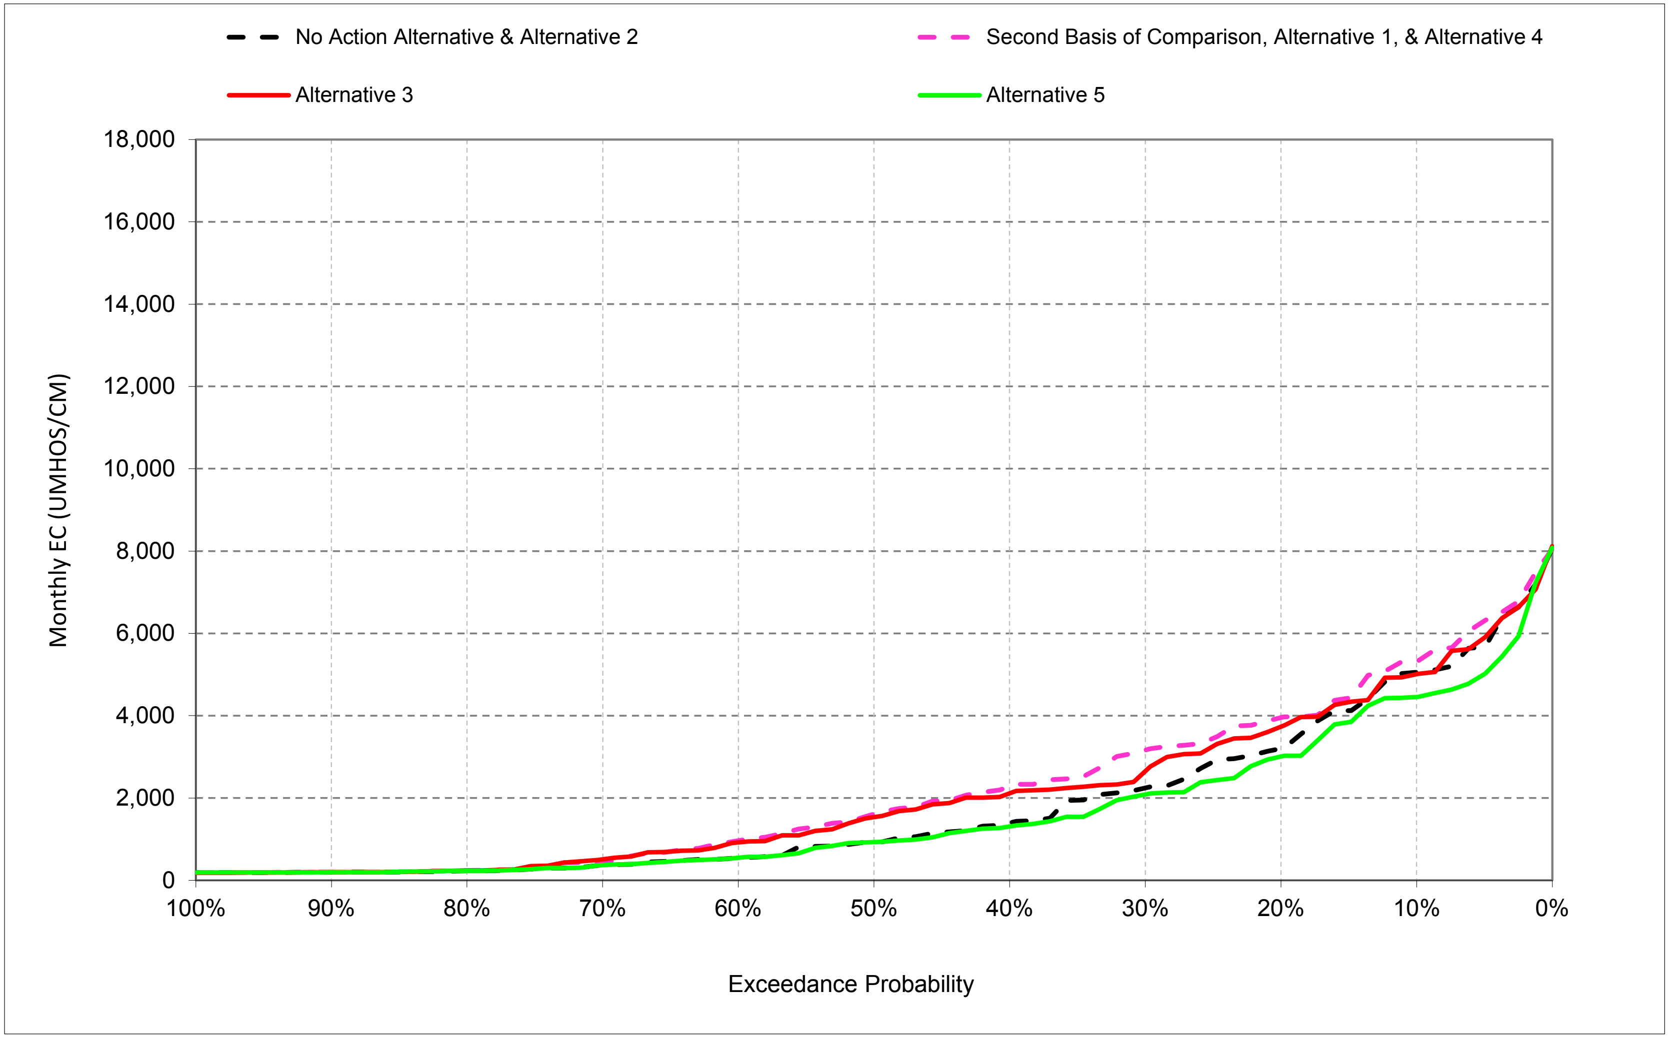
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.6. Chipps Island North Channel Salinity, Electrical Conductivity, March



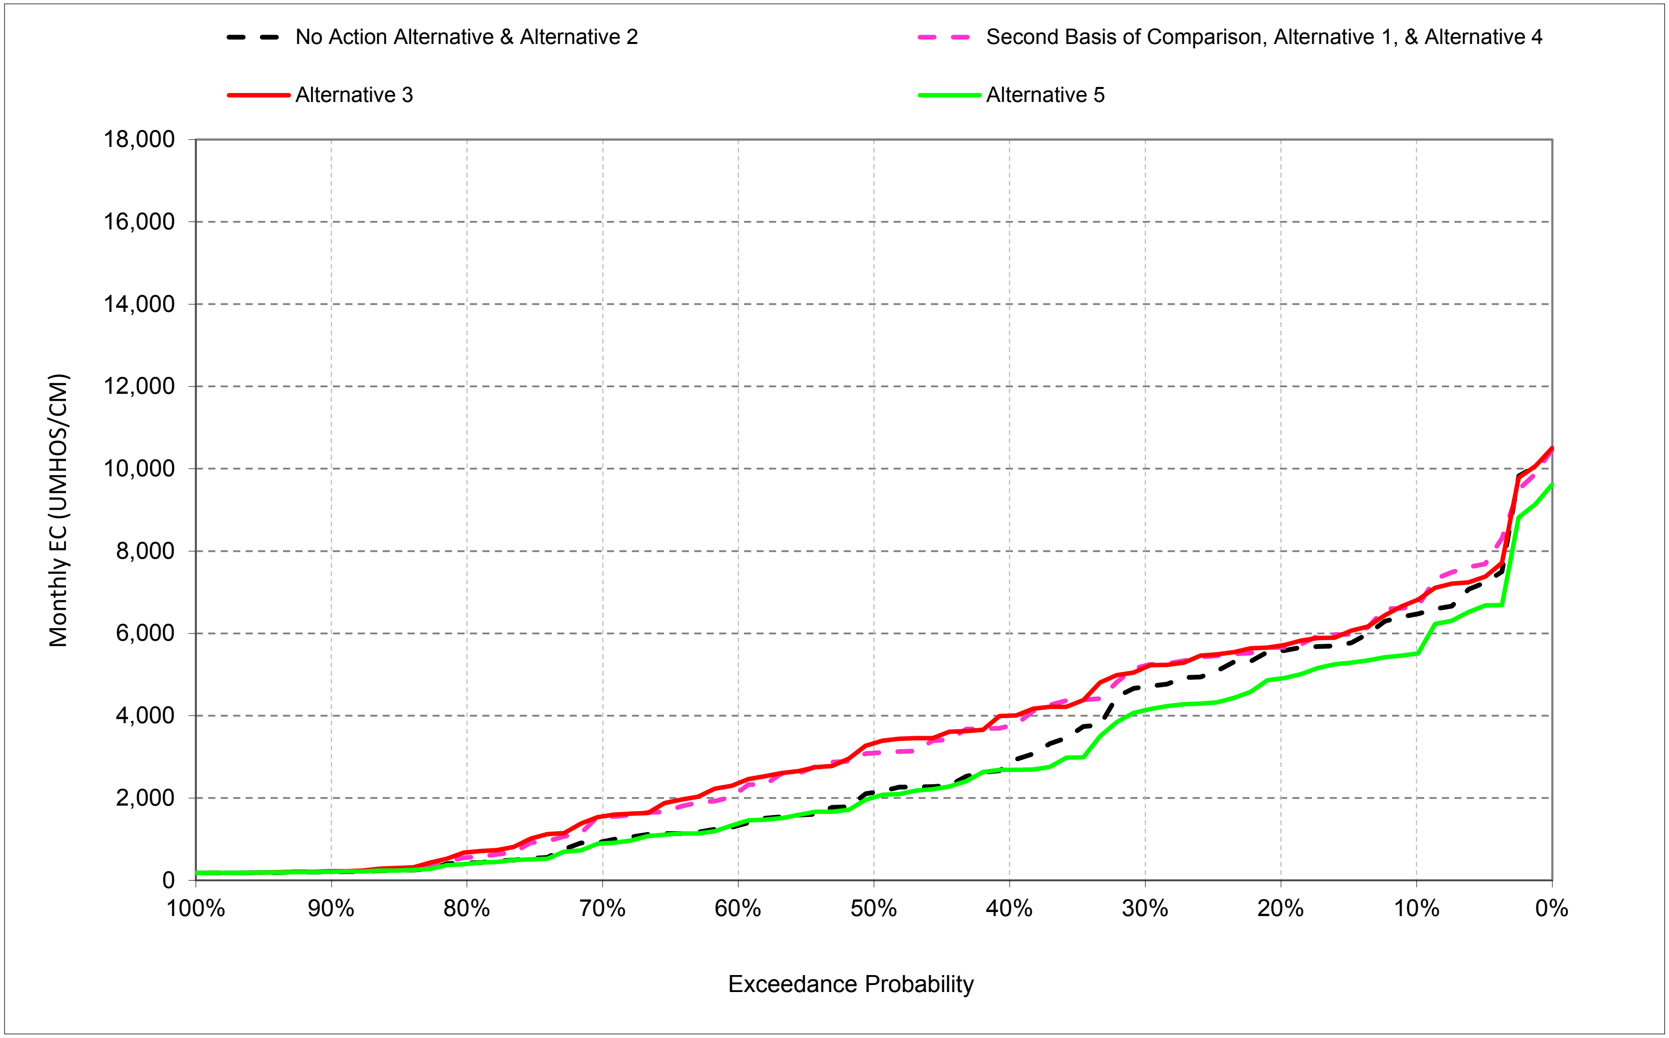
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.7. Chipps Island North Channel Salinity, Electrical Conductivity, April



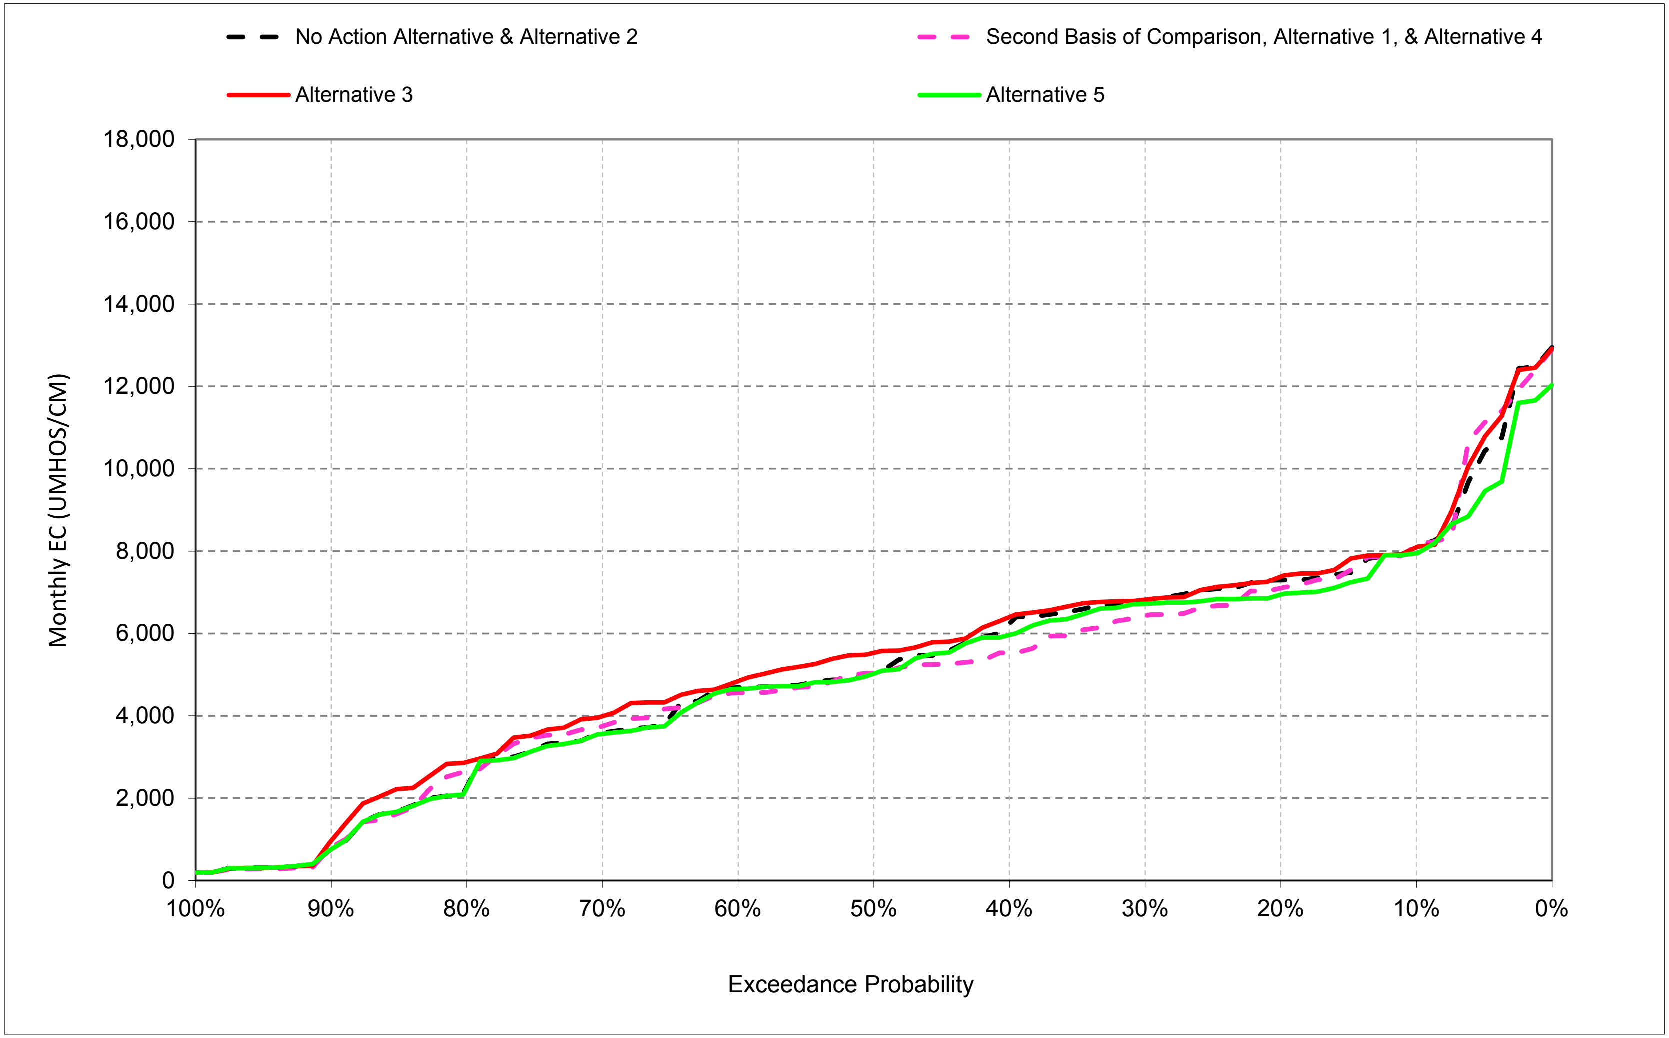
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.8. Chipps Island North Channel Salinity, Electrical Conductivity, May



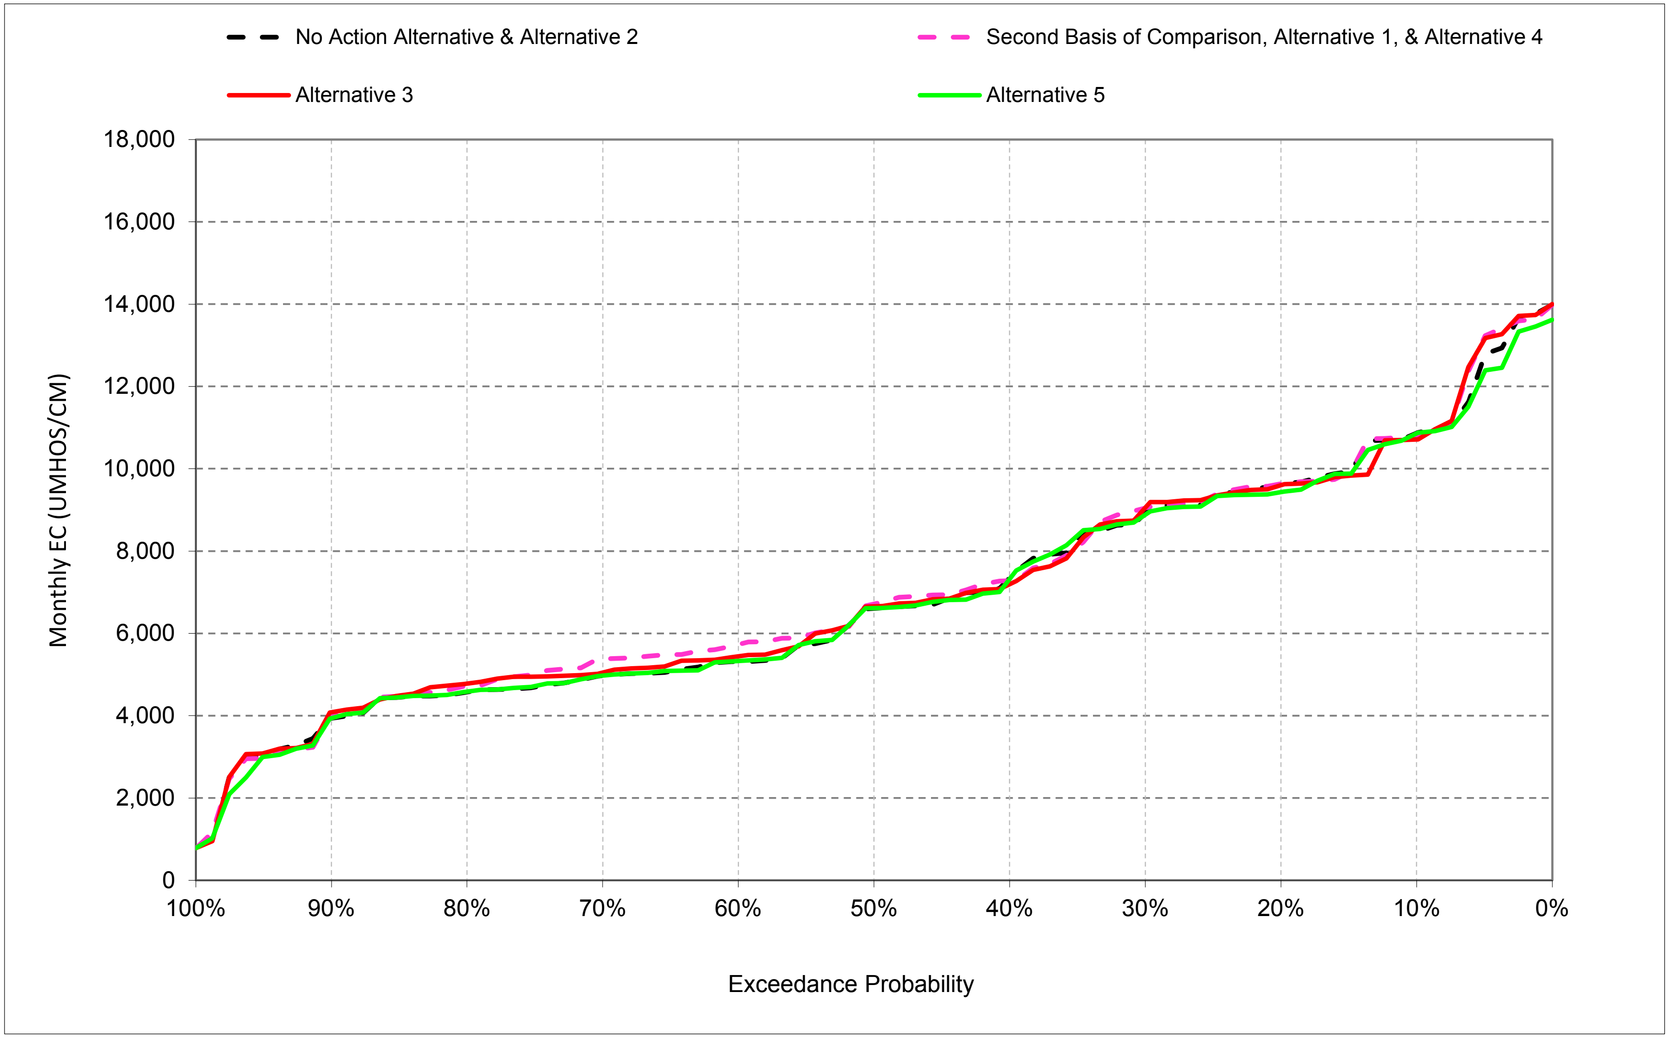
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.9. Chipps Island North Channel Salinity, Electrical Conductivity, June



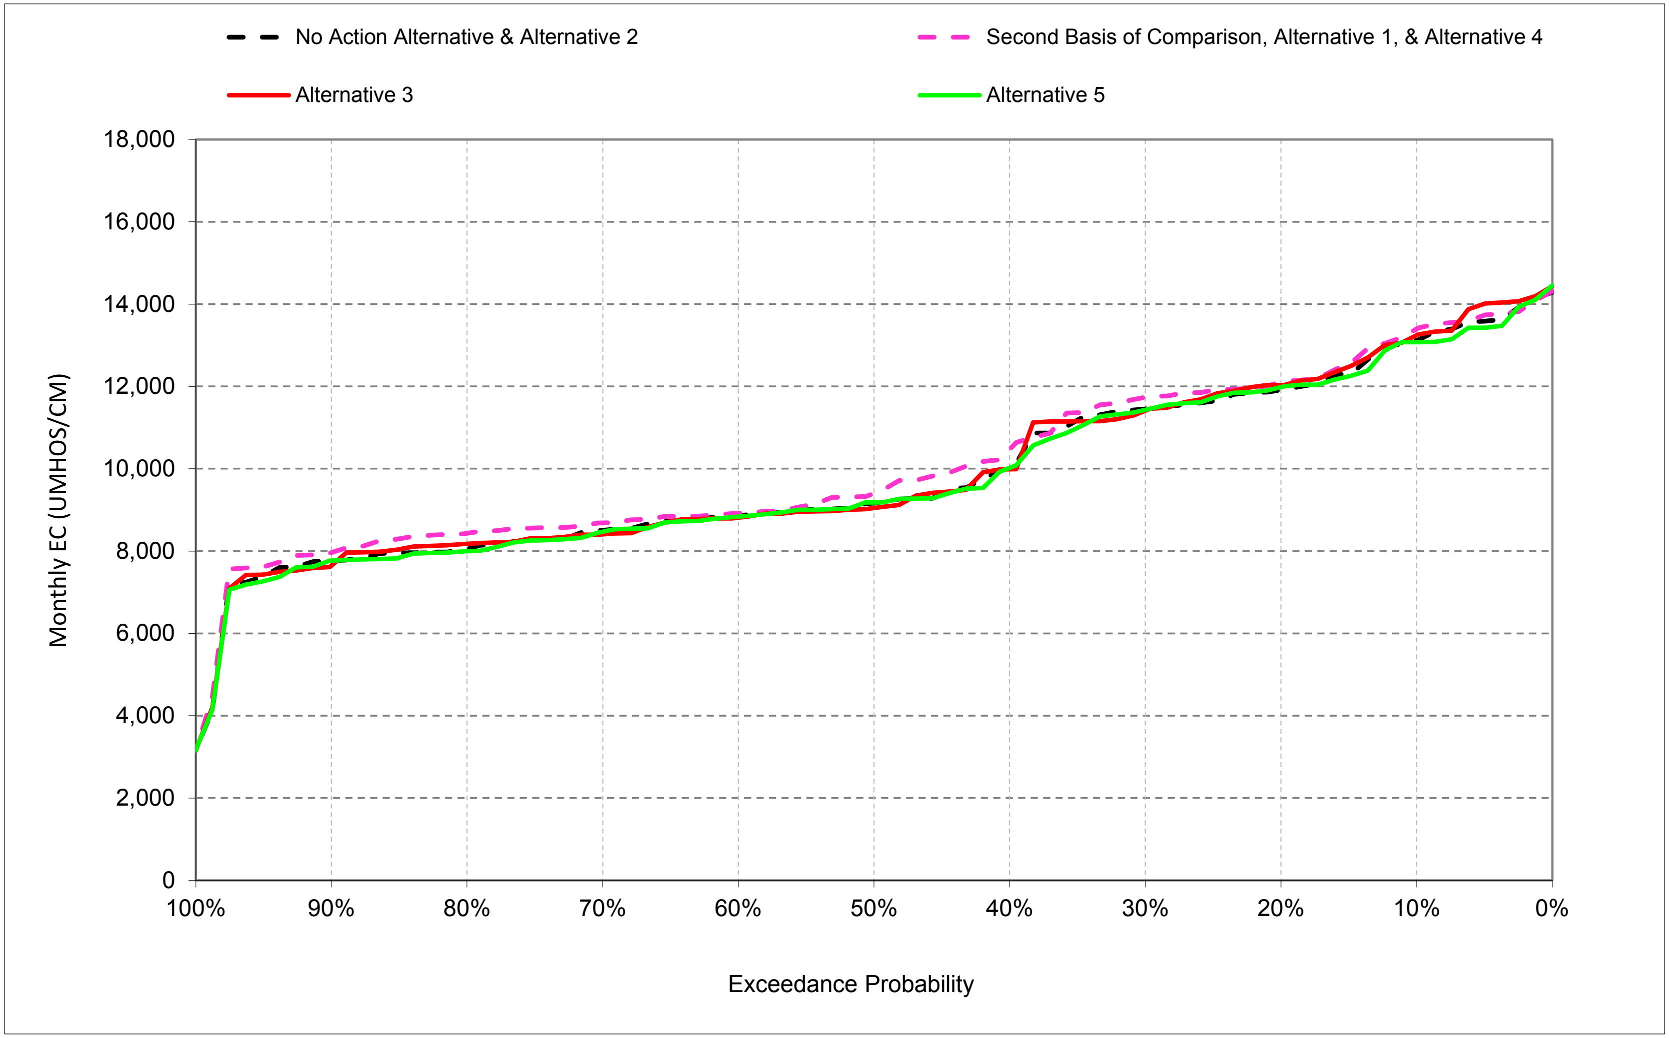
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.10. Chipps Island North Channel Salinity, Electrical Conductivity, July



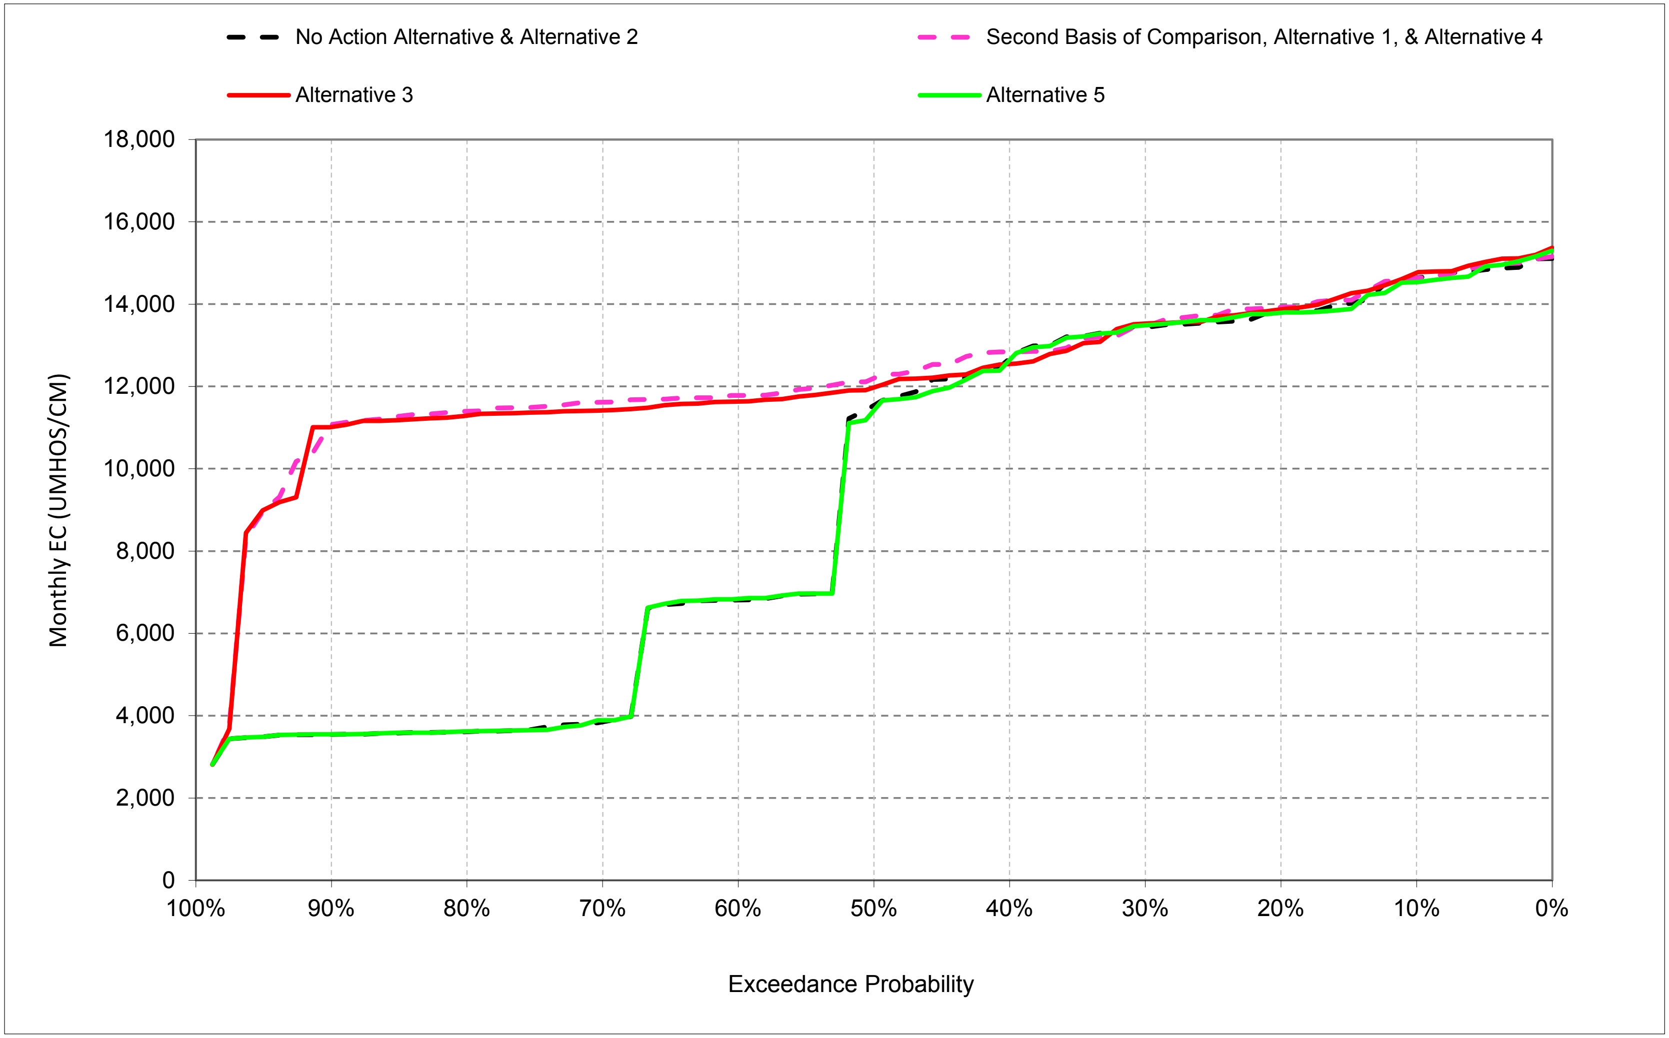
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.11. Chipps Island North Channel Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.1.12. Chipps Island North Channel Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

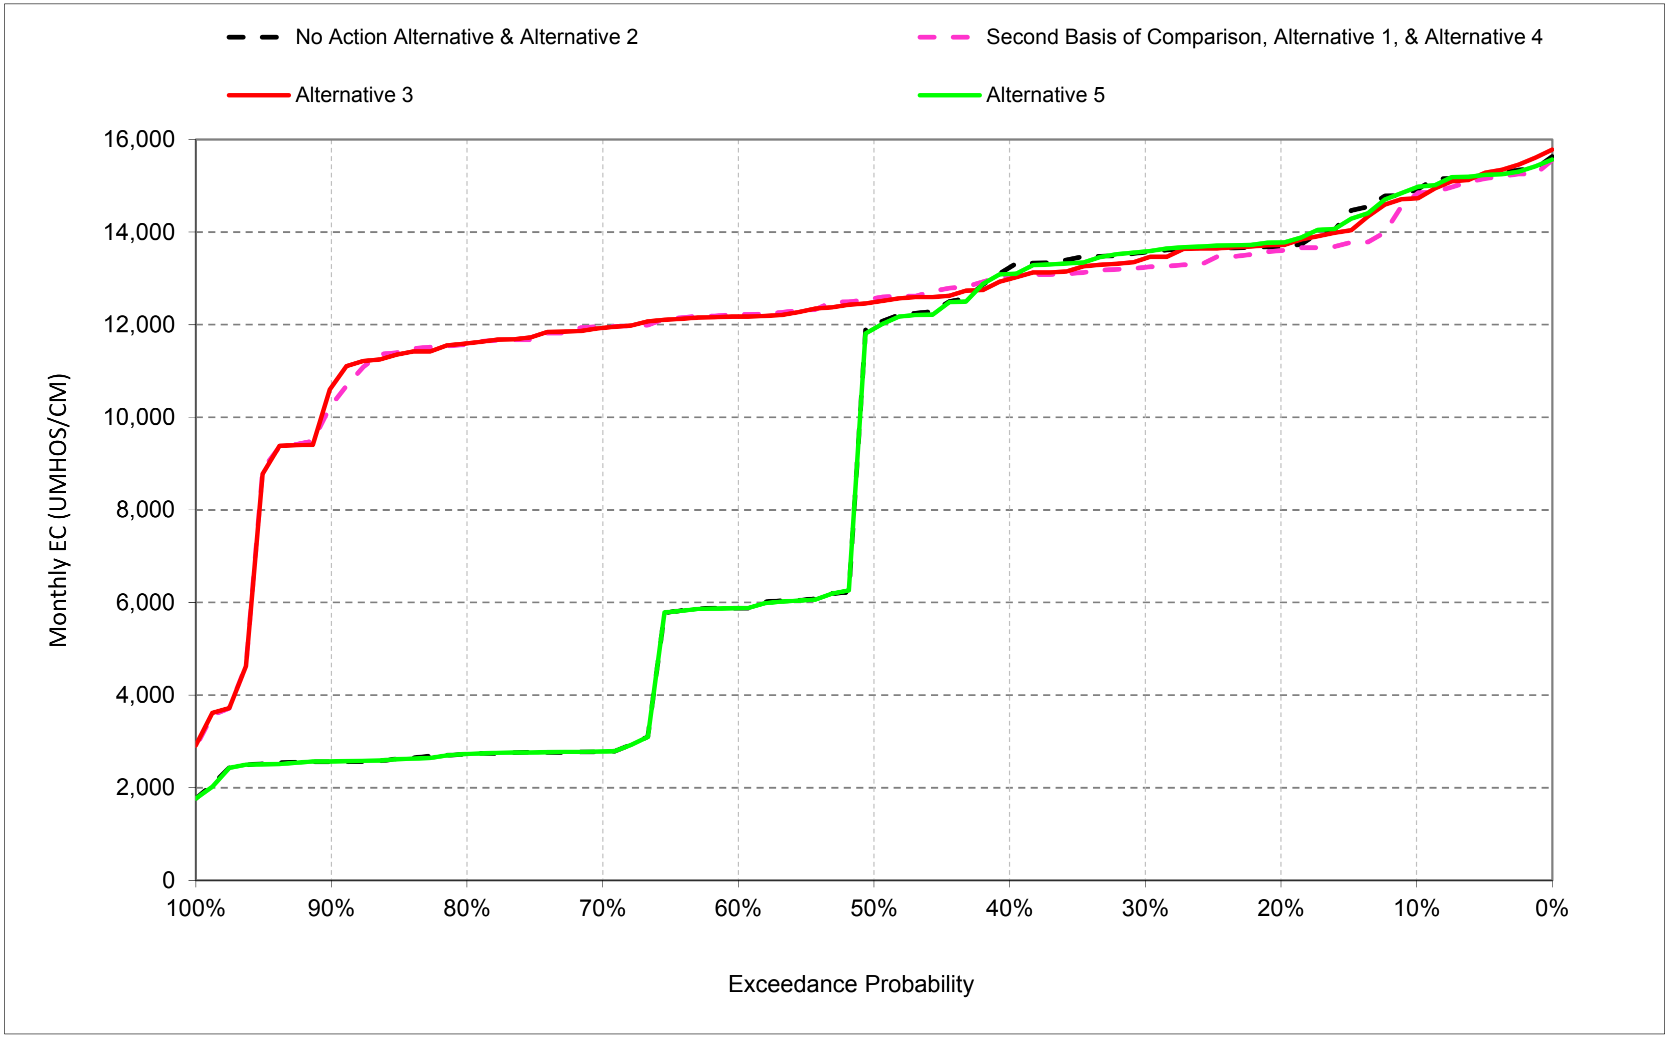
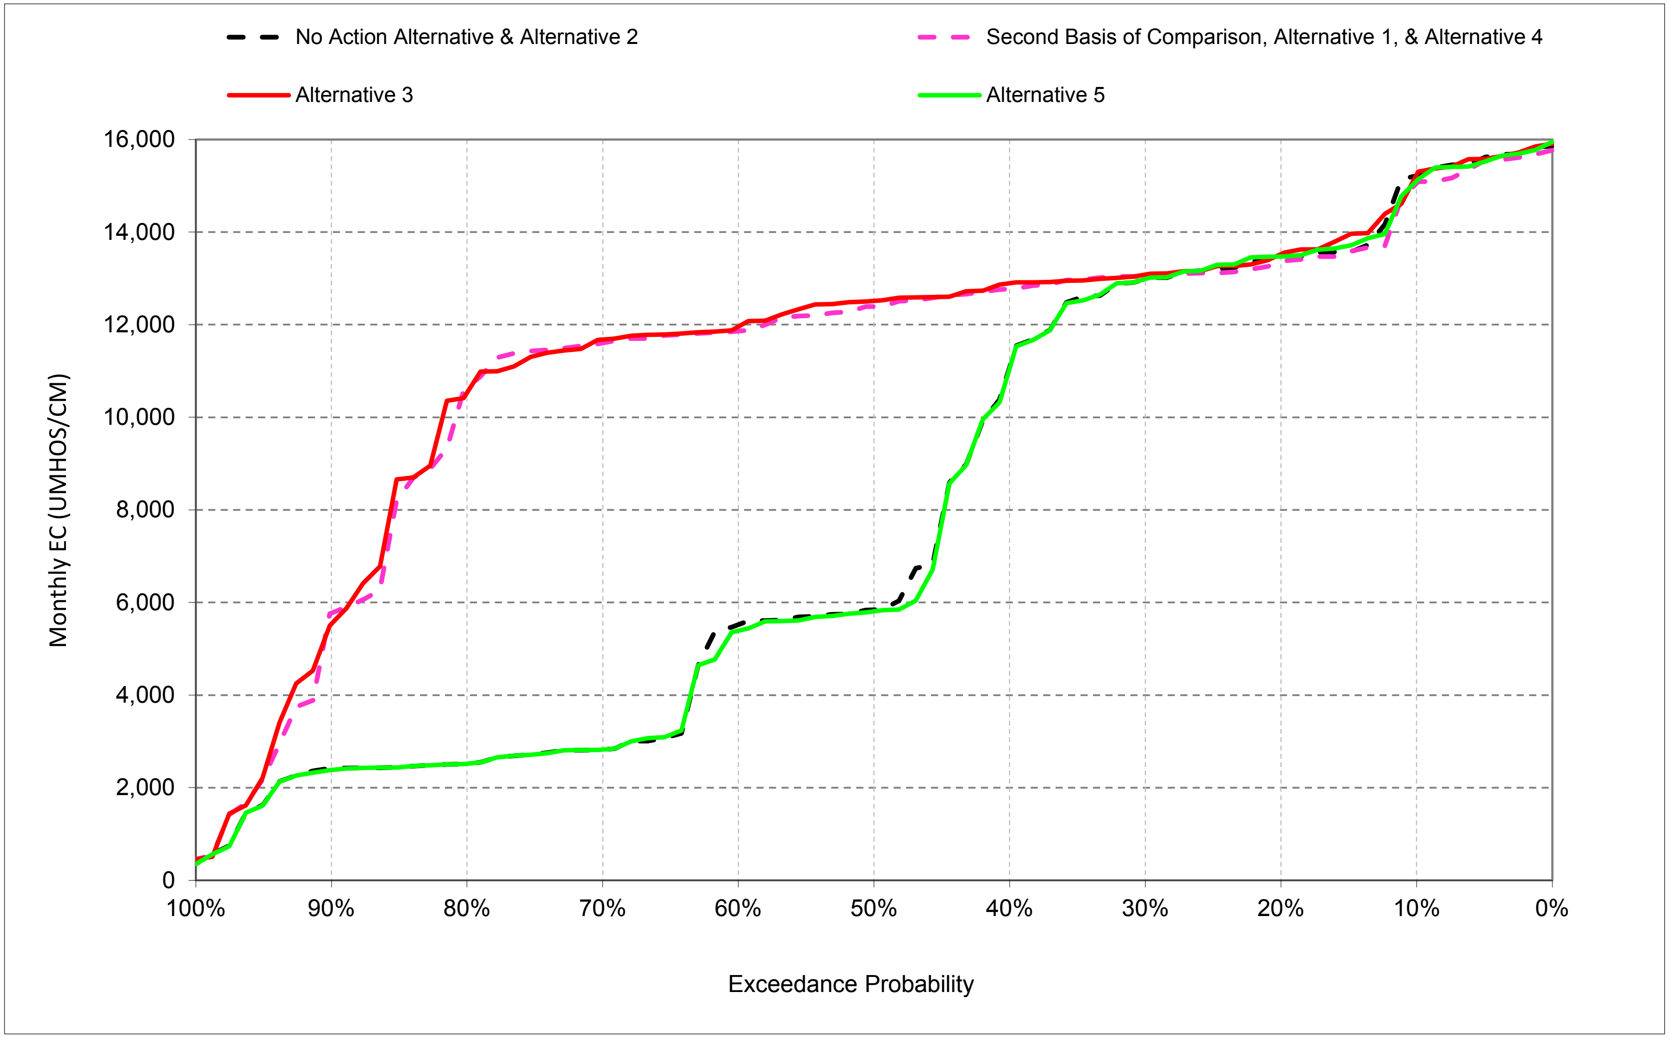
B.10.2 Chipps Island South Channel Salinity

Figure 6E.B.10.2.1. Chipps Island South Channel Salinity, Electrical Conductivity, October



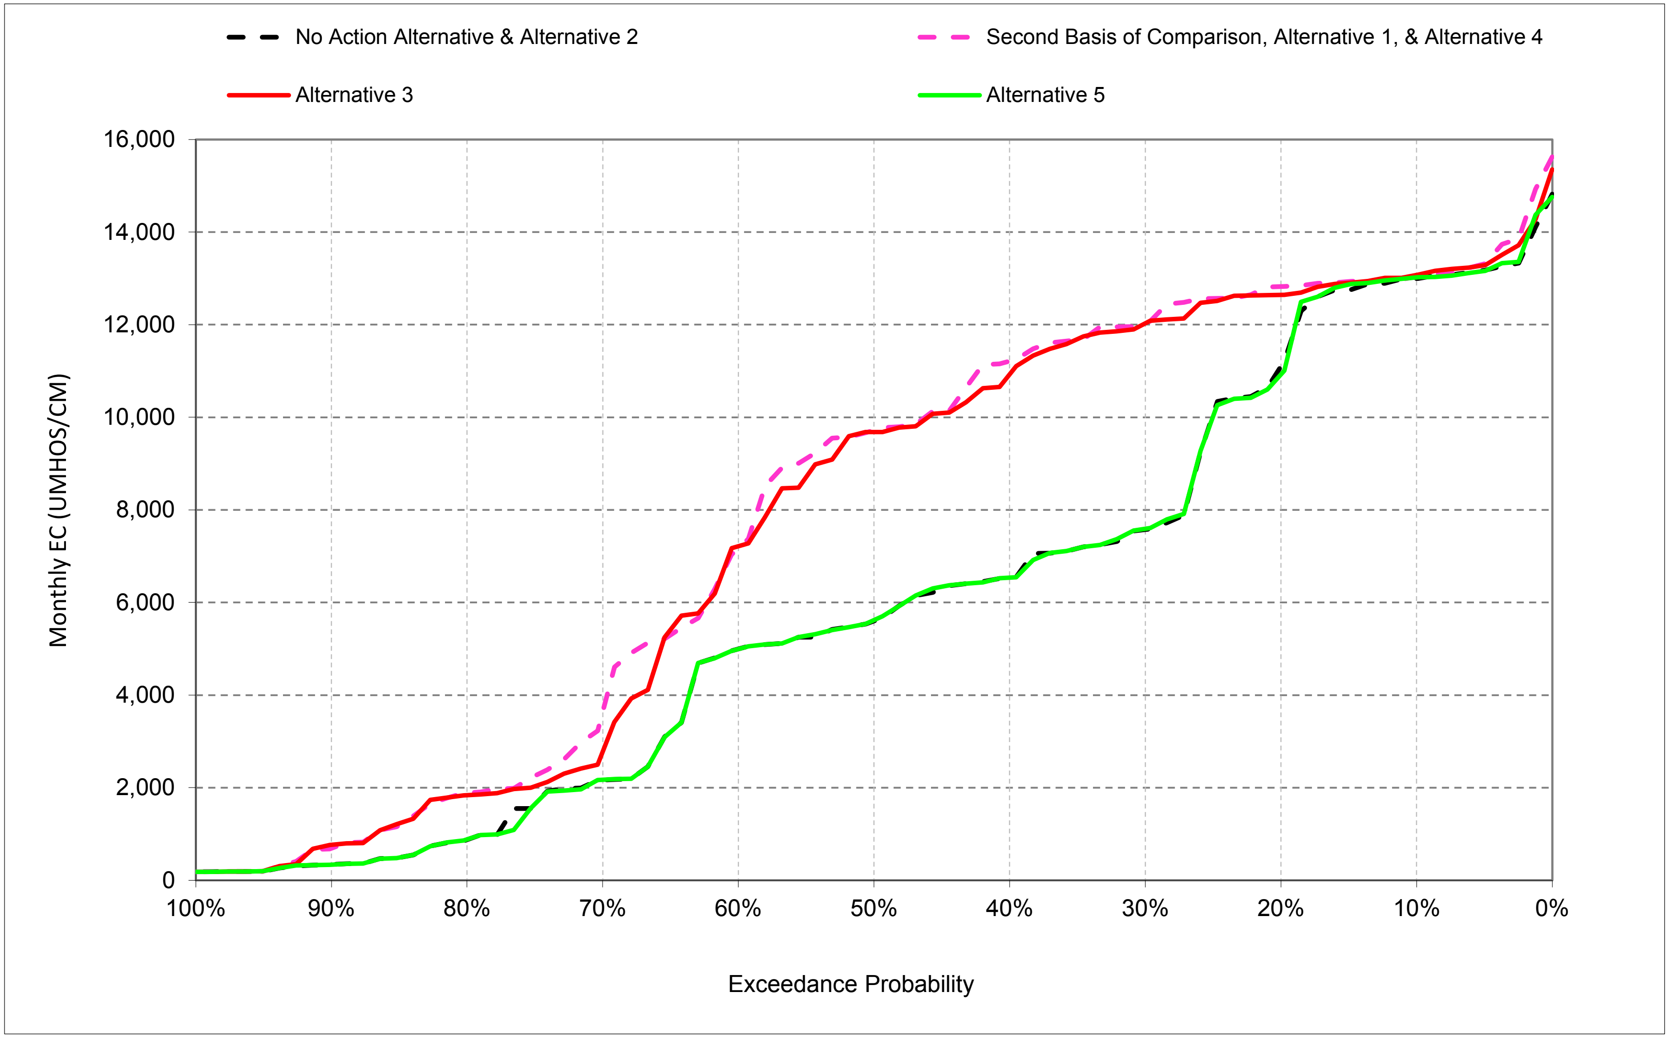
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.2. Chipps Island South Channel Salinity, Electrical Conductivity, November



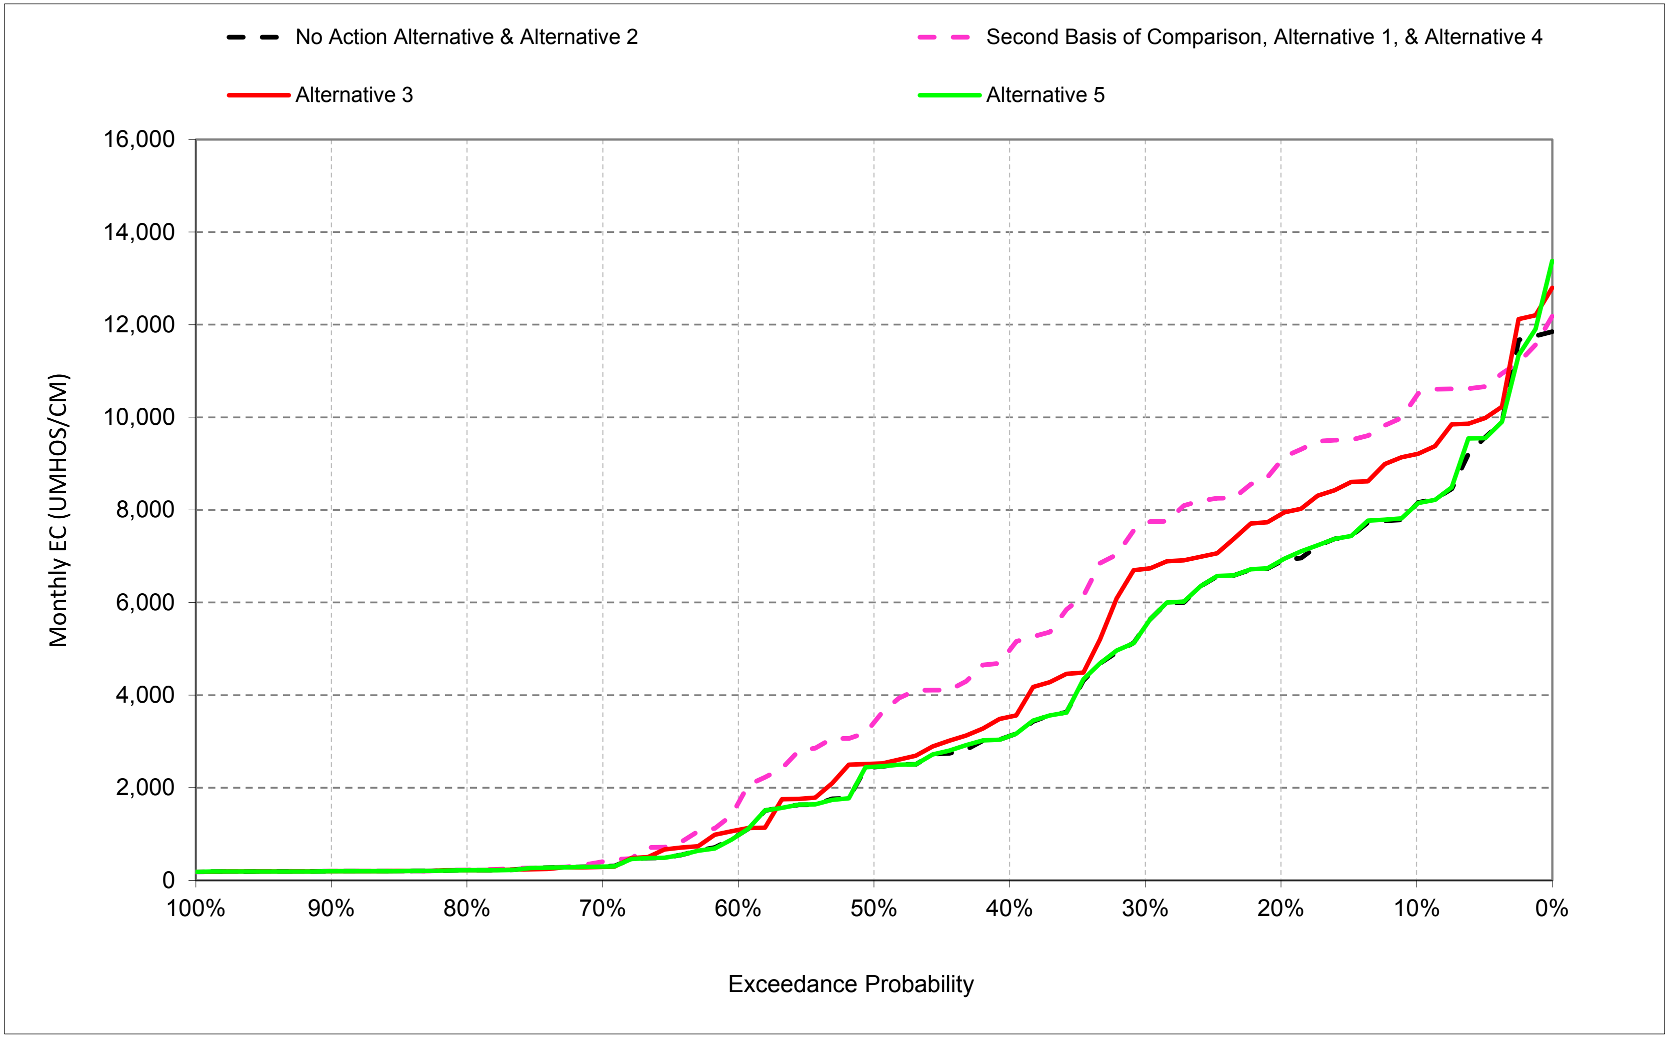
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.3. Chipps Island South Channel Salinity, Electrical Conductivity, December



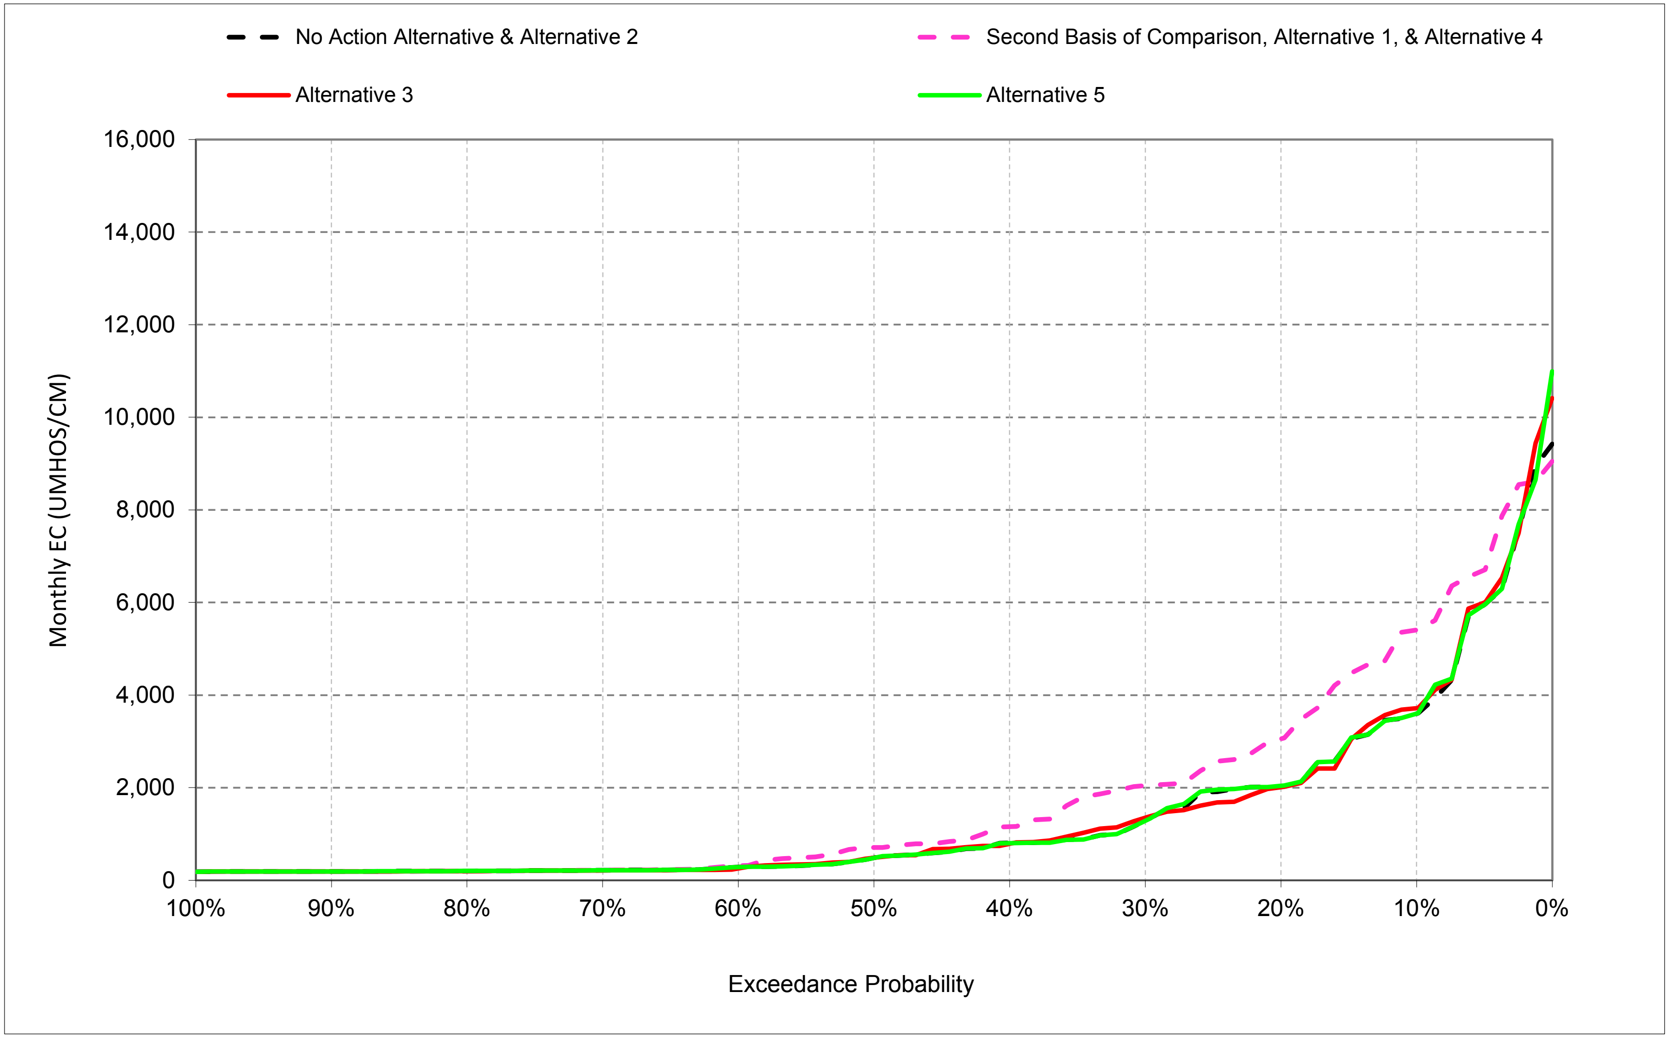
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.4. Chipps Island South Channel Salinity, Electrical Conductivity, January



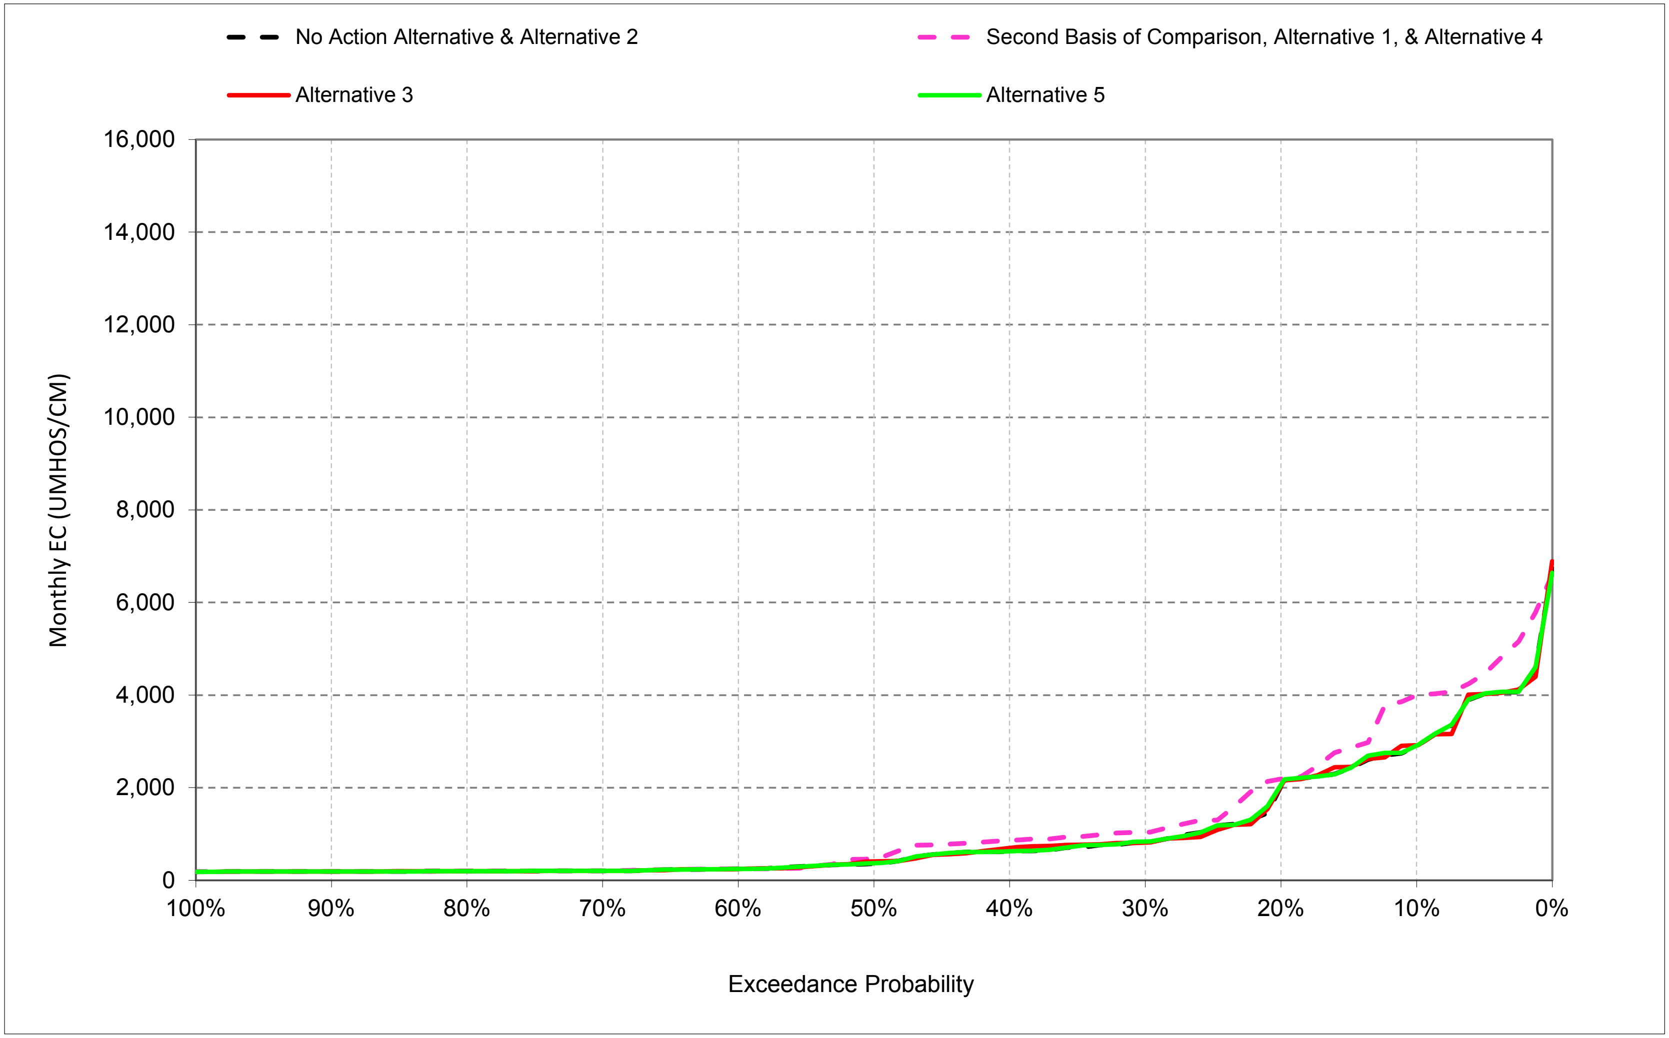
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.5. Chipps Island South Channel Salinity, Electrical Conductivity, February



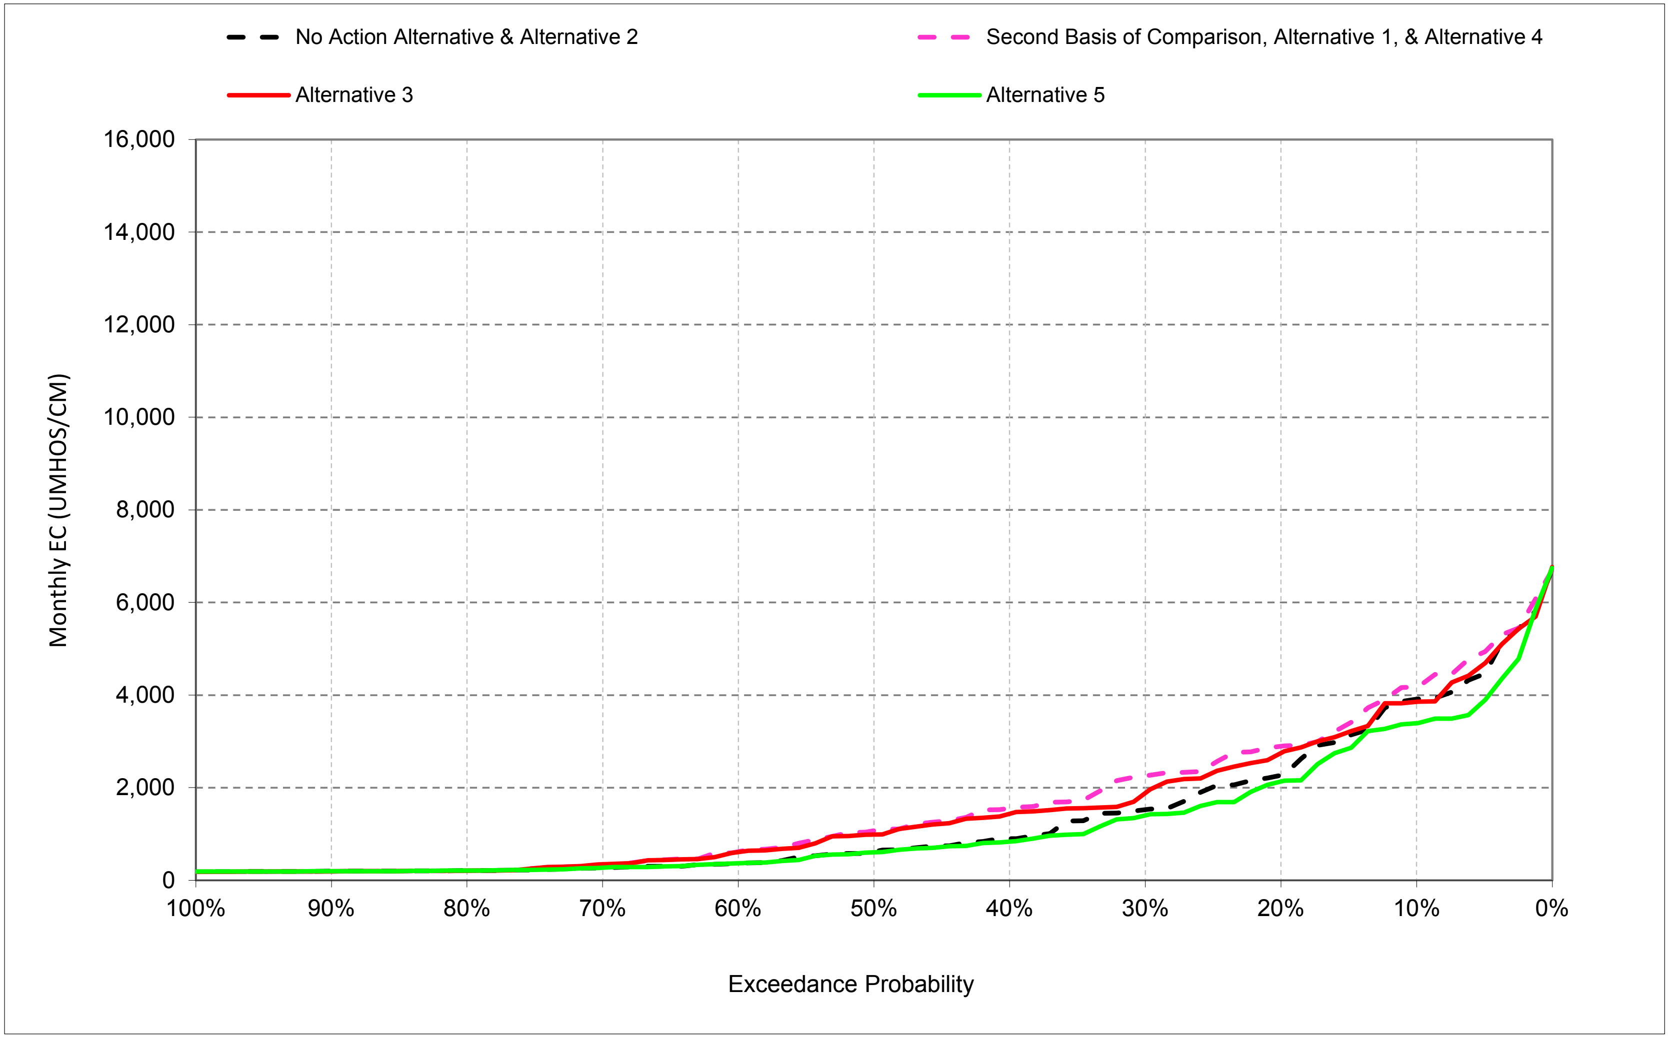
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.6. Chipps Island South Channel Salinity, Electrical Conductivity, March



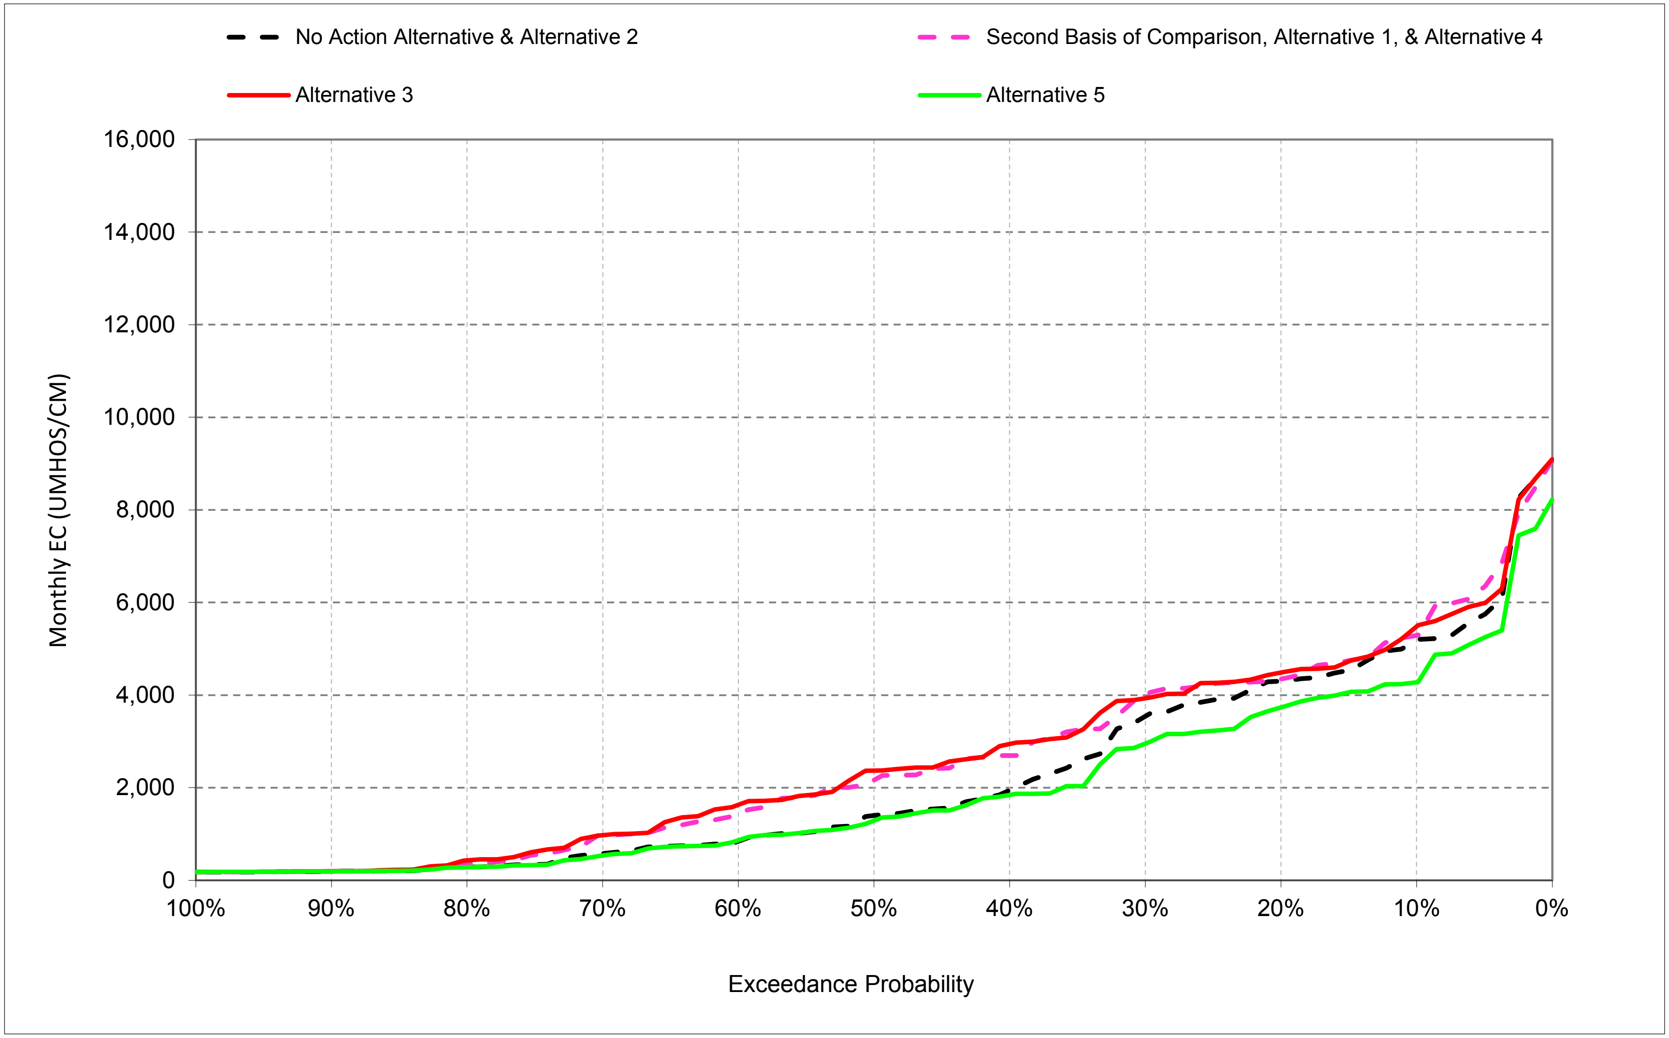
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.7. Chipps Island South Channel Salinity, Electrical Conductivity, April



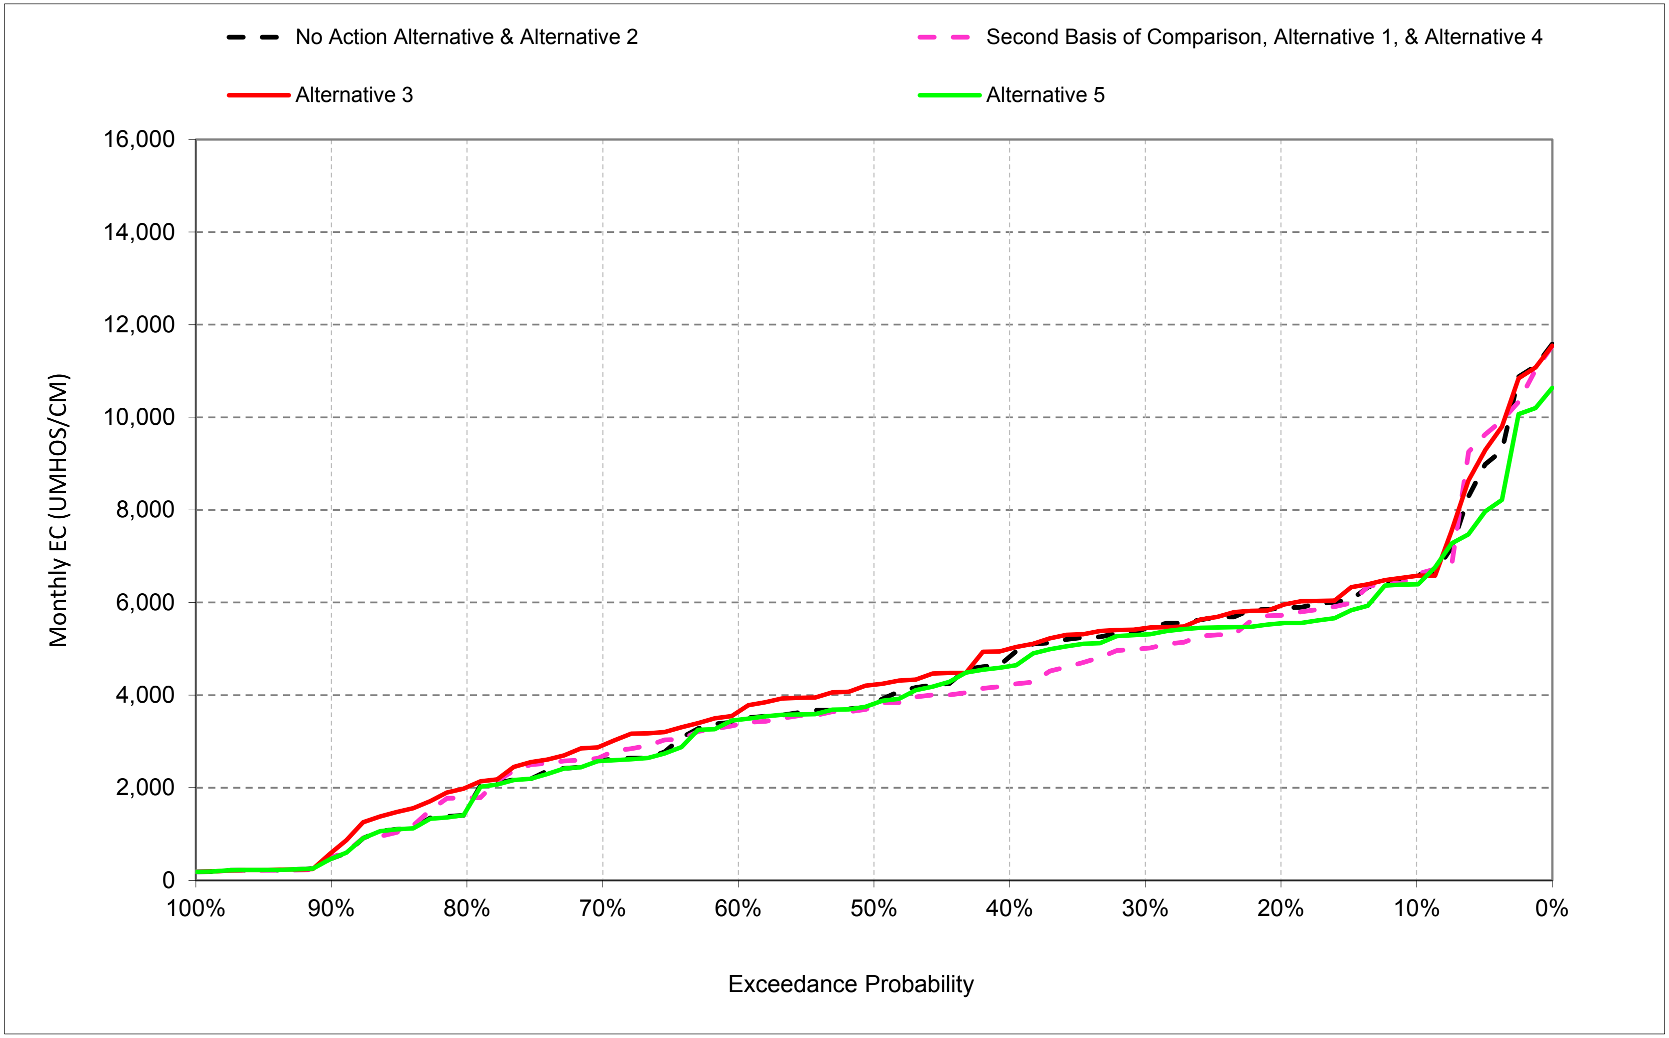
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.8. Chipps Island South Channel Salinity, Electrical Conductivity, May



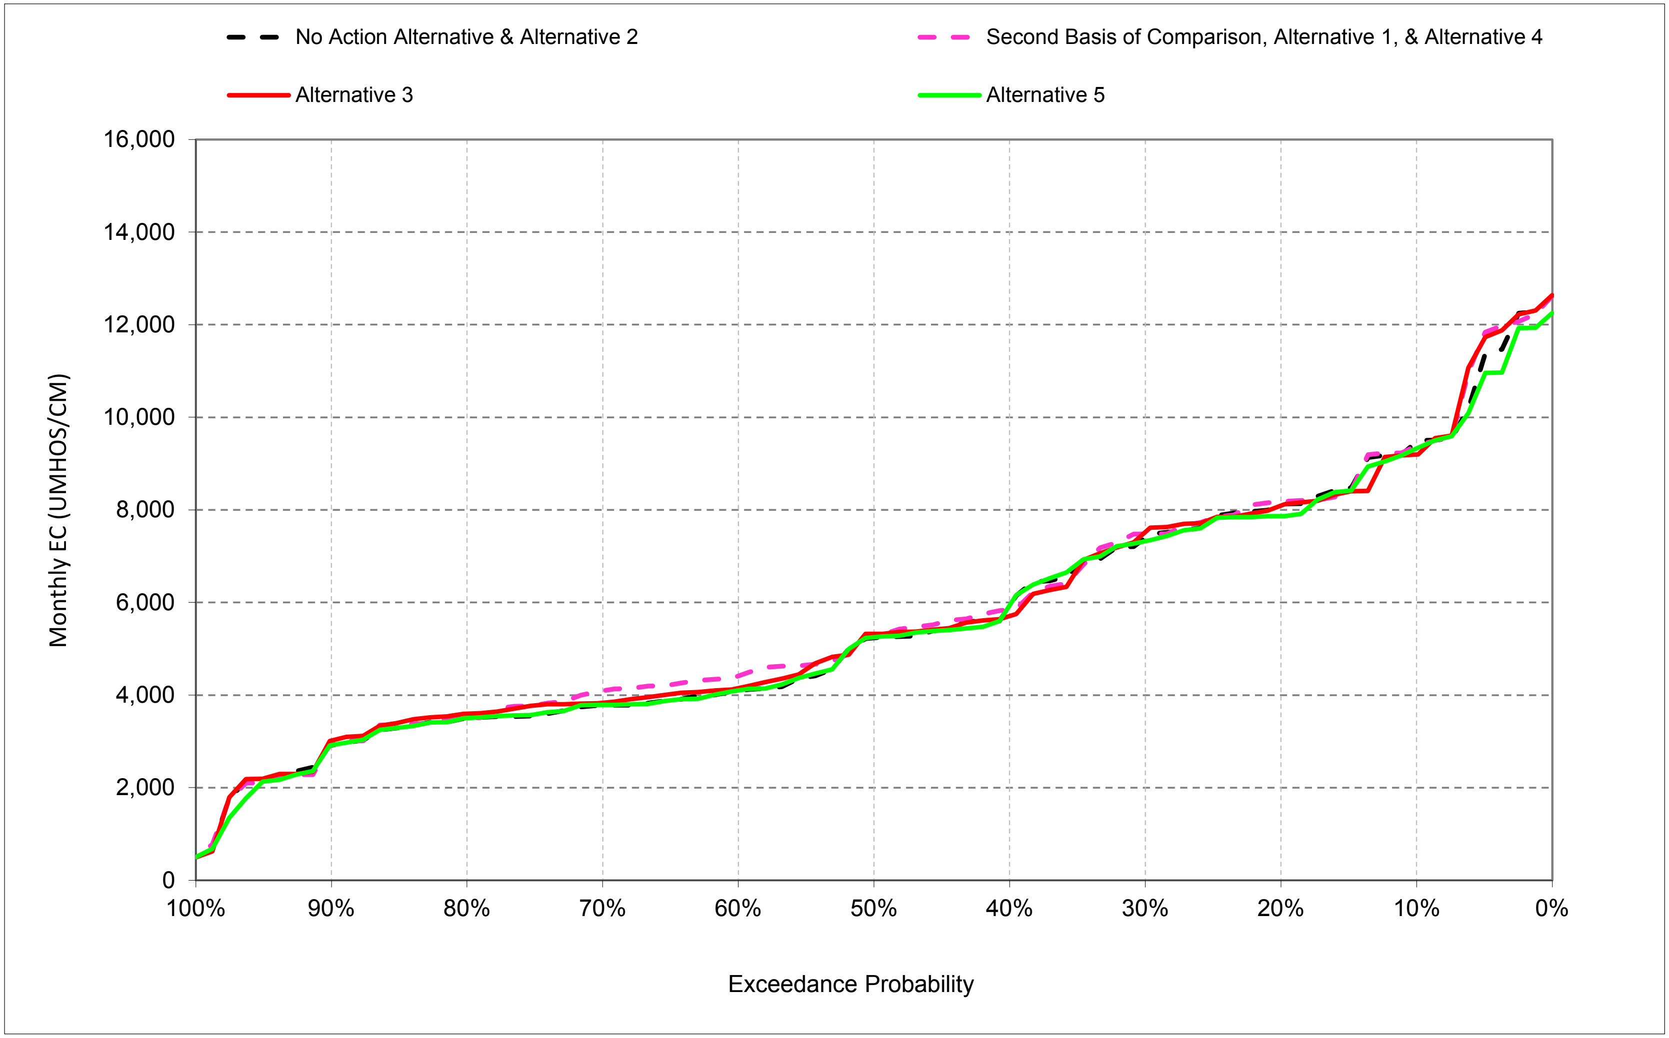
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.9. Chipps Island South Channel Salinity, Electrical Conductivity, June



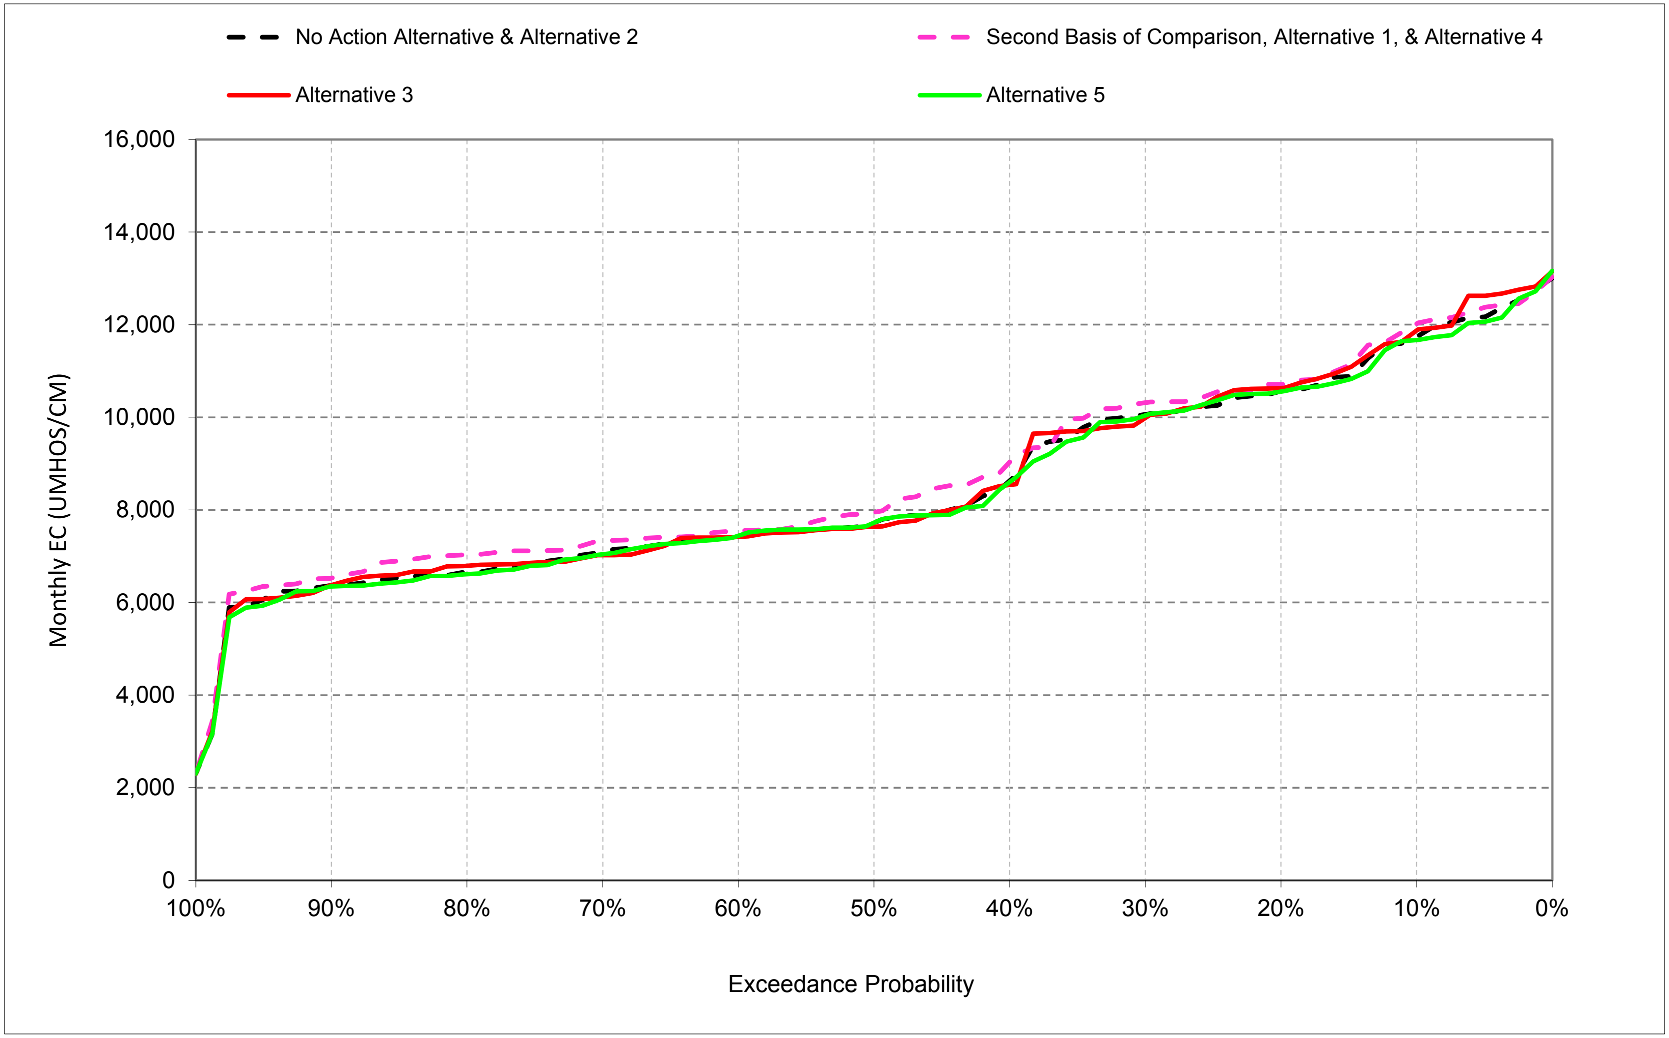
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.10. Chipps Island South Channel Salinity, Electrical Conductivity, July



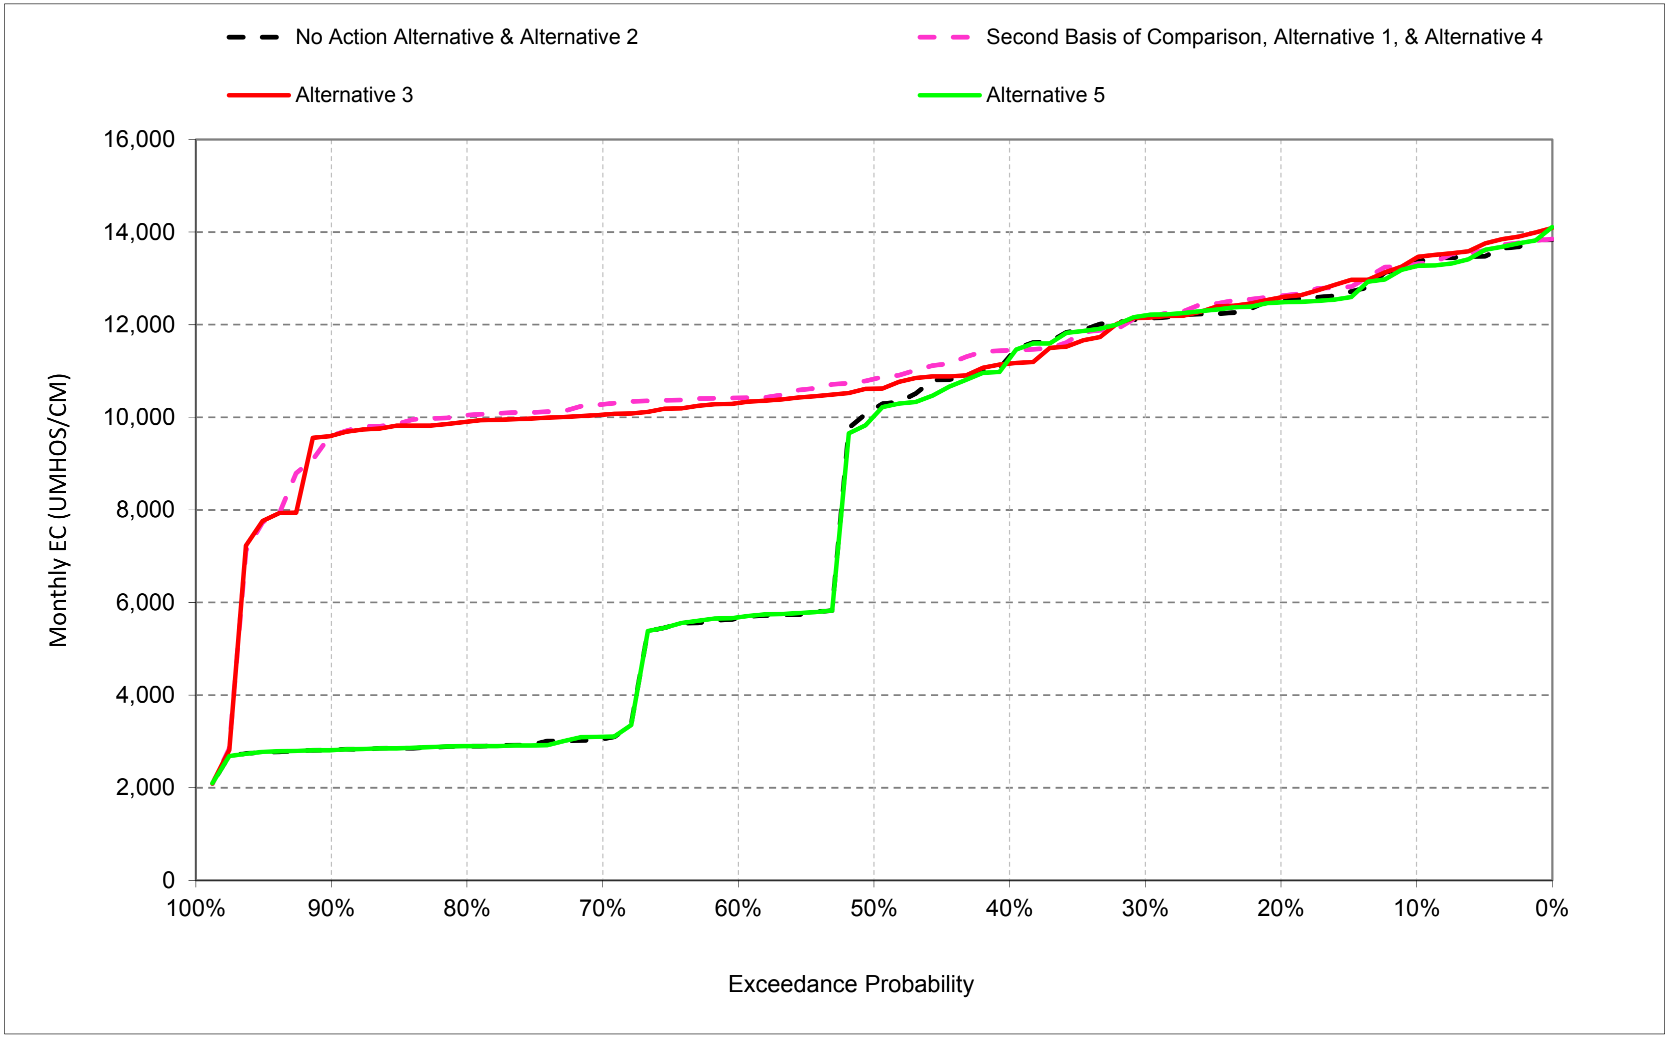
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.11. Chipps Island South Channel Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.10.2.12. Chipps Island South Channel Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

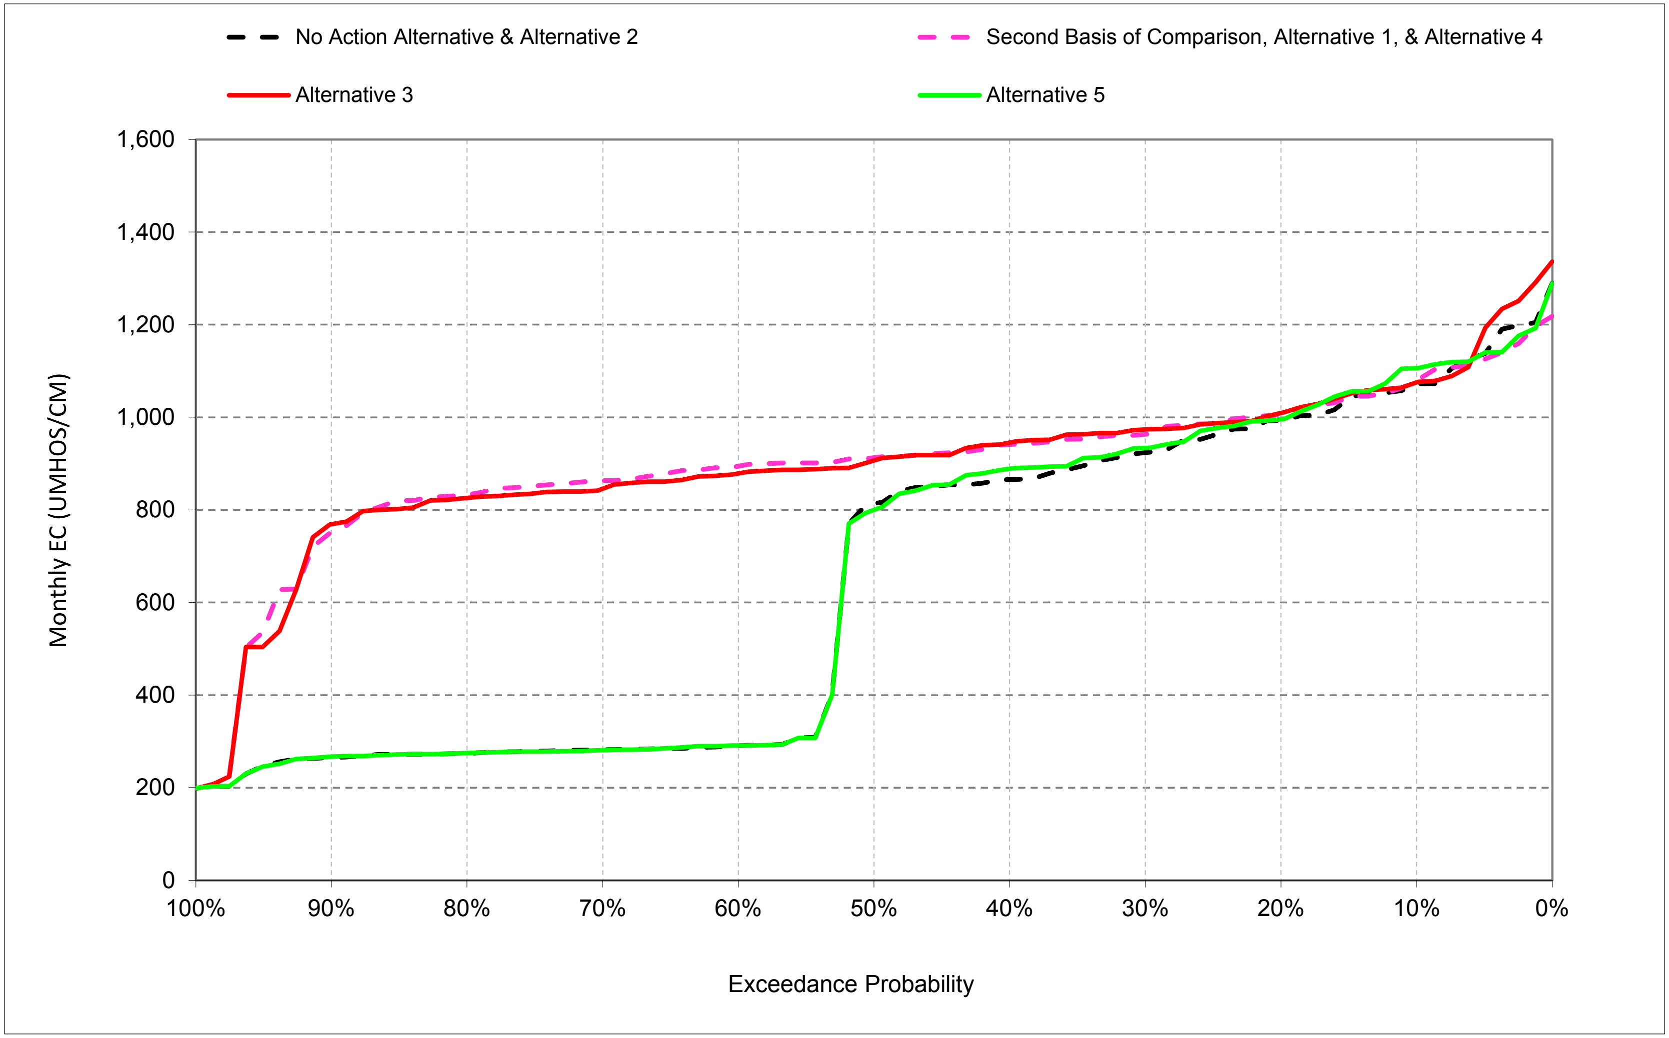
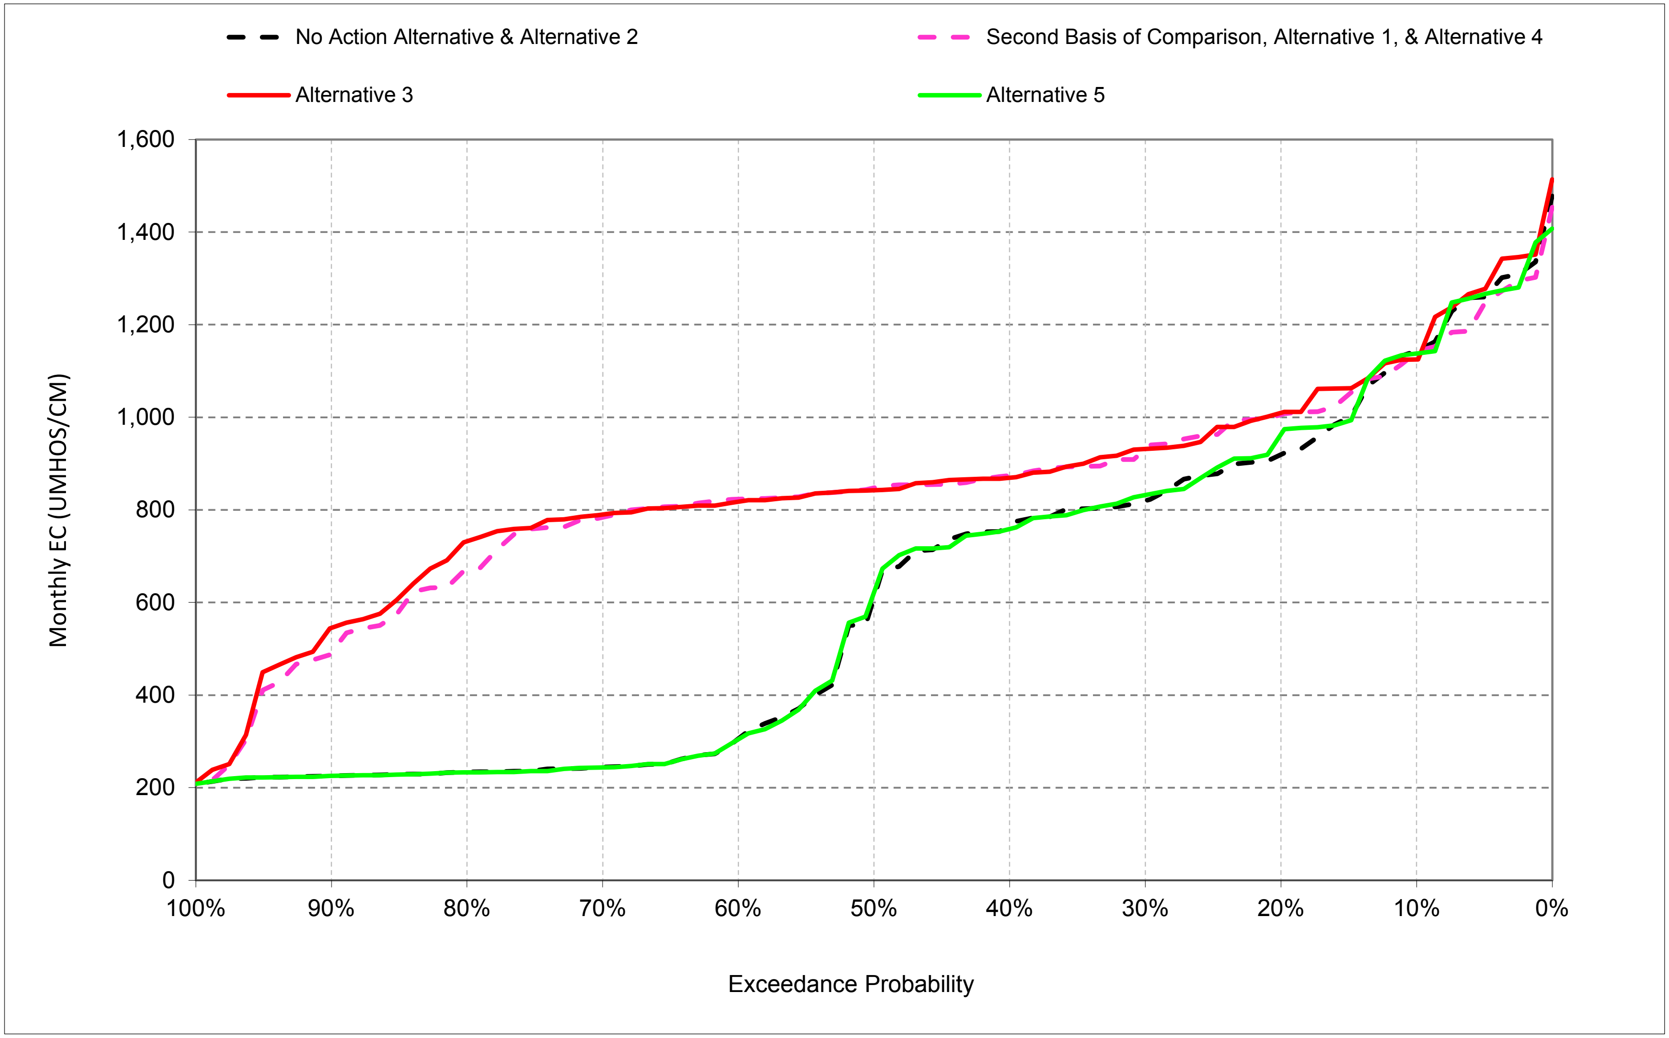
B.11 Old River at Rock Slough Salinity

Figure 6E.B.11.1. Old River at Rock Slough Salinity, Electrical Conductivity, October



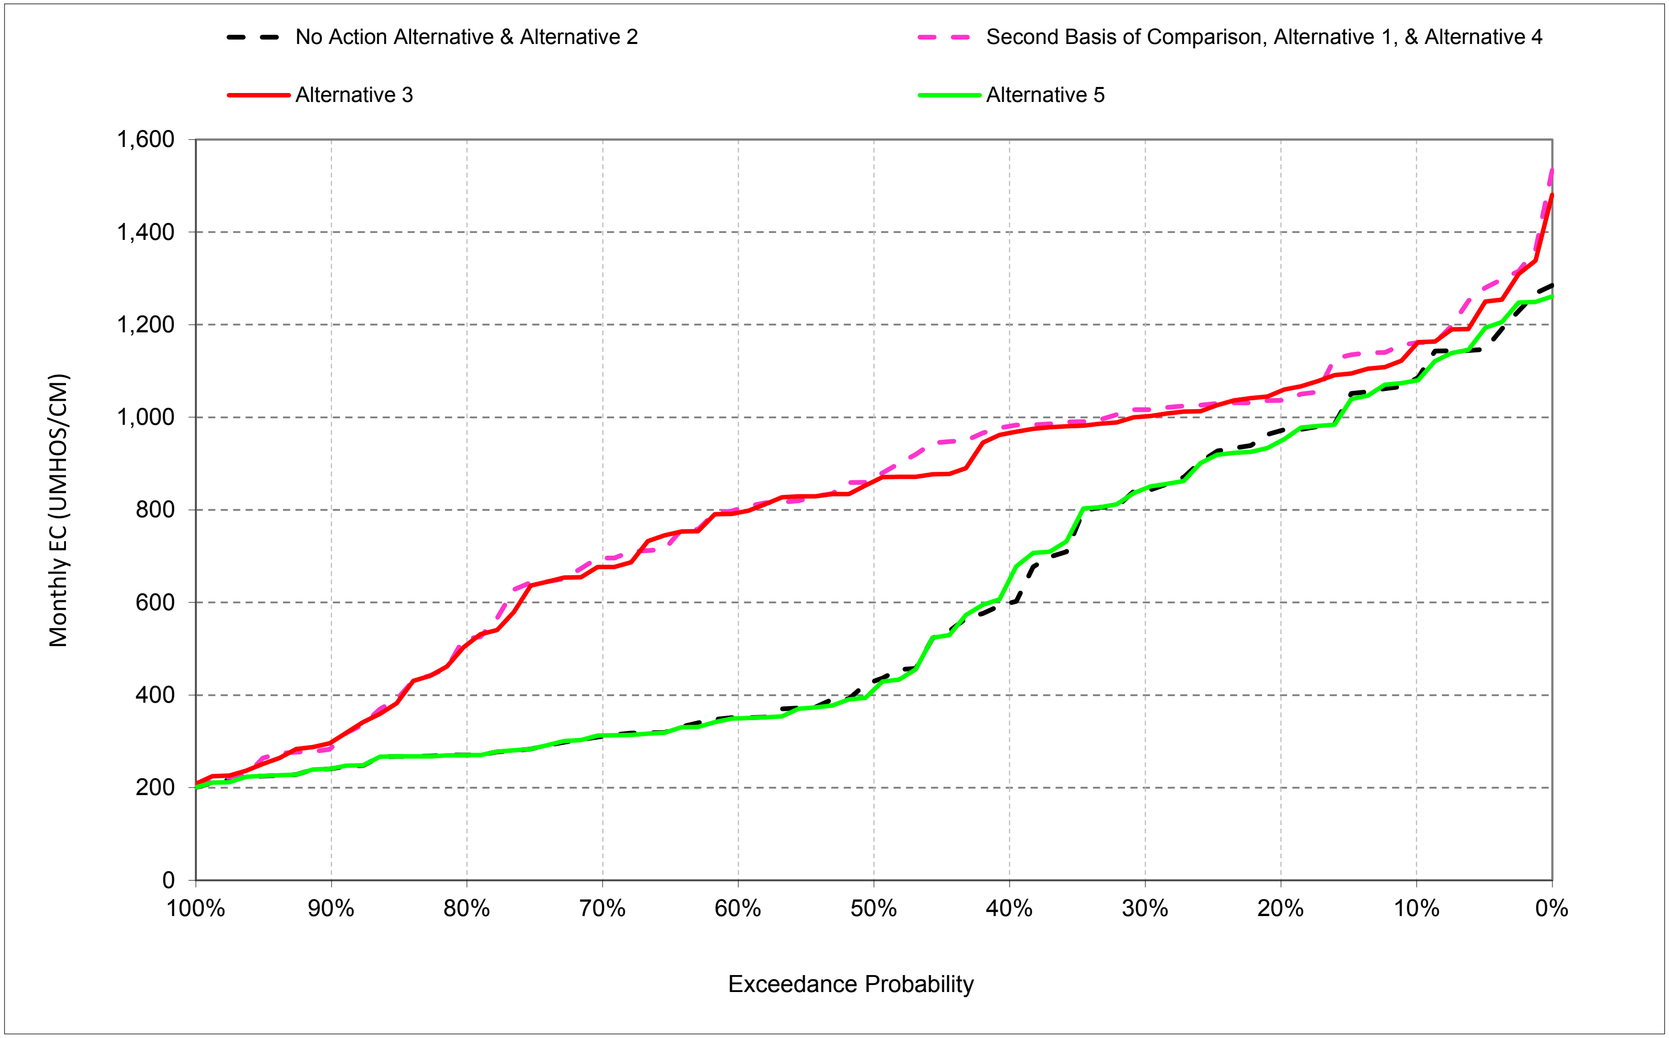
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.2. Old River at Rock Slough Salinity, Electrical Conductivity, November



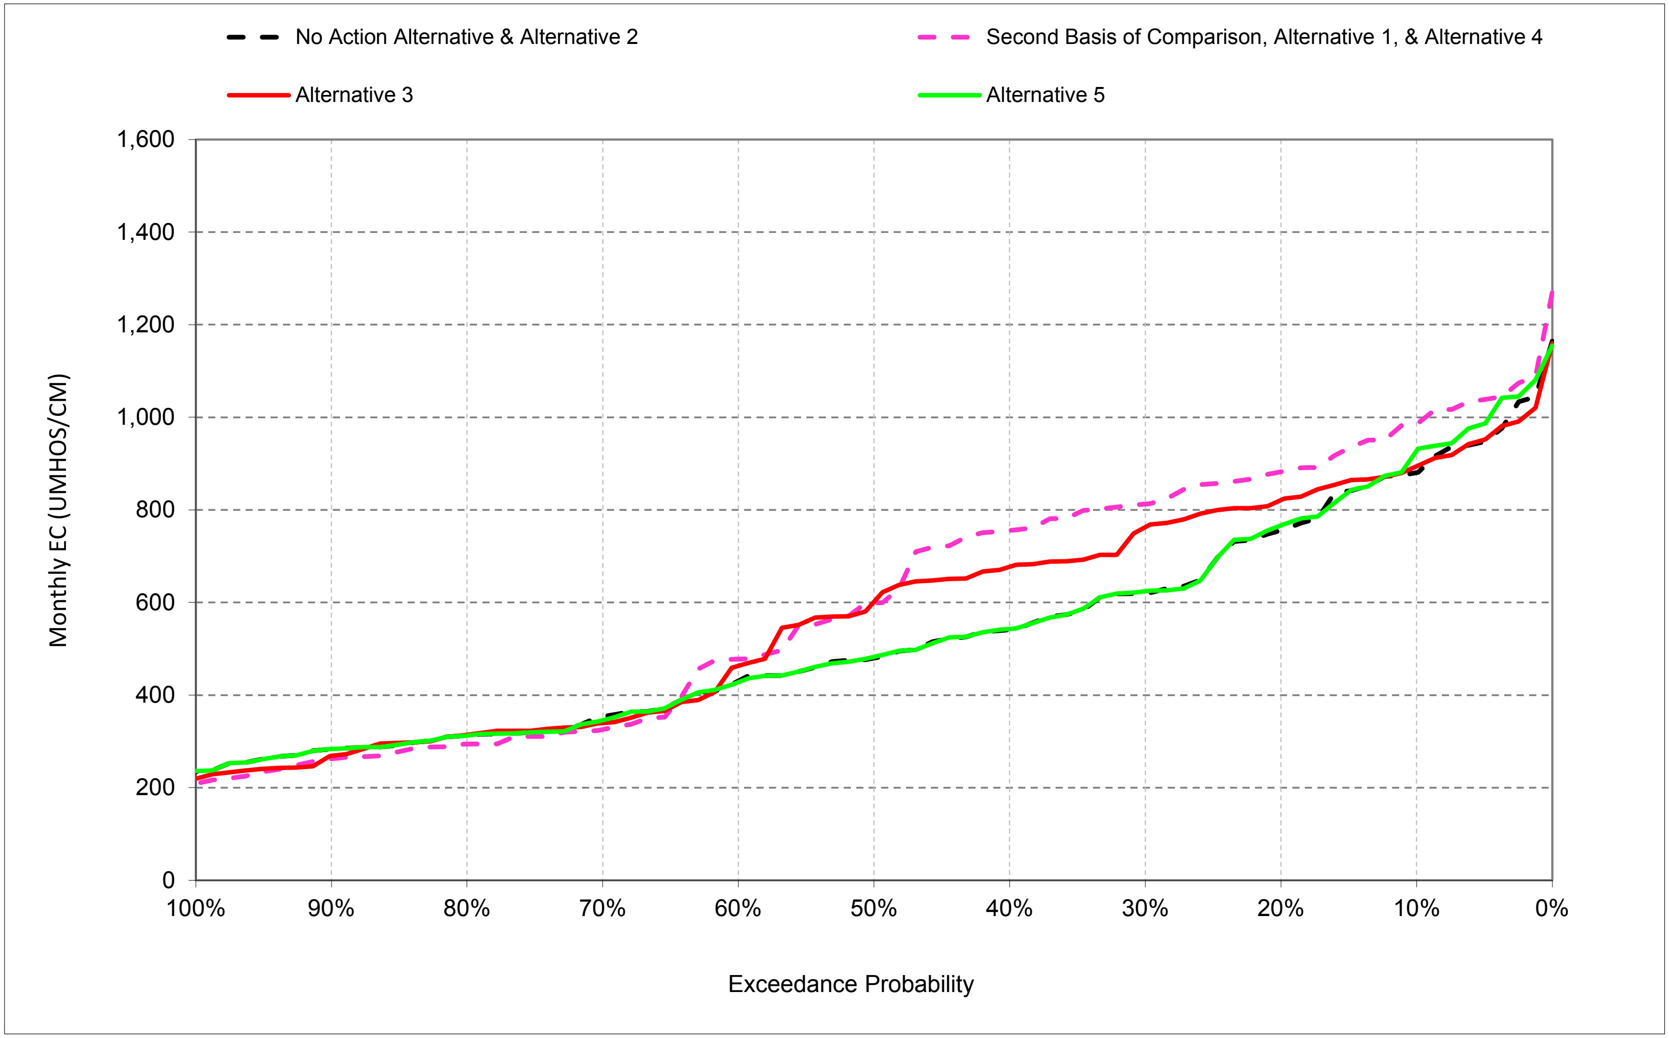
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.3. Old River at Rock Slough Salinity, Electrical Conductivity, December



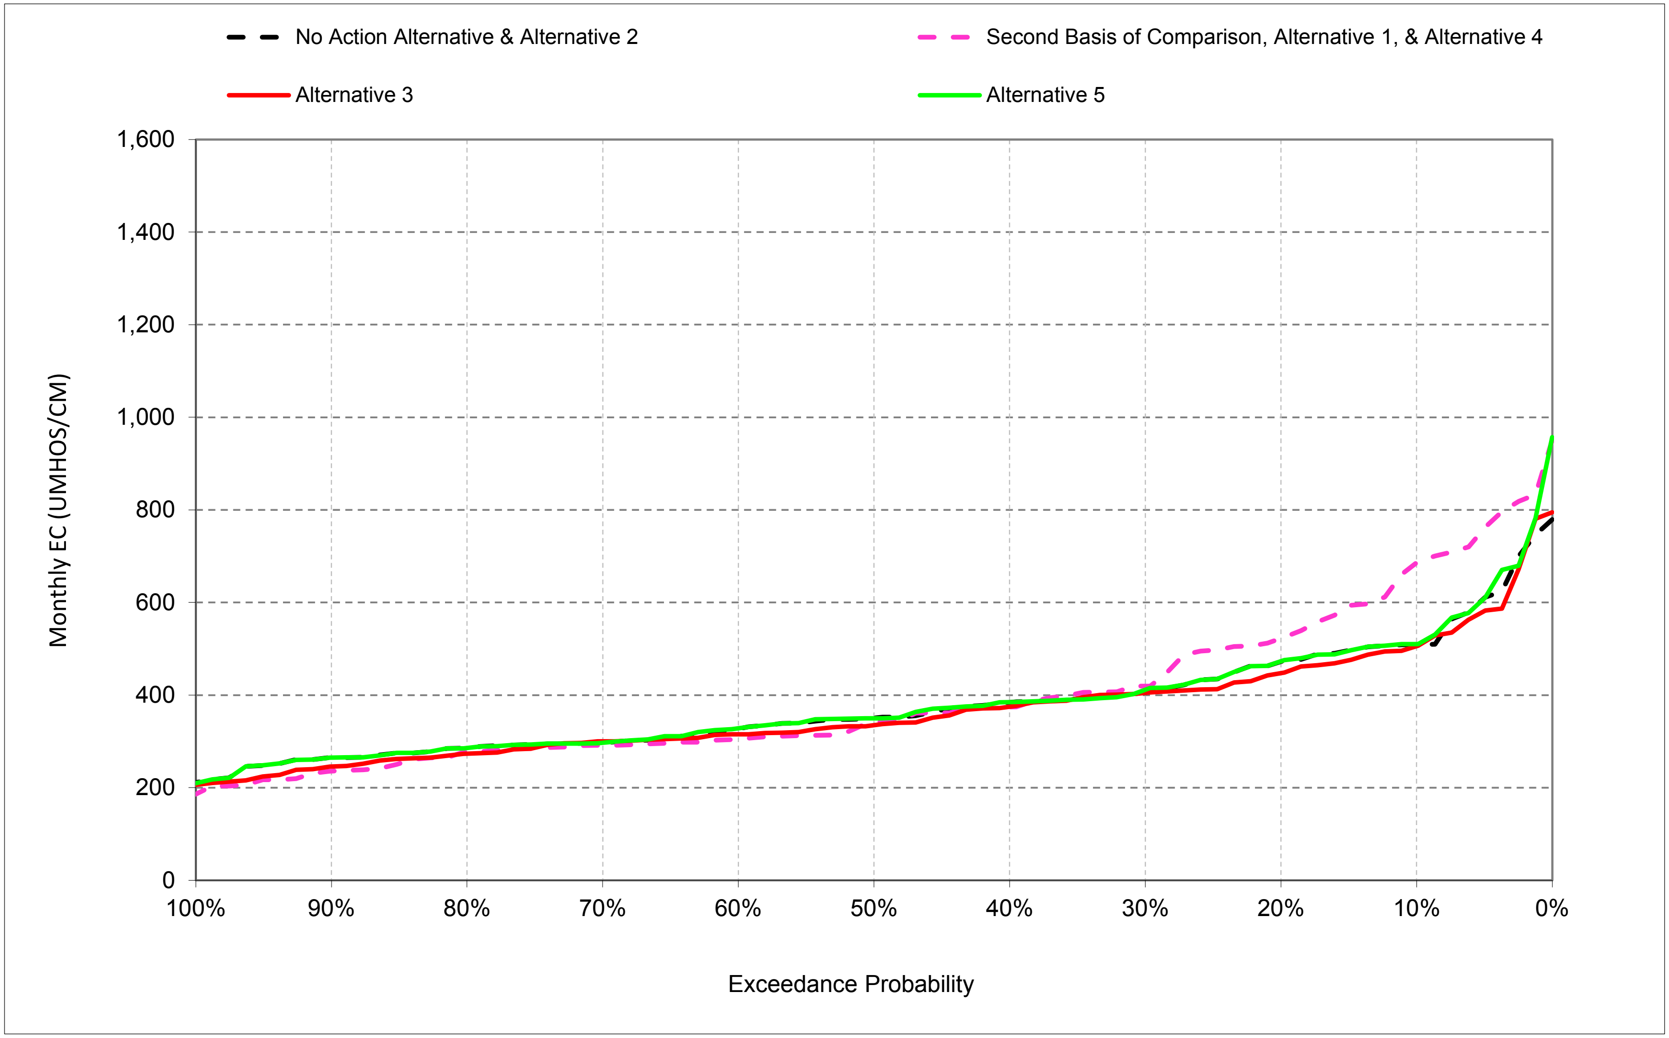
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.4. Old River at Rock Slough Salinity, Electrical Conductivity, January



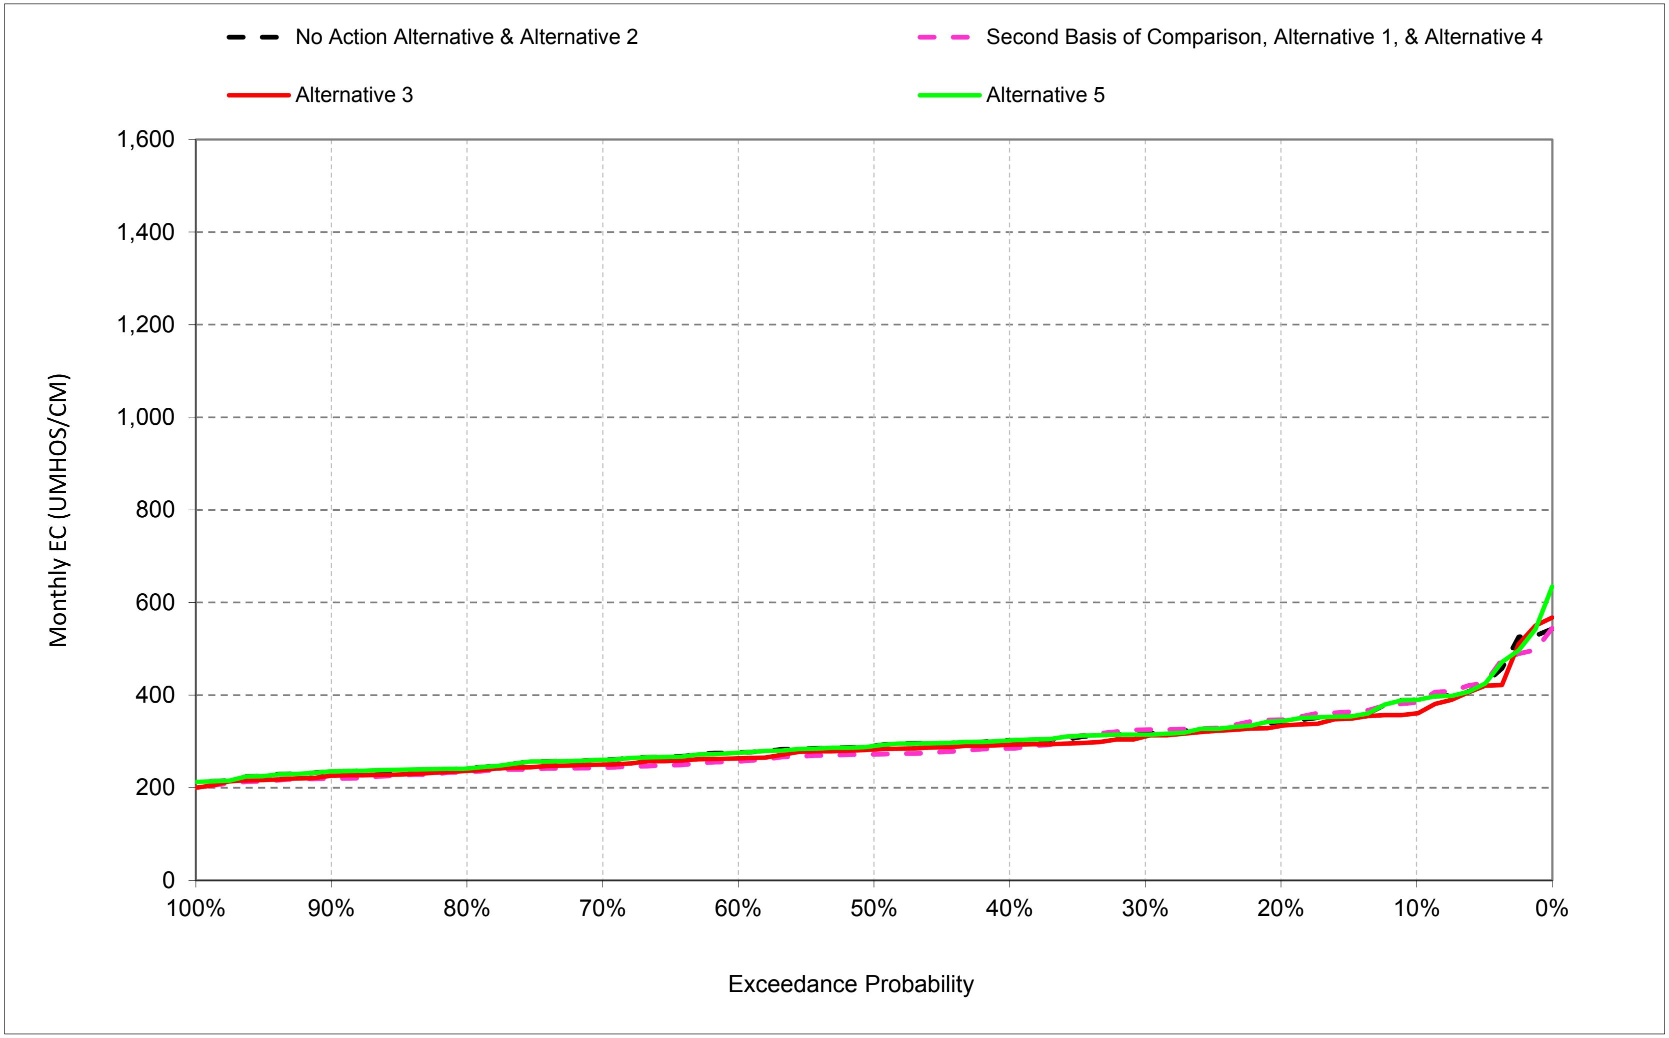
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.5. Old River at Rock Slough Salinity, Electrical Conductivity, February



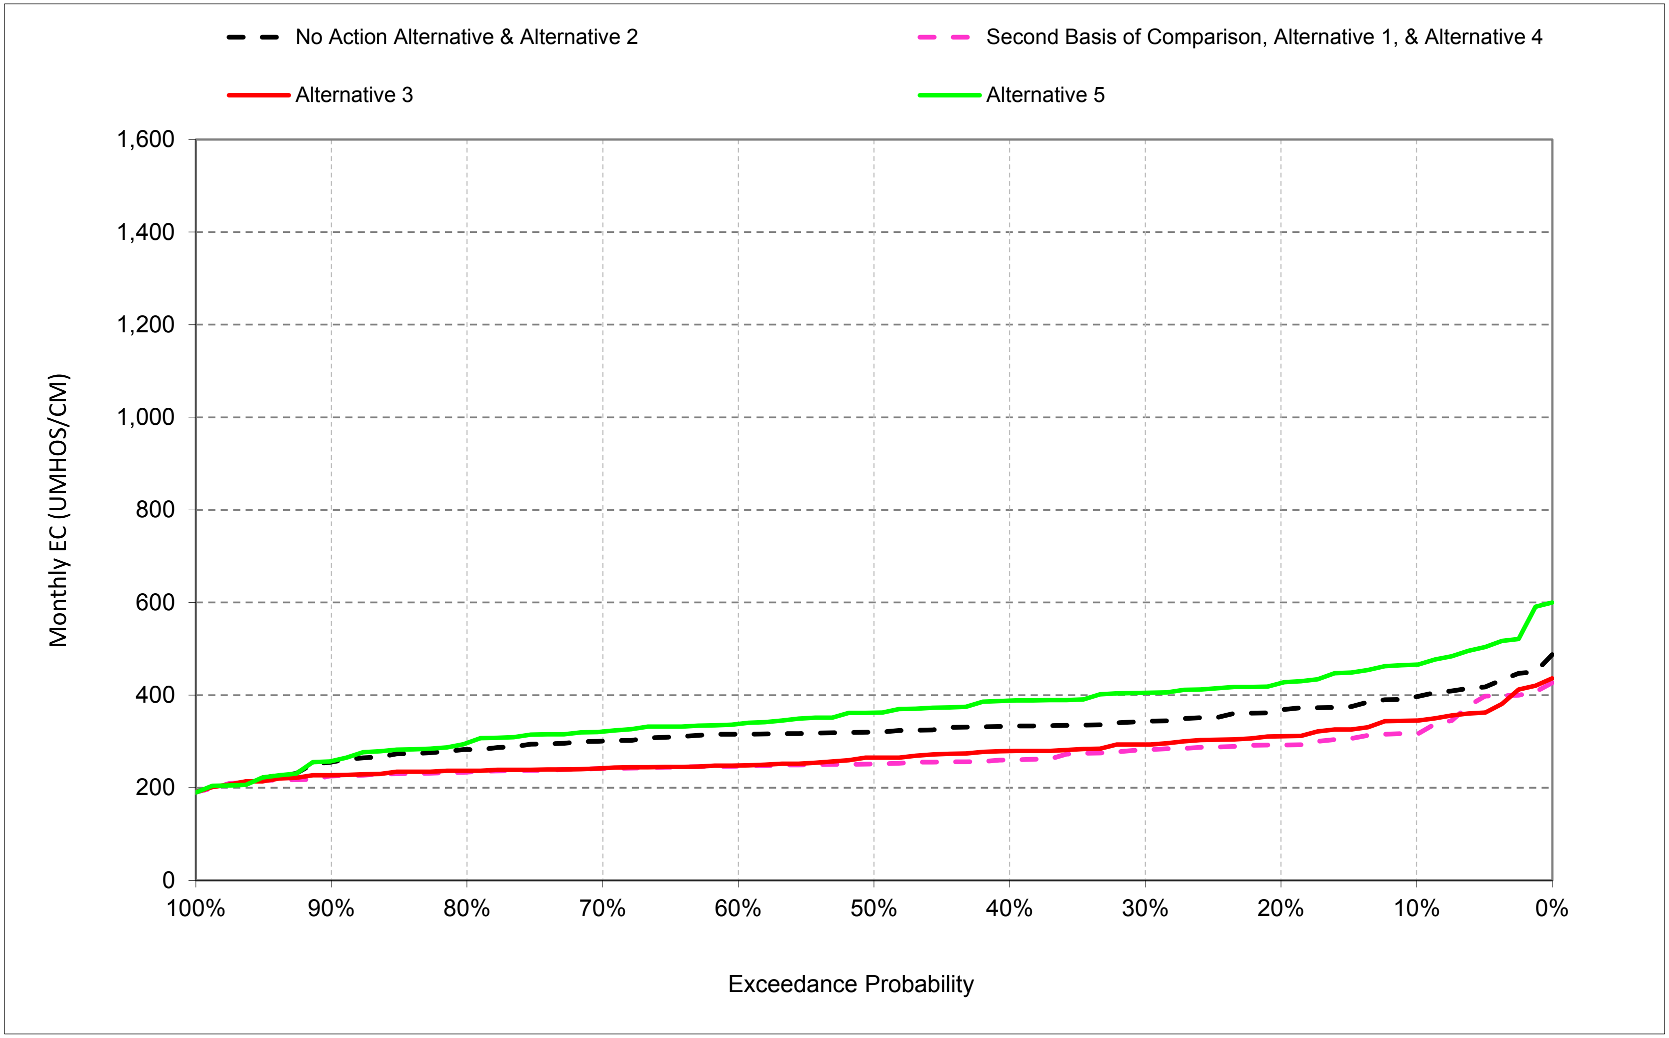
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.6. Old River at Rock Slough Salinity, Electrical Conductivity, March



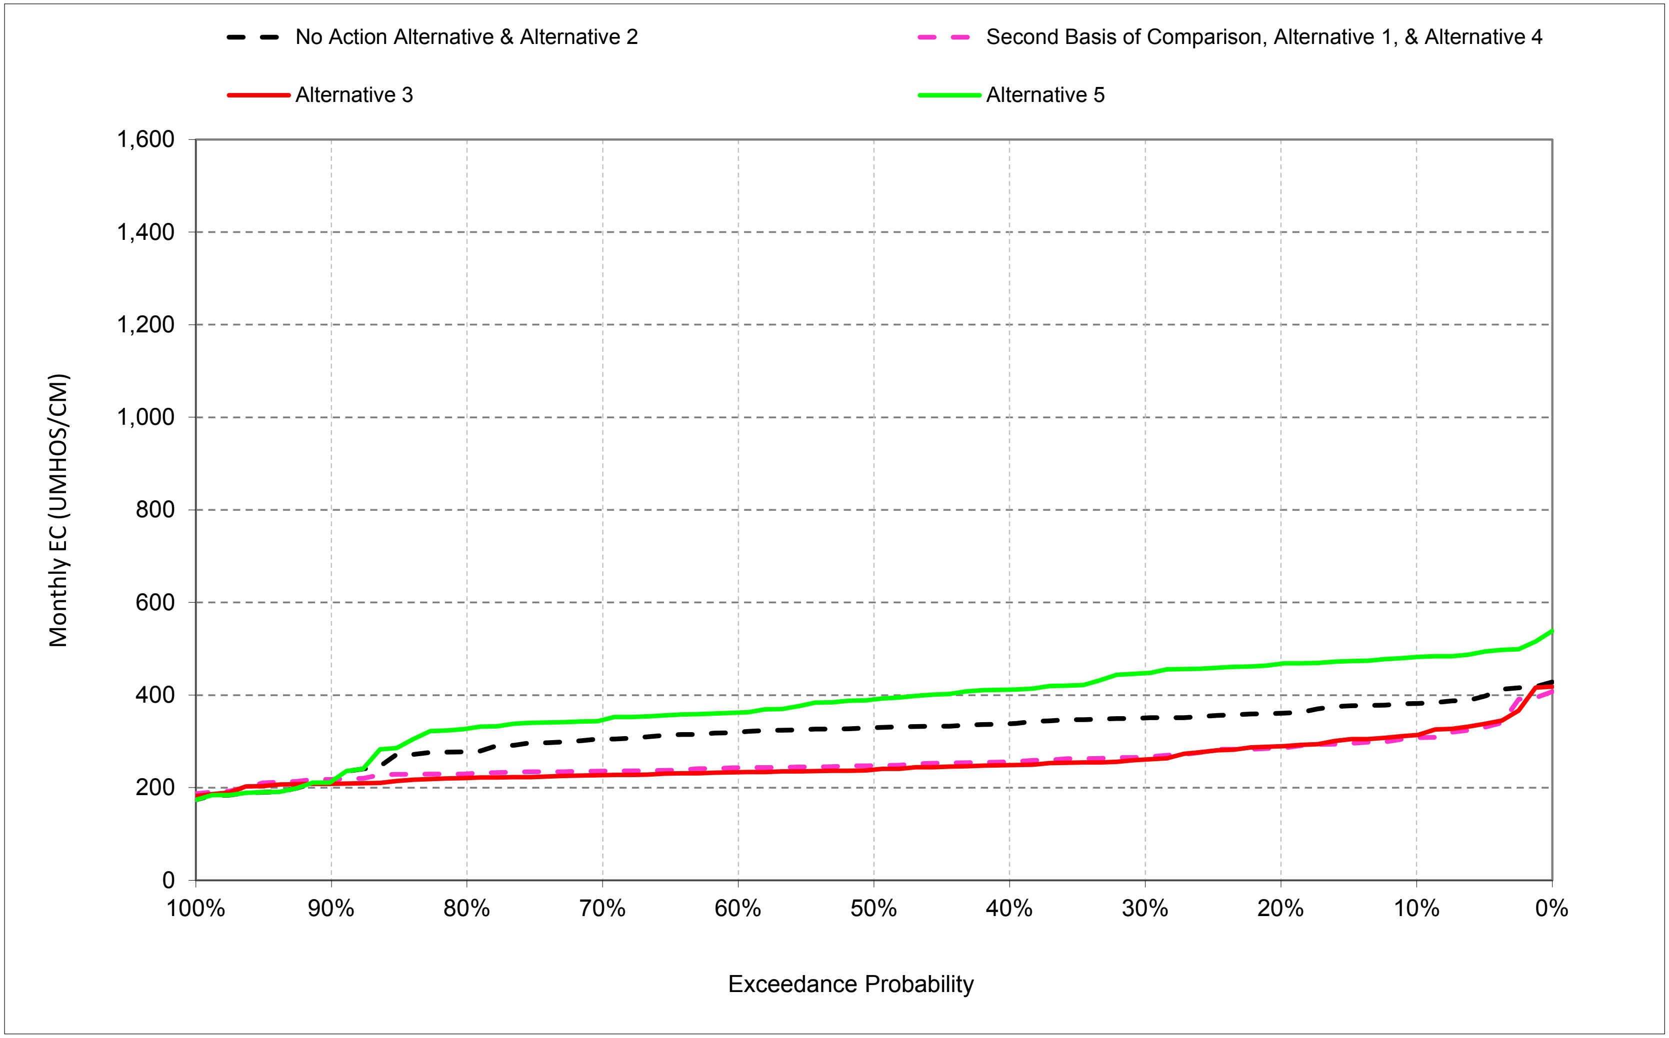
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.7. Old River at Rock Slough Salinity, Electrical Conductivity, April



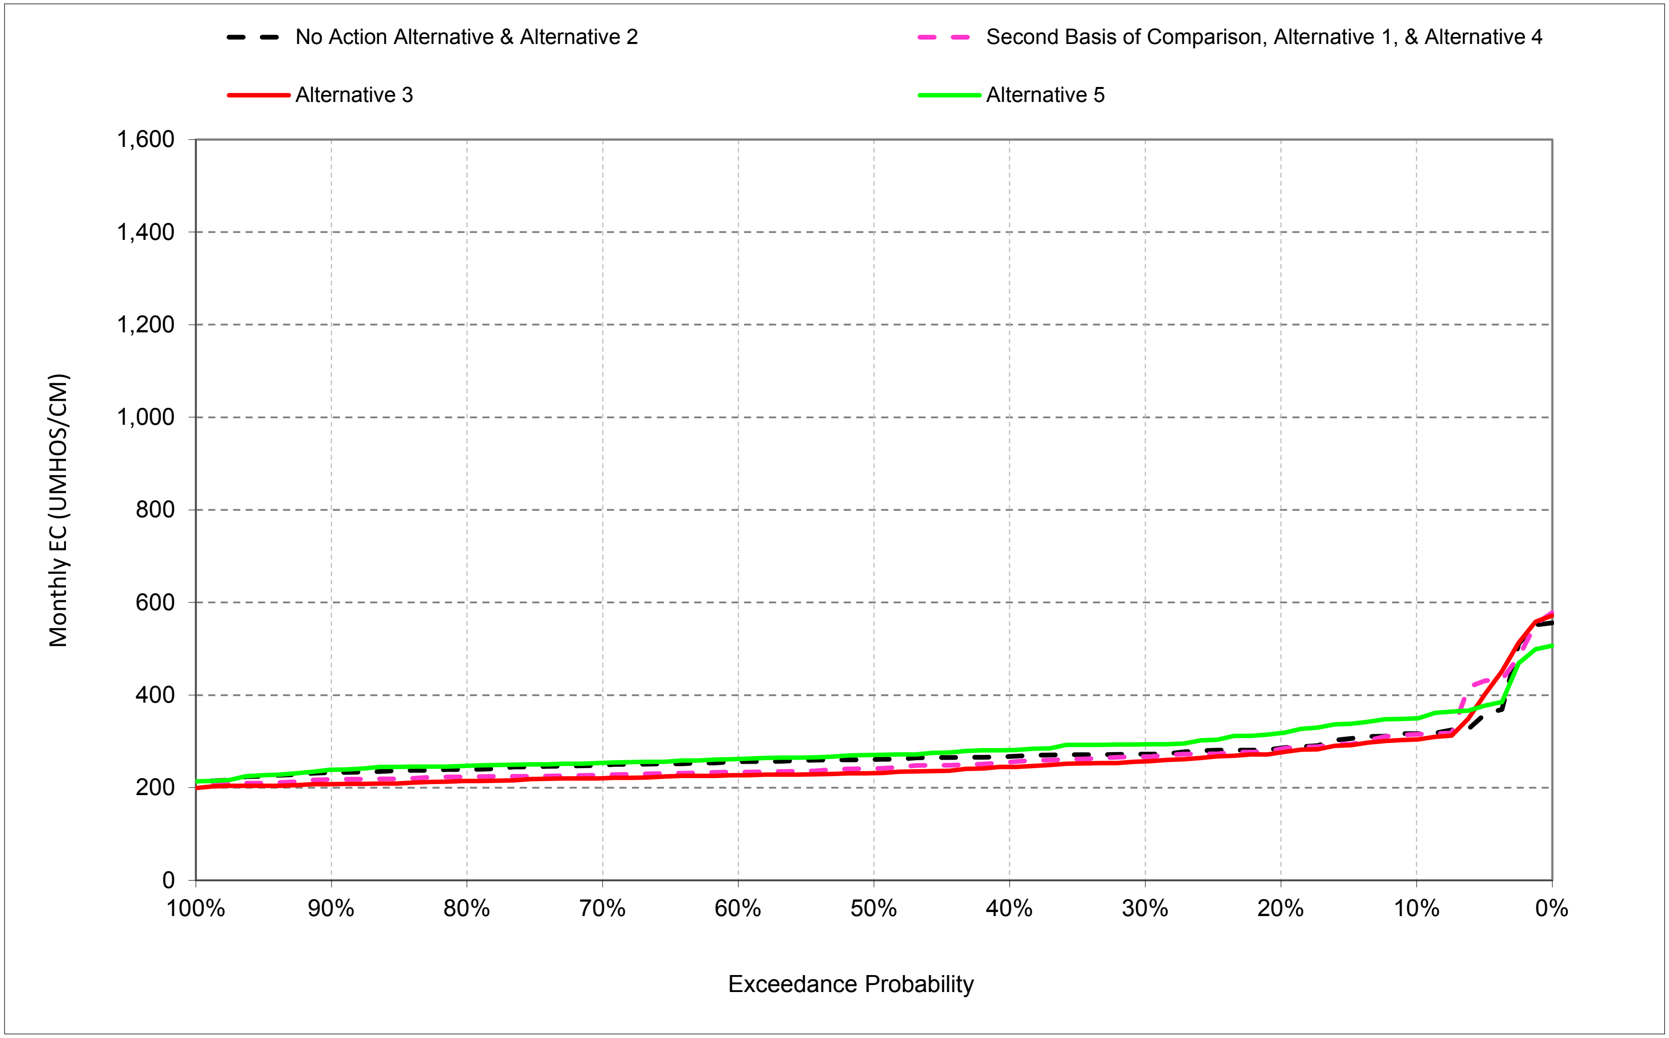
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.8. Old River at Rock Slough Salinity, Electrical Conductivity, May



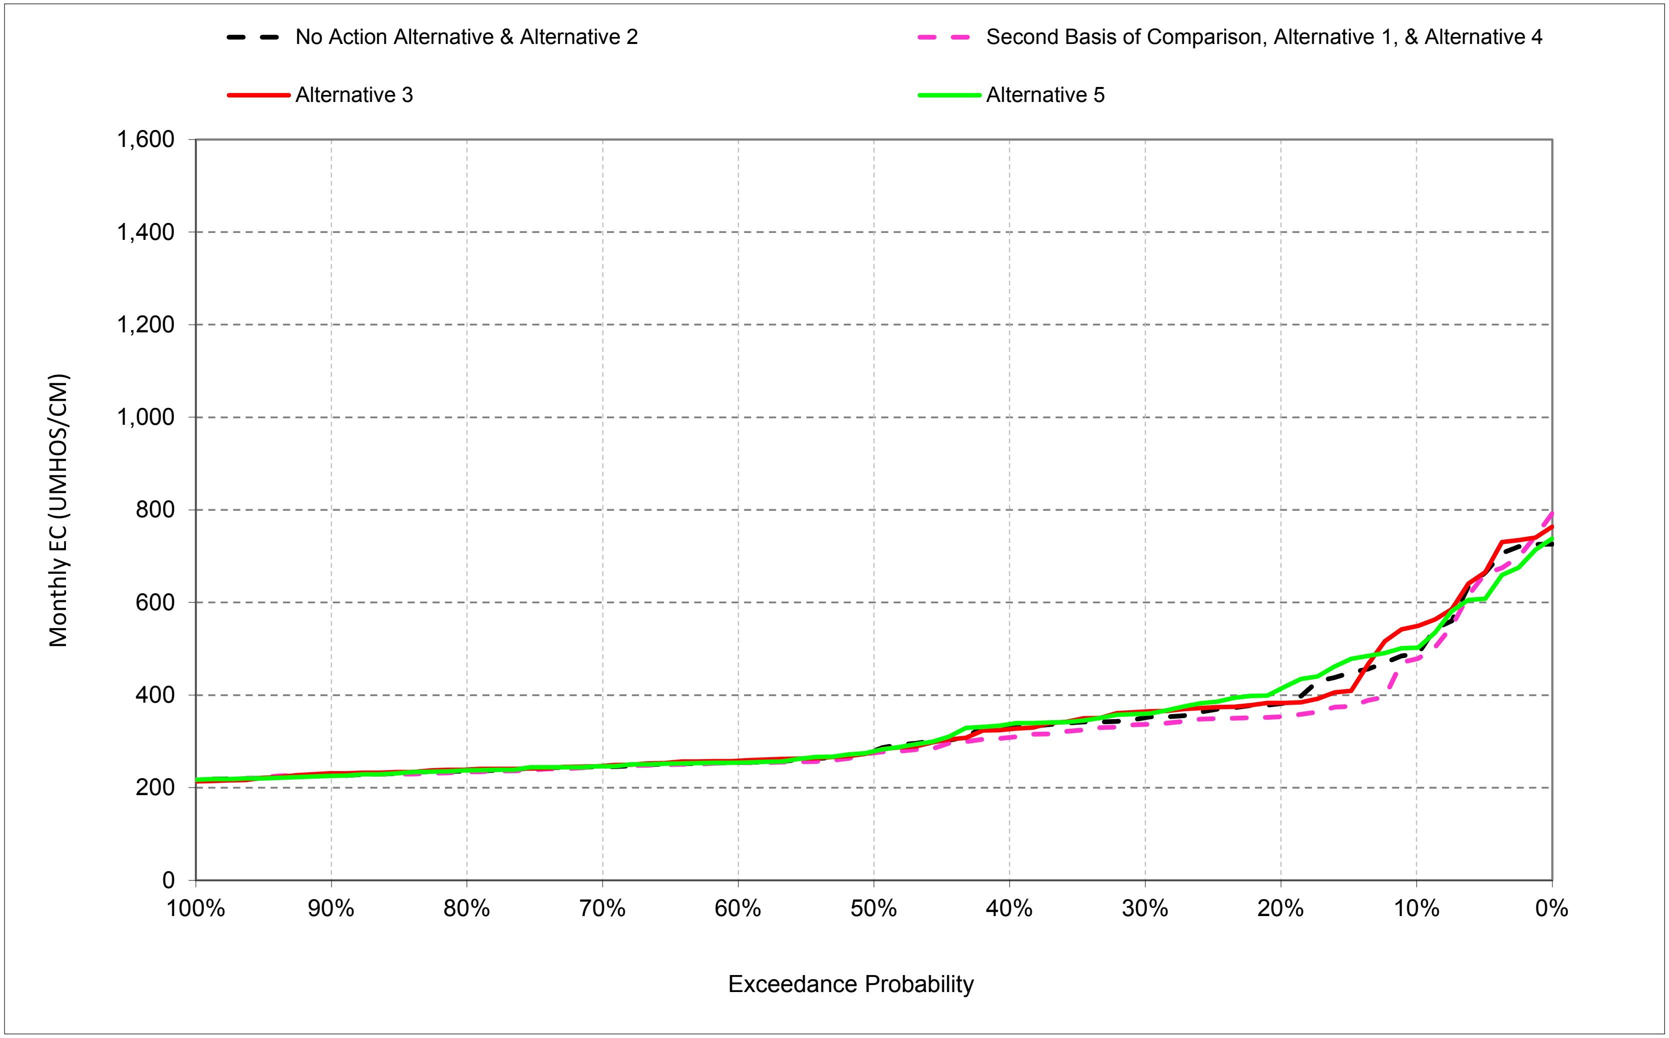
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.9. Old River at Rock Slough Salinity, Electrical Conductivity, June



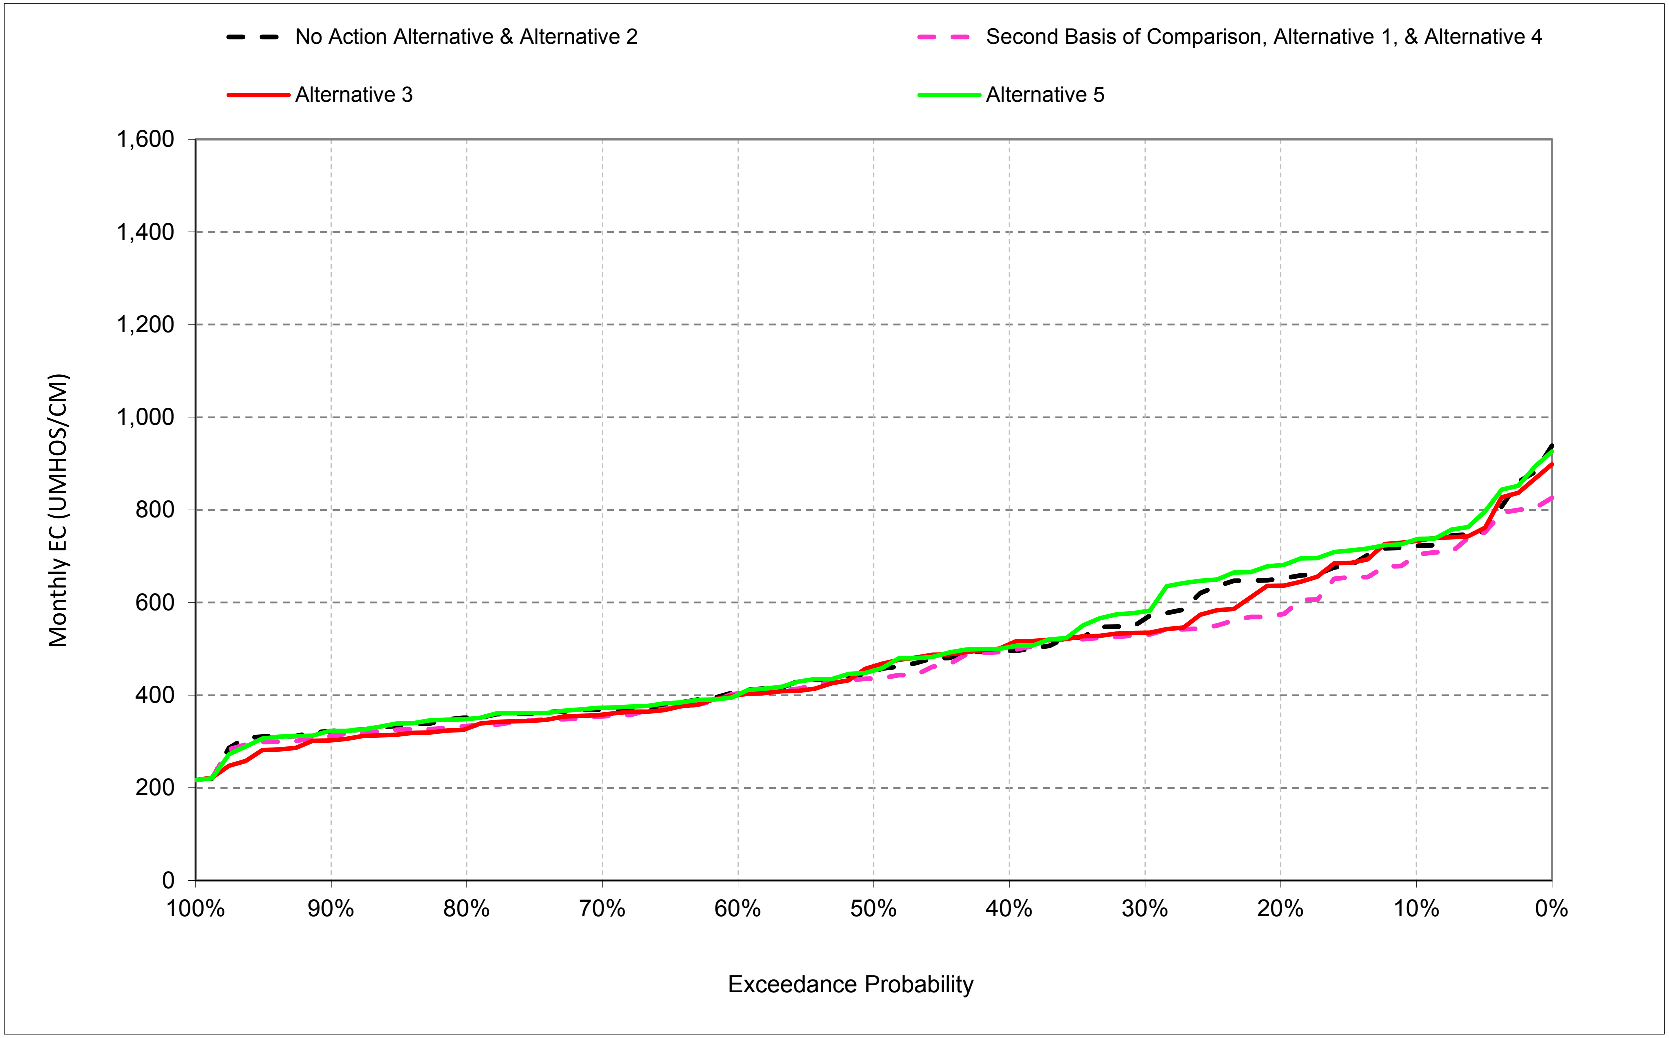
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.10. Old River at Rock Slough Salinity, Electrical Conductivity, July



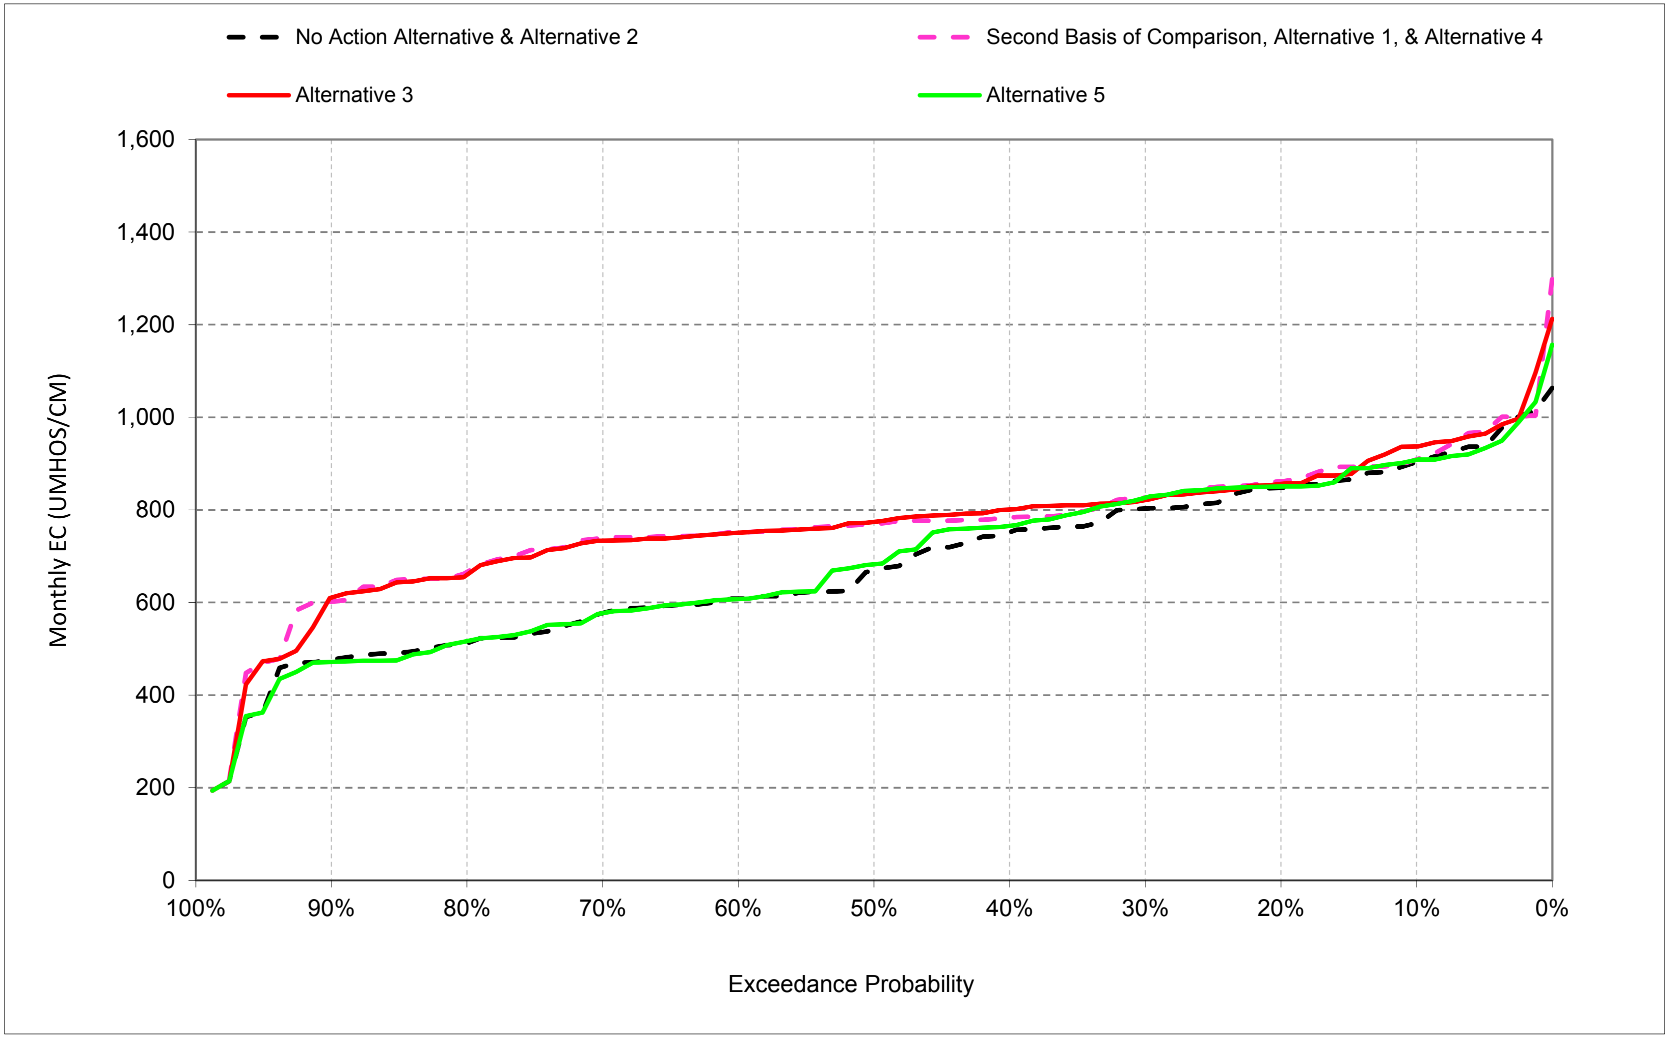
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.11. Old River at Rock Slough Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.11.12. Old River at Rock Slough Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

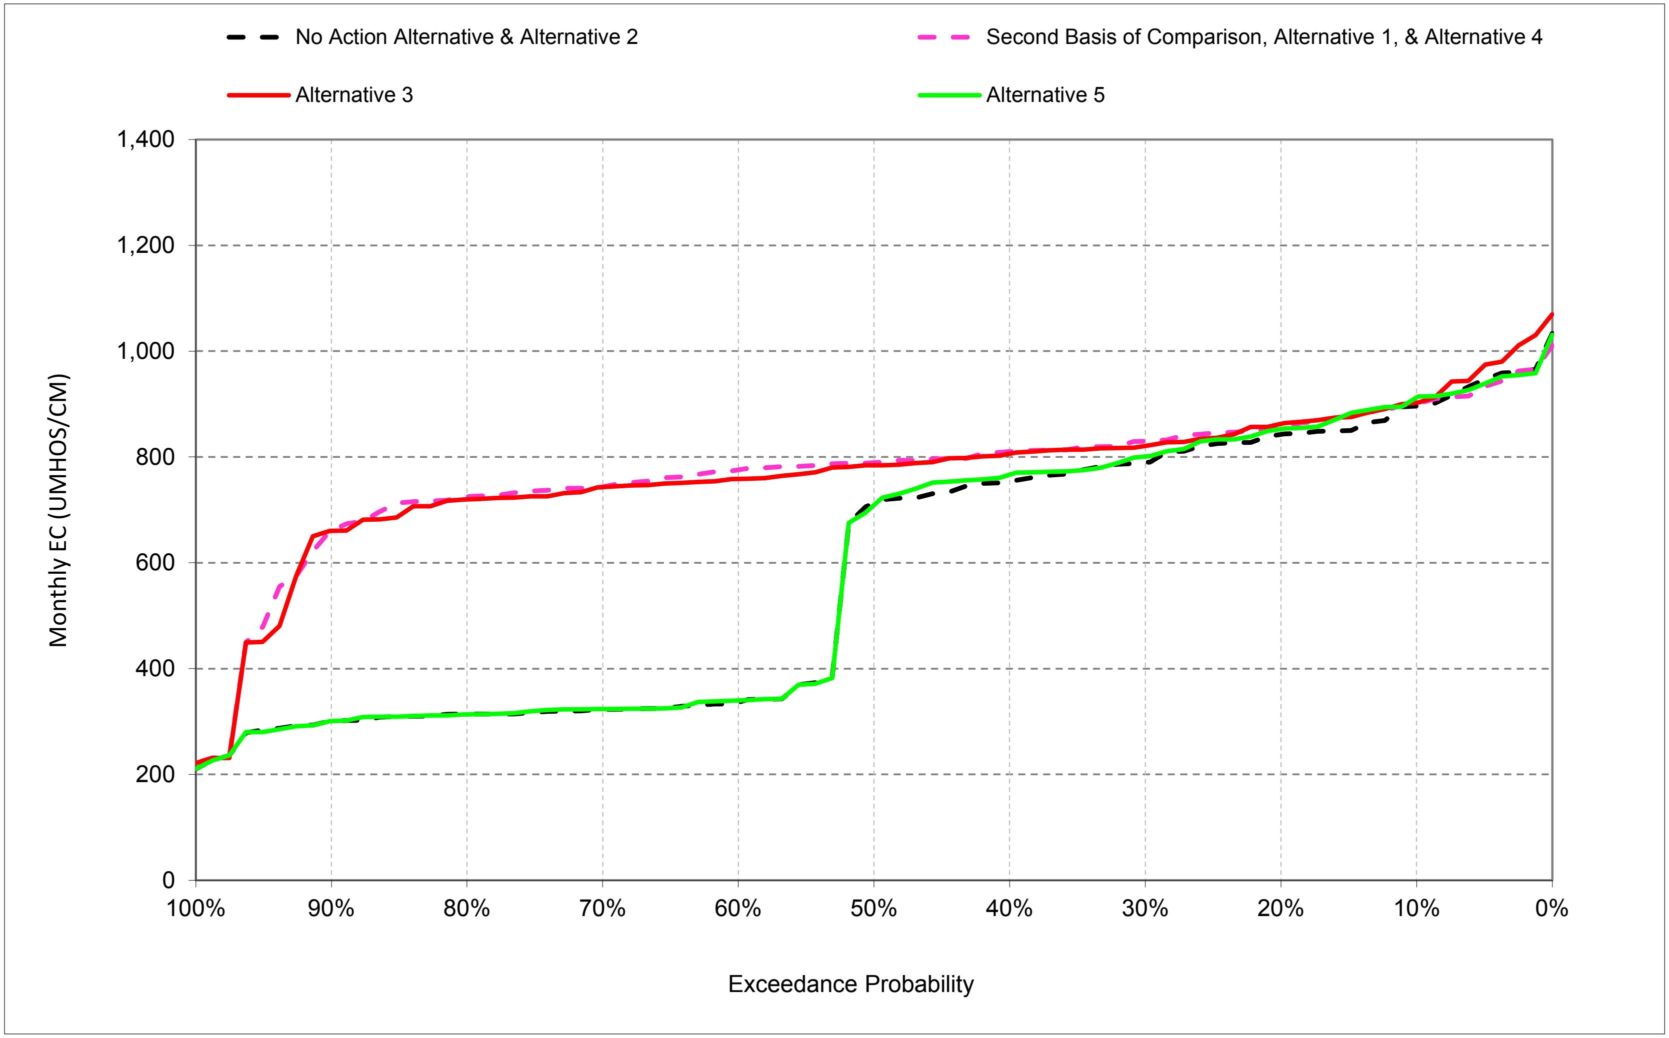
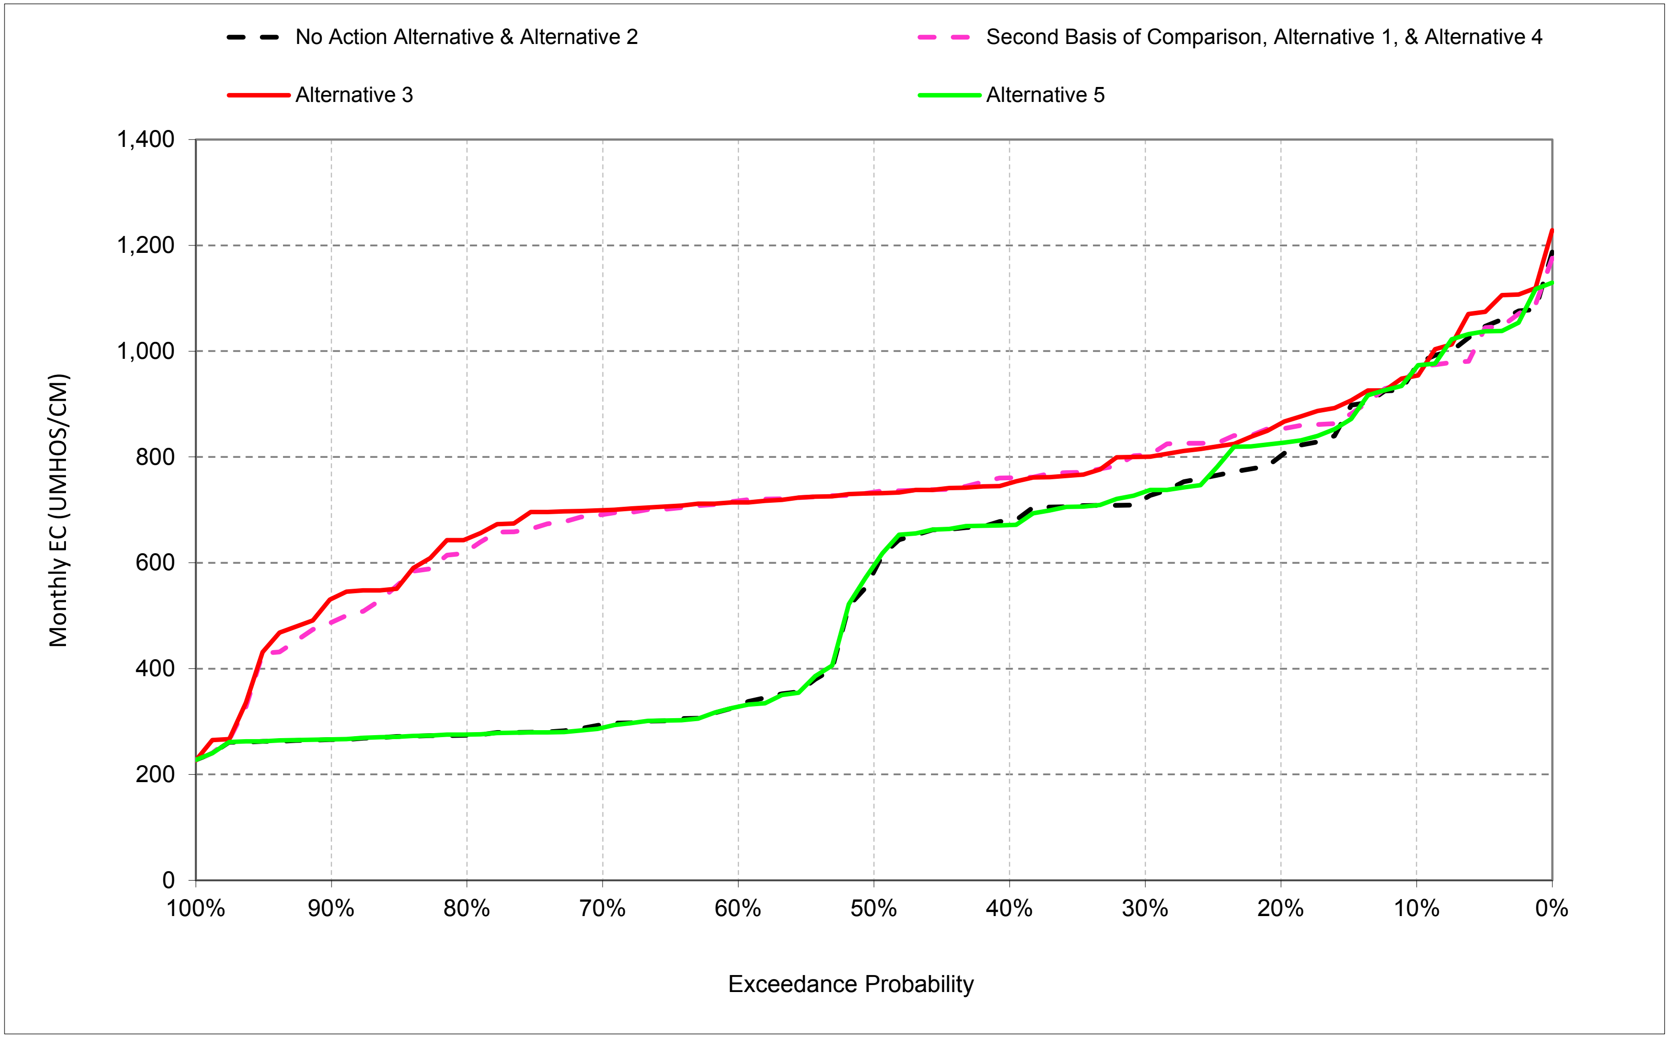
B.12 Contra Costa Water District Old River Intake Salinity

Figure 6E.B.12.1. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, October



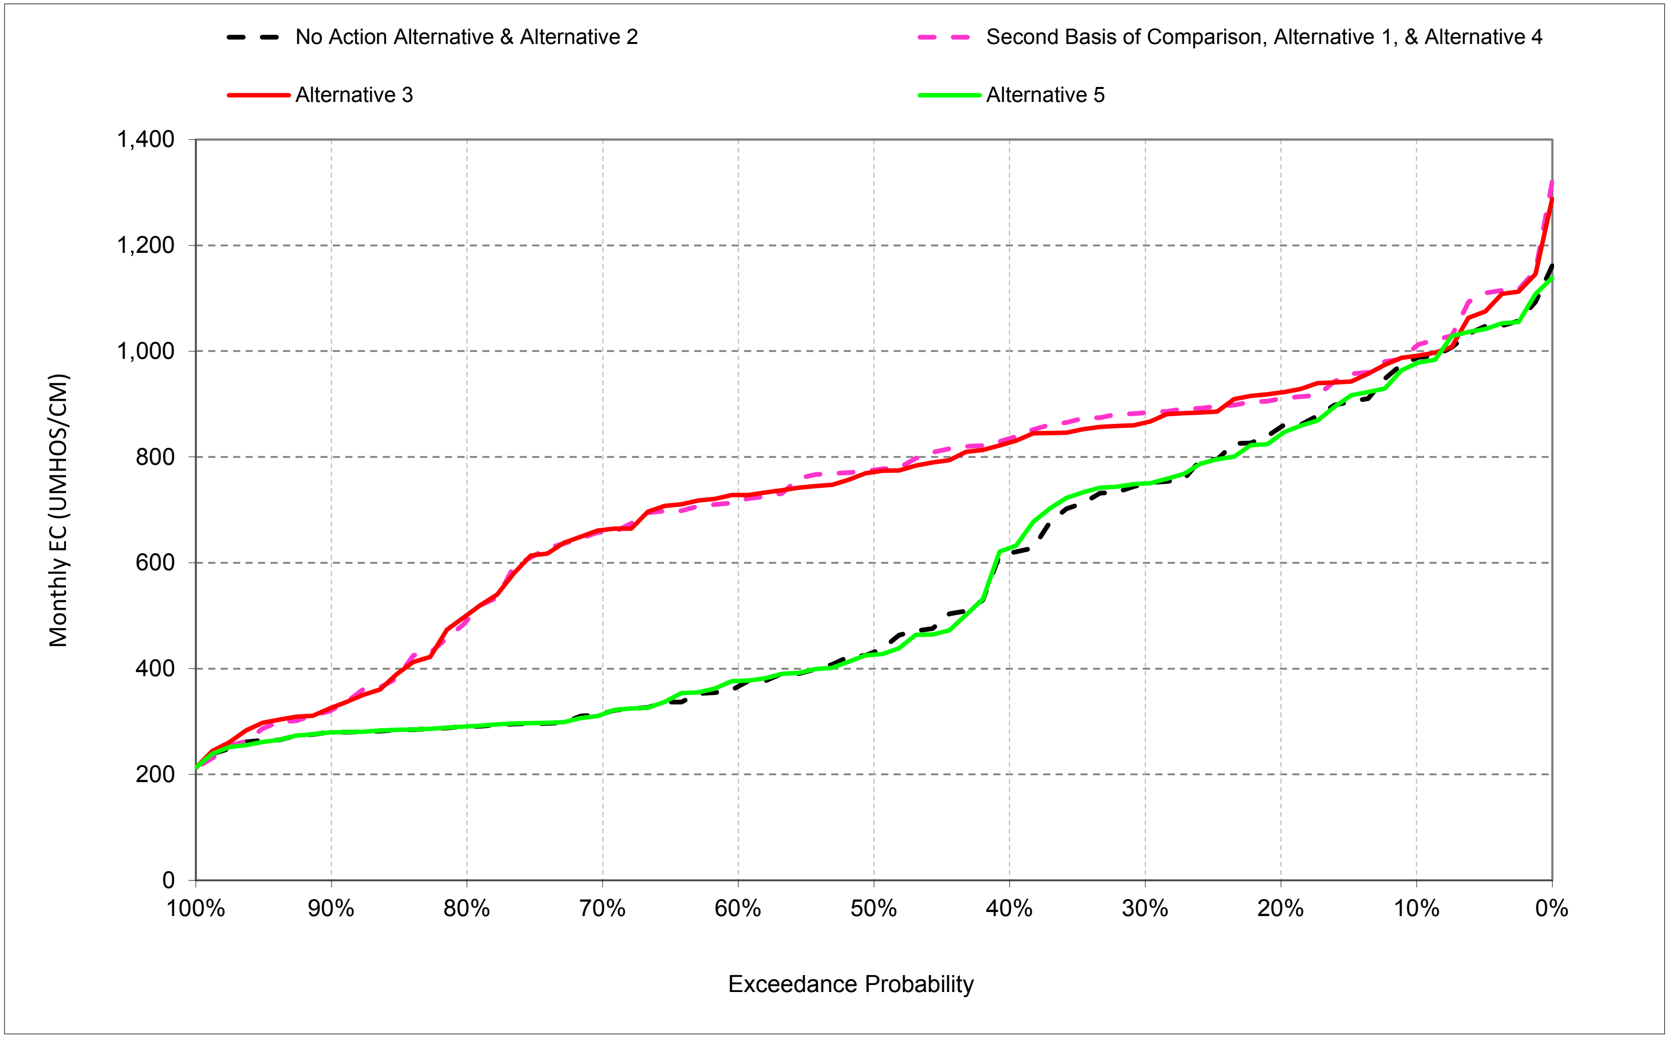
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.2. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, November



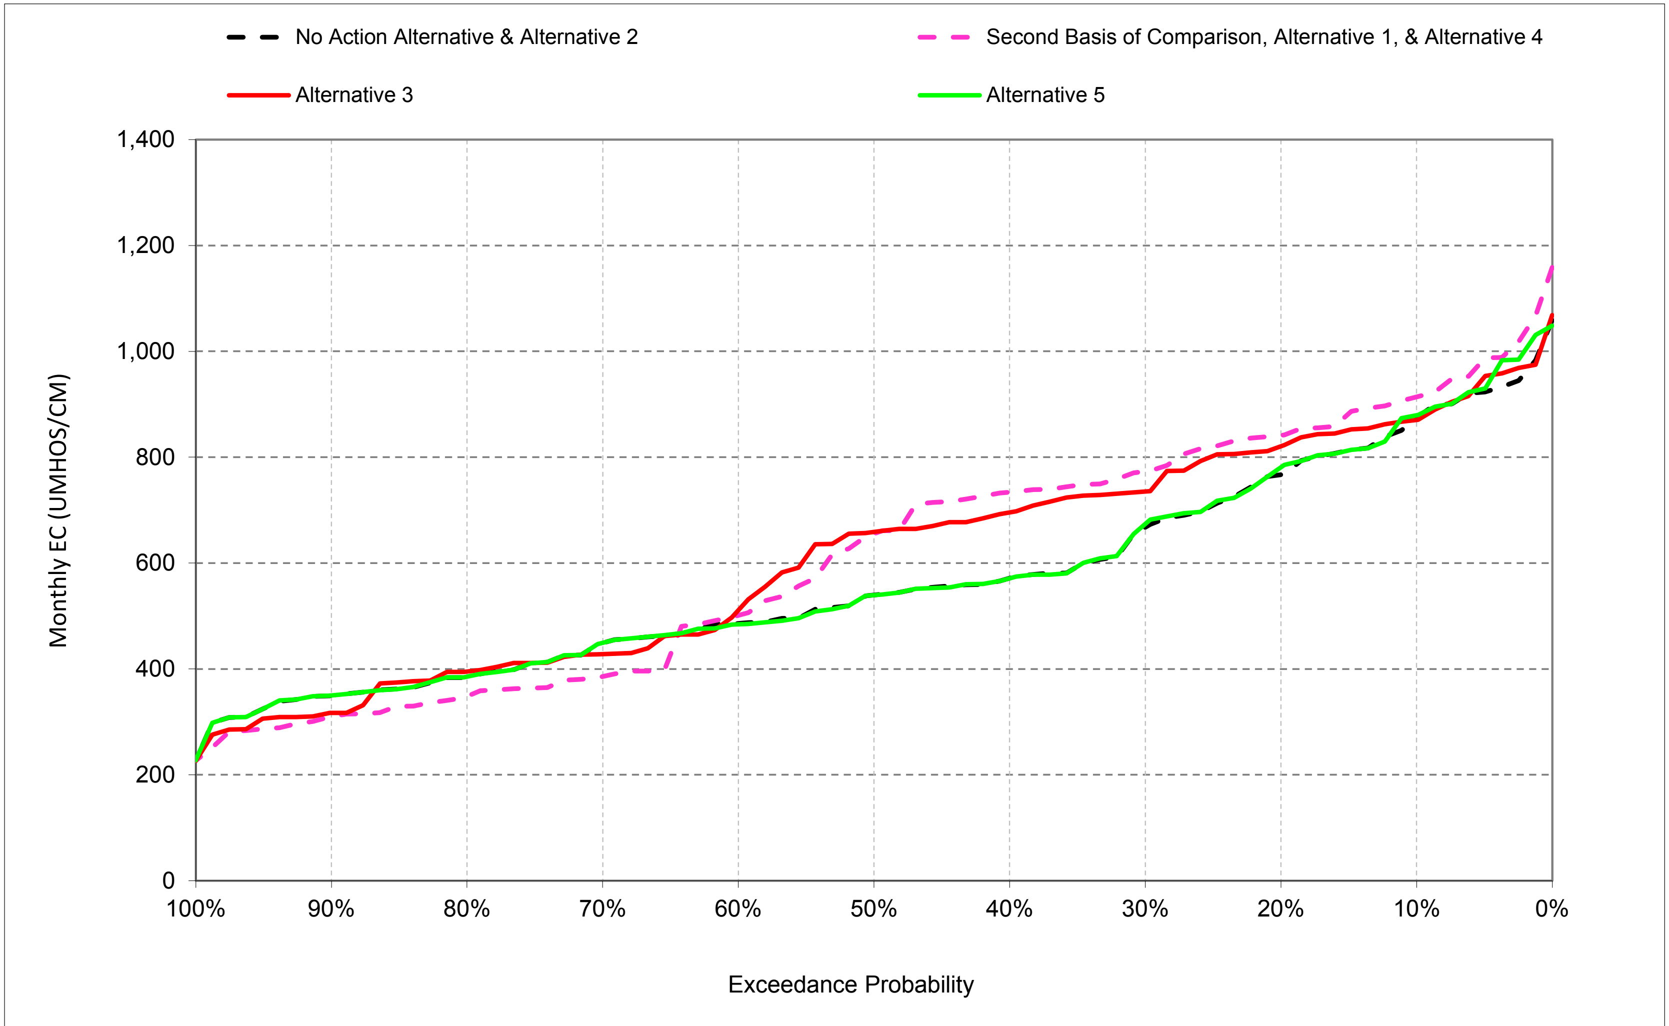
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.3. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, December



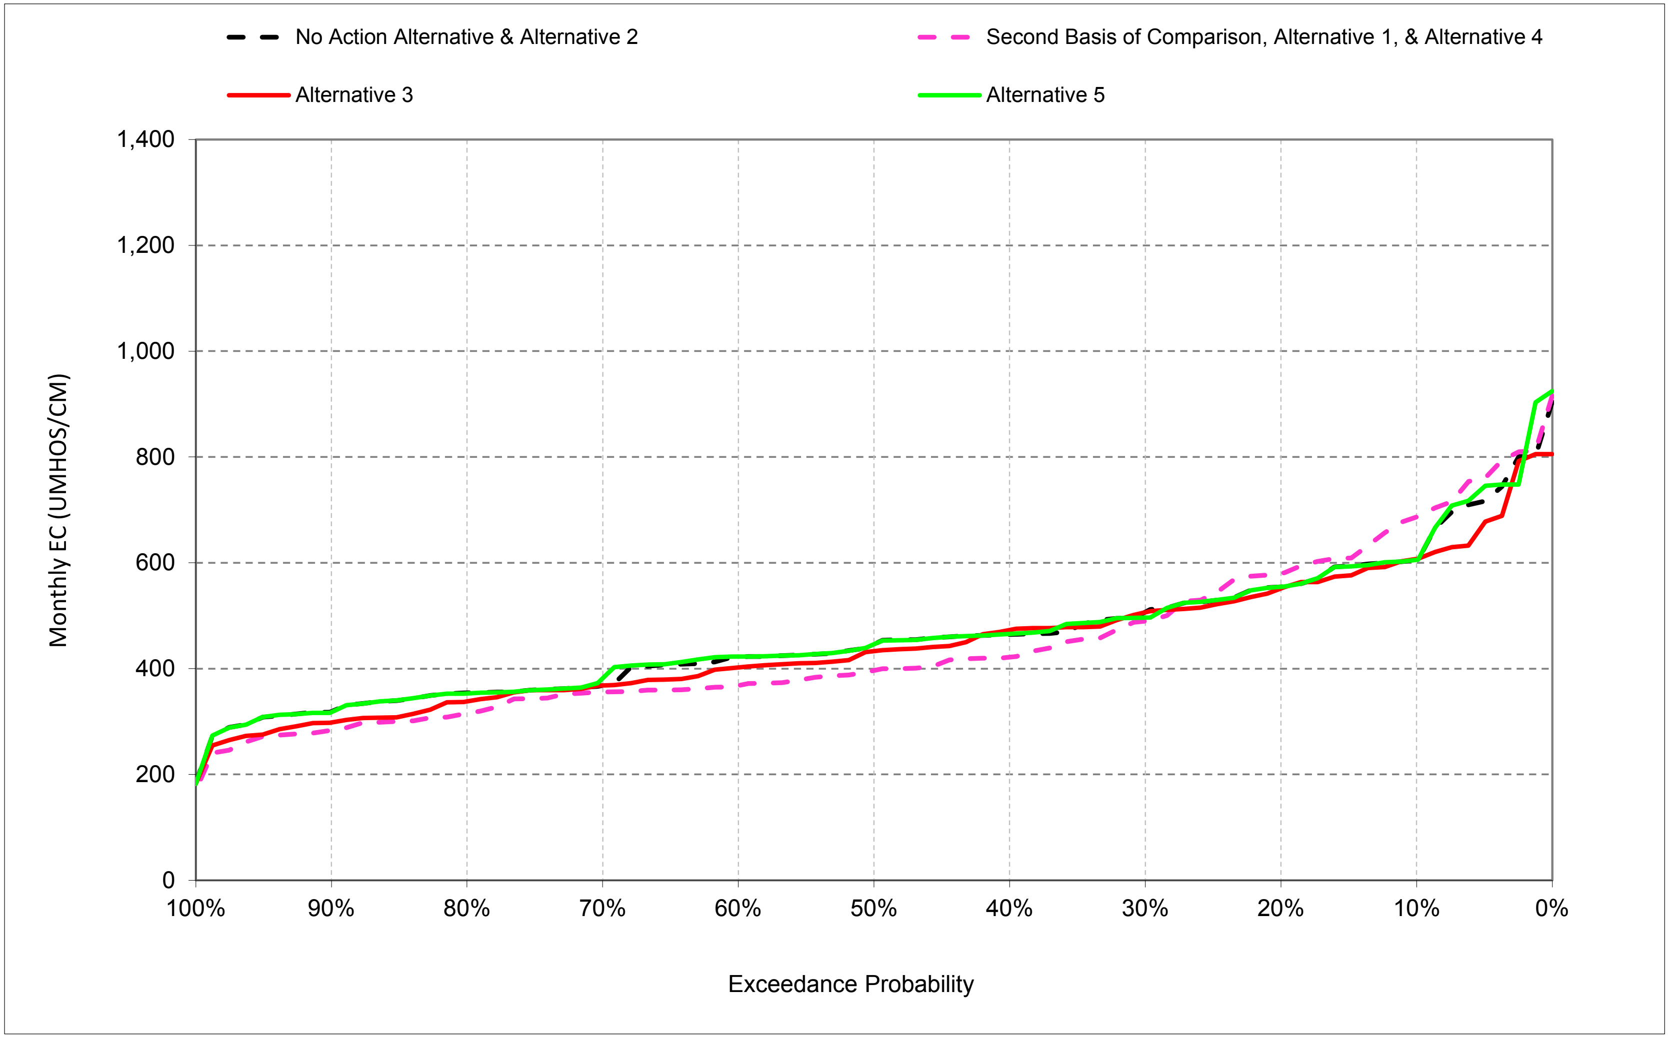
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.4. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, January



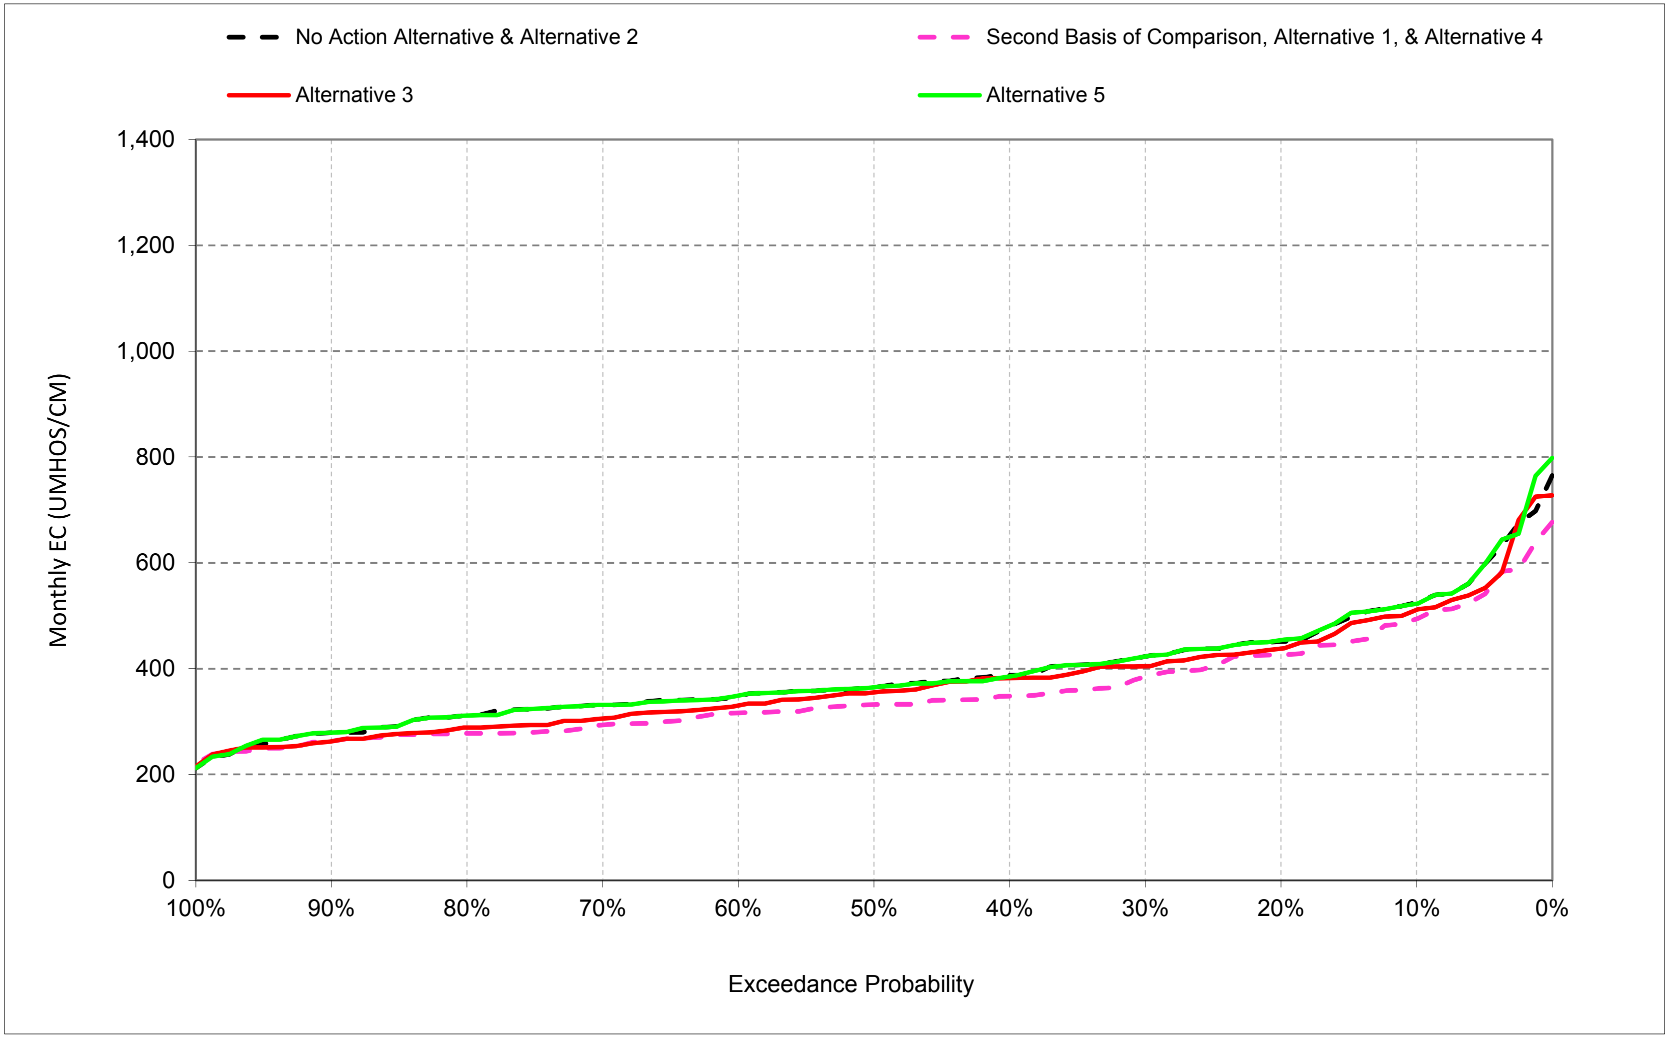
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.5. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, February



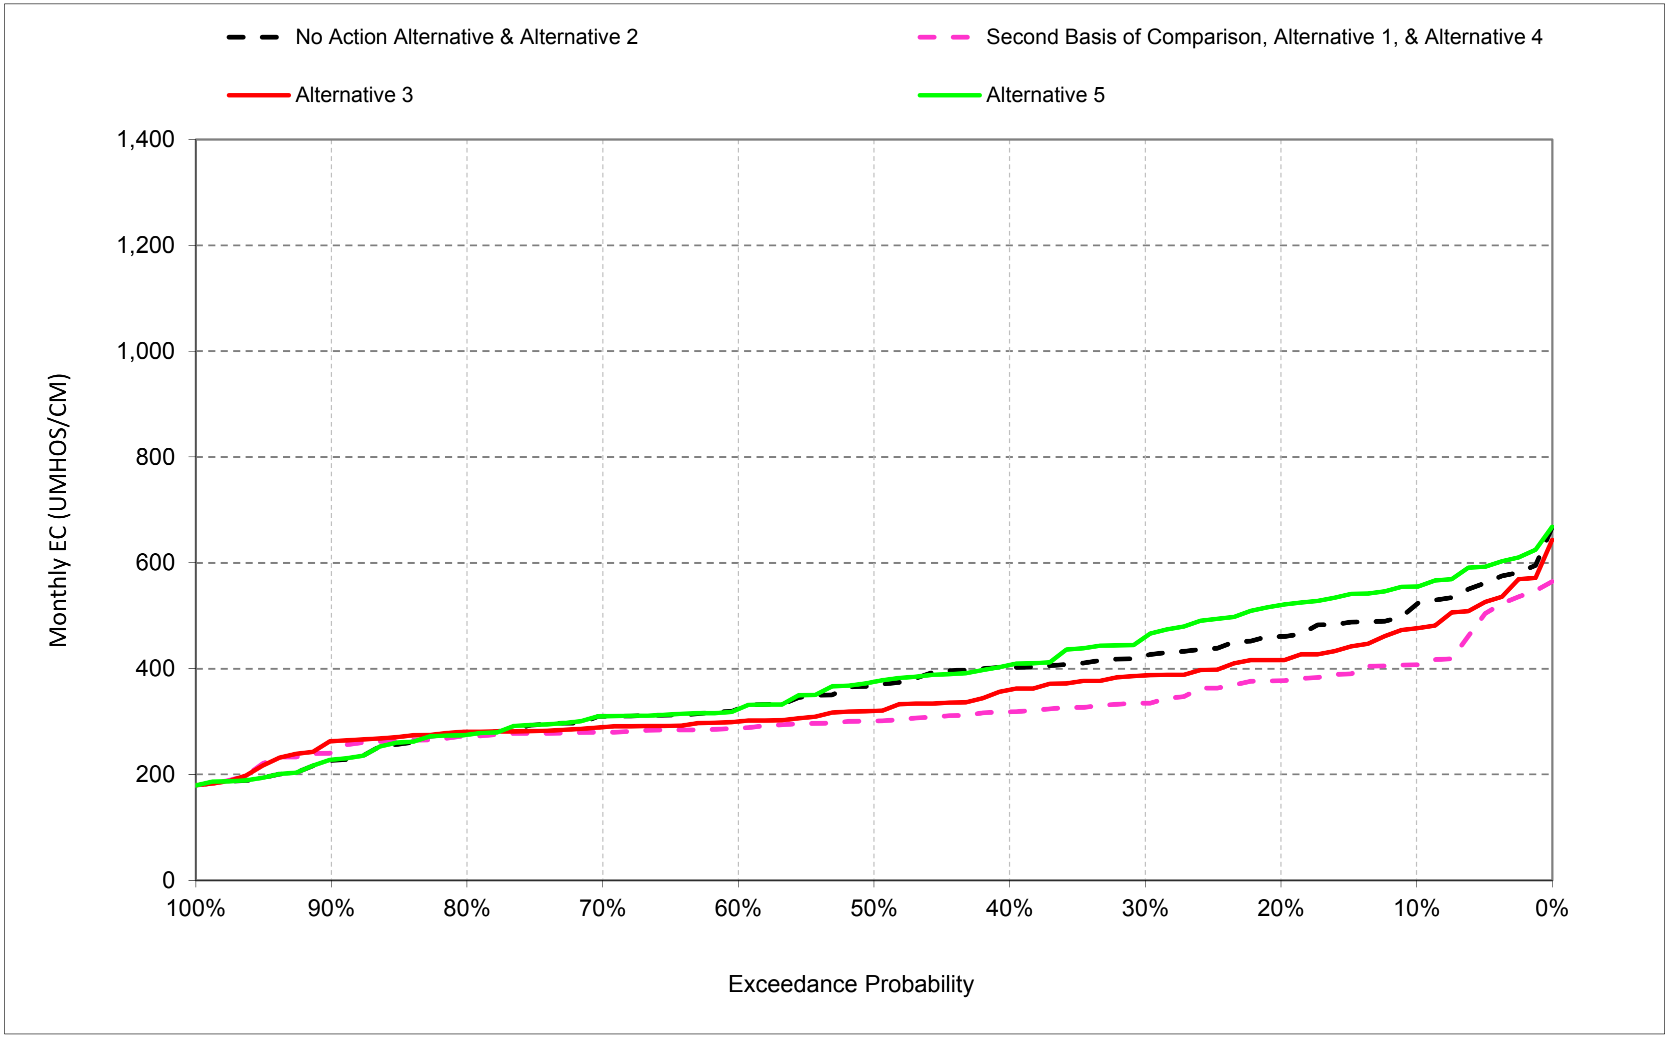
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.6. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, March



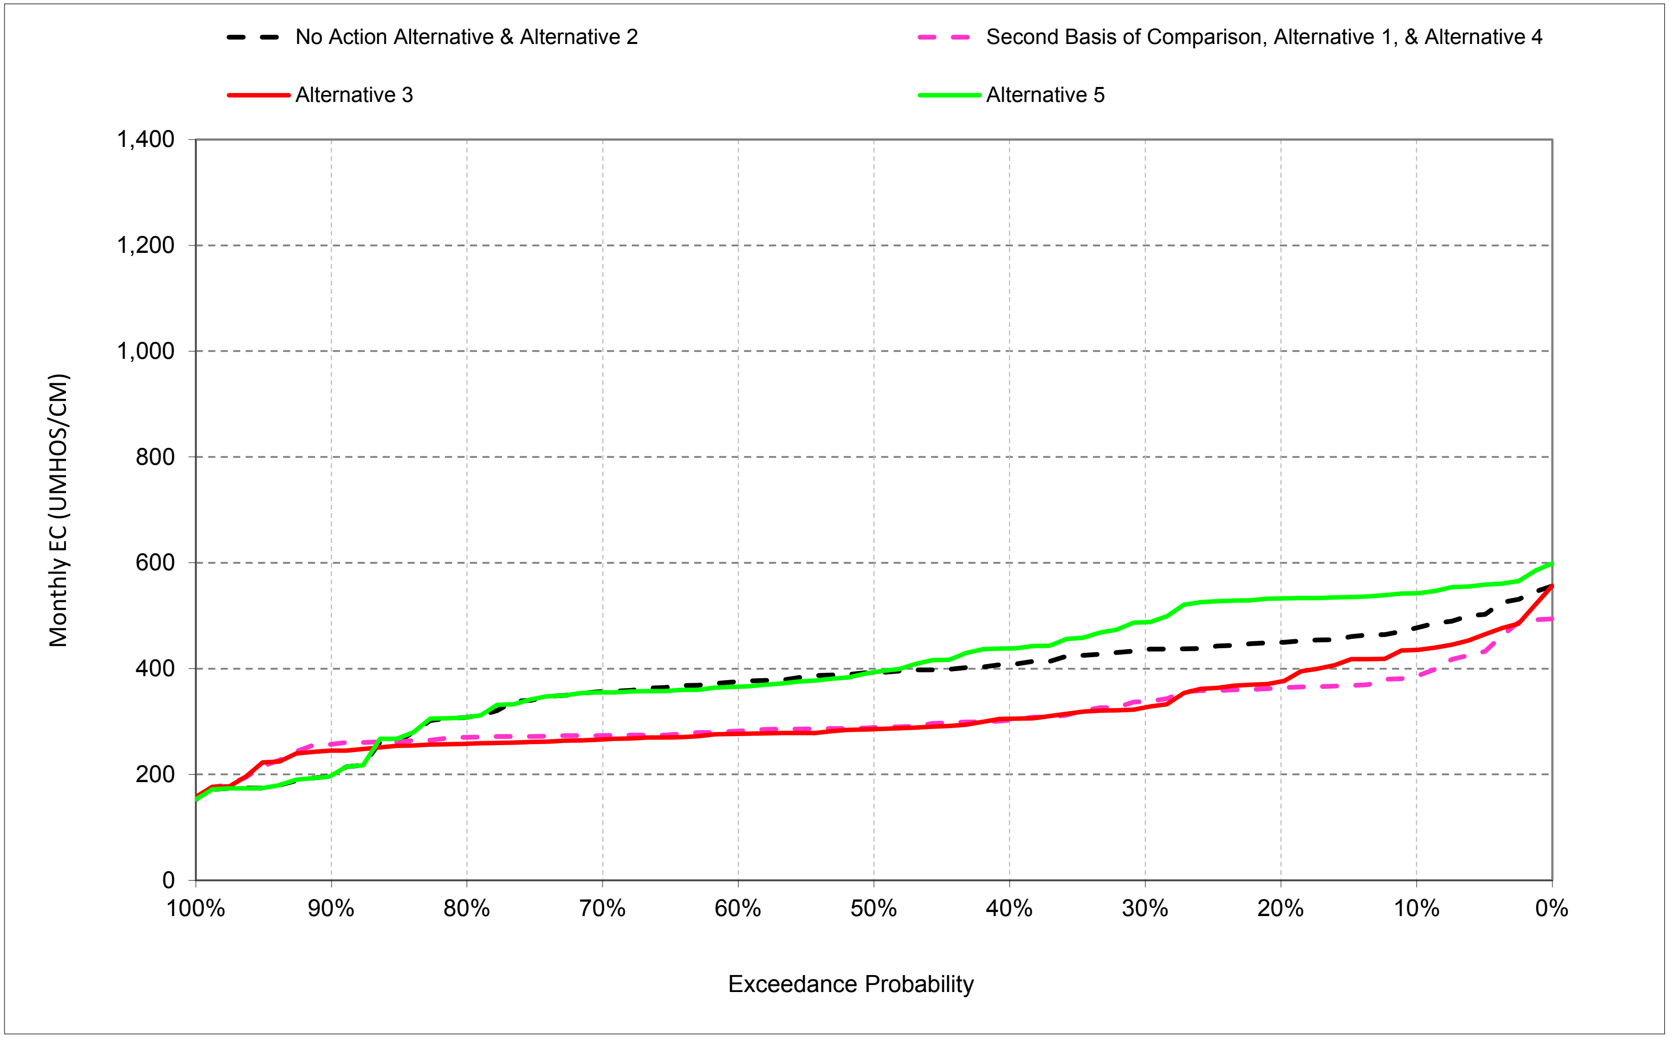
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.7. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, April



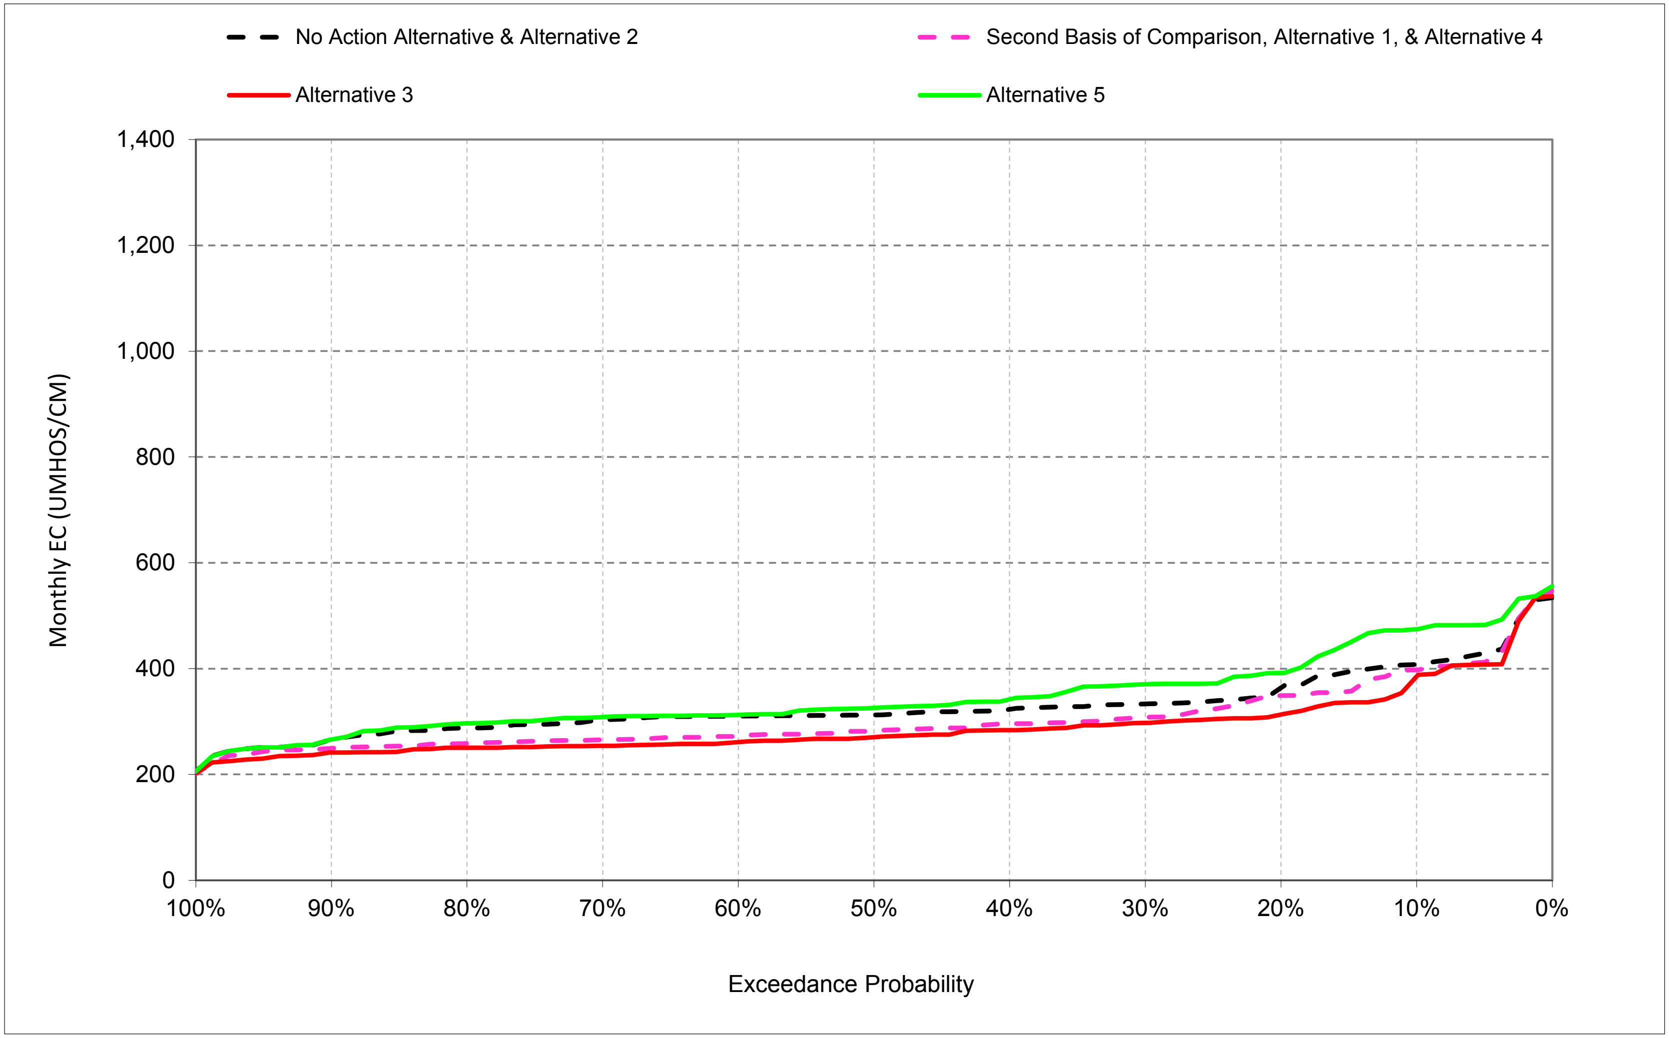
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.8. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, May



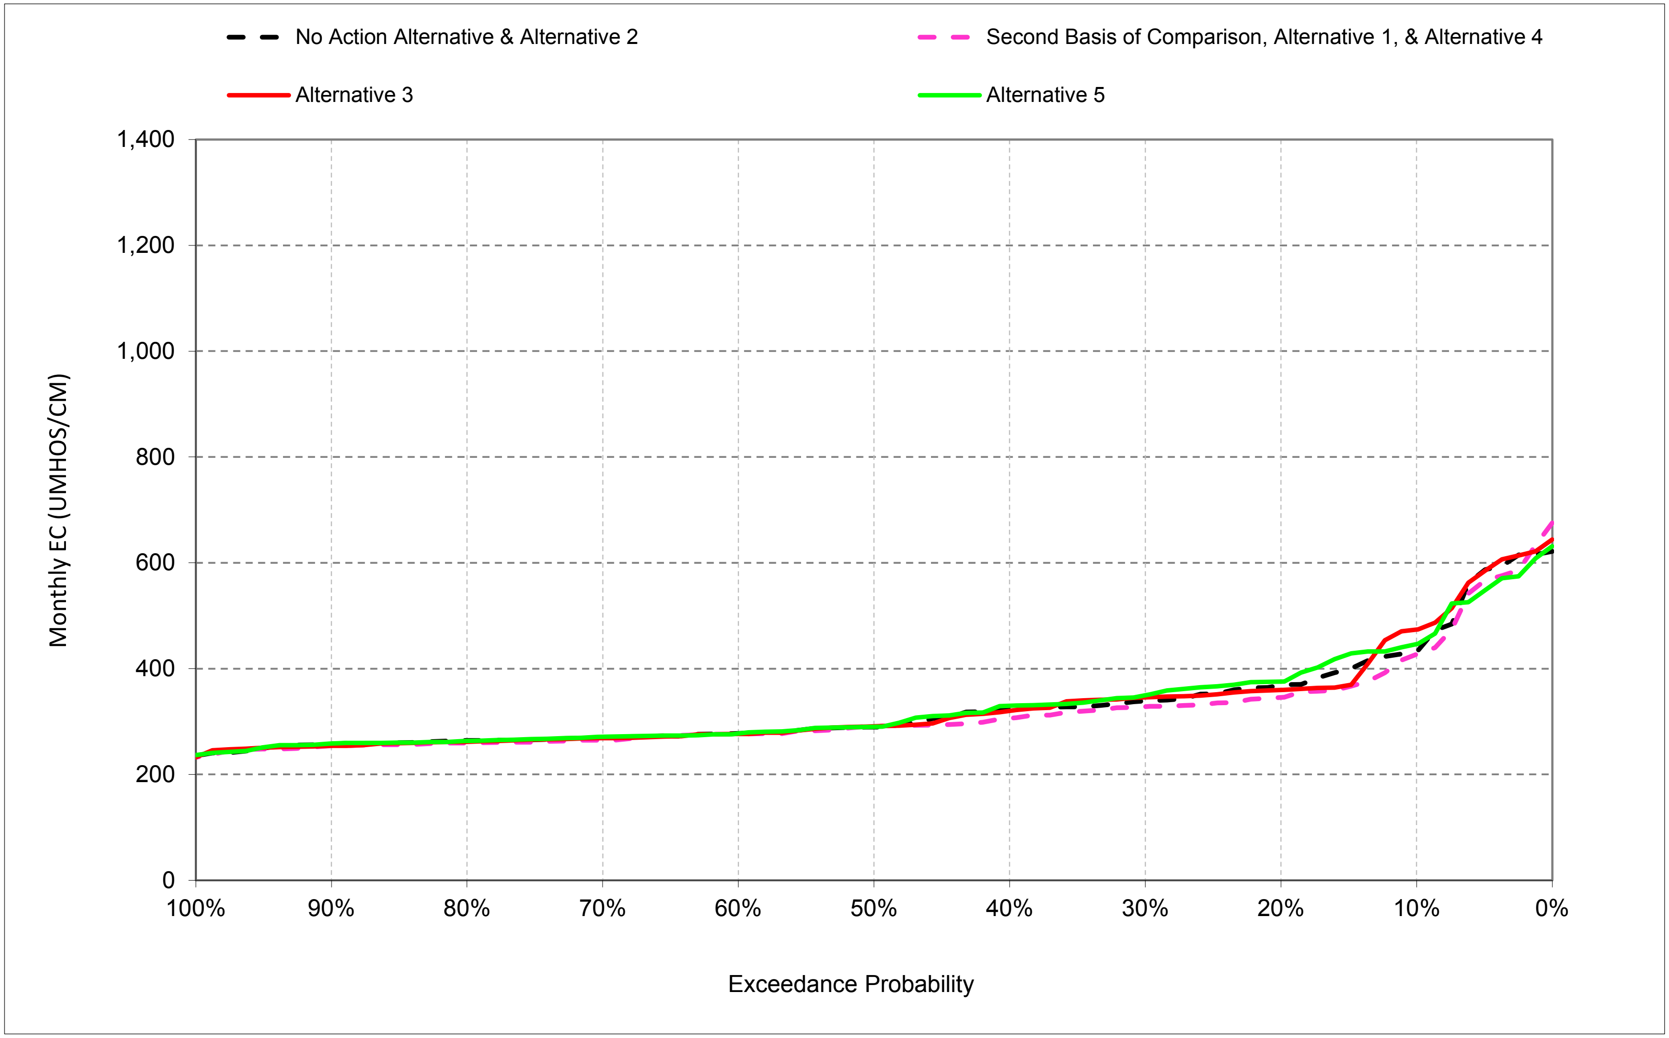
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.9. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, June



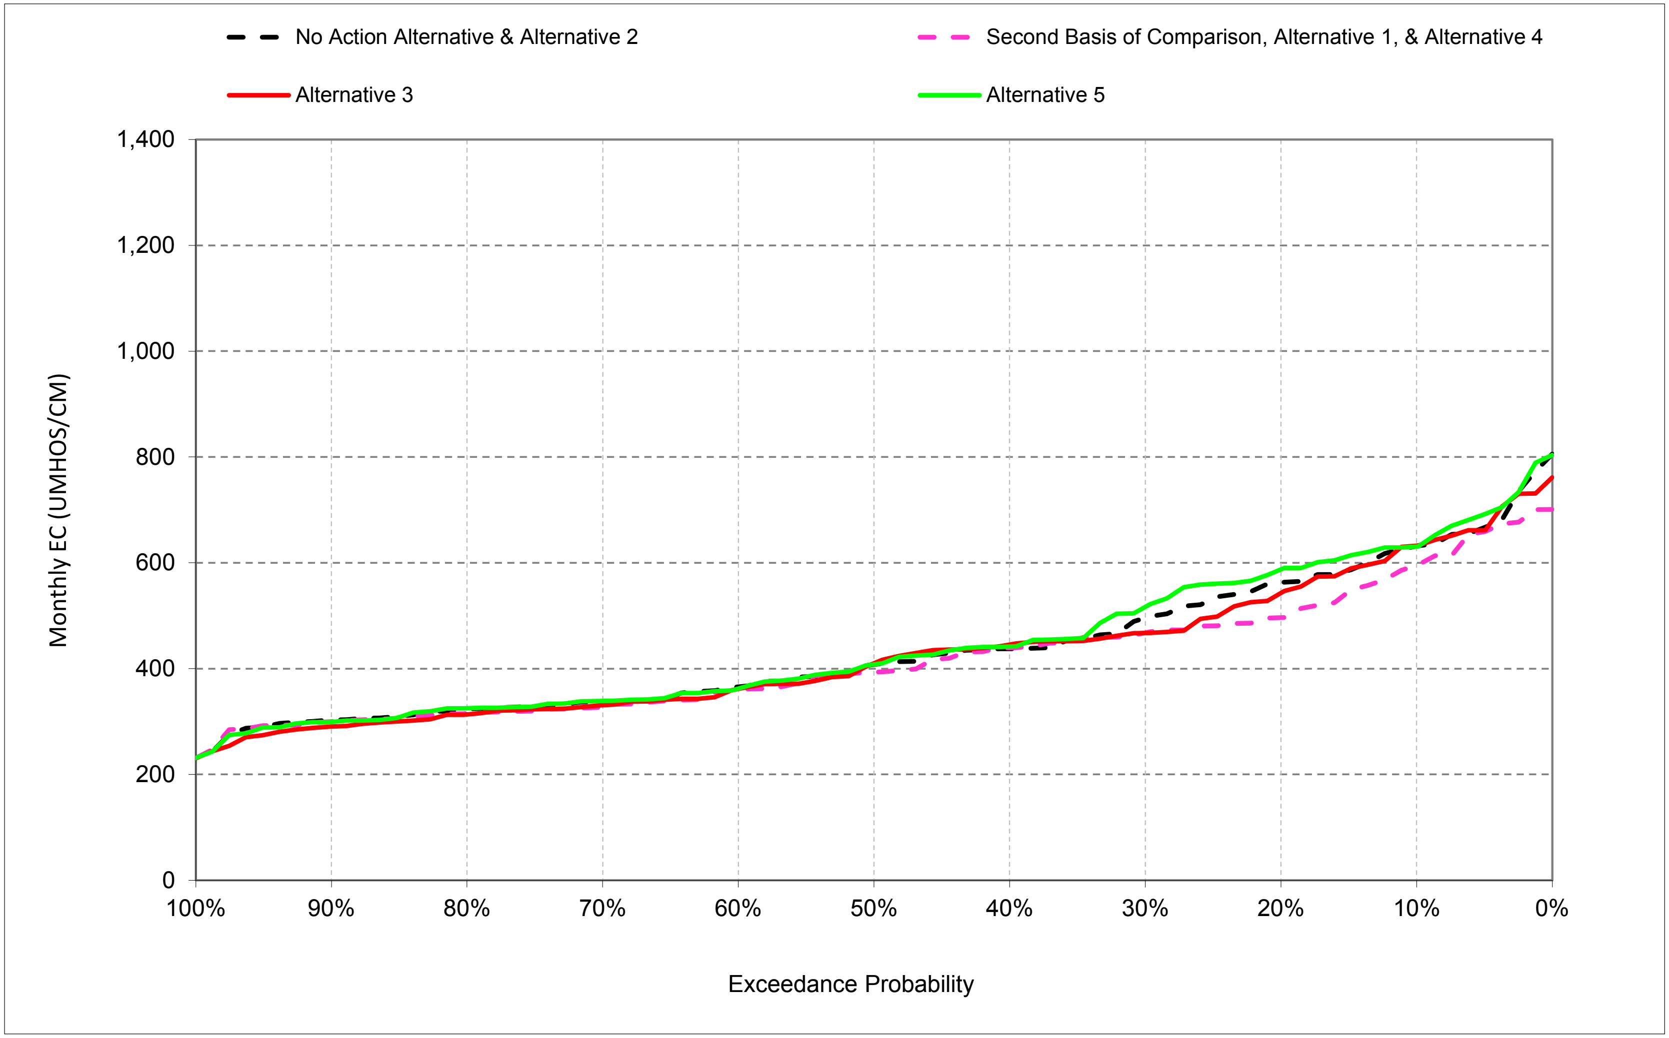
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.10. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, July



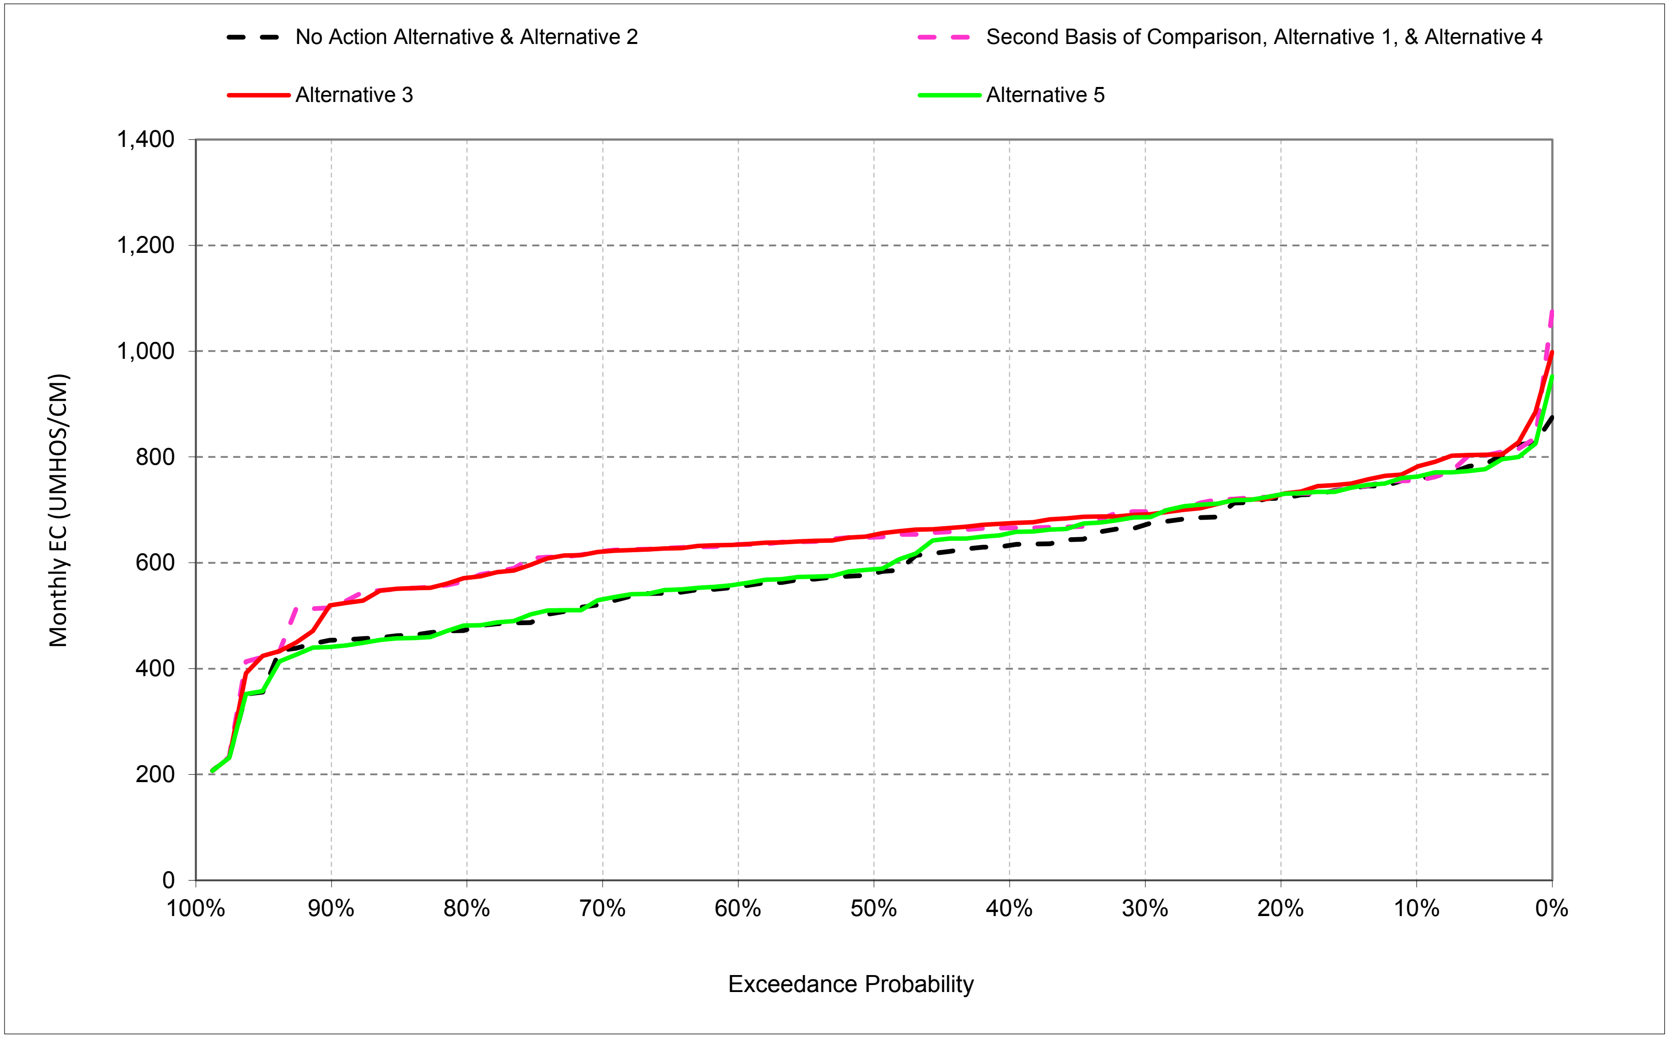
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.11. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.12.12. Contra Costa Water District Old River Intake Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Qualitative differences, if applicable, are discussed in the text.

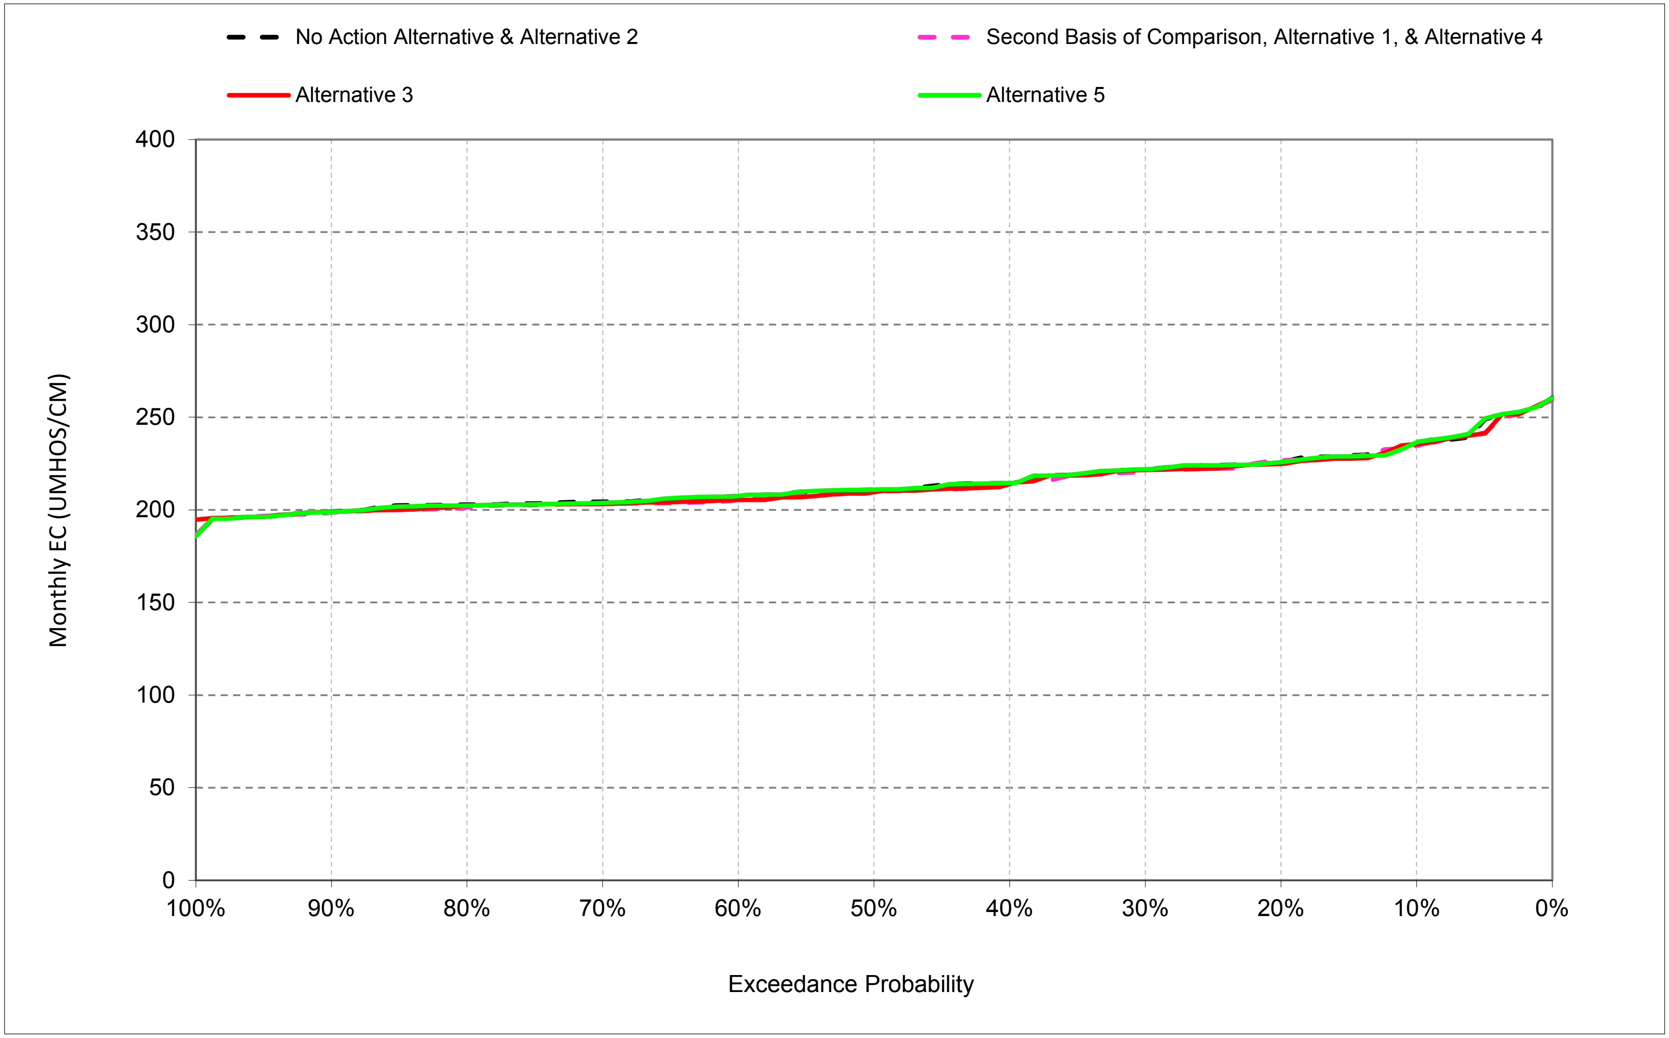
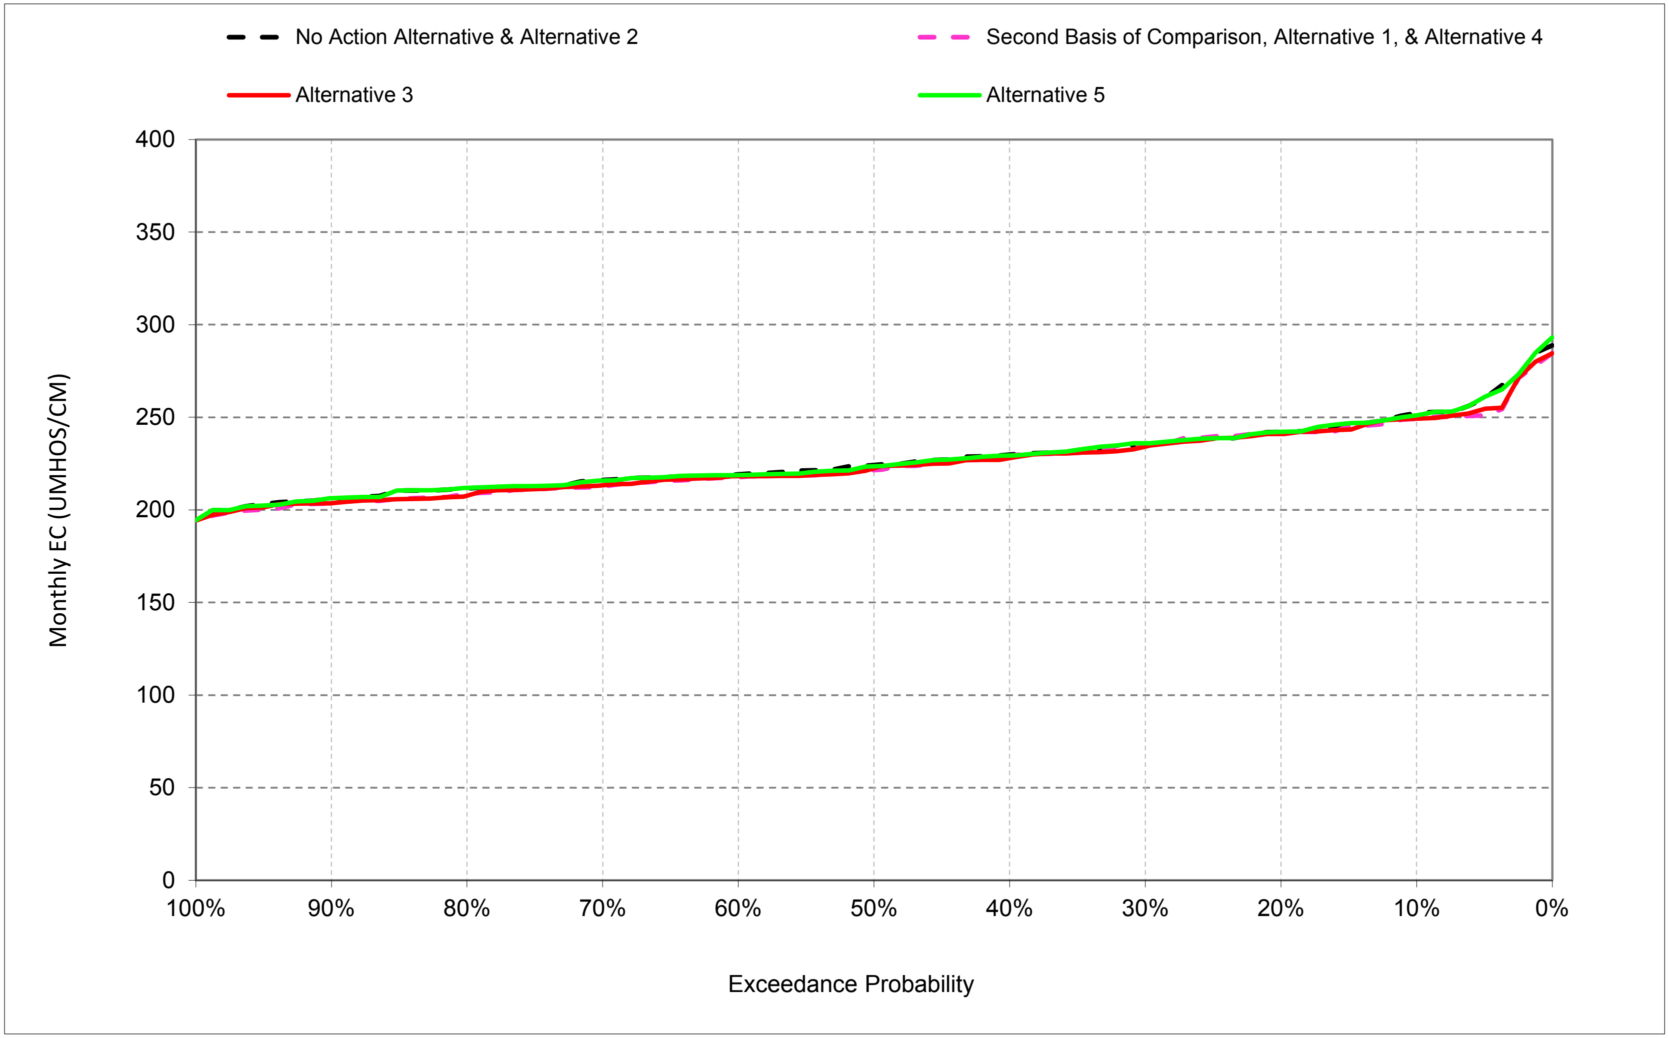
Figure 6E.B.14.4. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, January



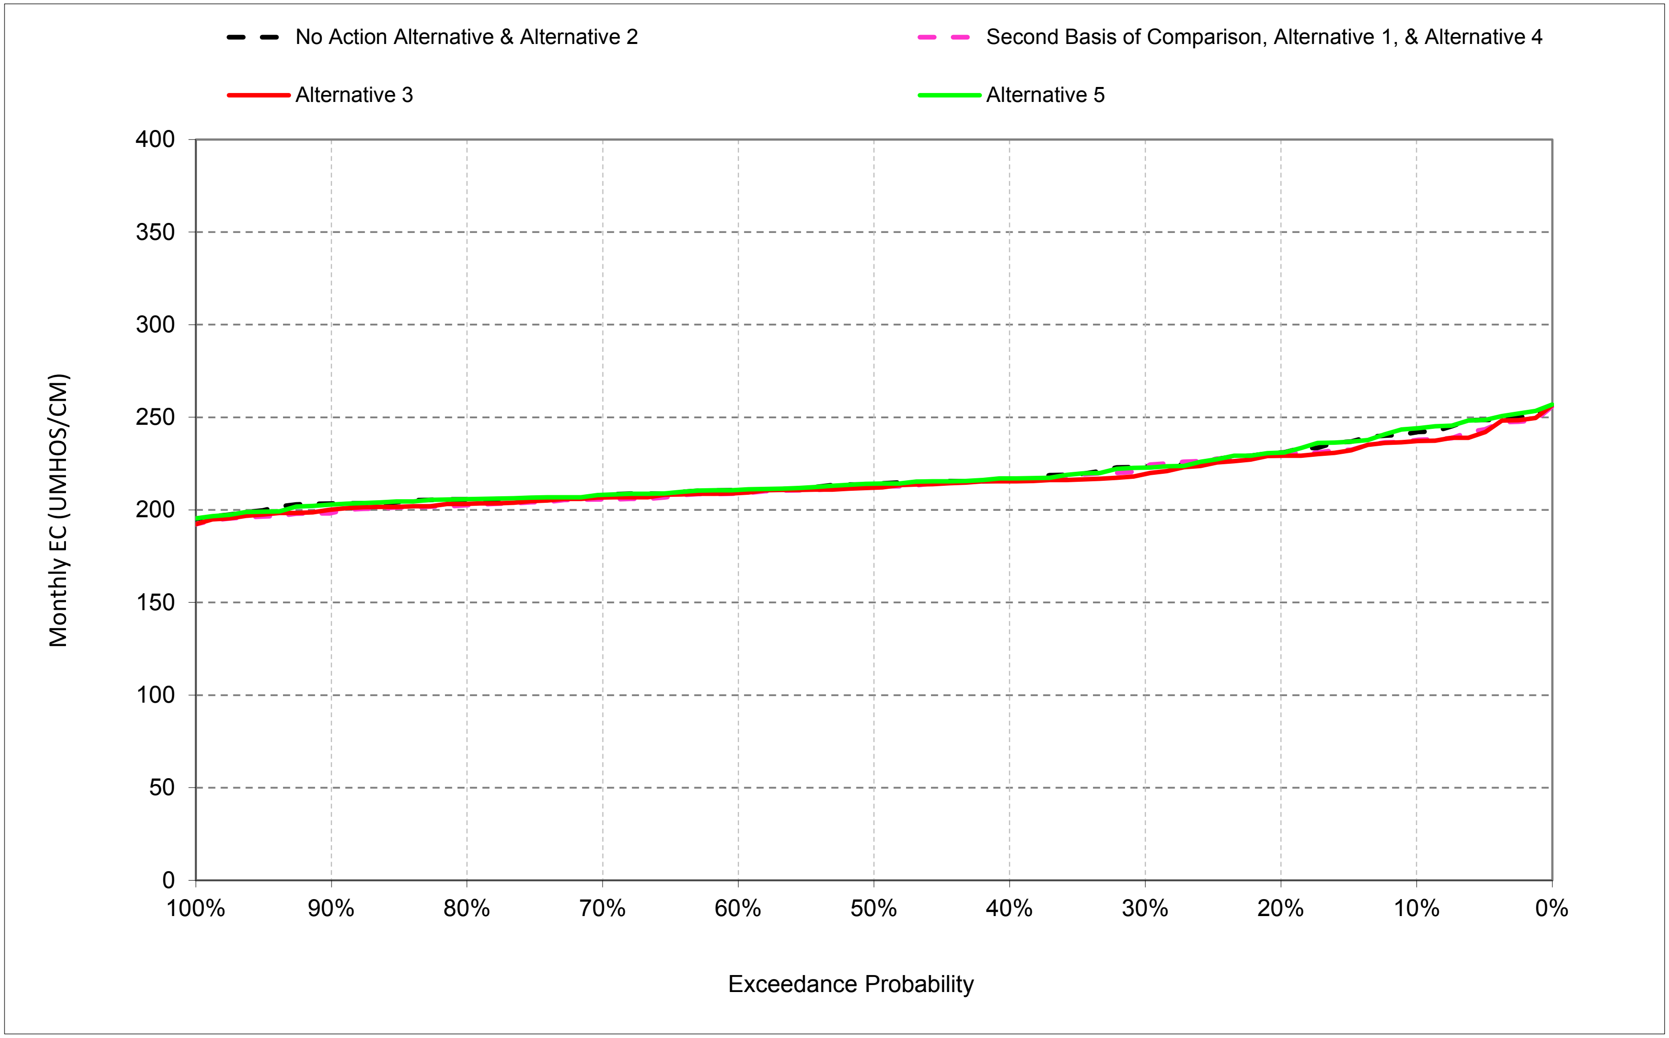
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.5. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, February



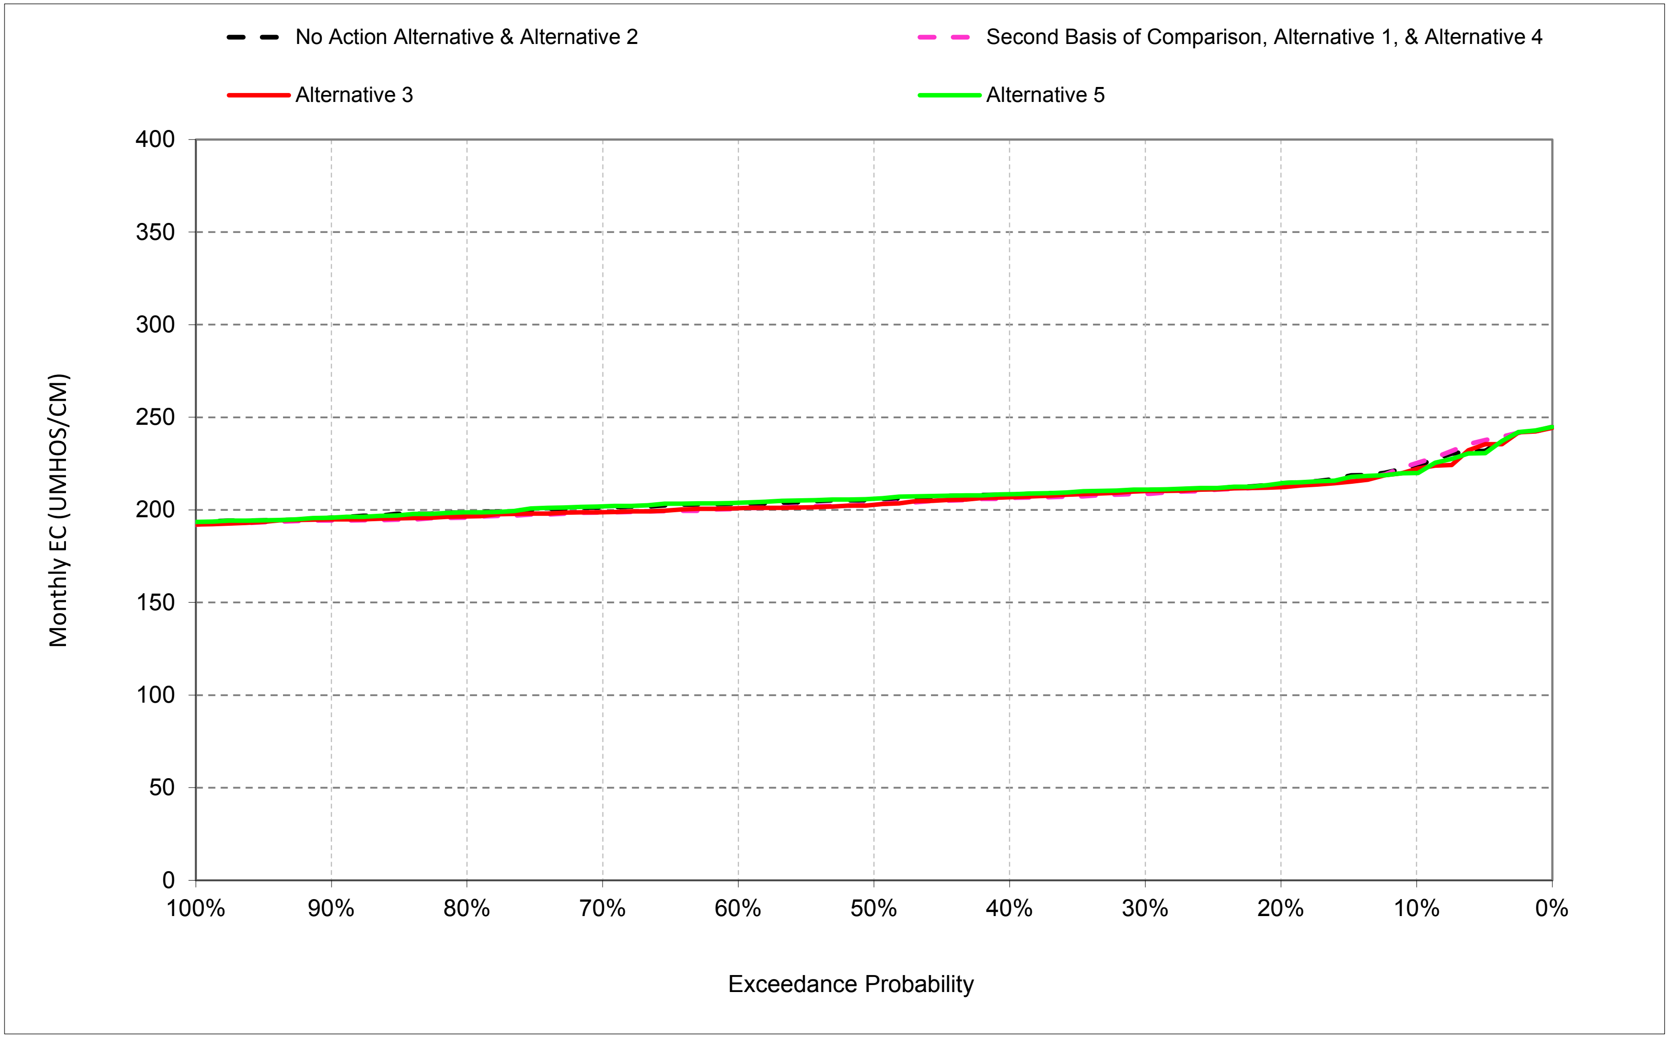
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.6. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, March



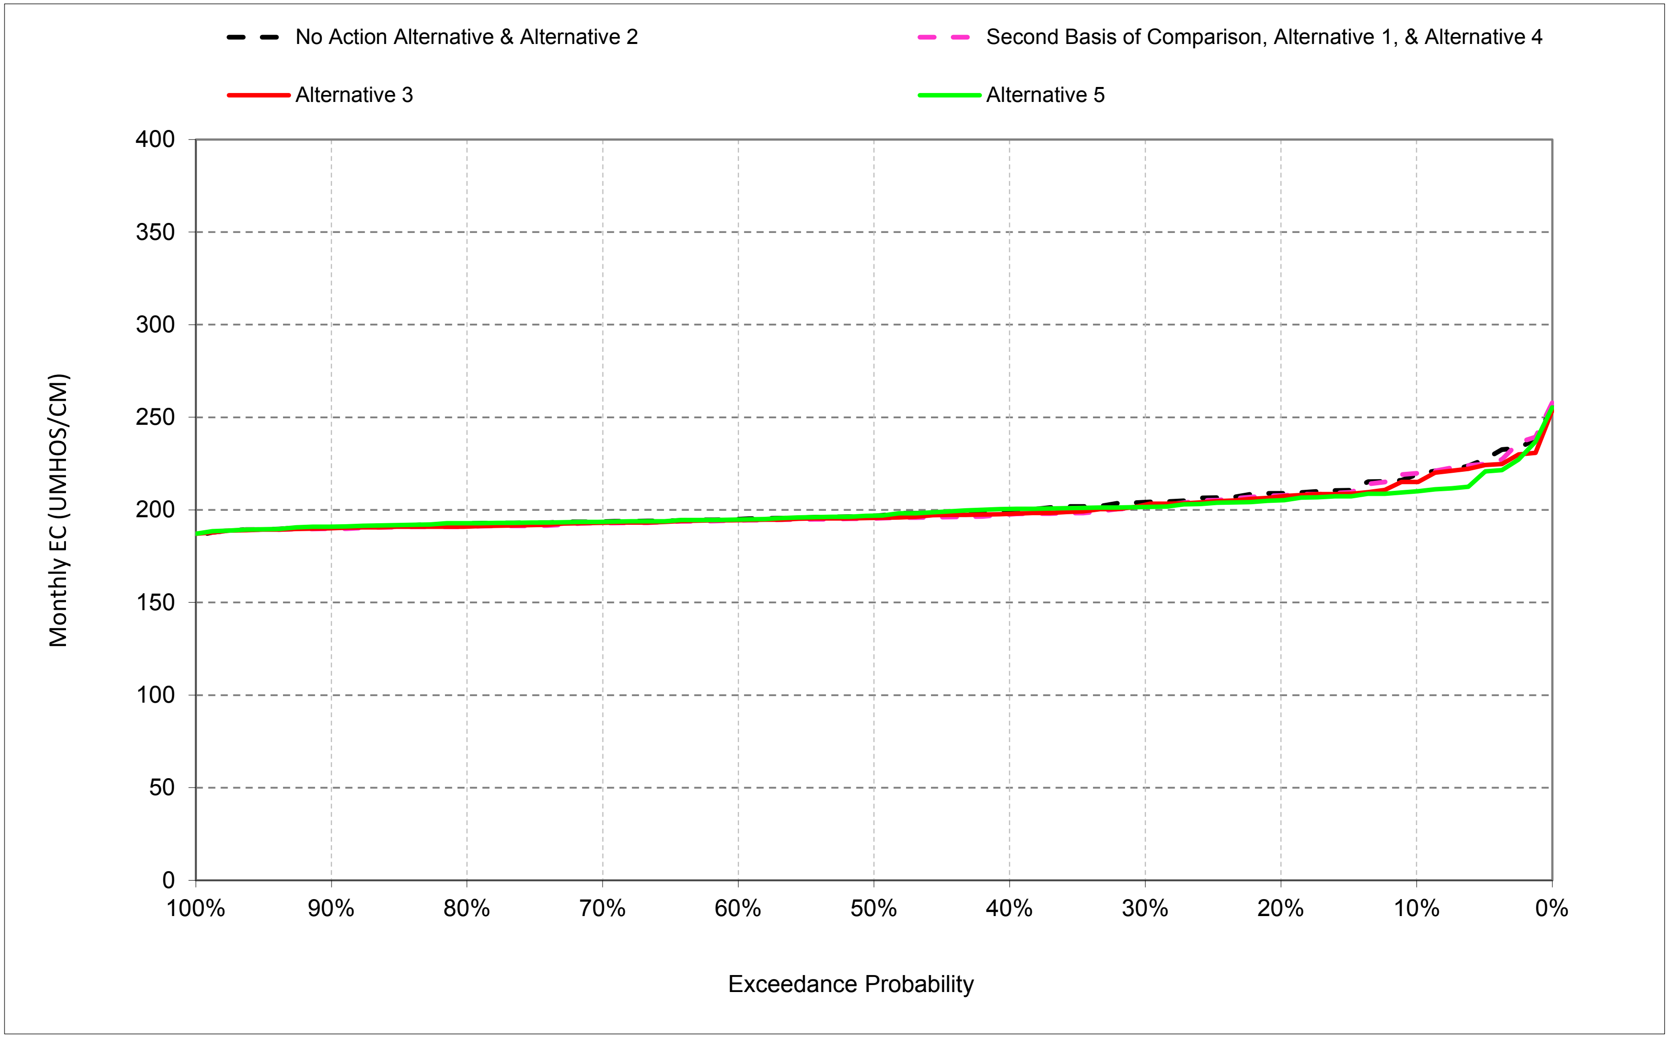
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.7. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, April



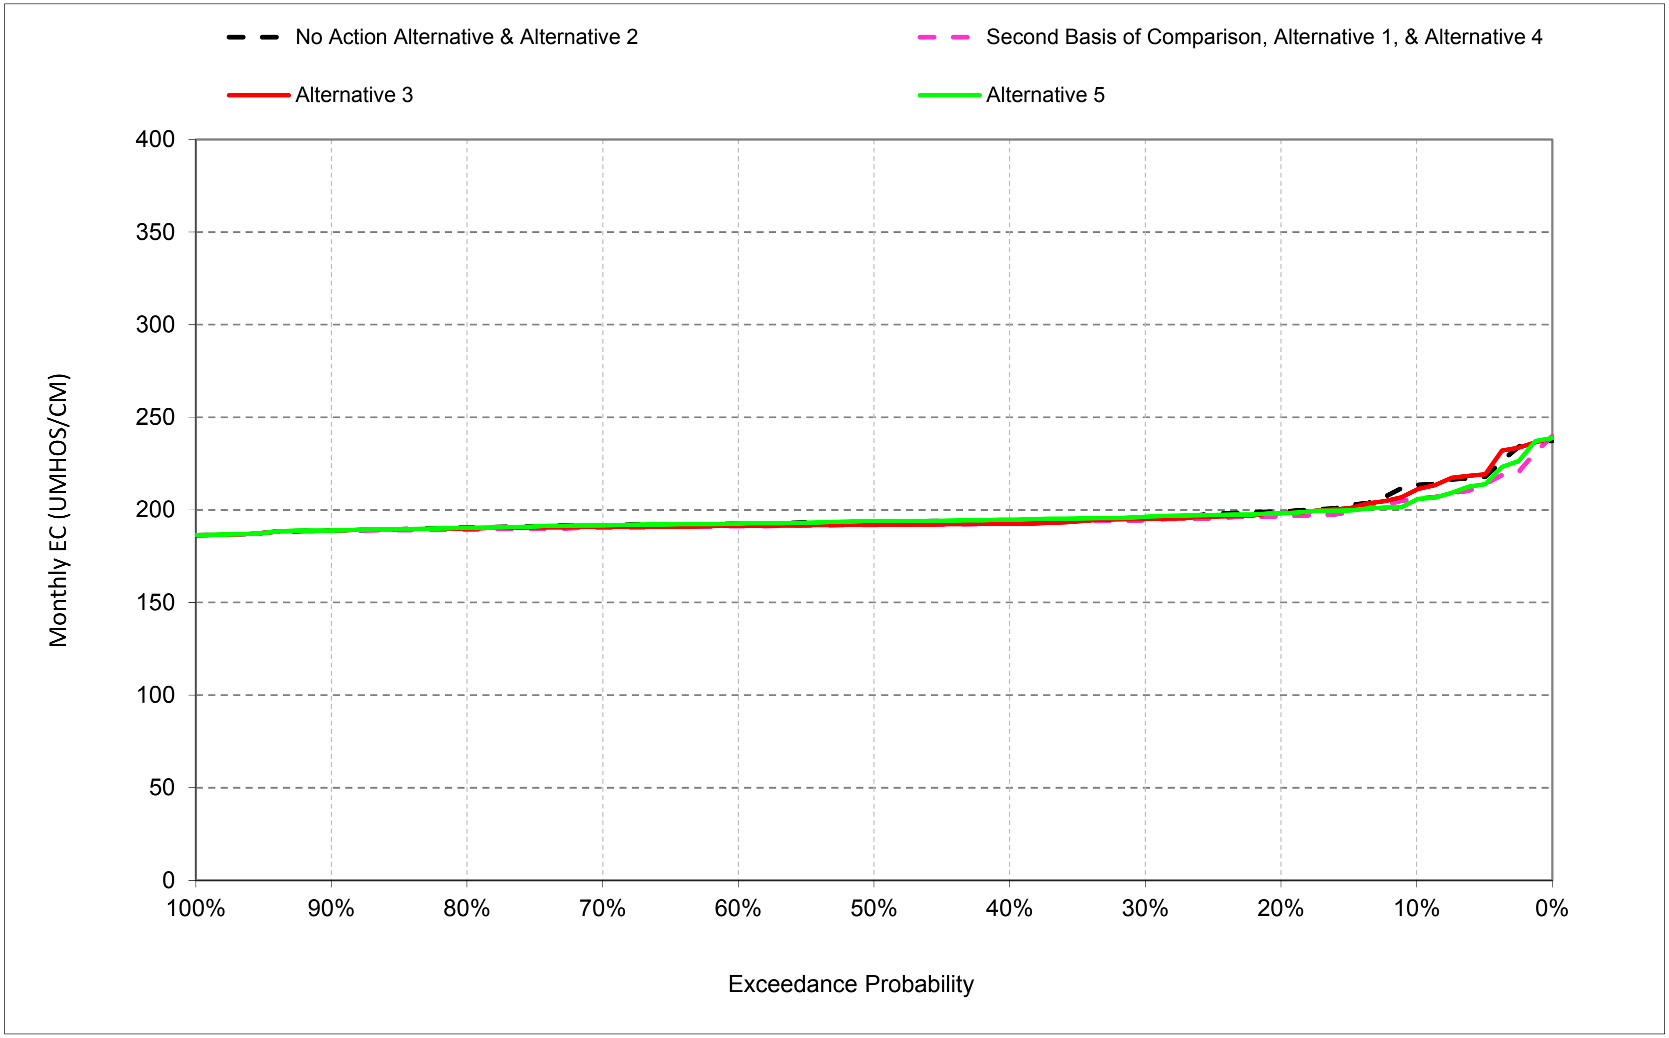
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.8. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, May



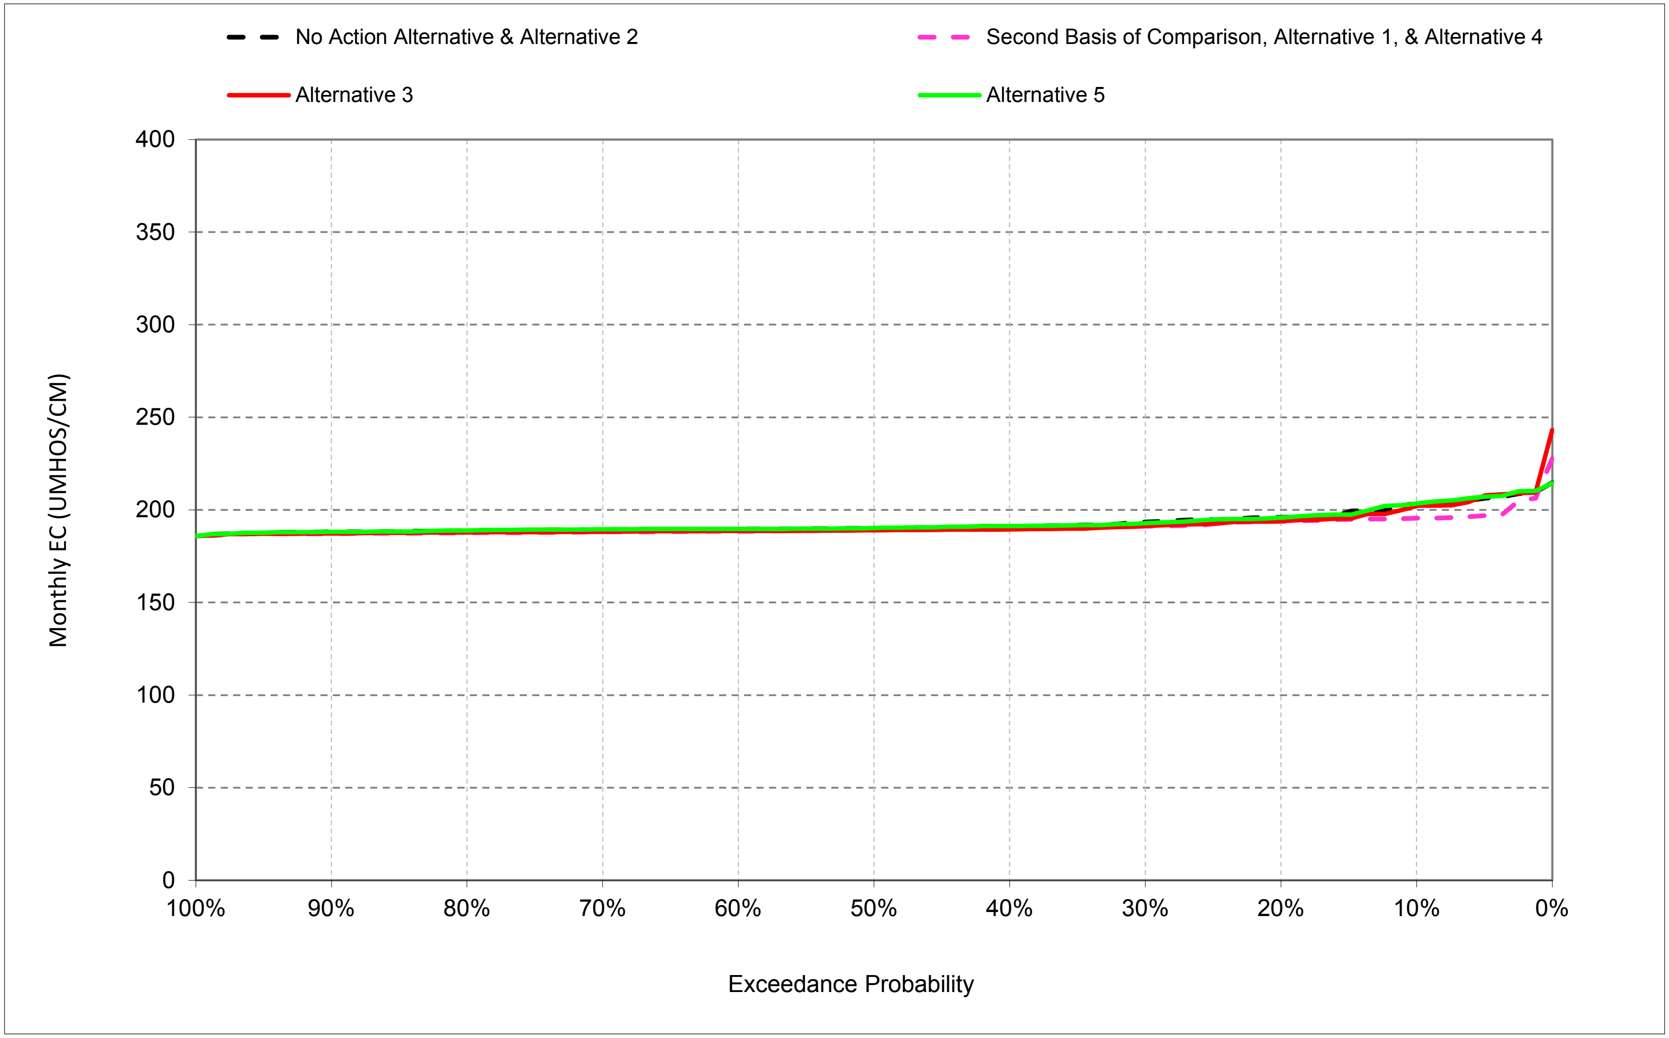
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.9. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, June



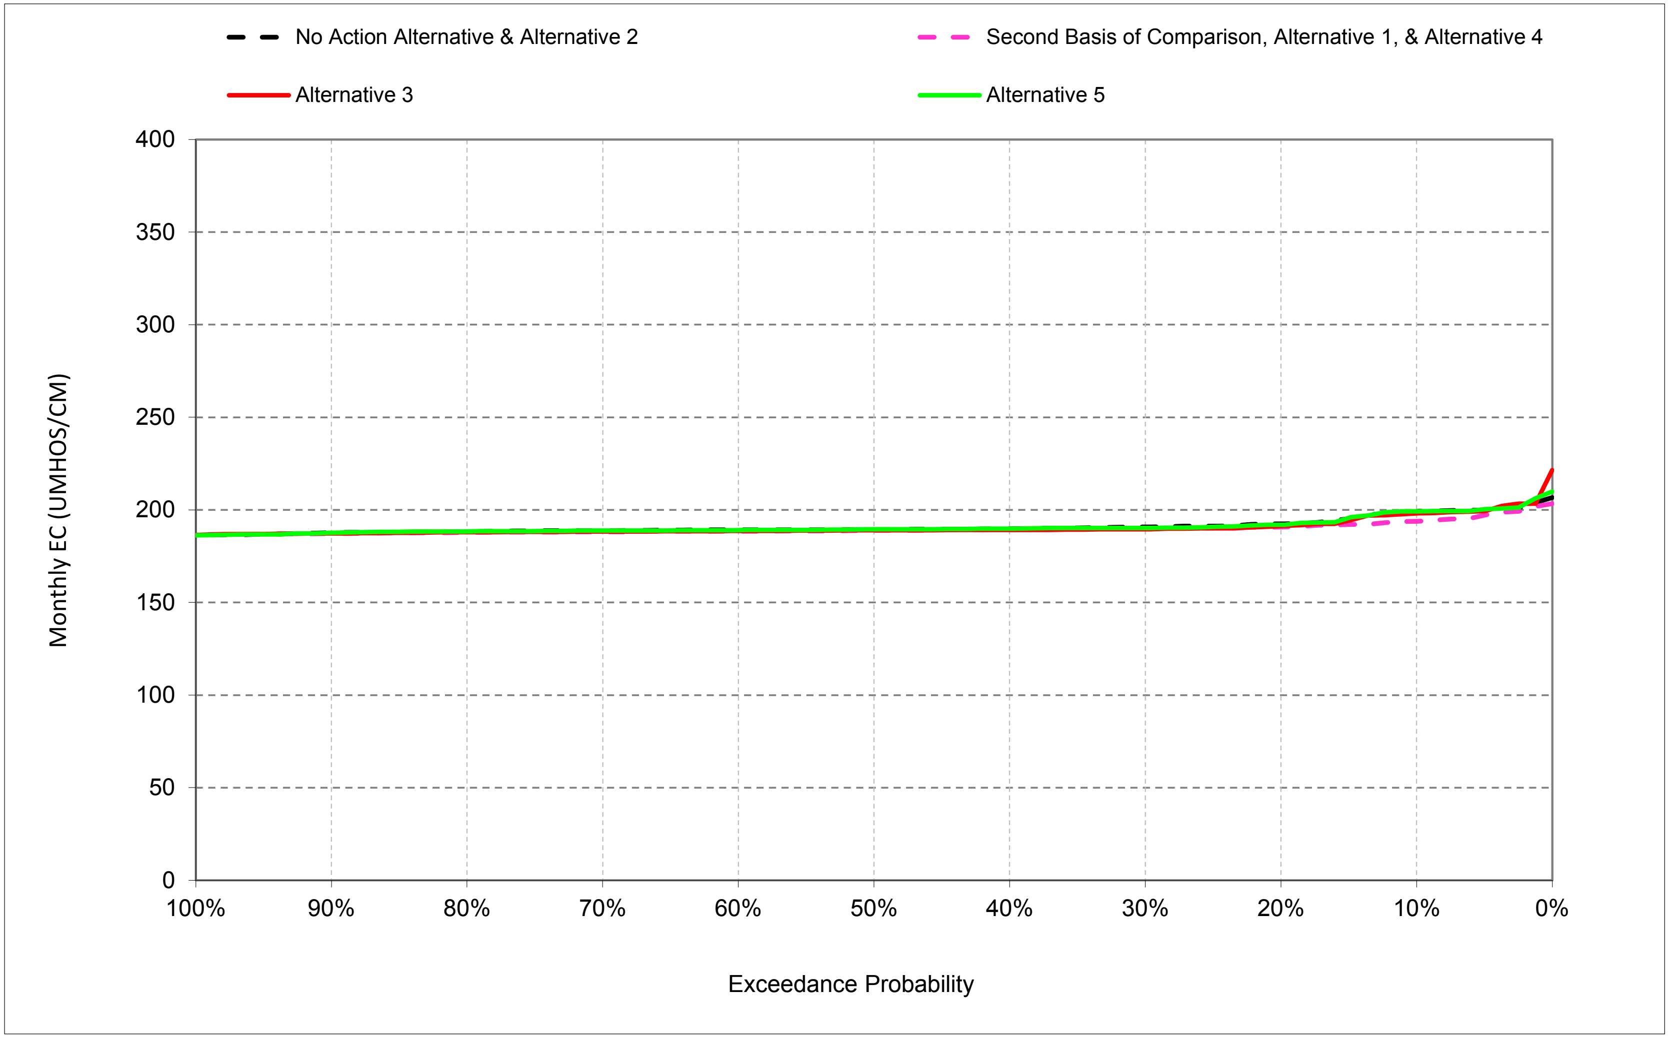
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.10. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, July



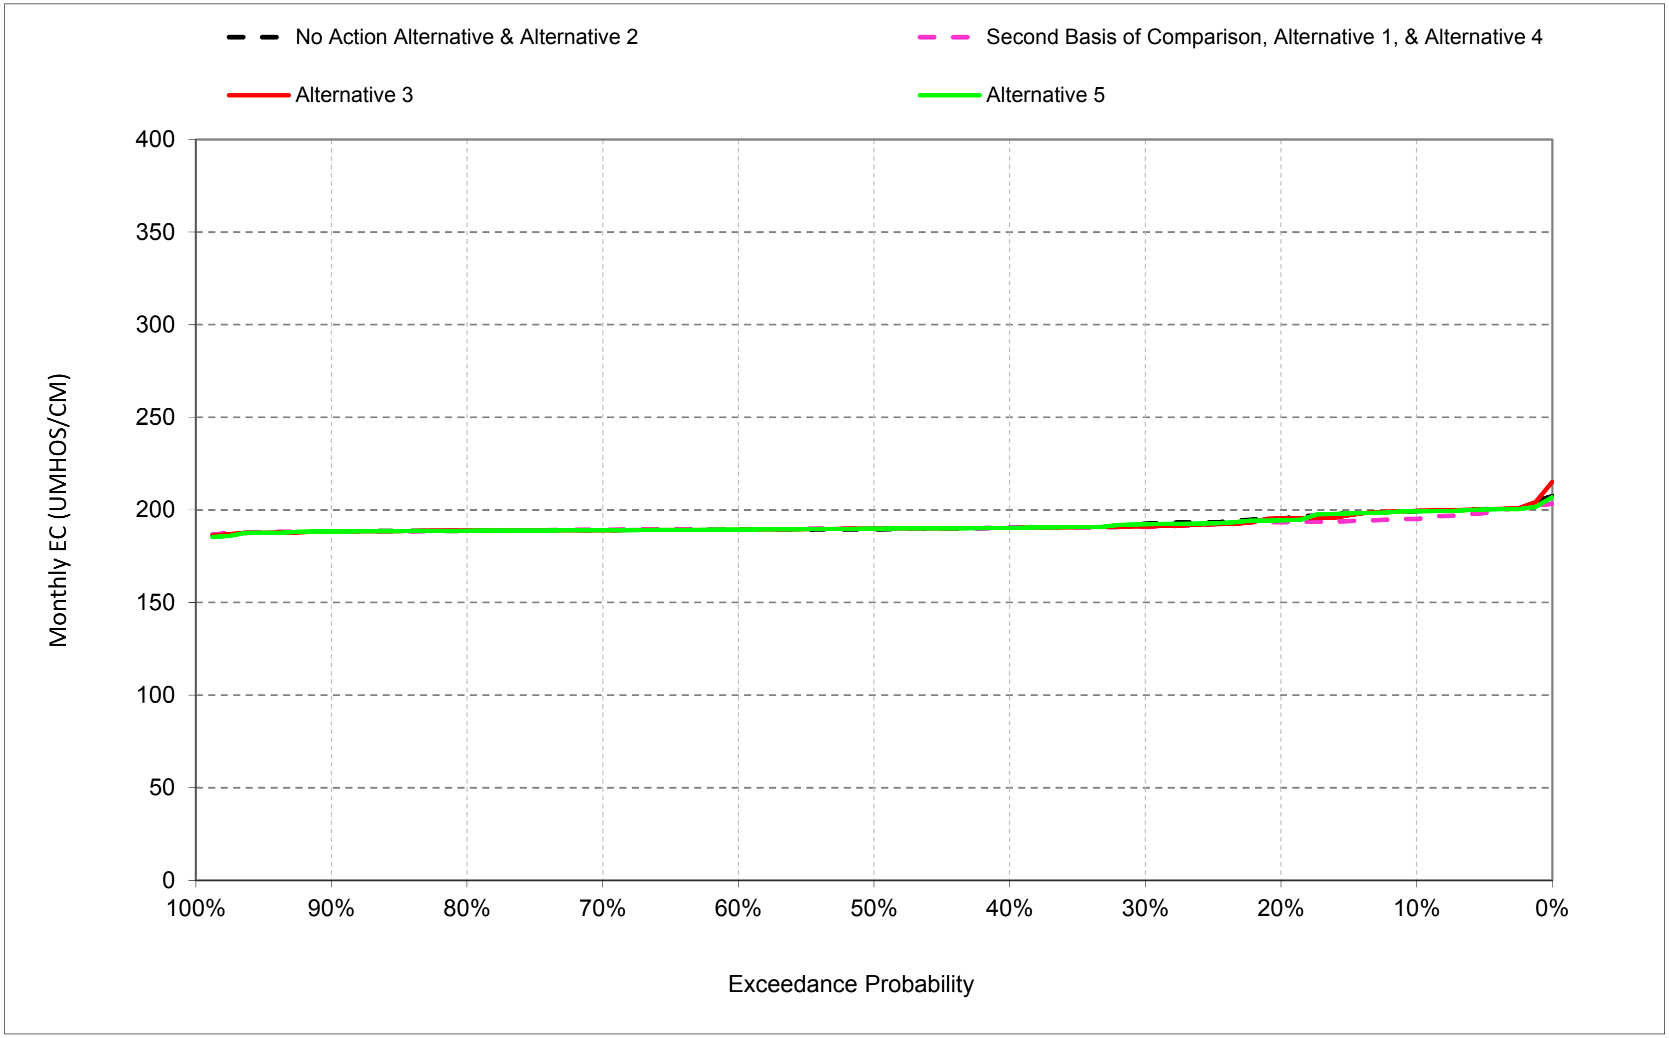
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.11. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.14.12. Barker Slough North Bay Aqueduct Intake Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

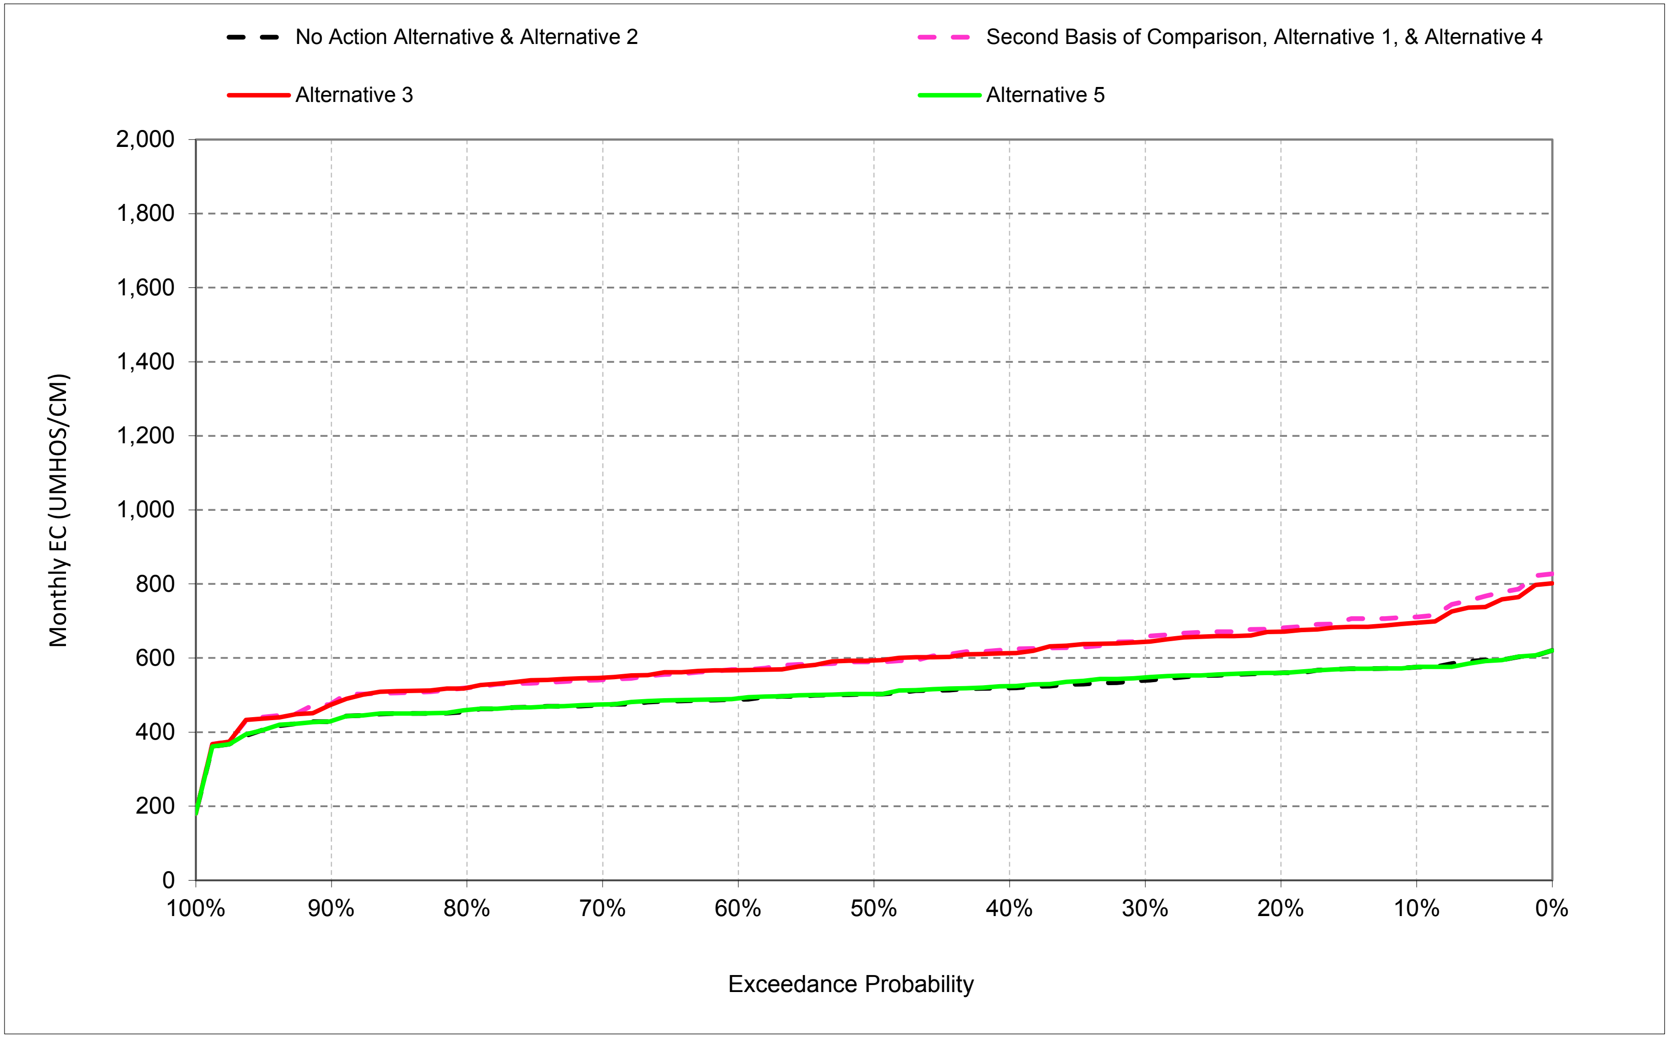
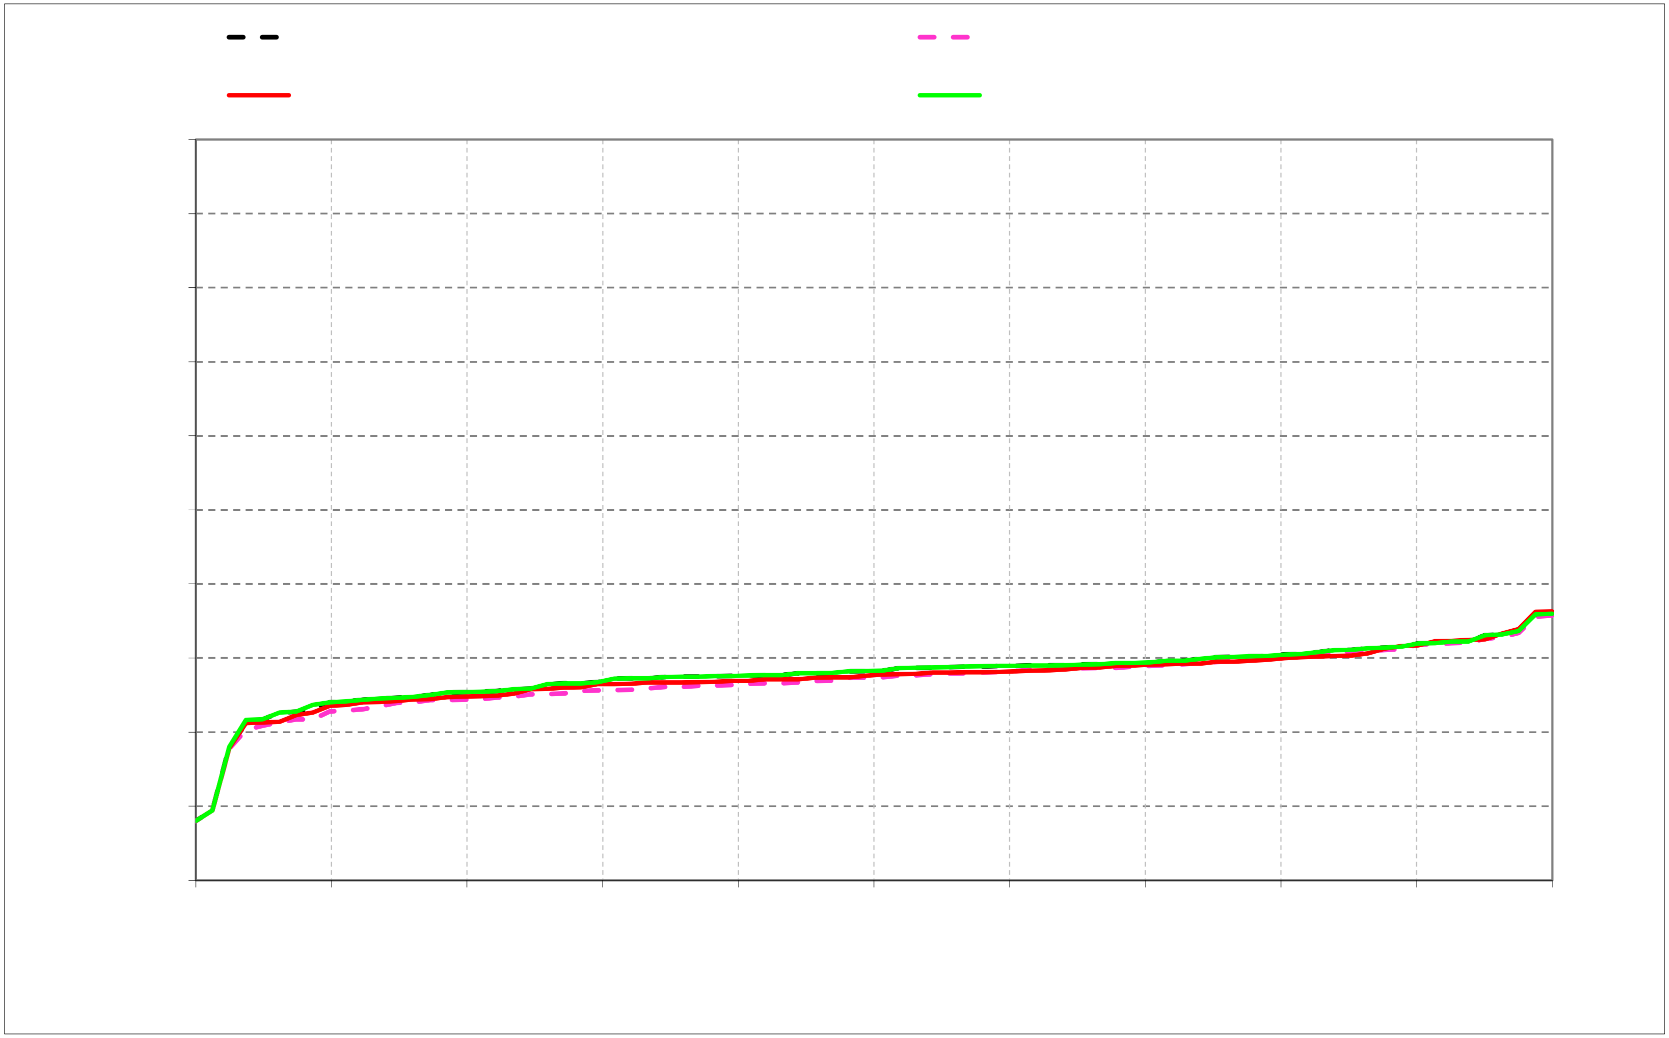
B.15. San Joaquin River at Vernalis Salinity

Figure 6E.B.15.1. San Joaquin River at Vernalis Salinity, Electrical Conductivity, October



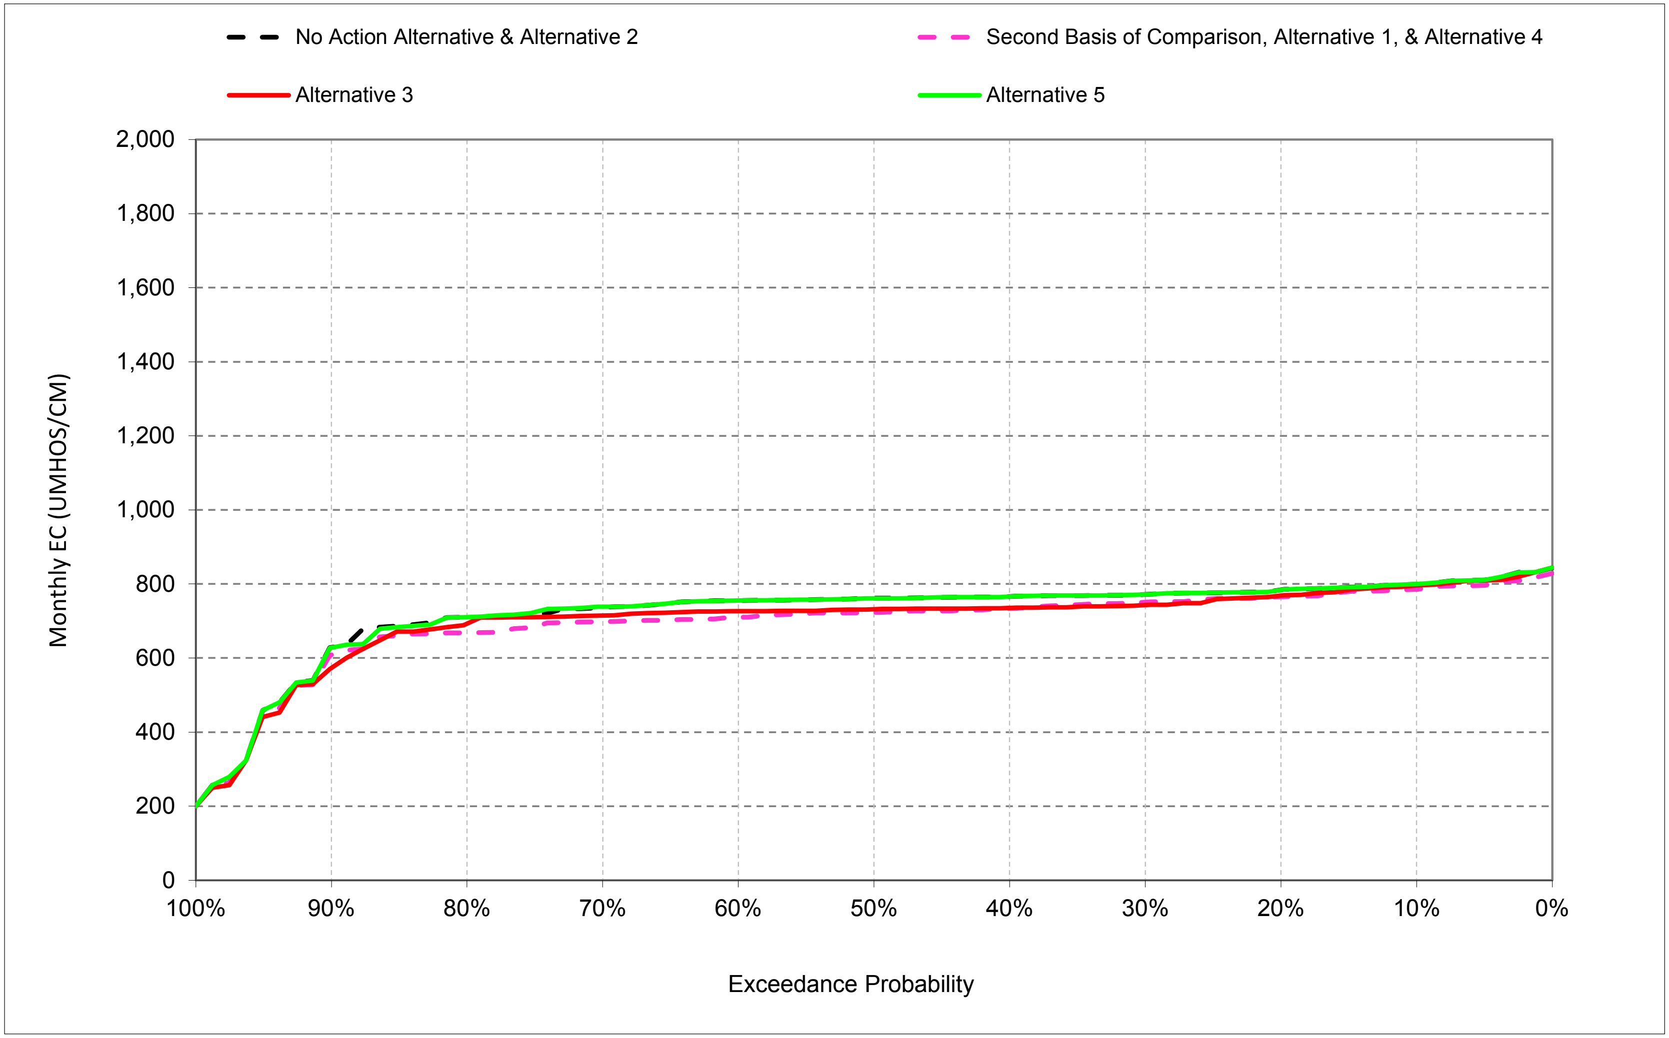
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.2. San Joaquin River at Vernalis Salinity, Electrical Conductivity, November



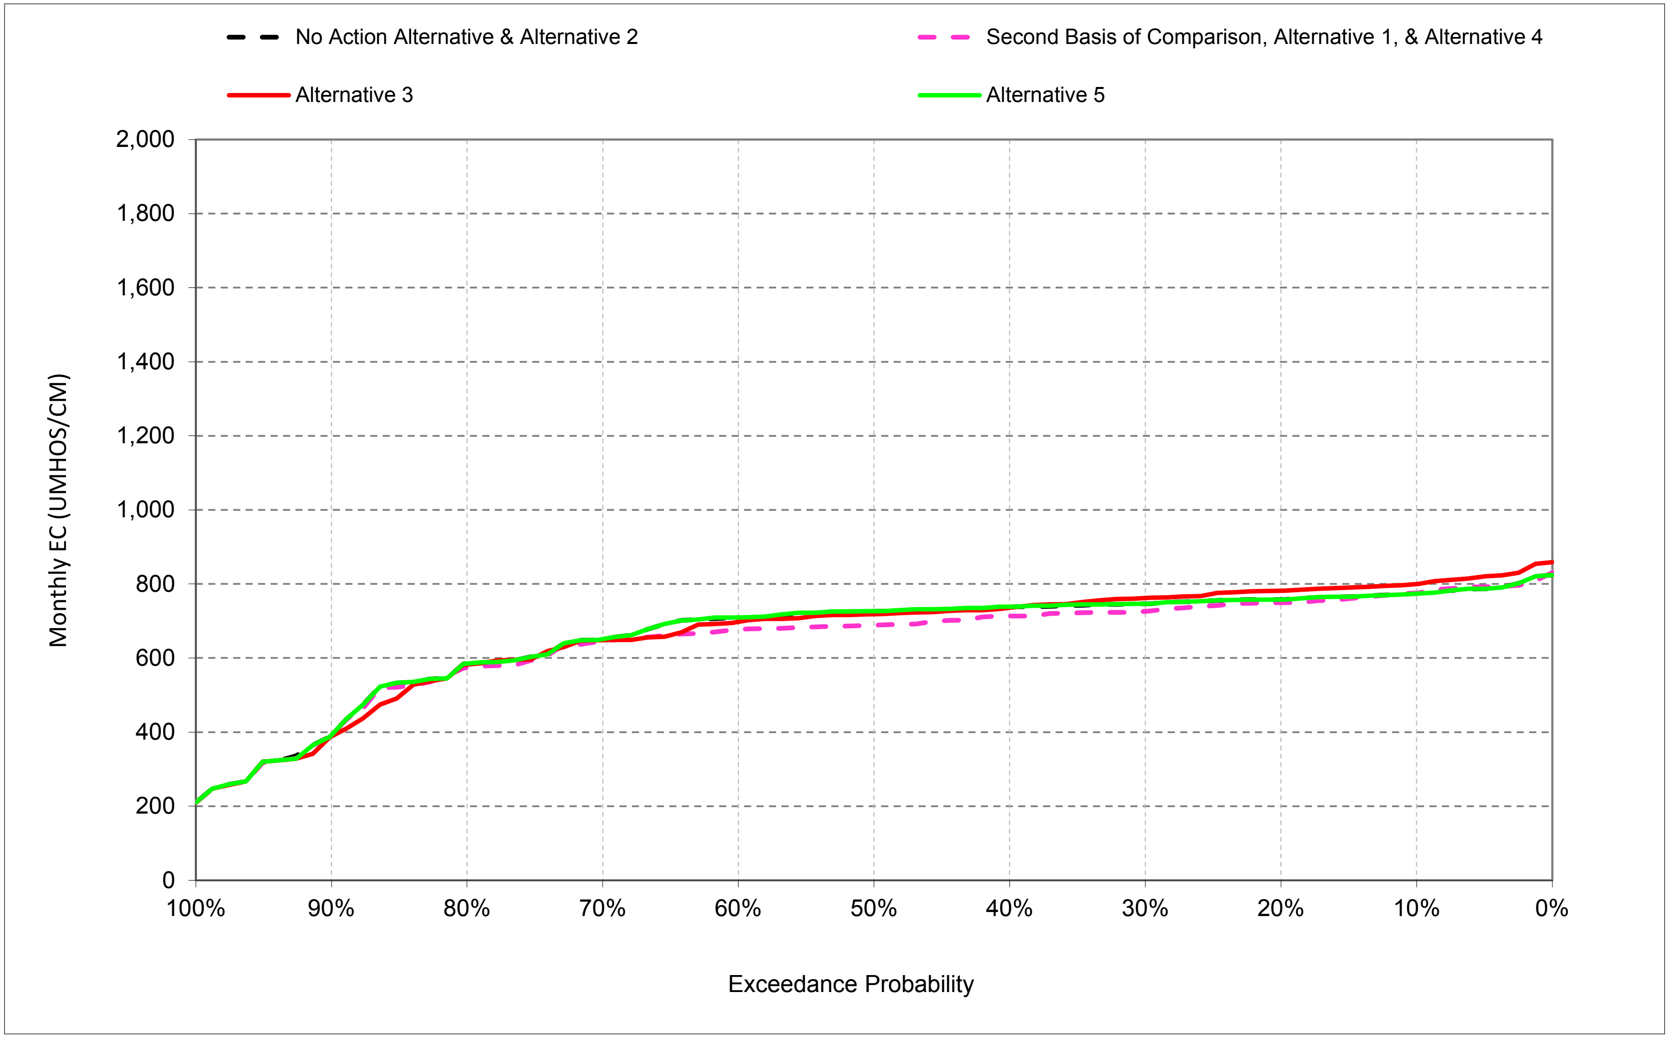
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.3. San Joaquin River at Vernalis Salinity, Electrical Conductivity, December



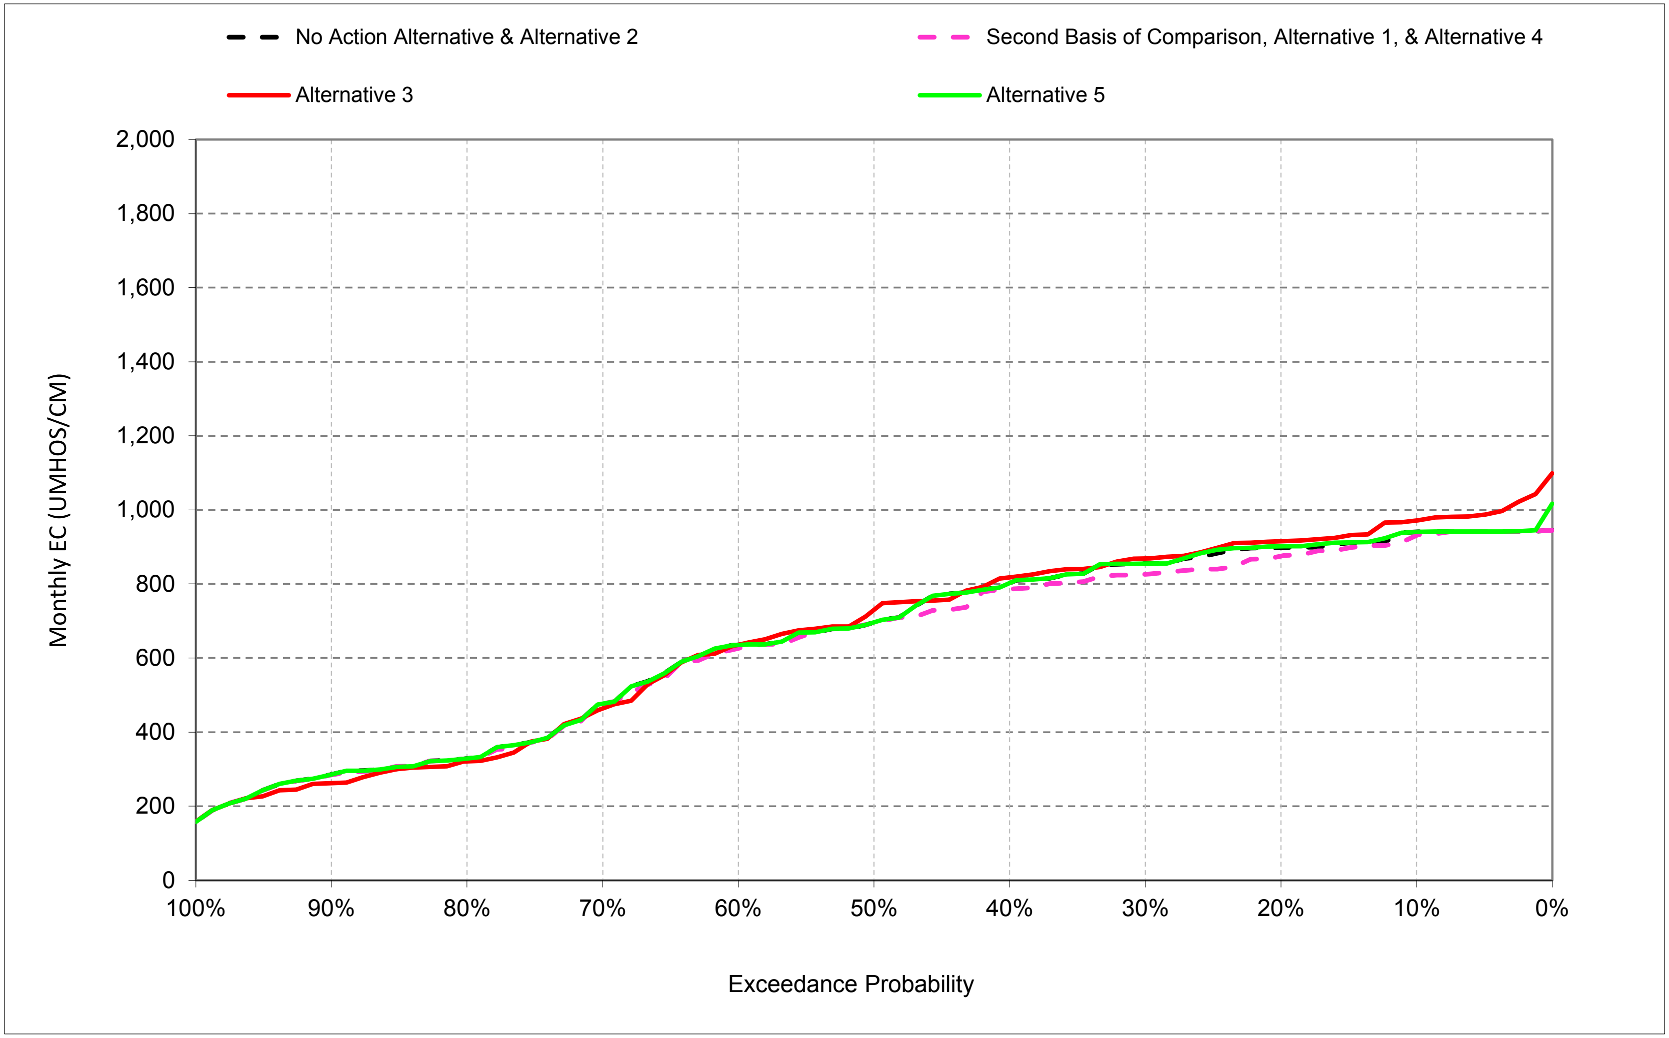
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.4. San Joaquin River at Vernalis Salinity, Electrical Conductivity, January



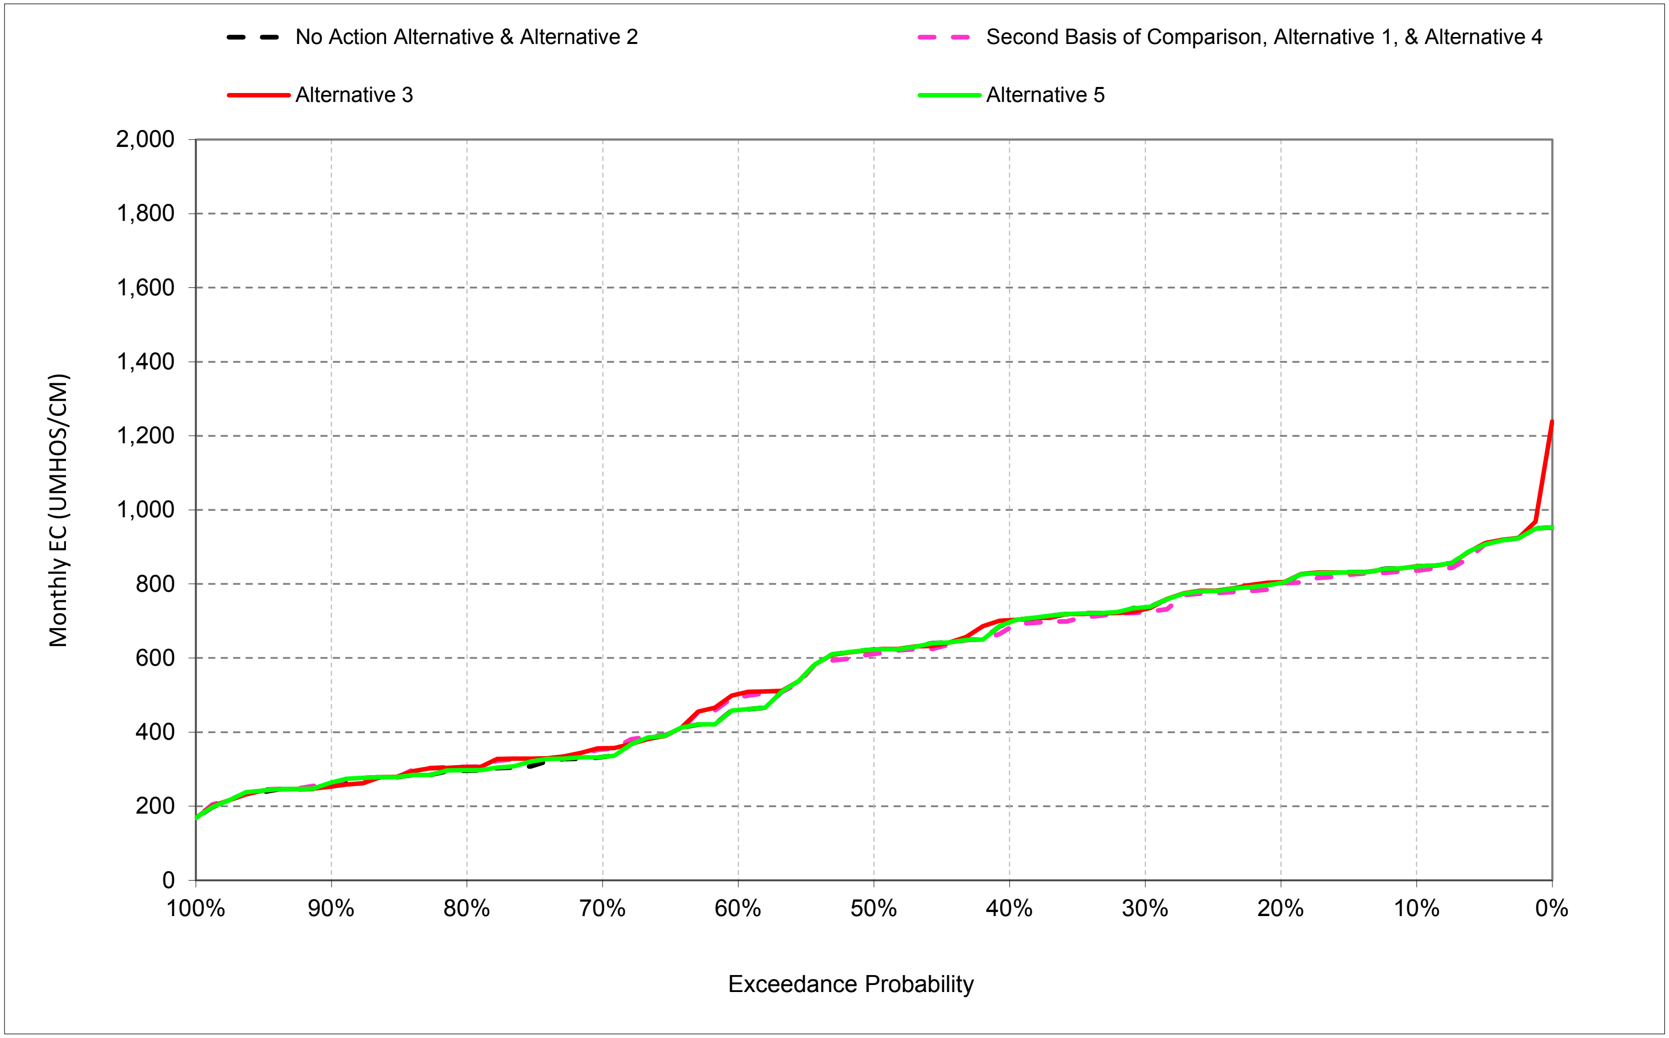
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.5. San Joaquin River at Vernalis Salinity, Electrical Conductivity, February



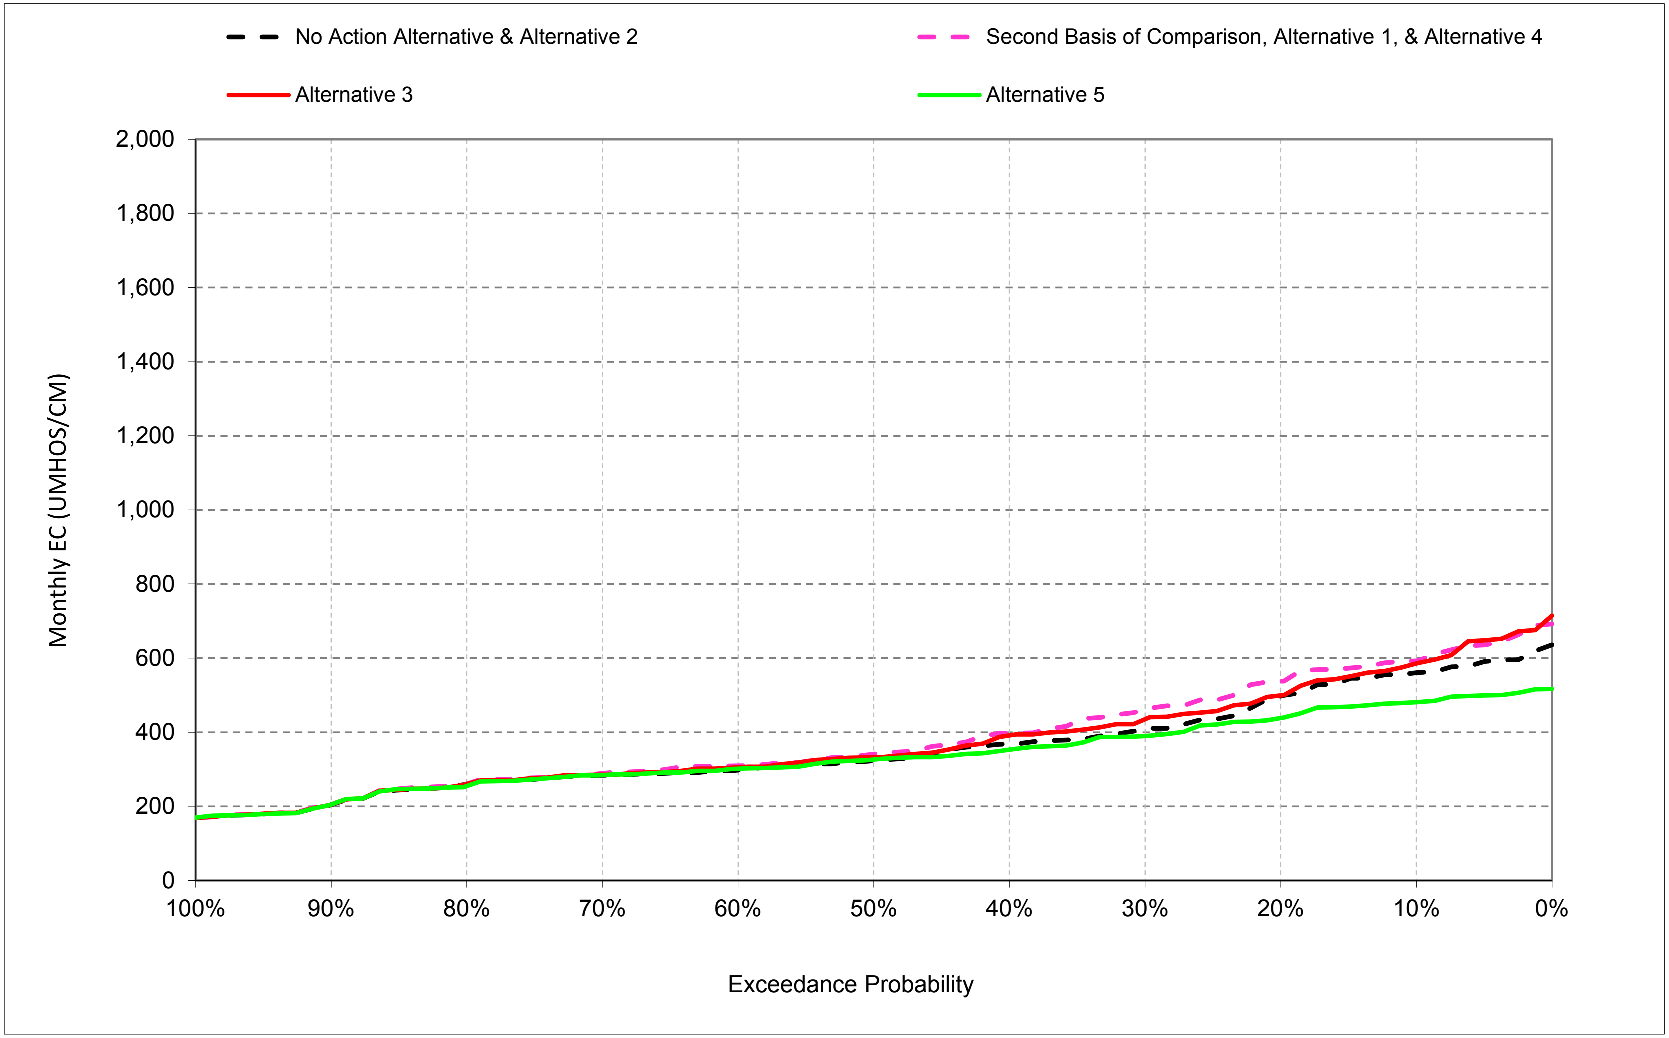
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.6. San Joaquin River at Vernalis Salinity, Electrical Conductivity, March



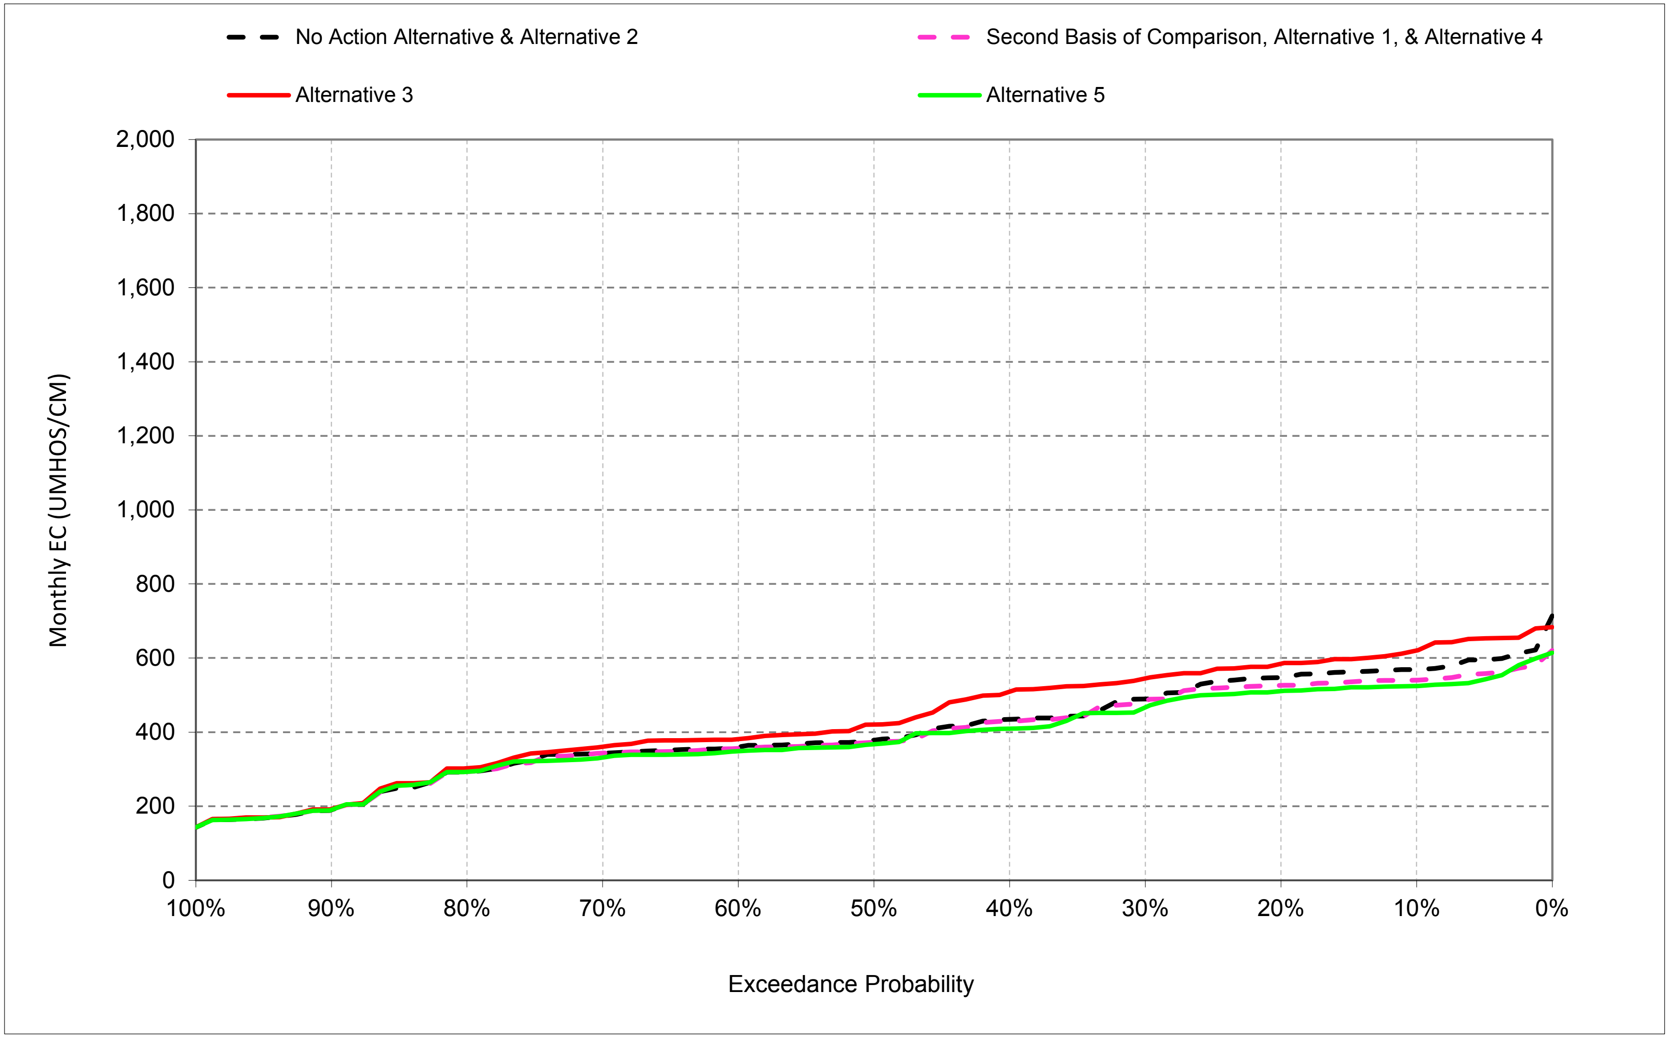
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.7. San Joaquin River at Vernalis Salinity, Electrical Conductivity, April



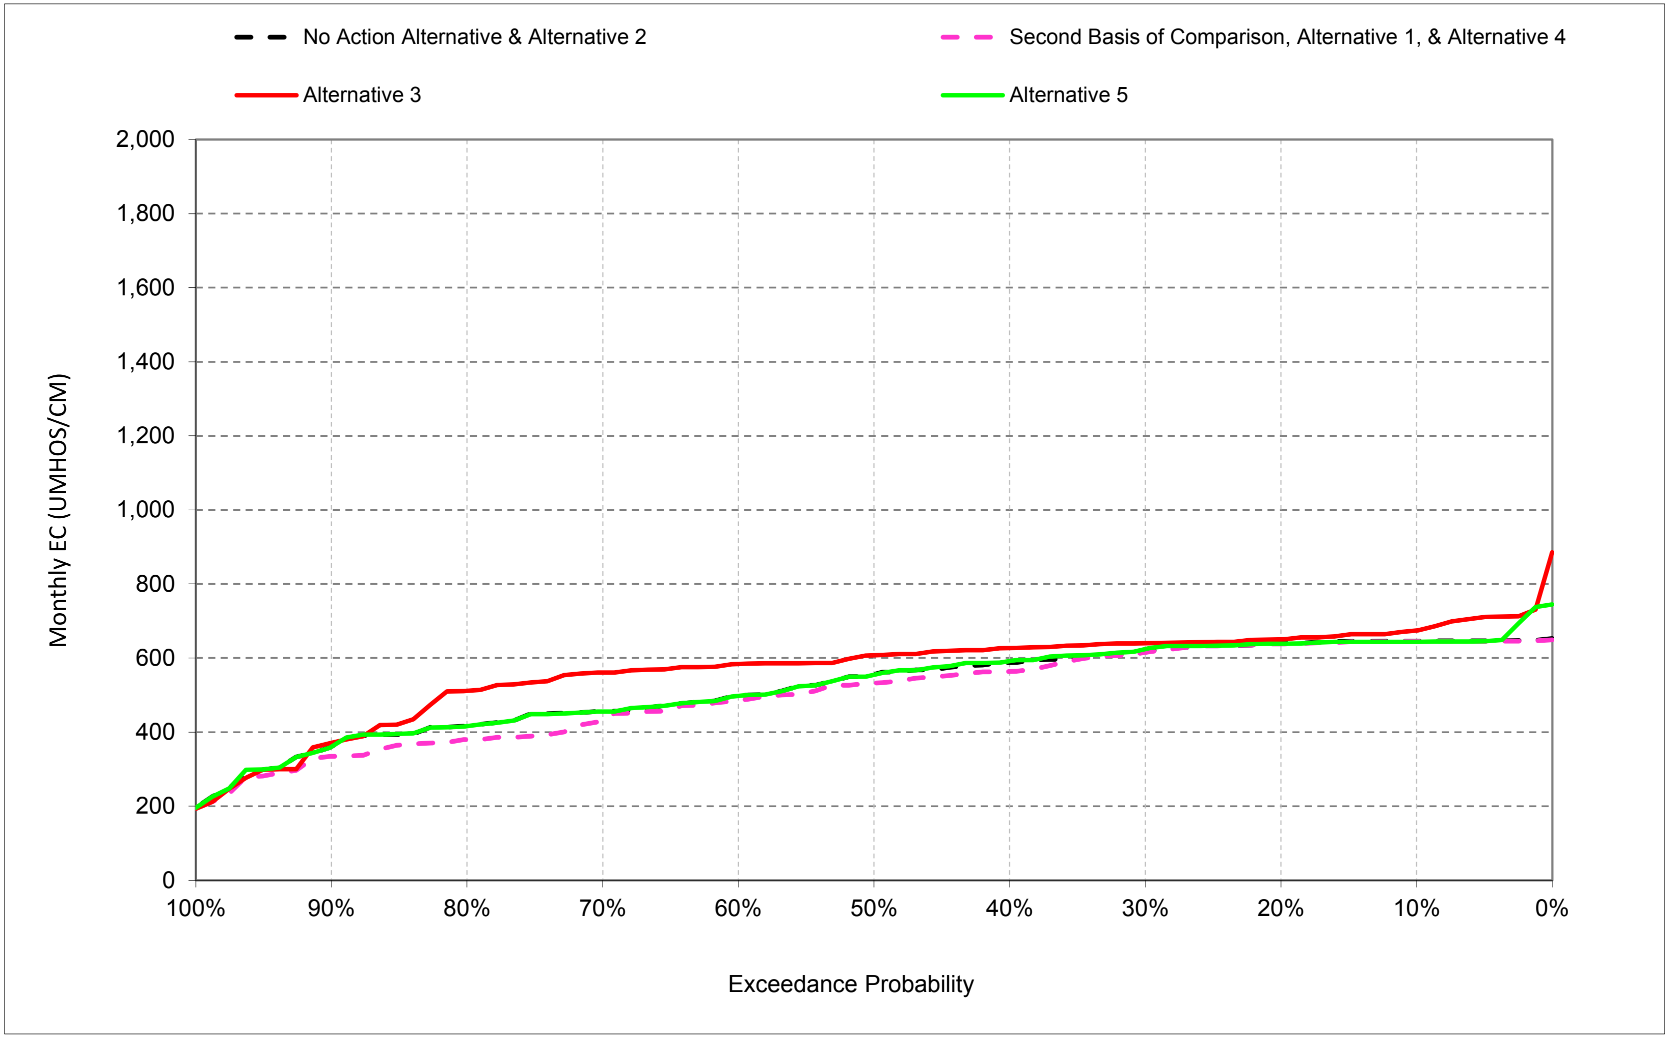
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.8. San Joaquin River at Vernalis Salinity, Electrical Conductivity, May



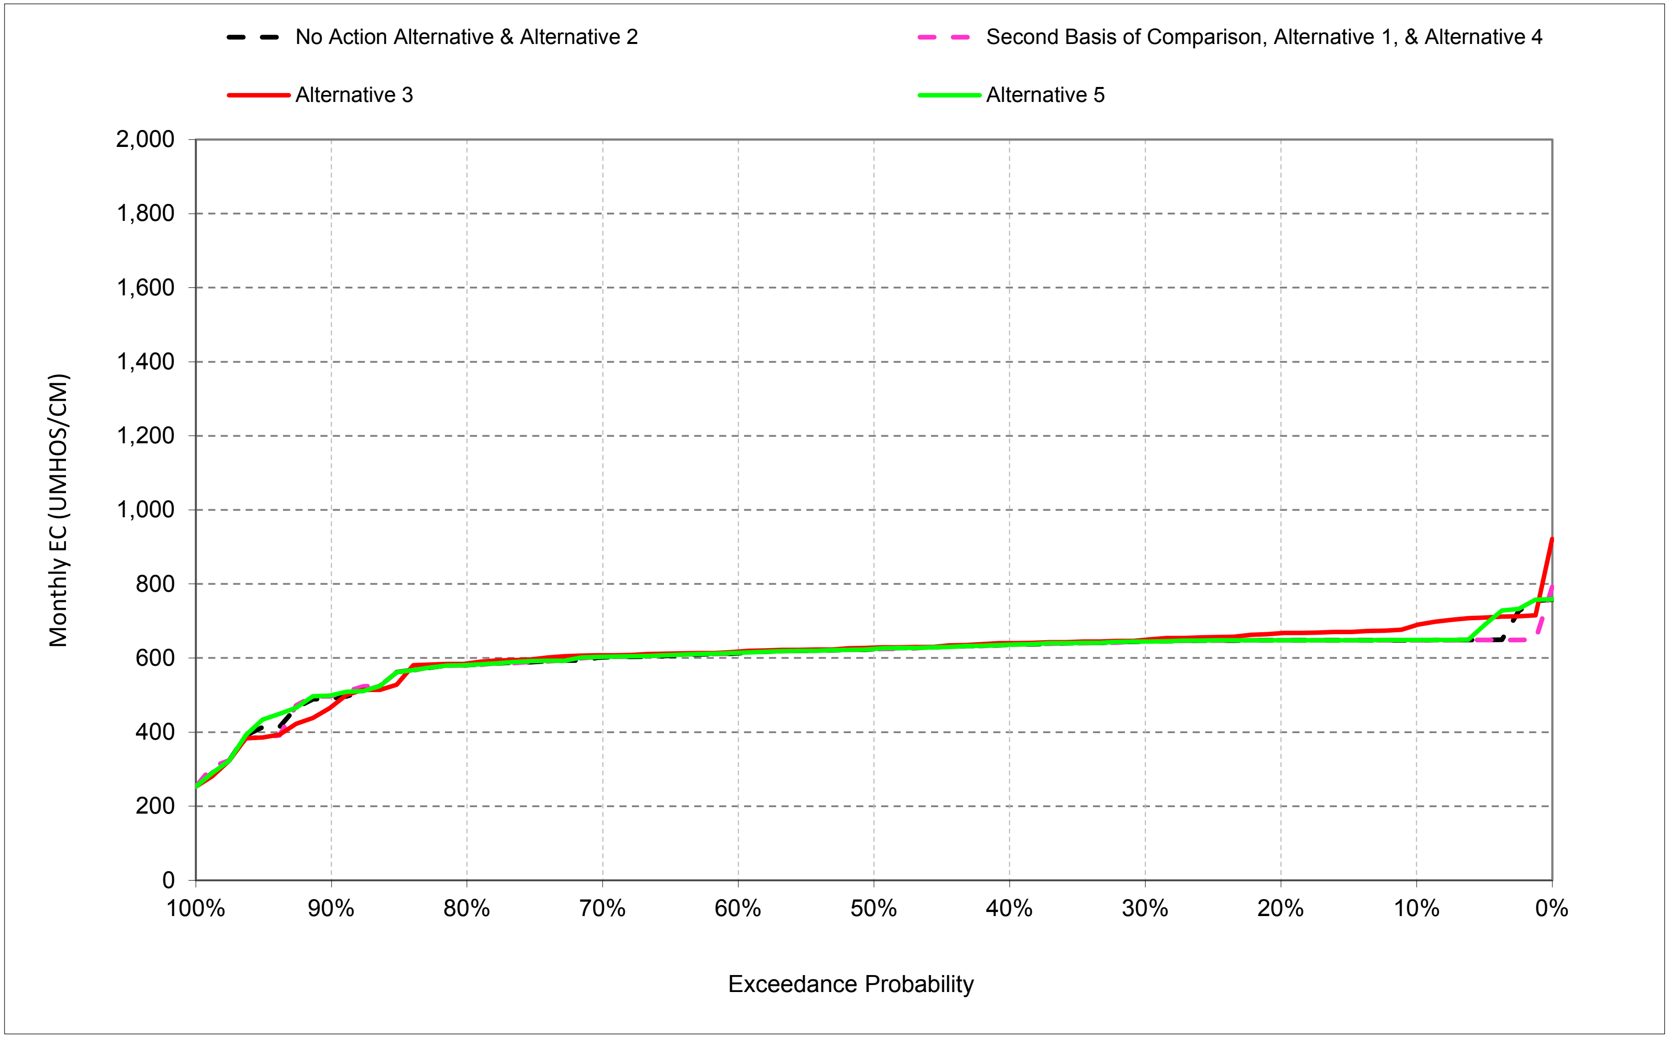
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.9. San Joaquin River at Vernalis Salinity, Electrical Conductivity, June



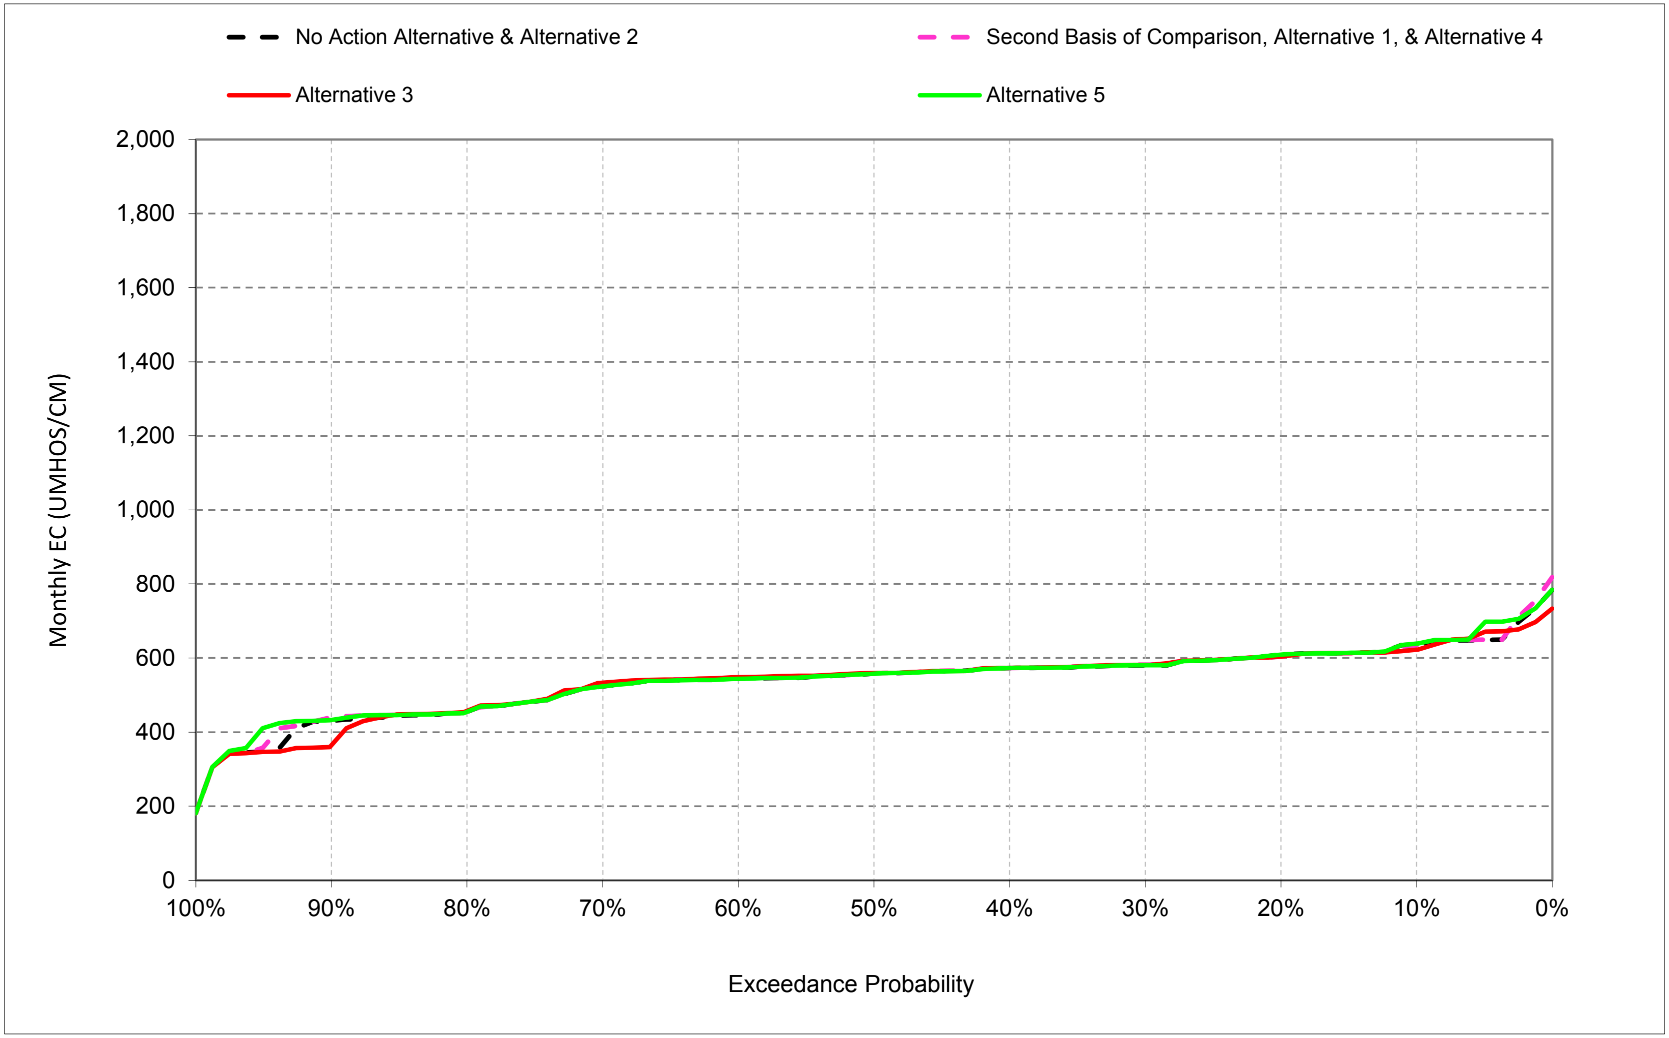
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.10. San Joaquin River at Vernalis Salinity, Electrical Conductivity, July



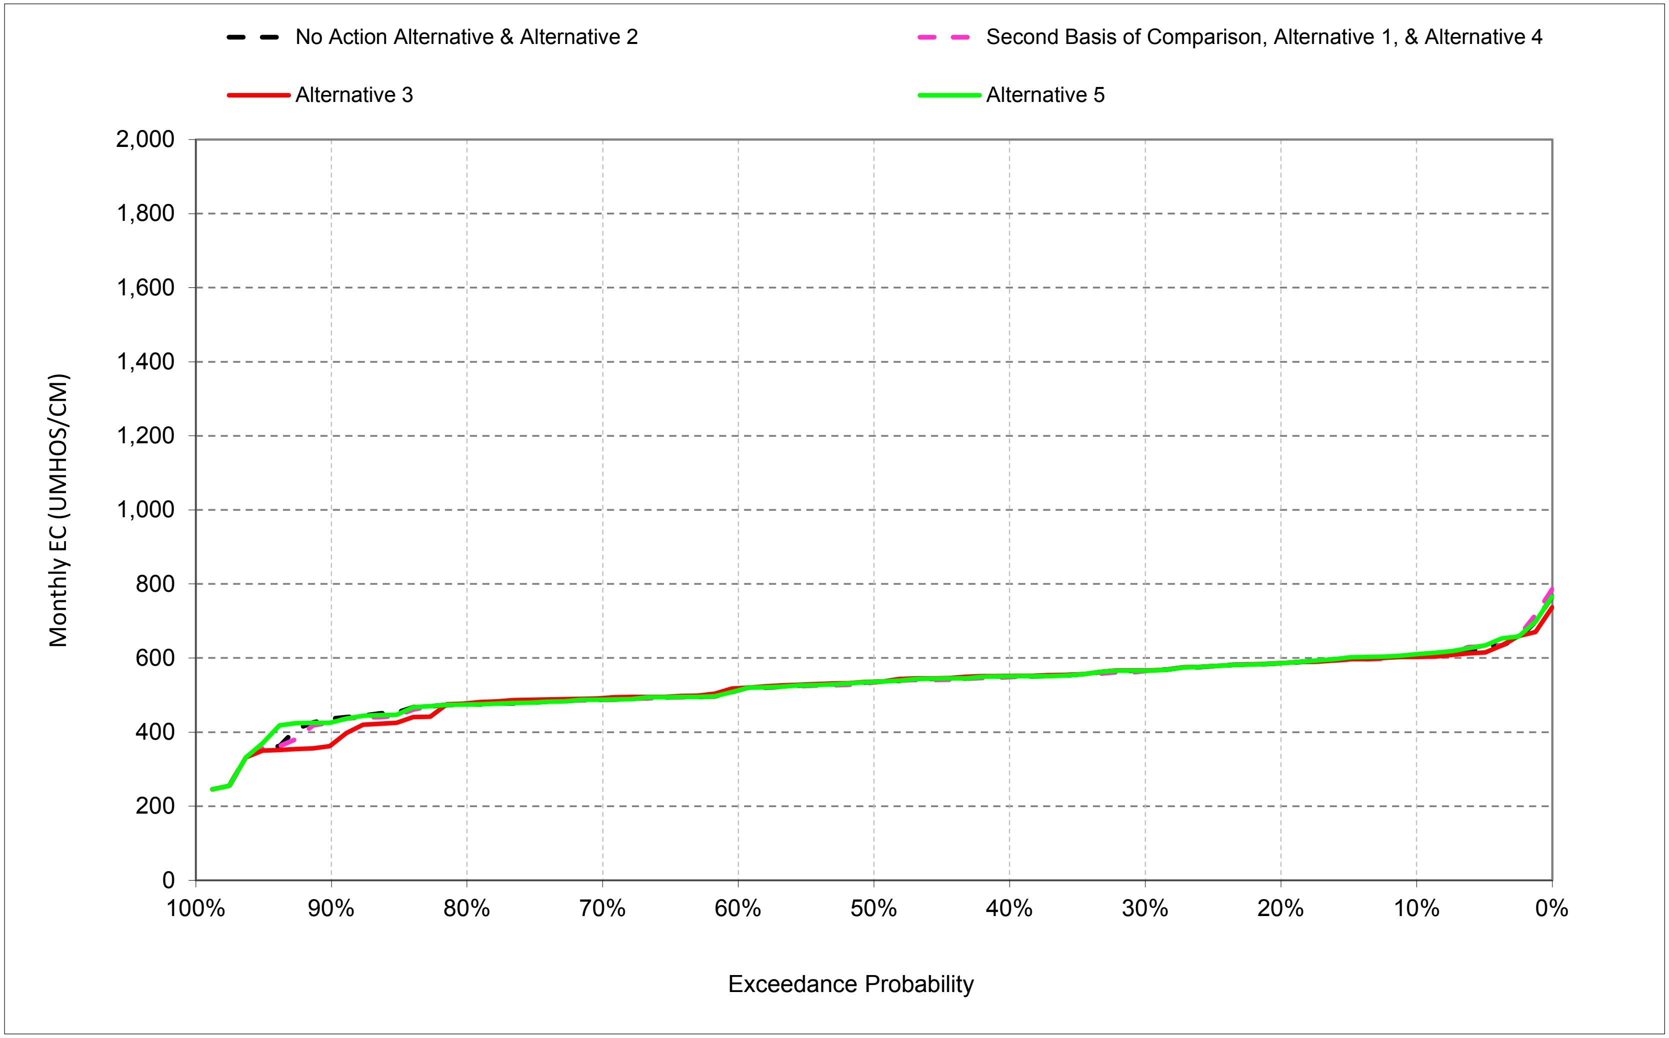
Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.11. San Joaquin River at Vernalis Salinity, Electrical Conductivity, August



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Figure 6E.B.15.12. San Joaquin River at Vernalis Salinity, Electrical Conductivity, September



Notes: 1) Exceedance probability is defined as the probability a given value will be exceeded in any one year. 2) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 3) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternatives 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 4) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period

c As defined by the San Joaquin Valley 60-20-20 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period

c As defined by the San Joaquin Valley 60-20-20 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Appendix 7A

Groundwater Model Documentation

This appendix provides information about the assumptions, modeling tools, and the methods used for the Coordinated Long-term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS) impact analysis including information for the No Action Alternative simulation. The appendix also describes model output processing and interpretation methods used for the impacts analysis and descriptions. Additional information pertaining to the development of the analytical tools, incorporating climate change, and using input data from other models is also provided.

This appendix is organized into three main sections that are briefly described below:

- Section 7A.1: Groundwater Modeling Methodology
  - The groundwater impacts analysis uses the Central Valley Hydrologic Model (CVHM) to forecast effects of the alternatives on the long-term operations and the environment. This section provides information about the overall analytical framework and how some of the model input information obtained from other models was processed using analytical tools.
- Section 7A.2: CVHM Modeling Simulations and Assumptions
  - This section provides a brief description of the assumptions for CVHM simulations of the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5.
- Section 7A.3: CVHM Modeling Results
  - This section describes the model simulation outputs used in the analysis and interpretation of modeling results for the alternatives impacts assessment. A description of post-processing tools is provided along with the different types of output display to facilitate data interpretation.

7A.1 Groundwater Modeling Methodology

This section summarizes the groundwater modeling methodology used for the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5. It describes the overall analytical framework and contains descriptions of the key analytical and numerical tools and approaches used in evaluating the alternatives. The project alternatives include several major components that will influence CVP and SWP operations and the hydrologic and hydrogeologic responses of the system.

In evaluating the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5, climate change assumptions centered on year 2025 (for assumed conditions at 2030) were used to develop modified climate input files. The modeling assumptions are provided in more detail in Section 7A.2.

The impacts on groundwater in the Central Valley and the CVP and SWP export service areas because of the project were analyzed using CVHM (USGS 2009). CVHM is a three-dimensional saturated groundwater flow model based on the widely used MODFLOW code (USGS 2000) and incorporates a number of modeling packages to simulate streamflow, crop demand, groundwater pumping, and subsidence.

7A.1.1 Overview of the Modeling Approach

To support the groundwater impact analysis of the alternatives, modeling of the physical groundwater system in the Central Valley has been undertaken to forecast changes to conditions affecting groundwater resources in areas that use CVP and SWP surface water deliveries.

CVHM is a calibrated historical model that includes a 42-year simulation period from water years 1962 through 2003. The model domain encompasses the entire Central Valley, including Sacramento Valley, San Joaquin Valley (including Tulare Basin), and the Sacramento-San Joaquin Delta. CVHM simulates primarily subsurface and limited surface hydrologic processes using a uniform grid-cell spacing of 1 mile.

CVHM was run over the 42-year hydrologic period, and boundary conditions were modified to reflect anticipated changes in surface water availability, including some potential effects of climate change. Surface water flows from operations models (descriptions of CalSim II methodology is included in Appendix 5A) were used to define selected surface water boundary conditions in CVHM. The linkage between CalSim II surface flows and CVHM inputs is further described below.

Future climate parameters centered on year 2025 were developed using the Variable Infiltration Capacity (VIC) model. Changes to the historical hydrology related to the future climate were applied in the CalSim II model and combined with the assumed operations for each alternative (Appendix 5A). The CalSim II model simulates the operation of the major CVP and SWP facilities in the Central Valley and generates river flows, exports, reservoir storage, deliveries, and other parameters for use with each alternative. River flows based on operational assumptions and reflected in the reservoir releases simulated in CalSim II are included in selected boundary conditions in the CVHM input files, along with the Delta exports to San Joaquin and Tulare service areas, and the surface water deliveries to CVP and SWP users in the Sacramento Valley. CVHM was used to forecast the changes in groundwater levels and groundwater pumping with implementation of the alternatives, and results are processed for input into the Statewide Agricultural Production (SWAP) model. The SWAP model then forecasts impacts on agricultural production based on pumping lifts and cost of groundwater pumping, as described in Chapter 12, Agricultural Resources. Figure 7A.1 shows the modeling tools applied in the groundwater impacts assessment and the relationship between these tools. Each model included in

Figure 7A.1 provides information to the subsequent "downstream" model in order to support the impacts analysis.

The results from this suite of computer models were used to assess potential groundwater effects from implementing each alternative considered in the EIS.

Modeling objectives included evaluating the following potential changes related to groundwater resources because of the various alternatives:

- Changes in groundwater elevations, which result from changes in groundwater use and could affect nearby municipal, agricultural, and domestic well yields
- Changes to groundwater quality based on a potential inducement of migration of poor-quality groundwater because of groundwater flow changes

7A.1.2 Key Components of the Groundwater Modeling Framework

7A.1.2.1 Model Function

CVHM was used to forecast groundwater level changes and other impacts to groundwater resulting from changes in assumed surface water deliveries from the CVP and SWP into the service areas located north and south of the Delta. More specifically, surface water operational changes from project implementation along with the effects of climate change were incorporated into CVHM as modified boundary inflows into the model domain and as semi-routed and nonrouted surface water deliveries to each CVHM water balance subregion (WBS). In addition, forecast climate variations were incorporated as modified precipitation and reference evapotranspiration (ET) rates in the model input files.

The overall construction and calibration of CVHM was left unchanged during this analysis. The only modifications to CVHM involved the prescribed surface water inflows and deliveries, which were modified based on simulations performed using CalSim II, as well as modified reference ET and precipitation input files to reflect potential climate change conditions centered on year 2025. CalSim II flows reflect operations in the Delta based on assumptions related to future operations of the project (see Chapter 5, Surface Water Resources and Water Supplies).

The active CVHM domain was subdivided into 21 WBSs, as originally defined by the California Department of Water Resources (DWR) (Figure 7A.2). During model simulations, applied water requirements for each WBS were computed based on crop type and available water from precipitation, shallow groundwater, and surface water (limited by surface water rights).

Selected major streams flowing through the Central Valley were explicitly represented in CVHM. Observed USGS gage flows were used as inflows into the model domain for natural, unregulated rivers and streams. Reservoir releases on regulated rivers were also used as boundary inflows into the model domain. The reservoir releases were modified for each alternative according to operational changes and are represented by modified time-series flow data obtained from the CalSim II simulations. Surface water deliveries to meet a portion of the applied water demands were diverted directly from the rivers, according to water rights constraints. Additional surface water was delivered through “nonrouted” methods in the model. Nonrouted surface water deliveries represent water transfers or surface water deliveries to a WBS not connected to a stream or major canal. This conveyance typically occurs through small canals or diversion ditches (USGS 2009). Some irrigation canals and aqueducts were not included in CVHM, such as the California Aqueduct and the Delta-Mendota Canal. Water delivered through these conveyances was simulated in CVHM as nonrouted deliveries, directly added to the destination WBS. The deliveries to WBSs south of the Delta from the CVP and SWP and associated conveyance losses were estimated from CalSim II simulations and included in CVHM. The surface water diversion flows for the CVP and SWP contractors and settlement contractors in the Sacramento Valley were also obtained from CalSim II simulations for each alternative.

7A.1.2.2 Computer Code Description

CVHM is a regional groundwater modeling application based on the MODFLOW-2000 (MF2K) computer code (USGS 2000) and incorporates a variety of additional modules that were specifically developed to interact with MF2K and increase the capabilities of the overall modeling package. The additional modules incorporated into the CVHM application are summarized in Table C1 of USGS Professional Paper 1766 (USGS 2009). The package that is responsible for simulating the majority of the agricultural water balance is the Farm Process (FMP) (USGS 2006). Within the FMP documentation, the WBSs are referred to as “farms”; WBS and farms are used interchangeably in this text. FMP computes the applied water demand for each farm based on crop types specified in each model cell and computes the availability of water from “natural” sources such as precipitation and shallow groundwater. After the available natural water is allocated, FMP computes the amount of water that needs to be delivered from other sources, such as surface water deliveries (routed and nonrouted) and groundwater pumping to meet the remaining applied water demand.

Another important module integrated into CVHM is the Stream Flow Routing (SFR1) package. This package simulates the routing of surface water through virtual channels within the model domain, accounts for surface water diversions and deliveries to individual WBSs, tracks the flow and associated stage in surface water reaches, and computes stream-aquifer exchange.

CVHM was chosen to simulate the impacts of the alternatives for three main reasons:

1. Readily available and peer-reviewed. CVHM was developed, calibrated, and tested by USGS and is based on a widely recognized computer code. It is publicly available, and extensive documentation has been published describing CVHM as well as all the modules and packages that make up the model.

2. Geographic extent. A large potentially impacted area to be evaluated as part of this project includes the Sacramento Valley and the San Joaquin Valley (including the Tulare Lake area). Surface water operational changes resulting

from project operations are defined at the margins of the Central Valley. The CVHM domain covers the entire Central Valley and allows for the efficient imposition of boundary conditions throughout the basin.

3. Model subareas and discretization. CVHM is divided into 21 WBSs that correspond to the historical water balance regions identified by DWR. Water balances are computed for each WBS by the model. This distribution of areas in the Central Valley is consistent with models used by other resource teams, provides for consistent model reporting to the other teams, and allows for efficient sharing of data with other models.

7A.1.2.3 General Numerical Model Description

CVHM simulates surface water flows, groundwater flows, and land subsidence in response to stresses from water use and climate variability throughout the entire Central Valley. It uses the MF2K (USGS 2000) groundwater flow model code combined with the FMP modular package to simulate groundwater and surface water flow, irrigated agriculture, and other key processes in the Central Valley on a monthly basis from April 1961 through September 2003. CVHM is discretized laterally over a 20,000-square-mile area and vertically into 10 layers ranging in thickness from 50 feet near the land surface to 400 feet at depth. Layers 4 and 5 represent the Corcoran Clay member where it exists in portions of the San Joaquin Valley. In the Sacramento Valley, the Corcoran Clay member is not present; therefore, the model layering effectively consists of eight layers.

The FMP allocates water deliveries, simulates crop-applied water demand processes, and computes mass balances for the 21 WBSs (or farms) in CVHM. The FMP was developed for MF2K to estimate applied irrigation water allocations from conjunctively used surface water and groundwater. It is designed to simulate the demand components representing crop irrigation requirements and on-farm inefficiency losses, and the supply components representing surface water deliveries and supplemental groundwater pumping. The FMP also simulates additional head-dependent inflows and outflows such as canal losses and gains, surface runoff, surface water return flows, evaporation, transpiration, and deep percolation of excess water. Unmetered pumping and surface water deliveries for the 21 WBSs are also included within the FMP (USGS 2006).

The original calibration of CVHM by USGS was accomplished using a combination of trial-and-error and automated methods. An autocalibration code called UCODE-2005 (USGS 2005) was used to help assess the ability of CVHM to estimate the effects of changing stresses on the hydrologic system. Simulated changes in water levels, streamflows, streamflow losses, and subsidence through time were compared by USGS to those measured in wells, at streamflow gages, and at extensometer sites. For model calibration, USGS screened groundwater levels and surface water stages to obtain a calibration target data set that is distributed spatially (geographically and vertically) throughout the Central Valley; distributed temporally throughout the simulation period (1961–2003); and available during both wet and dry climatic regimes. From the available wells records, a subset of 170 comparison wells was selected based on perforation depths, completeness of record, and locations throughout the Central Valley (USGS 2009). No changes were made to physical parameter values in CVHM for this project. A more detailed description of CVHM is in USGS Professional Paper 1766 (USGS 2009).

7A.2 CVHM Modeling Simulations and Assumptions

As described in Section 7A.1, groundwater modeling was performed for evaluating the alternatives considered in the EIS. This section describes the assumptions for the CVHM simulations of the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5.

The following model simulations were performed as the basis of evaluating the impacts of the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5:

- No Action Alternative
- Second Basis of Comparison
- Alternative 1 – for CVHM simulation purposes, considered the same as Second Basis of Comparison
- Alternative 2 – for CVHM simulation purposes, considered the same as No Action Alternative
- Alternative 3
- Alternative 4 – for CVHM simulation purposes, considered the same as Second Basis of Comparison.
- Alternative 5

Assumptions for each of these alternatives were developed with the surface water modeling tools and are described in Appendix 5.

The general CVHM modeling assumptions described below pertain to all the baseline and alternative runs.

7A.2.1 Climate Change Assumptions

Climate variables of interest from a climate-change perspective within CVHM include precipitation and reference ET, which are among the required inputs for the FMP module to compute the applied water demand. These two variables are formatted as two-dimensional model array input files with one value assigned to each surficial model grid cell.

The original historical climate input data for CVHM were developed for the simulation period 1961-2003 from Parameter-Elevation Regressions on Independent Slopes Model (PRISM) data (Climate Source 2006). For precipitation, PRISM data were interpolated onto the model domain, and reference ET data were computed from PRISM temperature data. Reference ET data were computed using the Penman-Monteith estimate of potential ET and are used to evaluate the crop potential ET in combination with crop coefficients, and minimum and maximum temperatures for each stress period (USGS 2009).

For the alternative simulations, climate conditions centered on year 2025 were assumed. Therefore, to be consistent with the other water supply and economics models, the climate input data for CVHM were modified to represent potential climate conditions centered on year 2025. A more detailed description of how climate change was incorporated into the CVHM forecast simulations follows.

The CVHM historical monthly precipitation and reference ET values were modified to incorporate potential climate change based on the median climate change scenario for the early long-term period (centered on 2025) (DWR, Reclamation, USFWS, and NMFS 2013). The analysis uses five statistically representative climate change scenarios to characterize the central tendency and the range of the ensemble uncertainty, including projections representing drier, less warming; drier, more warming; wetter, more warming; and wetter, less warming conditions as compared with the median projection. Climate change scenarios were developed from an ensemble of 112 bias-corrected, spatially downscaled global climate model (GCM) simulations. These GCM simulations were from 16 climate models for Special Report on Emissions Scenarios (SRES) A2, A1B, and B1 (Maurer et al. 2007) from the Coupled Model Intercomparison Project Phase 3 that are part of the Intergovernmental Panel on Climate Change Fourth Assessment Report. The forecast changes over the 30-year climatological period centered on 2025 (i.e., 2011-2040 to represent 2030 timeline) were combined with a set of historically observed temperature and precipitation (Hamlet and Lettenmaier 2005) to generate climate sequences that maintain important multiyear variability. The approach uses a technique called “quantile mapping”, which maps the statistical properties of climate variables from one data subset with the time series of events from a different data subset.

Historical temperature and precipitation data gridded to a 1/8 degree (°) spatial resolution across California (Hamlet and Lettenmaier 2005) were obtained from the Surface Water Modeling Group at the University of Washington (http://www.hydro.washington.edu). These data are based on the National Weather Service cooperative network of weather observations stations, augmented by information from the higher quality Global Historical Climatology Network stations. The Hamlet and Lettenmaier (2005) dataset includes the period from January 1915 through December 2003.

The historical and modified temperature (maximum and minimum values) based on the median early long-term climate-change scenario (centered on 2025) were used in the VIC hydrological model (Liang et al. 1994; Reclamation 2011) to simulate reference ET using the Penman–Monteith method (Allen et al. 1998).

Based on the above assumptions and methods, two sets of monthly fractional changes (i.e., perturbation factors) were computed to adjust the CVHM historical precipitation and reference ET input model array files. The first set of monthly fractional changes was computed from the historical and modified precipitation at each 1/8° VIC grid cell (future precipitation divided by historical precipitation). Similarly, the second set of monthly fractional changes was computed from reference ET simulated using historical and modified climate inputs that were computed using the Penman–Monteith method (Allen et al. 1998) embedded in the VIC hydrological model (simulated future reference ET divided by simulated reference ET). The fractional changes were computed for the historical period April 1961 through September 2003 for consistency with the CVHM simulation period.

The monthly fractional changes at 1/8° VIC grid cell were then applied to each CVHM monthly precipitation and reference ET data set at the corresponding CVHM grid cells by spatially mapping the two sets of grids. A utility tool was developed for intersecting the CVHM grid cells with the 1/8° VIC grids to assign fractional changes from the 1/8° VIC grid cell to historical precipitation and reference ET at each surficial CVHM cell to produce modified precipitation and reference ET values for planning level CVHM simulations that incorporate potential future climate change centered on year 2025. Figure 7A.3 illustrates the relationship between the VIC model grid and the CVHM grid.

7A.2.2 Land Use Assumptions

In CVHM, "the land use attributes are defined in the model on a cell-by-cell basis and include urban and agricultural areas, water bodies, and natural vegetation. The land use that covered the largest fraction of each 1-mi² model cell was the representative land use specified for that cell" (USGS 2009). Further, the agricultural land use is divided into 12 DWR Class 1 crop categories, also referred to as "virtual crops". As described in USGS 2009, the process of identifying a representative land use type and crop category for each model cell is very complex over the 42-year hydrologic period with different climate variations. This type of data is not readily available publicly, and other land use coverages require extensive processing to convert it into a format suitable for CVHM simulations. Thus, generating future land use changes for each cell of the CVHM grid was not undertaken in the impacts analysis in this EIS. In addition, other related FMP input files (such as crop coefficients and irrigation efficiencies) change over time and need to be updated accordingly with the land use.

For the groundwater modeling, the land use distribution for water year 2003 was used for the entire forecast simulation period. This was the most recent land use data available in a format appropriate for the model simulations. The limitation of using the 2003 land use distribution is that some of the most recent changes to crop production in the Central Valley over the past decade are not included in the simulations. In addition, projections of land use changes because of economic effects and climate change are not considered in CVHM, nor are the potential crop changes in response to water supply availability from CVP and SWP operational changes from the alternatives (see Chapter 12, Agricultural

Resources, for a discussion of changes in crops because of water supply availability and costs). However, these assumptions are the same for the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5; and are therefore adequate for the comparative analysis required in the EIS. There have been changes in crop patterns since 2003; however, those changes would be consistent in the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5.

7A.2.3 Stream Boundary Inflows Assumptions

CVHM includes 43 stream boundary inflows, which represent smaller natural streams as well as managed reservoir outflows. Of these, 13 inflows were linked to CalSim II reservoir releases. Natural stream inflows were kept unchanged from the original CVHM and therefore are linked to the historical climate data. It should be noted that CalSim II does not include the Tulare Lake area, and all stream inflows in that area were kept the same as those from the original CVHM.

For each alternative simulation, the surface water inflows at specific locations are updated in the SFR input file based on time series computed by CalSim II. Table 7A.1 lists the CVHM inflow locations at which updated CalSim II flows were applied based on simulation results from the corresponding CalSim II nodes. Figure 7A.4 provides a map with the stream boundary inflow locations in CVHM.

Table 7A.1 CVHM Modified Inflow Locations

CVHM Node ID	Description	CalSim II Equivalent Nodes
AMER_374	American River Downstream of Lake Natoma + South Folsom Canal	C9 + D9
MOKE_173	Mokelumne River below Comanche Reservoir	I504 + Original CVHM Diversions on Mokelumne River
CALV_161	Calaveras River (release from New Hogan Reservoir)	C92
STAN_146	Stanislaus River (below Goodwin + Oakdale Canal + SSJ Canal)	C520 + D520B + D520C
TUOL_135	Tuolumne River (Don Pedro Reservoir Release)	C81
SACR_205	Sacramento River (Keswick Reservoir Release)	C5
STON_263	Stony Creek (Black Butte Reservoir Release)	C42
FEAT_341	Feather River below Oroville + Palermo Canal	C6 + D6
YUBA_349	Yuba River below Englebright + Deer Creek inflow + French Dry Creek inflow	C230 + D230
MERC_116	Merced River (Lake McClure outflow)	C20
CHOW_080	Chowchilla River (Eastman Lake outflow)	C53
FRES_069	Fresno River (Hensley Lake outflow)	C52
SANJ_054	SJR at Friant Dam (Millerton Lake outflow)	C18

7A.2.4 Project Deliveries Assumptions

CVHM includes two different methods to deliver surface water diversions to a WBS: semi-routed deliveries and nonrouted deliveries. These deliveries occur through the interaction of the SFR and FMP modules and the WBS.

Semi-routed deliveries occur through the SFR package to account for water that is routed through stream networks. With the SFR package, CVHM conveys water from streams and canals as semi-routed deliveries to WBSs through the FMP based on model-computed applied water demand (USGS 2009).

The nonrouted delivery process allows the model to obtain surface water from a source that is not simulated with the stream network. For instance, not all canals are physically simulated within CVHM, but the water conveyed through those canals can still be delivered to the appropriate WBSs without actually simulating the conveyance features explicitly.

In the CVHM simulations, the nonrouted surface water supply components have first delivery and use priority, and semi-routed surface water deliveries have second priority. If the WBSs water delivery requirements computed by the crop consumptive use through FMP are not met using surface water, the FMP computes the amount of supplemental groundwater necessary to be pumped from "farm" (agricultural production) wells to satisfy the total WBS water demand (USGS 2009). The nonrouted and semi-routed surface water deliveries are simulated as monthly transient time series that set the upper bound of available surface water for the WBSs. The actual diversions and deliveries for each WBS are driven by agricultural water demand.

Within the CVHM configuration, nonrouted deliveries tend to be associated with the south-of-Delta exports to the San Joaquin Valley service areas, because the California Aqueduct and the Delta-Mendota Canal are not simulated in the model. Semi-routed deliveries occur in areas where diversions from streams and canals are simulated for both settlement contractors and riparian diverters. Because of the difference in water rights allocations and the different CVHM characteristics in the Sacramento Valley versus the San Joaquin Valley, the surface water allocations are simulated differently, as described below. Figure 7A.5 shows the surface water delivery types for each WBS as simulated in CVHM.

For the groundwater impacts simulations, the calibrated historical CVHM was set up to run in a "predictive mode" (for future planning simulations) with the diversion time series fixed at water year 2003 for all semi-routed diversions that represent riparian or other water rights users. This method provides the latest available (2003) diversion flows to agricultural water users for an average hydrology year with seasonal patterns. Project water deliveries were developed from CalSim II time series, as described below.

7A.2.4.1 Sacramento Valley

The Sacramento Valley is defined in CVHM as WBSs 1 through 8 (Figure 7A.2). In the Sacramento Valley, the diversion time series for the CVP and SWP settlement contractors and CVP contract agricultural diverters were linked to

CalSim II time series for consistent project delivery estimates for each alternative. Table 7A.2 shows the detailed linkage between CalSim II nodes and CVHM diversions nodes for the Sacramento Valley (also shown in Figure 7A.6).

Table 7A.2 CVHM Diversions linked to CalSim II Flows in the Sacramento Valley

CVHM WBS	CVHM Node ID	Type of Flow	Description – CVHM (CalSim II)	CalSim II Equivalent Node
1	BELL_0206	–	Bella Vista Conduit (ag only)	0.57*D104_PAG
1	SACR_A223	CVP Settlement Ag + CVP Ag Delivery	Diversions – Sacramento River between Keswick and Red Bluff (ag only)	D104_PAG - (BELL_0206) + (0.86*D104_PSC)
0*	SACR_B223	CVP M&I + CVP Settlement M&I Delivery	Diversions – Sacramento River between Keswick and Red Bluff (M&I only)	D104_PMI + 0.14*D104_PSC
2	CORN_0232	CVP Ag Delivery	Corning Canal	D171
2	TE10_0232	CVP Ag Delivery	Tehama Colusa Canal	D172
3	TE12_0323	CVP Ag Delivery	Tehama Colusa Canal	D174 + D178
3	GLEN_0261	CVP Settlement Ag Delivery	Glenn Colusa Canal	D143A + D145A

[*] WBS 0 means that water is diverted from the stream but not delivered to any to any of the WBSs. This occurs for M&I diversions not used for crop irrigation.

The linkage was based on the definition and assumptions of CalSim II and CVHM deliveries, and on the spatial approximation of the stream diversion location in CVHM. Each time series is updated in the SFR input file for each alternative simulation.

In addition to the semi-routed deliveries, WBSs 5 and 7 receive water from nonrouted deliveries. However, most of these deliveries are either linked to riparian (nonproject) water rights or deliveries from outside the model domain. Therefore, WBS 5 and 7 nonrouted deliveries remained unchanged from the calibrated CVHM model.

7A.2.4.2 San Joaquin Valley

In CVHM, the San Joaquin Valley is defined as WBSs 10 through 21 and includes the Tulare Lake portion of the San Joaquin Valley (Figure 7A.2). In the San Joaquin Valley, the majority of agricultural surface water deliveries are provided through south-of Delta exports from the CVP and SWP contract allocations. CalSim II time series representing project water deliveries for the San Joaquin Valley WBSs were aggregated into one time series for each WBS using a spreadsheet-based preprocessing tool. These time-series data were then used for the FMP nonrouted deliveries input file. The semi-routed deliveries in the San Joaquin Valley are either of riparian nature or for other non-project use, and therefore were not changed from the historical CVHM. The only exception occurred in WBS 11, in the East San Joaquin area, where two CVP agricultural deliveries were linked to CalSim II time series (Figure 7A.6):

- Deliveries for Oakdale Irrigation District North and South San Joaquin Irrigation District, simulated in CVHM as the diversions at the South San Joaquin Canal near Knights Ferry (SSJK_0147 in Figure 7A.6), were linked to CalSim II node D520B
- Deliveries for Oakdale Irrigation District South, simulated in CVHM as the diversions at the Oakdale Canal near Knights Ferry (OAKK_0147 in Figure 7A.6), were linked to CalSim II node D520C

These two semi-routed diversions and deliveries were incorporated into the SFR input file along with all the other surface water diversion and boundary inflow modifications for each alternative.

7A.2.5 Model Application Methodology

For each simulation scenario (No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5), boundary inflows in CVHM, WBS surface water estimates, and farm delivery estimates were updated with the appropriate CalSim II model outputs, which account for assumed operational changes for each alternative. The original 42-year hydrology for water years 1962 through 2003 was updated with climate conditions centered on year 2025 for each predictive simulation. Thus, impact evaluations assume the dry to wet hydrology patterns as indicated from climate model simulations centered on year 2025. The simulated groundwater levels for each alternative were compared to the No Action Alternative and Second Basis of Comparison simulations. Model outputs were processed such that impacts to groundwater were shown on an average monthly basis by water year type, and the analysis was centered on potential impacts occurring during the month with the largest agricultural deliveries, which generally is July. The simulation period did not intend to provide groundwater levels at exact future dates, but rather provide a range of groundwater level changes that could occur from implementing each alternative, given assumed future fluctuations in hydrology.

7A.2.5.1 No Action Alternative and Second Basis of Comparison Models

The overall purpose of the No Action Alternative and Second Basis of Comparison models is to provide a set of baseline conditions for comparison with the forecasts of the alternative models to assess whether implementing the proposed alternatives are likely to result in substantial changes to groundwater resources.

Preparing the CVHM No Action Alternative model and the Second Basis of Comparison model was based on the modified CalSim II flow time series for the reservoir outflows and the deliveries to the WBSs in the export service areas. The following are additional assumptions inherent in the predictive version of CVHM:

- The urban groundwater pumping locations for 2003, the most recent available in CVHM, were assumed to remain for the duration of the 42-year predictive simulation period.
- The original CVHM 2003 surface water diversions were assumed for the duration of the predictive simulation for nonproject diversions.
- The land use distribution and associated cropping patterns available in the calibrated CVHM at approximately year 2000-2003 were kept constant throughout the predictive simulation.
- The climatic data were updated to represent a wet to dry precipitation pattern centered on year 2025.

7A.2.5.2 Other Alternatives Models

For each alternative model simulation, the same procedure as described for the No Action Alternative and Second Basis of Comparison models was used, with similar assumptions, to update flows from the CalSim II simulations. Detailed modeling processes and impacts analysis procedures are described in the next section.

7A.3 CVHM Modeling Results

A complex and detailed model such as CVHM requires developing and applying preprocessing and post-processing tools to create input files, run the model, and view and interpret results. The processing tools range from geographic information system (GIS) and spreadsheet-based tools to custom-coded programming utilities that use viewing programs such as Golden Software Surfer. The general preprocessing and input files development are described in Section 7A.2. The following subsections describe data analyses and results.

7A.3.1 Post-Processing and Results Analysis

Output data resulting from CVHM simulations for each alternative were processed to provide a graphical depiction of applicable information that support the analysis and description of potential impacts to groundwater resources. As discussed previously, the primary outputs from CVHM used in this analysis were simulated heads and agricultural groundwater pumping to meet applied water demands.

CVHM outputs simulated hydraulic heads (heads) and groundwater fluxes for each model grid cell in each model layer. Based on analysis of common screen elevations of agricultural pumping wells, Model Layer 6 of the original CVHM includes the majority of the groundwater extraction. Actual locations of agricultural wells are not represented in the model; they are represented as "virtual wells" in model cells representing areas with known groundwater pumping and having a corresponding agricultural land use. The simulated heads in each cell for Model Layer 6 only are interpolated using triangulation with linear interpolation to facilitate viewing results for the entire Central Valley for each alternative. Because July generally has the highest agricultural groundwater pumping during the CVHM timeframe, the results analysis focuses on this month for each alternative. A post-processing utility was developed to create monthly average heads for July for each water-year type. The difference in monthly average heads between each alternative and No Action Alternative and each alternative and Second Basis of Comparison was then computed, interpolated, and displayed on a Central Valley map for change visualization. The differences were computed by subtracting the simulated heads for No Action Alternative and Second Basis of Comparison from the simulated heads for the alternatives, respectively.

A resulting positive head difference indicates that heads in the alternative simulation are higher than those from the No Action Alternative or Second Basis of Comparison simulation to which the alternative simulation is being compared. Conversely, a resulting negative head difference indicates that heads in the alternative simulation are lower than those from the No Action Alternative or Second Basis of Comparison simulation to which the alternative simulation is being compared. Results are provided in Figures 7.15 through 7.60 and a narrative of the forecast head differences (i.e., project effect to groundwater levels) is provided in Chapter 7, Groundwater Resources and Groundwater Quality.

The results give an indication of the horizontal distribution of the potential impacts to groundwater levels in Model Layer 6 for an average month of July for each water year type. To assess the temporal variations in groundwater level fluctuations, head difference hydrographs at eight model cells were developed to show a range of typical groundwater level variations and changes between alternatives and No Action Alternative and Second Basis of Comparison at different locations in the Central Valley. The location of the simulated groundwater level time series were chosen based on general areas of USGS wells that were used for calibrating CVHM. The hydrograph plots are shown on a CVHM WBS map for the Sacramento Valley and San Joaquin Valley (Figures 7.20, 7.21, 7.29, 7.30, 7.38, 7.39, 7.45, 7.46, 7.52, 7.53, 7.59, and 7.60).

In addition to spatial and temporal representations of groundwater level changes associated with the alternatives, agricultural groundwater pumping differences are also depicted on a map of the WBSs. This graphical representation shows which areas of the Central Valley are impacted the most by changes in surface water deliveries for each alternative. The data for these results were processed from the FMP output files, which include the amount of water used from each available source by the farm, based on the computed applied water demand for each WBS (Figures 7.22, 7.23, 7.31, and 7.32).

7A.3.2 Output Data for Other Models

Simulated heads from CVHM were post-processed for use in evaluating agricultural economic impacts related to each alternative. An agricultural economic impact evaluation of each alternative was performed using the SWAP model. For more information on using this model and the results, refer to

Chapter 12, Agricultural Resources and Appendix 12A. The simulated heads output file was processed to average the July head data for Model Layer 6 for each SWAP region. In addition, processing of CVHM heads for the SWAP model further separates the average simulated head between irrigated portions and non-irrigated portions of each SWAP region.

As a result, each SWAP region includes one estimated average head change representing the agricultural pumping impacts. This average value was used to compute a pumping lift for SWAP input, to compute average electrical cost to pump groundwater for irrigation.

7A.3.3 Model Limitations and Applicability

Although it is impossible to predict future hydrology, land use, and water use with certainty, CVHM was used to forecast impacts to groundwater resources that could result from implementing the No Action Alternative, Second Basis of Comparison, and Alternatives 1 through 5 to aid in developing the EIS. CVHM was used in a comparative manner to estimate potential changes by implementing Alternatives 1 through 5 as compared to the No Action Alternative, and the No Action Alternative and Alternatives 1 through 5 as compared to the Second Basis of Comparison. Mathematical models like CVHM can only approximate processes of physical systems. Models are inherently inexact because the mathematical description of the physical system is imperfect, and the understanding of interrelated physical processes is incomplete. However, CVHM is a powerful tool that, when used carefully, can provide useful insight into processes of the physical system. The following are some known limitations that should be considered when evaluating the forecast impacts.

- CVHM simulates groundwater conditions in the Central Valley with cells on 1-mile centers. Therefore, surface water and groundwater features that occur at a scale smaller than 1 mile cannot be simulated explicitly in CVHM. Likewise, CVHM simulates groundwater conditions using monthly stress periods. Thus, groundwater variations cannot be simulated explicitly in CVHM over timeframes shorter than 1 month.
- The “predictive” (future planning) version of CVHM used for the impacts analysis does not include land use changes after year 2003. Thus, land use changes that have occurred since 2003 and those that might occur in the future are not considered in the impacts analysis.
- The future planning version of CVHM incorporates potential climate-change effects centered on year 2025 (assumed conditions at year 2030). It is not possible to know whether these potential climate-change effects will actually occur in the future, as modeled.
- Operation of groundwater banks and groundwater transfer programs and how implementing the alternatives could affect them is not included in the future planning level CVHM simulations.
- The future planning version of CVHM does not include potential affects from planned or unplanned changes in groundwater regulations in California

(i.e., implementation of California Sustainable Groundwater Management Act).

- The subsidence package, as implemented in the version of CVHM used for the impacts analysis, does not consider the potential reduction in the rate of subsidence that would occur as the magnitude of compaction approaches the physical thickness of the affected fine-grained interbeds. Thus, subsidence forecasts from the predictive versions of CVHM were judged to be overly conservative. Therefore, a qualitative approach was used for estimating the potential for increased land subsidence in areas of the Central Valley that have historically experienced inelastic subsidence because of the compaction of fine-grained interbeds.

Power Model Documentation

Appendix 8A provides information about the assumptions, modeling tools, and methods used for the Coordinated Long-Term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS) Environmental Consequences. The appendix also provides model result processing and interpretation methods used for the impacts analysis and descriptions. Additional information pertaining to the development of the analytical tools and the use of input data from other models, is also provided.

Appendix 8A is organized into two main sections that are briefly described below:

- Section 8A.1: Power Modeling Methodology and Assumptions
  - The power impacts analysis uses the LTGen and SWP Power spreadsheet models to assess and quantify effects of the alternatives on the long-term operations and the environment. This section provides information about the modeling approach, equations, and assumptions used by the two power models.
- Section 8A.2: Power Modeling Results
  - This section provides a detailed description of the model simulation output formats used in the analysis and interpretation of modeling results for the alternatives impacts assessment.

8A.1 Power Model Methodology and Assumptions

This section summarizes the power modeling methodology used for the EIS No Action Alternative, Second Basis of Comparison, and other alternatives. There are two spreadsheet tools that are used to estimate average annual peaking power capacity, energy generation, and energy use at CVP and SWP facilities:

- LTGen (LTGen_BenchmarkBO_04-01-2015): analyzes CVP facilities
- SWP_Power (SWP_Gen_J604_02-23-2015): analyzes SWP facilities

The sections below describe the equations that are used to estimate energy use, generation, peaking power capacity, and transmission losses.

8A.1.1 Energy Use at Pumping Facilities

Energy use at CVP and SWP pumping facilities are determined using empirical energy factors provided by the Western Area Power Authority (Western) for CVP facilities and by the Department of Water Resources (DWR) Operations Control Office (OCO) for SWP facilities. For these facilities, energy use is estimated using the following equation:

Energy Use (in Megawatt-hour [MWh]) =

*Energy_Factor * (Q in cubic feet/second)*

The tools also estimate whether user-defined off-peak energy use targets can be met. For example, if it is desired that 90 percent of required pumping energy use during a particular month occur during off-peak hours, the tools determine whether this is feasible given power and flow capacity limits.

8A.1.2 Energy Generation

Energy generation at CVP and SWP power facilities are determined using empirical energy factors provided by Western for CVP facilities and by the OCO for SWP facilities. For these facilities, energy generation is estimated using the following equation:

Energy Generation (MWh) =

*Energy_Factor * (Q in cubic feet/second)*

8A.1.3 Energy Generation

Energy generation is limited on a monthly basis by an average power capacity at each facility. At any one time, power capacity can be higher or lower, depending upon reservoir levels and scheduled water releases. Power production in general will be high during summer months when reservoir levels are higher and water is being released to meet delivery requirements, and power operations are optimized to provide the greatest benefit to taxpayers.

Average monthly power capacity for CVP facilities is estimated using empirical equations provided by Western. The approach used to estimate average monthly power capacity for SWP facilities assumes that peak capacity is a function of total head and average power plant flow. The average monthly power capacity is estimated using the following equation:

Power Capacity (in megawatt [MW]) =

(0.7457 kilowatt/horsepower)(62.4 pounds/cubic foot)*(1MW/1000 kilowatt)* (1 horsepower/(550 pounds per foot/second))*(1/η)*(Head in feet)*(Average Power Plant Flow Rate in cubic feet/second)*

8A.1.4 Transmission Losses

Transmission losses are estimated to estimate energy use and generation at load center, as a percentage of energy use or generation.

8A.1.5 Assumptions Tables

Tables 8A.1 and 8A.2 show assumptions that are used to estimate energy use and transmission losses at CVP and SWP pumping facilities. Tables 8A.3 and 8A.4 show assumptions that are used to estimate energy generation, power capacity, and transmission losses at CVP and SWP generation facilities.

8A.1.6 Flow and Storage Inputs

CalSim II results are used as flow and storage inputs for the power models for each alternative, using the entire October 1921 to September 2003 simulation period. Climate change and sea-level rise are inherently represented through CalSim II outputs. As mentioned in Appendix 5A, the CalSim II simulations do not consider future climate change adaptation that may manage the CVP and SWP system in a different manner than today to reduce climate impacts.

8A.2 Power Model Results

Power Model results were processed individually for each alternative simulation. Tables for total monthly generation capacity, energy generation, energy use, and net energy use for both the CVP and SWP are presented in this section in the following order:

- B.1. CVP Total Generating Capacity
- B.2. CVP Total Energy Generation
- B.3. CVP Total Energy Use
- B.4. CVP Net Energy Generation
- B.5. SWP Total Generating Capacity
- B.6. SWP Total Energy Generation
- B.7. SWP Total Energy Use
- B.8. SWP Net Energy Generation

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Second Basis of Comparison and Alternative 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

a Exceedance probability is defined as the probability a given value will be exceeded in any one year.

b Based on the 82-year simulation period.

c As defined by the Sacramento Valley 40-30-30 Index Water Year Hydrologic Classification (SWRCB D-1641, 1999); projected to Year 2030.

Notes: 1) All alternatives are simulated with projected hydrology and sea level at Year 2030 conditions. 2) Model results for Alternatives 1, 4, and Second Basis of Comparison are the same, therefore Alternative 1 and 4 results are not presented. Qualitative differences, if applicable, are discussed in the text. 3) Model results for Alternative 2 and No Action Alternative are the same, therefore Alternative 2 results are not presented. Qualitative differences, if applicable, are discussed in the text.

Appendix 9A

Special-Status Aquatic Species

Table 9A.1 presents a list special-status aquatic species that occur within the study area and could be affected by changes under Alternatives 1 through 5 as compared to the No Action Alternative and Second Basis of Comparison.

Special status aquatic species that occur or may occur within areas potentially affected by actions that could occur under Alternatives 1 through 5 related to the Central Valley Project and State Water Project operations or ecosystem restoration activities. Impact potential is based on the likelihood of operational changes or restoration actions to impact suitable habitat occurring in defined area of analysis.

The area of analysis for operational changes includes open water areas of reservoirs, rivers, and creeks; adjacent riparian vegetation; wetlands supported by these waterbodies; and potential restoration areas in Yolo Bypass and Suisun Marsh. Aquatic species are presented in alphabetical order based on scientific name.

Table 9A.1 Special-Status Aquatic Species

Species or Population	Federal Status	State Status	Occurrence within Area of Analysis
River Lamprey	None	None	Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
Pacific Lamprey	None	None	Trinity River, Klamath River, Clear Creek , Feather River, Sacramento River, American River, Delta, Stanislaus River, San Joaquin River
Green Sturgeon Southern DPS	Threatened	Species of Special Concern	Trinity River, Klamath River, Feather River , Sacramento River, Delta and Suisun Marsh
White Sturgeon	None	None	Trinity River, Klamath River, Feather River, Sacramento River, American River, San Joaquin River, Delta and Suisun Marsh
Eulachon Southern DPS	Threatened	None	Klamath River
Coho Salmon Southern Oregon/ Northern California Coast ESU	Threatened	Threatened	Trinity River, Klamath River

Species or Population	Federal Status	State Status	Occurrence within Area of Analysis
Spring-run Chinook Salmon Upper Klamath-Trinity River ESU	Candidate	Species of Special Concern	Trinity River, Klamath River
Fall-/Late-Fall-run Chinook Salmon Central Valley ESU	None	Species of Special Concern	Clear Creek, Feather River, Sacramento River, American River, Stanislaus River, San Joaquin River, Delta and Suisun Marsh
Winter-run Chinook Salmon Sacramento River ESU	Endangered	Endangered	Sacramento River, Delta and Suisun Marsh
Spring-run Chinook Salmon Central Valley ESU	Threatened	Threatened	Clear Creek, Sacramento River, Feather River, American River, Delta and Suisun Marsh
Steelhead (winter- and summer-run) Klamath Mountains Province DPS	None	Species of Special Concern	Trinity River, Klamath River
Steelhead Central Valley DPS	Threatened	None	Clear Creek, Feather River, Sacramento River, American River, Stanislaus River, San Joaquin River, Delta and Suisun Marsh
Steelhead Central California Coast DPS	Threatened	None	San Francisco Bay region
Delta Smelt	Threatened	Endangered	Delta and Suisun Marsh
Longfin Smelt Bay Delta DPS	Candidate	Threatened	Delta and Suisun Marsh
Sacramento Splittail	None	Species of Special Concern	Feather River, American River, Sacramento River, Delta and Suisun Marsh, San Joaquin River
Hardhead	None	Species of Special Concern	Clear Creek, Feather River, Sacramento River, American River, Delta, Stanislaus River, San Joaquin River
Sacramento-San Joaquin Roach	None	Species of Special Concern	Clear Creek, Feather River, American River, Sacramento River, Delta, Stanislaus River, San Joaquin River

Species or Population	Federal Status	State Status	Occurrence within Area of Analysis
Striped Bass	None	None	Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
American Shad	None	None	Trinity River, Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
Black Bass (largemouth, smallmouth, spotted)	None	None	Trinity River, Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
Killer Whale Southern Resident DPS	Endangered	None	Pacific Coast

Notes:
DPS = distinct population segment
ESU = evolutionarily significant unit

Appendix 9B

Aquatic Species Life History Accounts

This appendix provides additional information on the life history characteristics of the target aquatic species assessed in the Remanded Biological Opinions on the Coordinated Long-Term Operation of the Central Valley Project (CVP) and State Water Project (SWP) Environmental Impact Statement (EIS). This information is intended to provide a more holistic understanding of how these species use the water bodies influenced by operation of the CVP and SWP and to help clarify relationships that provide the logical foundation for conclusions regarding the potential environmental consequences associated with changes in operation.

This appendix addresses the following species:

- River Lamprey
- Pacific Lamprey
- Green Sturgeon
- White Sturgeon
- Chinook Salmon
  - Winter-run Chinook Salmon
  - Central Valley Spring-run Chinook Salmon
  - Central Valley Fall-run and Late Fall-run Chinook Salmon
  - Upper Klamath and Trinity Rivers Spring-run Chinook Salmon
- Central Valley Steelhead
- Klamath Mountains Province Steelhead
- Sacramento Splittail
- Longfin Smelt
- American Shad
- Eulachon
- Striped Bass
- Southern Resident Killer Whale

9B.1 River Lamprey (*Lampetra ayresii*)

9B.1.1 Legal Status

Federal: None
State: Species of Special Concern

River Lamprey was petitioned for listing by a number of conservation groups in 2003, along with three other lamprey species (Klamath-Siskiyou Wildlands Center et al. 2003). The petition was declined by the U.S. Fish and Wildlife Service (USFWS) in 2004 because of insufficient evidence that listing was warranted.

9B.1.2 Distribution

River Lamprey are found in large coastal streams from just north of Juneau, Alaska, to the San Francisco Bay (Vladykov and Follett 1958, Wydoski and Whitney 1979). The Sacramento and San Joaquin basins are at the southern edge of their range (Moyle et al. 2009). Little is known regarding their abundance and distribution within California; they seem to be primarily associated with the lower portions of certain large river systems, and most records for the state are from the lower Sacramento-San Joaquin system, especially the Stanislaus and Tuolumne rivers (Moyle et al. 1989, Moyle 2002). In the Sacramento River, they have been documented upstream to at least Red Bluff Diversion Dam (RBDD) (Hanni et al. 2006, Moyle et al. 2009). River Lamprey have also been collected in the Feather River, American River, Mill and Cache creeks (Vladykov and Follett 1958, Hanni et al. 2006, Moyle et al. 2009). River Lamprey have not been documented during rotary screw trapping efforts in Clear, Battle, and Deer creeks, or in the Yuba River (Hanni et al. 2006). Other streams where they have been found in California outside of the Central Valley include the Napa and Russian rivers, and Alameda, Sonoma, and Salmon creeks (DWR et al. 2013).

9B.1.3 Life History and Habitat Requirements

River Lamprey are a small parasitic anadromous species. Most studies of their biology have been conducted in British Columbia; relatively little is known regarding their life history and habitat requirements in California (Moyle 2002).

Adult River Lamprey migrate from the ocean into spawning areas in the fall. Adults of both sexes construct nests in gravel at the upstream end of riffles (Wydoski and Whitney 1979, Beamish and Youson 1987, Moyle 2002). Eggs are deposited and fertilized in these depressions, after which the adults typically die, similar to other species of lampreys. In the Sacramento-San Joaquin basin of California, most spawning is believed to occur in April and May (Vladykov and Follett 1958; Scott and Crossman 1973) at temperatures of about 55 to 56 degrees Fahrenheit (°F) (Wang 1986). Two females in Cache Creek were reported to have 11,400 and 37,300 eggs each (Vladykov and Follett 1958).

After hatching, young ammocoetes (the larval stage of lamprey) drift downstream to settle in the silt-sand substrates of backwaters, eddies, and pools, where they remain burrowed for approximately 3 to 5 years (Moyle 2002). At this stage, they are filter feeders, with a diet consisting of algae (primarily diatoms) and other organic detritus and microorganisms (Wydoski and Whitney 1979). Good water quality and temperatures not exceeding 77°F are believed to be necessary for their survival (Moyle 2002). Their metamorphosis into adults begins in July when they reach about 12 centimeters (cm) (4.7 in) (Beamish 1980), and is not complete for about 9 to 10 months until around April the following spring, when the esophagus opens and adults are able to osmoregulate (Beamish and Youson 1987, Moyle 2002). This is a more extended period of metamorphosis than observed in other lamprey species. During this time, they are believed to live in deep waters of the river channel. Just prior to the completion of metamorphosis, the juvenile lampreys (macropthalmia) congregate immediately upstream of salt water and enter the estuary or ocean from May to July (Beamish and Youson 1987).

Adults spend 3 to 4 months in salt water, remaining close to shore and growing to lengths of about 25 to 31 cm. In the estuary or ocean, River Lamprey are obligate parasites, typically killing their host in the process of feeding. They most commonly parasitize fishes 10 to 30 cm long, feeding near the surface on smelt, herring, and mid-size salmonids (Beamish 1980, Roos et al. 1973, Beamish and Neville 1995). In Canada, they have been documented to be an important source of mortality on salmon (Beamish and Neville 1995). In the fall, adults migrate back upstream into spawning areas and cease to feed. Fidelity to the streams in which they were spawned remains unknown.

The species is expected to use Delta habitats primarily as a migration corridor (DWR et al. 2013), and have been collected in Suisun Bay, Montezuma Slough, and Delta sloughs during California Department of Fish and Wildlife (DFW) plankton sampling efforts. CVP and SWP salvage data indicate that they are found in the salvage primarily from December through March (DWR et al. 2013). Juveniles are weak swimmers, frequently becoming entrained in water diversions or turbine intakes of hydroelectric projects or becoming impinged on screens meant to bypass juvenile salmonids or other fish (USFWS 2007).

Very little is known regarding the distribution, habitat use, and life history of this species in the action area. Numerous adults (less than 200 millimeters [mm]), presumably of spawning age, have been captured in rotary screw traps at RBDD from March through June (Hanni et al. 2006). Individuals smaller than most adults (greater than 200 mm), likely outmigrating macropthalmia, have been captured at RBDD and Feather River rotary screw traps from late September through early June (Hanni et al. 2006). Factors limiting River Lamprey populations in the Sacramento River are likely similar to those limiting salmonids (Moyle et al. 2009). Quantitative data on populations are extremely limited, but loss and degradation of historical habitats suggest populations have likely declined (Moyle et al. 2009).

9B.2 Pacific Lamprey (*Entosphenus tridentatus*)

9B.2.1 Legal Status

Federal: None
State: None

The Pacific Lamprey was petitioned for listing by 12 conservation groups in 2003, along with three other lamprey species (Klamath-Siskiyou Wildlands Center et al. 2003). The petition was declined by USFWS in 2004 because of insufficient evidence that listing was warranted (USFWS 2004).

9B.2.2 Distribution

The Pacific Lamprey is a widely distributed anadromous species found in river systems along the northern margin of the Pacific Ocean from central Baja California north along the west coast of North America to the Bering Sea in Alaska (Ruiz-Campos and Gonzales-Guzman 1996, Lin et al. 2008). Historically, Pacific Lamprey were generally distributed wherever salmon and steelhead occurred and sometimes upstream of waterfalls that are impassable to anadromous salmonids. In California, they were historically found along the entire coast and far inland (Moyle et al. 2009). However, recent data and anecdotal accounts indicate that distribution of the Pacific Lamprey has been reduced in many river systems, including the Sacramento-San Joaquin (Moyle et al. 2009). Although widely distributed in the Sacramento-San Joaquin basin, the species is absent from as much as 80 percent of its historical spawning habitats, primarily due to migratory barriers (Moyle et al. 2009).

9B.2.3 Life History and Habitat Requirements

9B.2.3.1 Adult Migration

Pacific Lamprey are anadromous, rearing in freshwater before outmigrating to the ocean, where they grow to full size prior to returning to their natal streams to spawn. Pacific Lamprey are thought to remain in the ocean for approximately 18 to 40 months before returning to freshwater as sexually immature adults, typically from late winter until early summer (Kan 1975, Beamish 1980). After entering freshwater from the ocean, adult Pacific Lamprey typically spend approximately 1 year in freshwater prior to spawning (Robinson and Bayer 2005, Clemens et al. 2009, Stillwater Sciences 2010, Lampman 2011). The adult freshwater residence period can be divided into three distinct stages: (1) Initial migration from the ocean to holding areas, (2) pre-spawning holding, and (3) secondary migration to spawn (Robinson and Bayer 2005; Clemens et al. 2010, 2012).

The initial migration from the ocean to upstream holding areas occurs from approximately January until early August (Stillwater Sciences 2010, McCovey 2011, Clemens et al. 2012). In the Eel River and the nearby Klamath River, where ample information exists, entry into freshwater from the ocean generally begins in January and ends by June (Petersen-Lewis 2009, McCovey 2010, Stillwater Sciences 2010). Most individuals cease upstream migration by mid-July, although some individuals continue moving into August (McCovey 2010). Data from mid-water trawls in Suisun Bay and the lower Sacramento and San Joaquin rivers indicate that adults likely migrate into the Sacramento-San Joaquin Basin from late winter through early summer (Hanni and Blalock-Herod 2006).

The pre-spawning holding stage begins when individuals cease upstream movement in the summer, and continues until fish began their secondary migration to spawn, generally in late winter or early spring (Robinson and Bayer 2005, McCovey 2010). During this holding period, most fish remain stationary throughout the summer and fall, but some individuals undergo additional upstream movements in the winter following high flow events (Robinson and Bayer 2005, McCovey 2010). In the Sacramento River, adults, likely either in the holding or spawning stage, have been detected at Glenn-Colusa Irrigation District (GCID) from December through July and nearly year-round at RBDD (Hanni and Blalock-Herod 2006). It is expected that adult Pacific Lamprey with varying levels of sexual maturity are present in the Sacramento-San Joaquin Basin throughout the year.

After the pre-spawning holding period, individuals undergo a secondary migration from holding areas to spawning areas. This migration generally begins in late winter and continues through July, by which time most individuals have spawned and died (Robinson and Bayer 2005, Stillwater Sciences 2010, Lampman 2011). During this secondary migration, movement to spawning areas can be both upstream and downstream (Robinson and Bayer 2005, Lampman 2011).

Unlike Pacific salmon and steelhead (and like the Great Lakes Sea Lamprey; Bergstedt and Seelye 1995), Pacific Lamprey do not necessarily home to natal spawning streams (Moyle et al. 2009). Instead, migratory lampreys may select spawning locations based on the presence of a pheromone-like substance secreted by ammocoetes (Bjerselius et al. 2000, Vrieze and Sorensen 2001, Yun et al. 2011). Results of recent genetics research supports lack of homing by the Pacific Lamprey. A study of Pacific Lamprey population structure found few genetic differences among individuals sampled at widely dispersed sites across their range, indicating substantial genetic exchange among populations from different streams (Goodman et al. 2006).

9B.2.3.2 Spawning

Spawning typically takes place from March through July depending on water temperature and local conditions such as seasonal flow regimes (Kan 1975, Brumo et al. 2009, Gunckel et al. 2009). Evidence from the Santa Clara River in southern California suggests that individuals in the southern portion of the species' range can spawn as early as January, with peak spawning from February to April (Chase 2001), whereas inland and northern populations initiate spawning considerably later in the spring (Kan 1975, Beamish 1980, Brumo et al. 2009). Hannon and Deason (2007) have documented Pacific Lamprey spawning in the American River between early January and late May, with peak spawning typically occurring in early April. Spawning occurs in both the mainstem of medium-sized rivers and smaller tributaries (Luzier et al. 2006, Brumo et al. 2009, Gunckel et al. 2009), and generally takes place in pool and run tailouts and low gradient riffles. Both males and females build redds that are approximately 40-by-40 cm in area and are constructed in gravel and cobble substrate (Brumo 2006, Gunckel et al. 2009). Spawning substrate size typically ranges from approximately 25 to 90 mm (1.0 to 3.5 inches), with a median of 48 mm (1.9 inches) (Gunckel et al. 2009). Water velocity above redds ranges from 0.2 to 1.0 meters per second (m/s) (median 0.6 m/s), and depth varies from approximately 0.2 to 1.1 m (0.7 to 3.6 feet [ft]) (Gunckel et al. 2009). Depending on their size, females lay between 30,000 and 240,000 eggs (Kan 1975), which are approximately 1.4 mm (0.06 inch) in diameter (Meeuwig et al. 2004). In comparison, Chinook Salmon generally lay approximately 4,000 to 12,000 eggs (Jasper and Evensen 2006). During spawning, eggs are released in clutches of about 500 every 2 to 5 minutes (Pletcher 1963). Upon fertilization, eggs adhere to sandy substrate in the gravel redd (Pletcher 1963).

Depending on water temperature, hatching occurs in approximately 2 to 3 weeks, and yolk-sac larvae known as prolarvae remain in redd gravels for approximately 2 to 3 more weeks before emerging at night as 8-to-9-mm larvae, and drift downstream to rear in depositional areas (Meeuwig et al. 2005, Brumo 2006). Pacific Lamprey typically die soon after spawning (Kan 1975; Brumo 2006), although there is some anecdotal evidence that this is not always the case (Moyle 2002; Michael 1980; Michael 1984).

9B.2.3.3 Juvenile Rearing and Outmigration

After larvae emerge from redds drifting downstream, the eyeless, toothless larvae known as ammocoetes settle out of the water column and burrow into fine silt and sand substrate in low-velocity, depositional areas such as pools, alcoves, and side channels (Moore and Mallatt 1980, Torgensen and Close 2004, Stone and Barndt 2005). Ammocoete presence has also been shown to be associated with presence of woody debris (Roni 2003, Graham and Brun 2006). Rearing Pacific Lamprey ammocoetes appear to prefer rearing temperatures below 68°F (20 degrees Celsius [°C]) (BioAnalysts, Inc. 2000); and temperatures above 82.4°F (28°C) result in mortality of ammocoetes (van de Wetering and Ewing 1999). Depending on factors influencing their growth rates, they remain in this habitat from 4 to 10 years, filter-feeding on algae and detrital matter prior to metamorphosing into an adult form (Pletcher 1963, Moore and Mallatt 1980, Beamish and Levings 1991, van de Wetering 1998). During the ammocoete stage, individuals may periodically move and relocate in response to changing water levels, channel adjustments, or substrate movements (ULEP 1998). These factors generally result in a gradual downstream movement that may lead to higher densities in downstream reaches (Richards 1980). During metamorphosis, individuals develop eyes, a suctoral disc, sharp teeth, and more-defined fins (McGree et al. 2008). After metamorphosis, smolt-like individuals known as macropthalmia migrate to the ocean—typically in conjunction with high-flow events between fall and spring (van de Wetering 1998). Data from rotary screw trapping at sites in the Sacramento-San Joaquin Basin indicate that emigration of Pacific Lamprey macropthalmia peaks from early winter through early summer; however, some outmigration has been observed year-round in the mainstem Sacramento River at both RBDD and GCID (Hanni and Blalock-Herod 2006). When abundant, outmigrating Pacific Lamprey may act to buffer predation on juvenile and smolt salmon because they are easier to capture than salmonids (Close et al. 2002).

9B.2.3.4 Ocean Residence

In the ocean, adult Pacific Lamprey feed parasitically on a variety of marine and anadromous fishes such as salmon, flatfish, rockfish, and pollock. Pacific Lamprey are preyed upon by sharks, sea lions, and other marine animals (Richards and Beamish 1981, Beamish and Levings 1991, Close et al. 2002), and have been captured in depths from 300 to 2,600 ft and as far as 62 miles off the coast (USFWS 2007).

9B.2.4 Population Trends

In recent years, state, federal, and tribal agencies have expressed concern at the apparent decline of lamprey populations in the Northwestern United States (Close et al. 2002; Moser and Close 2003; CRBLTW 2005). Widespread anecdotal accounts of decreased Pacific Lamprey spawning and carcasses have been supported by a substantial reduction in counts of migrating individuals at dams since the late 1960s (Moser and Close 2003, Klamath-Siskiyou Wildlands Center et al. 2003). Very few data on Pacific Lamprey populations are available to assess status in the Sacramento-San Joaquin Basin; however, loss of access to historical habitat throughout California indicates that populations are greatly suppressed compared with historical levels (Moyle et al. 2009).

Factors limiting Pacific Lamprey populations are numerous and interrelated (Moser and Close 2003, Moyle et al. 2009). Although very little data or published studies are available for Pacific Lamprey in the region, parallels in their life cycle with salmon and steelhead suggest that these species are adversely affected by many of the same factors. Lack of access to historical spawning habitats because of dams, entrainment by water diversions, agricultural practices, urban development, harvesting, mining, transportation, estuary modification, prey abundance, and nonnative invasive species have all been cited as important anthropogenic factors limiting the viability of Pacific Lamprey populations in California (Moyle et al. 2009). In the Delta, the impacts of agricultural practices, development, estuary modification, and predation by nonnative species are expected to be particularly pronounced.

9B.3 Green Sturgeon (*Acipenser medirostris*)

9B.3.1 Legal Status

Federal: Threatened, Designated Critical Habitat
State: Species of Special Concern

The National Marine Fisheries Service (NMFS) has divided North American Green Sturgeon into two Distinct Population Segments (DPSs) using the Eel River in California as the line of demarcation (Adams et al. 2002). The Southern DPS of North American Green Sturgeon includes all coastal and Central Valley populations south of the Eel River, including the Sacramento River basin

(NMFS 2006). Although the Southern DPS is considered a separate population from the Northern DPS based on genetic data and spawning locations, their ranges outside the spawning season overlap (DFG 2002, Israel et al. 2004, Moser and Lindley 2007).

After a status review was completed in 2002 (Adams et al. 2002), NMFS determined that the Southern DPS did not warrant listing as threatened or endangered but should be identified as a Species of Concern. This determination was challenged in April 2003, and NMFS was asked to consider new information on the species. NMFS updated its status review in February 2005 and determined that the Southern DPS should be listed as threatened under the Federal Endangered Species Act (ESA) (NMFS 2005a). NMFS published a final rule (NMFS 2006) in April 2006 that listed the Southern DPS as threatened; the rule took effect on June 6, 2006.

NMFS made a final critical habitat designation for the Southern DPS in October 2009 (74 *Federal Register* [FR] 52300). Designated critical habitat in California includes the Sacramento, lower Feather, and lower Yuba rivers; the Delta; and Suisun, San Pablo, and San Francisco bays (NMFS 2014). NMFS published a final 4(d) rule to apply ESA take prohibitions to the Southern DPS in July 2010 (75 FR 30714). In California, Green Sturgeon is a Class 1 Species of Special Concern (qualifying as threatened under the California Endangered Species Act).

9B.3.2 Distribution

North American Green Sturgeon are the most wide-ranging sturgeon species, with ocean migrations ranging between northern Mexico and southern Alaska (Adams et al. 2002). Ocean abundance and densities of Green Sturgeon increase north of the Golden Gate because both the Southern DPS and Northern DPS generally migrate northward along the coast when at sea (NMFS 2005b), as confirmed by radio telemetry studies conducted on Sacramento River Green Sturgeon (DFG 2002). Subadult and adult Green Sturgeon migrate thousands of miles along the western coast of the United States, often venturing into coastal estuaries like Willapa Bay and Grays Harbor in Washington, where they concentrate during summer (Adams et al. 2002). Two adults tagged in Willapa Bay have been detected by radio telemetry stations in the Sacramento River (Heublein et al. 2009), indicating that Green Sturgeon from the Sacramento River migrate as far north as Washington before returning to the Sacramento River to spawn. Concentrations of Green Sturgeon have also been detected near Vancouver Island in Canada (NMFS 2005b).

Though Green Sturgeon migrate thousands of miles through rivers, estuaries, and ocean, they do not readily establish new spawning populations; they are known from only three river systems: the Sacramento, Rogue, and Klamath. However, data suggest there may be spawning populations in both the Eel River and the Umpqua River in Oregon (NMFS 2005b), which could indicate previously undetected relict populations or the seeds of new subpopulations. The population that spawns in the Sacramento River constitutes the only known spawning population in the Southern DPS. Populations may have formerly spawned in the

San Joaquin and South Fork Trinity rivers, but have since been extirpated (Israel and Klimley 2008).

Green Sturgeon juveniles, subadults, and adults are widely distributed in the Sacramento-San Joaquin Delta and estuary areas including San Pablo Bay (Beamesderfer et al. 2004). The Sacramento-San Joaquin Delta serves as a migratory corridor, feeding area, and juvenile rearing area for North American Green Sturgeon in the Southern DPS.

9B.3.2.1 Current Distribution in Sacramento River

Within the Sacramento River, data only support an approximation of spawning locations. Larval Green Sturgeon have been captured routinely, but in small numbers in the RBDD rotary screw traps (River Mile [RM] 243.5) and the GCID fish facility (RM 206), suggesting that spawning generally occurs upstream of Hamilton City (RM 199), though spawning may occur as far downstream as Chico Landing (RM 194) (Heublein et al. 2009). Adult Green Sturgeon have been observed congregating below RBDD during late spring and early summer when the gates are down (Beamesderfer et al. 2004), suggesting that these may be ripe adults trying to migrate upstream to spawn. Spawning may occur in reaches upstream of RBDD (DFG 2002), but the upstream extent of spawning is unknown. In 1999, USFWS placed egg mats in the Sacramento River from Anderson Cottonwood Irrigation District (ACID) Dam (RM 298.4) to 10 miles downstream of RBDD to identify Green Sturgeon spawning sites; however, only two eggs were captured, both at mats downstream of RBDD, so the study did not clarify the location of specific spawning sites or the upstream extent of spawning (Beamesderfer et al. 2004). A radio telemetry study detected two adult Green Sturgeon migrating past a remote monitoring station above RBDD, suggesting possible spawning migration upstream (Heublein et al. 2009).

9B.3.2.2 Historical Distribution in Sacramento River

The location and character of spawning sites in the Rogue and Klamath rivers suggest that Green Sturgeon spawned in the Sacramento River above Keswick Dam (RM 302), including in the Pit, McCloud, and Little Sacramento rivers (Nakamoto et al. 1995, NMFS 2005b). The timing of upstream migration (February through July) corresponds with winter base and high flows and spring snowmelt. Adult Green Sturgeon likely entered the Sacramento River during winter, holding in pools in the middle and upper Sacramento River until high-flow events triggered upstream migration; high flows would have allowed adults to navigate through areas that might otherwise act as passage barriers at lower flows, providing them with access to steeper reaches with higher-velocity flows and coarser substrates for broadcast spawning. Such areas may have resulted in higher egg survival—crevices between substrate particles would provide the Green Sturgeon’s relatively non-adhesive eggs to settle in areas less accessible to egg predators.

The location and characteristics of preferred Green Sturgeon spawning habitats in the Rogue and Klamath rivers suggest that most of the historical spawning habitat in the Sacramento River likely occurred upstream of Keswick Dam (RM 302), with dam construction in the 1940s creating a permanent barrier that eliminated access to the majority of spawning habitat. Upstream passage may have been impeded even earlier by the seasonal operation of the ACID Dam, which began in 1916. Later-arriving adults would have even less access to spawning habitat because of the operation of RBDD, which blocked upstream passage when the gates were lowered in mid-May. Beginning in the late 1800s, those adults that successfully spawned upstream might have had their larvae entrained by water diversions such as the GCID diversion near Hamilton City.

9B.3.3 Life History and Habitat Requirements

Sturgeon live 40 to 50 years, delay maturation to large sizes (125 cm total length), and spawn multiple times over their lifespan. This life history strategy has been successful through normal environmental variation in the large river habitats where spawning occurs. Their long lifespan, repeat spawning in multiple years, and high fecundity allow them to persist through periodic droughts and environmental catastrophes. The high fecundity associated with large size allows them to produce large numbers of offspring when suitable spawning conditions occur and compensate for years of poor reproductive and juvenile rearing conditions. Adult Green Sturgeon do not spawn every year, and only a fraction of the population enters fresh water where they might be at risk of a catastrophic event (Beamesderfer et al. 2007). Though there are general descriptions of preferred habitat conditions for Green Sturgeon, much of this information is derived from Rogue River and Klamath River data, and little is known about specific spawning, rearing, or holding locations in the Sacramento River.

9B.3.3.1 Adult Migration

Though Green Sturgeon spend most of their life in marine and estuarine environments, they periodically migrate into freshwater streams to spawn, spending up to 6 months in fresh water during their spawning migration. Upstream migration generally begins in February and may last until late July (Adams et al. 2002). In the Rogue River, telemetry studies have shown that adult Green Sturgeon hold in low-velocity, deep-water habitats prior to migrating upstream to spawn (Erickson et al. 2002). The adults move around in the pools and may stray short distances, but the scope of their movement is limited. In the Sacramento River, adult Green Sturgeon begin their upstream spawning migrations into the San Francisco Bay in March and reach Knights Landing on the Sacramento River during April (Heublein et al. 2006).

9B.3.3.2 Spawning

Spawning occurs between March and July, peaking between mid-April and mid-June (Emmett et al. 1991). Based on the distribution of sturgeon eggs, larvae, and juveniles in the Sacramento River, DFG (2002) indicated that Green Sturgeon spawn in late spring and early summer above Hamilton City, possibly up to Keswick Dam (Brown 2007). Israel and Klimley (2008) state that Green Sturgeon spawn in the mainstem from the confluence of Battle Creek (river kilometer 438) to the area upstream of Molinos, but may also spawn below RBDD closer to GCID in some years. Adults spawn within about a week, and females appear to spawn regardless of habitat conditions (Beamesderfer et al. 2007).

Green Sturgeon prefer areas of fast, deep, turbulent water in mainstem channels for spawning (Moyle 2002). They spawn in a variety of substrates, from clean sand to bedrock, but prefer bed surfaces composed of coarse cobble (Moyle 2002). In the Rogue River, suspected spawning sites (inferred from the movement of radio-tagged Green Sturgeon) have beds composed of cobbles and boulders, with water depths greater than 10 to 15 feet (3 to 4.6 meters) and turbulent water over slope breaks in the channel (Wildlife Conservation Society 2005). The interstitial spaces between large particles may provide eggs with cover from predation (Moyle 2002). Eggs and larvae require cool water temperatures and high dissolved oxygen concentrations while digesting their yolk sac (Van Eenennaam et al. 2005).

Female Green Sturgeon produce 59,000 to 242,000 eggs, about 4.34 mm in diameter (Van Eenennaam et al. 2001, 2006). Green Sturgeon eggs have the largest mean diameter of any sturgeon species (Cech et al. 2000), but they lay fewer eggs. The larger eggs may allow embryos to grow larger before hatching and emerging from cover, increasing their survival relative to other sturgeon species. Fecundity peaks at around age 24 years (Beamesderfer et al. 2007).

9B.3.3.3 Juvenile Rearing

Hatchling Green Sturgeon embryos seek nearby cover and remain under rocks (Deng et al. 2002). After about 6 to 9 days, the hatchings develop into larvae and initiate exogenous foraging on the benthos (Deng et al. 2002, Kynard et al. 2005). After a day or so, larvae disperse downstream for 1 to 2 weeks. Movements and foraging activity during this period are nocturnal (Cech et al. 2000, Kynard et al. 2005). Larval Green Sturgeon are regularly captured during this dispersal stage at about 2 weeks old (24- to 34-mm fork length) in rotary screw traps at RBDD (DFG 2002, USFWS 2002) and 3 weeks old when captured farther downstream at the GCID fish facility (Van Eenennaam et al. 2001). Following emergence in early summer, larval Green Sturgeon migrating downstream with snowmelt flows between May and July, growing quickly and becoming more tolerant of increasing water temperatures and salinities. The upper thermal limit for optimal development and hatching is between 17 to 18°C; temperatures higher than this may affect development and hatching success, and complete mortality occurs at temperatures above 23°C (Van Eenennaam et al. 2005).

Young Green Sturgeon appear to rear for the first 1 to 2 months in the Sacramento River between Keswick Dam and Hamilton City (DFG 2002). Larvae and post-larvae are present in the lower Sacramento River and North Delta between May and October, primarily in June and July (DFG 2002). Little is known of distribution and movements of young-of-the-year and riverine juveniles, but observations suggest they may be distributed primarily in the mainstem Sacramento River downstream of Anderson and in the brackish portions of the north and interior Delta (Israel and Klimley 2008). Juvenile Green Sturgeon have been captured in the Delta during all months of the year (Borthwick et al. 1999, DFG 2002). Catches of 1- and 2-year-old Southern DPS Green Sturgeon on the shoals in the lower San Joaquin River, at the CVP/SWP fish salvage facilities, and in Suisun and San Pablo bays indicate that some fish rear in the estuary for at least 2 years (DFG 2002). Larger juvenile and subadult Green Sturgeon occur throughout the estuary, possibly temporarily, after spending time in the ocean (DFG 2002, Kelly et al. 2007).

The rearing habitat preferences of Green Sturgeon larvae and juveniles in the Sacramento River are not well understood. Laboratory research has identified water temperature thresholds for larval Green Sturgeon. Water temperatures above 68°F (20°C) were found to be lethal to Green Sturgeon embryos by Cech et al. (2000), and temperatures above 63 to 64°F (17 to 18°C) were found to be stressful by Van Eenennaam et al. (2005). Cech et al. (2000) found that optimal growth of larvae occurred at 59°F (15°C), with growth slowing at temperatures below 52°F (11°C) and above 62°F (19°C).

Several studies suggest that juvenile Green Sturgeon rear in fresh water for 1 to 4 years, acclimating gradually to brackish environments before migrating to the ocean (Beamesderfer and Webb 2002, Nakamoto et al. 1995). Larval Green Sturgeon are captured at RBDD and the GCID fish facility between May and August, with peak capture at RBDD in June and July and at the GCID fish facility in July (Adams et al. 2002). Green Sturgeon larvae trapped at RBDD average 1.1 inches (2.9 cm) in length, while larvae trapped at the GCID fish facility average 1.4 inches (3.6 cm) (Adams et al. 2002), suggesting that larvae move downstream soon after hatching; however, it is not clear how long larval and juvenile Green Sturgeon remain in the middle Sacramento River. Larval Green Sturgeon grow quickly, reaching 2.9 inches (74 mm) by the time they become juveniles at around 45 days posthatching (Deng 2000). Klamath River studies indicate that juvenile Green Sturgeon can grow to 12 inches (30 cm) in their first year and 24 inches (60 cm) within 2 to 3 years (Nakamoto et al. 1995). The small size of salvaged juvenile Green Sturgeon at the CVP and SWP fish facilities indicates that they move downstream to rear in the Bay-Delta estuary (Adams et al. 2002), though it is unclear how long they remain before migrating to the ocean.

While in the riverine environment, juveniles occupy low-light habitat and are active at night (Kynard et al. 2005). Older juveniles may be adapted to move through habitats with variable gradients of salinity, temperature, and dissolved oxygen (Kelly et al. 2007, Moser and Lindley 2007). Their diet during their Sacramento River residence is unknown, but likely consists of drifting and benthic aquatic macroinvertebrates (Israel and Klimley 2008).

Stomach contents from adult and juvenile Green Sturgeon captured in the Sacramento-San Joaquin Delta included shrimp, mollusks, amphipods, and small fish (Radtke 1966, Houston 1988, Moyle et al. 1992). Stomachs of Green Sturgeon caught in Suisun Bay contained *Corophium* sp. (amphipod), *Cragon franciscorum* (bay shrimp), *Neomysis awatchensis* (Opossum shrimp: synonymous with *Neomysis mercedis*), and annelid worms (Ganssle 1966). Stomachs of Green Sturgeon caught in San Pablo Bay contained *C. franciscorum*, *Macoma* sp. (clam), *Photis californica* (amphipod), *Corophium* sp., *Synidotea laticauda* (isopod), and unidentified crab and fish (Ganssle 1966). Stomachs of Green Sturgeon caught in the Delta contained *Corophium* sp. and *N. awatchensis* (Radtke 1966). As a result of recent changes in the species composition of macroinvertebrates inhabiting the Bay-Delta estuary due to nonnative species introductions, the current diet of Green Sturgeon is likely to differ from that reported in the 1960s.

In the Rogue River, adults hold in deep pools after spawning until late fall or early winter, when they emigrate to downstream estuaries or the ocean, perhaps cued by winter freshets that cause water temperatures to drop (Erickson et al. 2002). Erickson et al. (2002) noted that adult downstream migration appeared correlated with water temperatures below 50°F (10°C).

9B.3.3.4 Ocean Residence

Green Sturgeon from the Southern DPS pass through the San Francisco Bay to the ocean where they commingle with other sturgeon populations (DFG 2002). Subadult and adult sturgeon tagged in San Pablo Bay oversummer in bays and estuaries along the coast of California, Oregon, and Washington, between Monterey Bay and Willapa Bay, before moving farther north in the fall to overwinter north of Vancouver Island. Individual Southern DPS Green Sturgeon tagged by DFW in the San Francisco estuary have been recaptured off Santa Cruz, California; in Winchester Bay on the southern Oregon coast; at the mouth of the Columbia River; and in Grays Harbor, Washington (USFWS 1993, Moyle 2002). Most Southern DPS Green Sturgeon tagged in the San Francisco estuary have been returned from outside that estuary (Moyle 2002).

Subadult and adult Green Sturgeon generally migrate north along the coast once they reach the ocean, concentrating in coastal estuaries like Willapa Bay, Grays Harbor, and the Columbia River estuary during summer (Adams et al. 2002). The strategy underlying summer visits to coastal estuaries is unclear because sampling indicates they have relatively empty stomachs, suggesting they may not be entering the estuaries to feed (Beamesderfer 2000). Females reach sexual maturity after about 17 years and males after about 15 years (Adams et al. 2002). Spawning was believed to occur every 3 to 5 years (Tracy 1990), but may occur as frequently as every 2 years (NMFS 2005a).

9B.3.4 Population Trends

Empirical estimates of Green Sturgeon abundance are not available for any west coast population including the Sacramento River population. Interpretations of available time series of abundance index data for Green Sturgeon are confounded by small sample sizes, intermittent reporting, fishery-dependent data, lack of directed sampling, subsamples representing only a portion of the population, and potential confusion with White Sturgeon (Adams et al. 2002). Musick et al. (2000) noted that the North American Green Sturgeon population has declined by 88 percent throughout much of its range. The current population status of Southern DPS Green Sturgeon is unknown (Beamesderfer et al. 2007, Adams et al. 2007). Based on captures of Green Sturgeon during surveys for White

Sturgeon in San Francisco Bay (USFWS 1995), the population is believed to range from several hundred to a few thousand adults.

Population estimates of Green Sturgeon in the Sacramento River have been derived from data collected by monitoring programs that generally focus on other species because few monitoring programs specifically address Green Sturgeon in the Sacramento River. Green Sturgeon larvae are captured annually in the RBDD rotary screw traps, the GCID fish screen, and the CVP/SWP fish salvage facilities in the South Delta. DFW conducts annual trammel net surveys in San Pablo Bay to track the White Sturgeon population, and Green Sturgeon often form part of the incidental catch. Eggs, larvae, and post-larval Green Sturgeon are now commonly reported in sampling directed at Green Sturgeon and other species (Beamesderfer et al. 2004, Brown 2007). Young-of-the-year Green Sturgeon have been observed annually since the late 1980s in fish sampling efforts at RBDD and the Glenn-Colusa Canal (Beamesderfer et al. 2004). Green Sturgeon in the Sacramento River are believed to have declined over the last 2 decades, with fewer than 50 spawning adults observed annually in the best spawning habitat along the middle section of the Sacramento River (Israel and Klimley 2008).

Similar to other anadromous fish, Green Sturgeon in the Sacramento River likely exhibit seasonal behavioral patterns in response to changes in flows, water temperature, or other environmental cues affected by flows, but it is not clear if anthropogenically induced changes in the flow regime have contributed to the apparent decline in Green Sturgeon spawners. Researchers have hypothesized that high spring flows, or the turbidity associated with them, may act as an upstream migration cue. The annual catch of larval sturgeon at the RBDD and GCID fish screens suggests that spawning occurs in the Sacramento River in most years, regardless of water year type; however, it is unclear how many adults return to spawn each year and whether there is a relationship between flows and the number of adult spawners in any given year. The relationship between flow and water temperature in the Sacramento River may influence Green Sturgeon through controlling the amount of suitable rearing habitat available for larvae and juveniles (Adams et al. 2002).

The most consistent sample data for Sacramento Green Sturgeon are for subadults captured in San Pablo Bay during periodic White Sturgeon assessments since 1948. The California Department of Fish and Game (now DFW) measured and identified 15,901 sturgeon of both species between 1954 and 1991 (USFWS 1996). Catches of subadult and adult North American Green Sturgeon by the Interagency Ecological Program between 1996 and 2004 ranged from 1 to 212 Green Sturgeon per year, with the highest catch in 2001. Various attempts have been made to infer Green Sturgeon abundance based on White Sturgeon mark-recapture estimates and relative numbers of White and Green Sturgeon in the catch (USFWS 1996, Moyle 2002). However, low catches of Green Sturgeon preclude estimates or indices of Green Sturgeon abundance from these data (Schaffter and Kohlhorst 1999, Gingras 2005). It is unclear if the high annual variability in length distributions in these samples reflects variable recruitment and abundance or is an artifact of small sample sizes, pooling of sample years, or variable distribution patterns between freshwater and ocean portions of the population.

Anecdotal information is also available on young-of-the-year Green Sturgeon from juvenile fish monitoring efforts at RBDD and the GCID pumping facility on the upper Sacramento River. Fish traps at these facilities captured between 0 and 2,068 juvenile Green Sturgeon per year (Adams et al. 2002), which suggests that at least some Green Sturgeon reproduction occurred during the 1990s.

Approximately 3,000 juvenile Green Sturgeon have been observed in rotary screw traps operated for juvenile salmon at RBDD from 1994 to 2000. Annual catches have declined from 1995 through 2000 although the relationship of these catches to actual abundance is unknown. Recent data indicate that little production occurred in 2007 and 2008 (13 and 3 larvae, respectively, were captured in the rotary screw traps at RBDD) (Poytress et al. 2009). Larger production occurred in 2009, 2010, and 2011 (45, 122, and 643 larvae, respectively, were captured using a benthic D-net), and no larvae were captured in 2012 (Poytress et al. 2010, 2011, 2012, 2013).

More than 2,000 juvenile Green Sturgeon have been collected in fyke and rotary screw traps operated at the GCID diversion from 1986 to 2003. Operation of the screw trap at the GCID site began in 1991 and has continued year-round with the exception of 1998. Juvenile Green Sturgeon at the GCID site were consistently larger in average size, but the number captured varied widely with no apparent patterns in abundance between the two sites. Abundance of juveniles peaked during June and July with a slightly earlier peak at RBDD (Adams et al. 2002).

Variable numbers of juvenile Green Sturgeon are observed each year from two south Delta water diversion facilities (DFG 2002). When water is exported through the CVP/SWP export facilities, fish become entrained into the diversion. Since 1957, Reclamation has salvaged fish at the CVP Tracy Fish Collection Facility. DFW's Fish Facilities Unit, in cooperation with DWR, began salvaging fish at the SWP Skinner Delta Fish Protective Facility in 1968. The salvaged fish are trucked daily and released at several sites in the western Delta. Salvage of fish at both facilities is conducted 24 hours a day, 7 days a week, at regular intervals. Salvaged fish are subsampled for species composition and numbers. Numbers of Green Sturgeon observed at these fish facilities have declined since the 1980s, which contributed to NMFS' decision to list the Southern DPS as a threatened species. From the SWP Skinner Fish Facility, Green Sturgeon counts averaged 87 individuals per year between 1981 and 2000 and 20 individuals per year from 2001 through 2007. From the CVP Tracy Fish Collection Facility, Green Sturgeon counts averaged 246 individuals per year between 1981 and 2000 and 53 individuals per year from 2001 through 2007 (Reclamation 2008). Patterns were similar between total numbers per year and numbers adjusted for water export volumes, which increased during the 1970s and 1980s. Annual counts of Green Sturgeon from the SWP and CVP fish facilities are not significantly correlated (Beamesderfer 2005).

USFWS (1996) reported substantial uncertainty in the interpretation of salvage data for Green Sturgeon because of poor quality control on both counts and species identification, expansions from small sample sizes, variability in sturgeon dispersal patterns and collection vulnerability in response to complex changes in Delta flow dynamics, and changes in configuration and operations over time. Estimated sturgeon salvage numbers are expanded from subsamples, and actual numbers of Green Sturgeon observed are substantially smaller. Historical expansions were based on variable expansion rates (subsample duration) ranging from 15 seconds per 2 hours when fish numbers were high to 100 percent counting during periods when fish numbers were low. Under current conditions, NMFS (2004) requires sampling of fish salvage at both the SWP and CVP facilities at intervals of no less than 10 minutes every 2 hours. Green Sturgeon salvage estimates reported for years before 1993 may be in error because of uncertainty whether smaller sturgeon were correctly identified (USFWS 1996, DFG 2002). Reclamation and DWR recommended that only more recent (from 1993 and later) CVP and SWP salvage data be used to analyze the effects of water project operations on Green Sturgeon and other anadromous fishes.

9B.4 White Sturgeon (*Acipenser transmontanus*)

9B.4.1 Legal Status

Federal: None
State: None

9B.4.2 Distribution

White Sturgeon have a marine distribution spanning from the Gulf of Alaska south to Mexico, but a spawning distribution ranging only from the Sacramento River northward. Currently, self-sustaining spawning populations are only known to occur in the Sacramento, Fraser, and Columbia rivers.

In California, the largest numbers are in the San Francisco Bay estuary, with spawning occurring mainly in the Sacramento and Feather rivers. White Sturgeon historically ranged into upper portions of the Sacramento system including the Pit River, and a substantial number were trapped in and above Lake Shasta when Shasta Dam was closed in 1944 and successfully reproduced until the early 1960s (State Water Contractors 2004). They may have occurred historically in the San Joaquin River based on habitat similarities with these other watersheds.

Adult sturgeon were caught in the sport fishery industry in the San Joaquin River between Mossdale and the confluence with the Merced River in late winter and early spring, suggesting this was a spawning run (Kohlhorst 1976). Kohlhorst et al. (1991) estimated that approximately 10 percent of the Sacramento River system spawning population migrated up the San Joaquin River. Spawning may occur in the San Joaquin River when flows and water quality permit; however, no evidence of spawning is present (Kohlhorst1976, Kohlhorst et al. 1991).

Landlocked populations are located above major dams in the Columbia River basin, and residual non-reproducing fish above the Shasta Dam and Friant Dam have been occasionally found.

Adult White Sturgeon are occasionally noted in the San Joaquin River during DFW fall midwater trawls, DFW summer townet surveys, and University of California Davis Suisun Marsh fisheries monitoring. White Sturgeon spawning has recently been confirmed in the lower San Joaquin River (Jackson and Van Eenennaam 2013), and the U.S. Geological Survey (USGS) is currently mapping and characterizing White Sturgeon spawning habitat in the lower portion of the river (USGS 2015).

9B.4.3 Life History and Habitat Requirements

White Sturgeon are long-lived, late maturing, and have a high fecundity (Israel et al. 2015) Because White Sturgeon require a long time to mature, large year classes are typically associated with years of high outflow (Kohlhorst et al. 1991, Schaffter and Kohlhorst 1999), and population size can fluctuate to extremes (Schaffter and Kohlhorst 1999).

Reports of maximum size and age of White Sturgeon are as great as 6 meters fork length (FL) (820 kilograms) and greater than 100 years, although they generally do not exceed 2 meters FL or 27 years of age. Males mature in 10 to 12 years (75 to 105 centimeters FL) and females in 12 to 16 years (95 to 135 centimeters FL). Maturation depends largely on temperature and photoperiod.

9B.4.3.1 Adult Migrations and Spawning

White Sturgeon migrate upstream in late winter. Upstream migration is usually initiated by a large pulse flow (Schaffter 1997), and not all adults will spawn each year. Because of this, successful year classes tend to occur at irregular intervals, and therefore numbers of adult fish within a population can fluctuate significantly. Although males may spawn each year, females usually spawn once every 2 to 4 years. White Sturgeon have high fecundities, and typical females may have as many as 200,000 eggs. Spawning occurs over deep gravel riffles or in deep pools with swift currents and rock bottoms between late February and early June when temperatures are between 8°C and 19°C. Eggs become adhesive subsequent to fertilization, and adhere to the substrate until they hatch 4 to 12 days later, depending on temperature. Once the eggs have been deposited, the adults move back downstream to the estuary. Larvae hatch in 1 to 2 weeks, depending on temperature. Once the yolk sac is absorbed (approximately 1 week after hatching), the larvae can begin to actively forage along the benthos.

In the Sacramento River, most White Sturgeon spawn downstream of the Glenn-Colusa Irrigation Dam.

9B.4.3.2 Juvenile Rearing

White Sturgeon are benthic feeders, and adults may move into food-rich areas to forage. Juveniles consume mainly crustaceans, especially amphipods and opossum shrimp. Adult diets include invertebrates (mainly clams, crabs, and shrimp), as well as fish, especially herring, anchovy, Striped Bass, and smelt. White Sturgeon are opportunistic predators and may feed on many introduced species.

Juvenile sturgeon are often found in upper reaches of estuaries in comparison to adults, which suggests that there is a correlation between size and salinity tolerance.

9B.4.3.3 Estuary and Ocean Residence

White Sturgeon primarily live in brackish portions of estuaries where they tend to concentrate in deep sections having soft substrate. They move according to salinity changes, and may swim into intertidal zones to feed at high tide.

Recent stomach content analysis of White Sturgeon from the San Francisco Bay estuary indicates that the invasive overbite clam, *Corbula amurensis*, may now be a major component of the White Sturgeon diet (Zeug et al. 2014), and unopened clams were often observed throughout the alimentary canal (Kogut 2008). Kogut's study found that at least 91 percent of clams that passed through sturgeon digestive tracts were alive. This suggests sturgeon are potential vehicles for transport of adult overbite clams and also raise concern about the effect of this invasive clam on sturgeon nutrition and contaminant exposure.

In the ocean, White Sturgeon have been known to migrate long distances, but spend most of their life in brackish portions of large river estuaries.

9B.4.4 Population Trends

There is a relatively strong relationship between Delta outflow and year class strength during the period when white sturgeon are spawning and young white sturgeon are migrating downstream (March-July). There is a threshold at about 50,000 cfs such that year classes are generally strong when flows are above the threshold (Gingras et al. 2014). NMFS (2005) also noted a relationships between flow and apparent White Sturgeon spawning success. A sturgeon population study conducted by the California Department of Fish and Wildlife has been ongoing intermittently since 1967. In 2014, catch per 100 net-fathom hour of white sturgeon within the current slot limit (102-152 cm FL) was 0.46 ± 0.05 (SE); in 2013, catch per 100 net-fathom hour of white sturgeon within the current slot limit was 0.4 ± 0.1 (SE). Both of these values are well below the historical average of 2.8 (DuBois et al. 2014). Large numbers of young white sturgeon have only been produced twice in the last 15 years, in 1998 and 2006 (Gingras et al. 2014). The 2010-2014 White Sturgeon length frequency distributions show: (1) strong cohorts (from mid-to-late 1990s) within the legally-harvestable size range have substantially diminished; and (2) the progression of a strong cohort (from 2006) toward harvestable size (DuBois et al. 2014). Given the trends in catch-per-unit-effort (CPUE) and harvest, the amount of harvest, and harvest rates, it's quite clear that harvest is the main reason CPUE and abundance have declined so steeply (Gingras et al. 2014).

Periodic high flows in the 1990s produced small increases in White Sturgeon salvage catches, but salvage numbers were much lower than prior to 1985. USFWS (1996) in the *Sacramento/San Joaquin Delta Native Fishes Recovery Plan* also reported that juvenile sturgeon are probably more vulnerable to entrainment at the SWP and CVP at low to intermediate flows during those years when river and Delta inflow are normal or below normal.

9B.5 Chinook Salmon (*Oncorhynchus tshawytscha*)

9B.5.1 Introduction

The Sacramento-San Joaquin Delta functions as a migration corridor and potential rearing area for adult and juvenile Chinook Salmon in the Sacramento and San Joaquin River basins. The Sacramento River basin supports four runs of Chinook Salmon: winter-run, spring-run, fall-run, and late fall-run. The San Joaquin River basin currently supports fall-run (and possibly late fall-run) Chinook Salmon in its lower tributaries: the Merced, Tuolumne, and Stanislaus rivers. The winter-run consists of a single population spawning in the Sacramento River mainstem below Keswick Dam. The other runs consist of populations that spawn in multiple tributaries. Three ESUs of Chinook Salmon are represented in the combined basins: Sacramento River winter-run (federally listed as endangered), Sacramento River spring-run (federally listed as threatened), and Central Valley fall-run and late fall-run (species of concern). Each of these runs exhibits a variety of different life-history strategies.

9B.5.2 Chinook Salmon Habitat Requirements

The Sacramento River basin is the largest watershed in California (about 27,000 mi^2) and empties into the largest estuary on the west coast of the United States. This diverse basin is unique in that it supports four runs of Chinook Salmon, including the winter-run, which only occurs in the Sacramento River basin. Because the four runs exhibit a variety of different life-history strategies, anthropogenic activities in the basin have affected each of the runs differently. The habitat requirements and the life-history strategies of the four runs are discussed below.

9B.5.2.1 Upstream Migration and Holding

Adult Chinook Salmon require water deeper than 0.8 ft (24 cm) and water velocities less than 8 ft/s (2.4 m/s) for successful upstream migration (Thompson 1972). Adult Chinook Salmon appear to be less capable of negotiating fish ladders, culverts, and waterfalls during upstream migration than Coho Salmon or steelhead (Nicholas and Hankin 1989), due in part to slower swimming speeds and inferior jumping ability compared to steelhead (Reiser and Peacock 1985, Bell 1986). The maximum jumping height for Chinook Salmon has been calculated to be approximately 7.9 ft (2.4 m) (Bjornn and Reiser 1991).

Both winter-run and spring-run Chinook Salmon return to the Sacramento River when reproductively immature, typically holding for a few months in deep pools near spawning areas until spawning. Adult winter-run and spring-run Chinook Salmon require large, deep pools with flowing water for summer holding, tending to hold in pools with depths greater than 4.9 ft (greater than 1.5 m) that contain cover from undercut banks, overhanging vegetation, boulders, or woody debris (Lindsay et al. 1986), and have water velocities ranging from 0.5 to 1.2 ft/s (15 to 37 cm/s) (Marcotte 1984). Water temperatures for adult Chinook holding are reportedly best when less than 60.8°F (less than 16°C), and lethal when greater than 80.6°F (greater than 27°C) (Moyle et al. 1995). Spring-run Chinook Salmon in the Sacramento River system typically hold in pools below 69.8 to 77°F (21 to 25°C).

In general, adult Chinook Salmon appear capable of migrating upstream under a wide range of temperatures. Bell (1986) reported that salmon and steelhead migrate upstream in water temperatures that range from 3 to 20ºC (37 to 68°F). Bell (1986) reports that temperatures ranging from 3 to 13ºC (37 to 55°F) are suitable for upstream migration of spring-run Chinook Salmon, and 10 to 19ºC (50 to 66°F) is suitable for upstream migration of fall-run Chinook Salmon. In a review of available literature, Marine (1992) reported a water temperature range of 6 to 14ºC (43 to 57°F) as optimal for pre-spawning broodstock survival, maturation, and spawning for adult Chinook Salmon.

9B.5.2.2 Spawning

Most Chinook Salmon spawn in larger rivers or tributaries, although spawning has been observed in streams as small as 7 to 10 ft (2 to 3 m) wide (Vronskiy 1972). Chinook Salmon typically spawn in low- to moderate-gradient reaches of streams, but can navigate shorter reaches with steeper gradients to access suitable spawning areas. Armantrout (ULEP 1998) concluded that Chinook Salmon seldom inhabit streams with gradients greater than 3 percent after examining extensive inventory data from Oregon. The upper extent of Chinook Salmon distribution in the Umpqua River basin in Oregon appears to occur where gradients are less than 3 percent (ULEP 1998).

Upon arrival at the spawning grounds, adult females dig shallow depressions or pits (redds) in suitably sized gravels (discussed in further detail below), deposit eggs in the bottom during the act of spawning, and cover them with additional gravel. Over a period of one to several days, the female gradually enlarges the redd by digging additional pits in an upstream direction (Burner 1951). Redd areas vary considerably depending on female size, substrate size, and water velocities, and can range from 5.4 (Neilson and Banford 1983) to 482 ft^2 (0.5 to 44.8 m^2) (Chapman et al. 1986).

Chinook Salmon tend to seek spawning sites with high rates of intergravel flow. Upwelling, which is associated with a concave bed profile, may be an important feature selected by spawning Chinook Salmon (Vaux 1968).

Chinook Salmon are capable of spawning within a wide range of water depths and velocities, provided that intergravel flow is adequate for delivering sufficient oxygen to eggs and alevins (Healey 1991). Depths most often recorded for Chinook Salmon redds range from 4 to 80 inches (10 to 200 cm) (Burner 1951, Chambers et al. 1955, Vronskiy 1972), and velocities range from 0.5 to 3.3 ft/s (15 to 100 cm/s) (Burner 1951, Chambers et al. 1955, Thompson 1972, Vronskiy 1972, Smith 1973), although values may vary between races and stream basins.

Fall-run Chinook Salmon, for instance, are able to spawn in deeper water with higher velocities such as the mainstem Sacramento River because of their larger size (Hallock et al. 1957).

Substrate particle size composition has been shown to have a significant influence on intragravel flow dynamics (Platts et al. 1979). Chinook Salmon may therefore have evolved to select redd sites with specific particle size criteria that will ensure adequate delivery of dissolved oxygen to their incubating eggs and developing alevins. In addition, salmon are limited by the size of substrate that they can physically move during the redd building process. Substrates selected likely reflect a balance between water depth and velocity, substrate composition and angularity, and fish size. As depth, velocity, and fish size increase, Chinook Salmon are able to displace larger substrate particles. D50 values (the median diameter of substrate particles found within a redd) for spring-run Chinook have been found to range from 10.8 to 78.0 mm (0.43 to 3.12 inches) (Platts et al. 1979; Chambers et al. 1954, 1955).

In 1997, USFWS researchers collected data on substrate particle size, velocity, and depth at hundreds of Chinook Salmon redds in the Sacramento River between Keswick Dam and Battle Creek to develop habitat suitability criteria for use in models that can aid in determining instream flows beneficial for anadromous salmonids. Redds in both shallow and deep areas were sampled. Table 9B.1 summarizes habitat suitability criteria data collected in this study for three of the four runs (too few spring-run redds were found from which to collect data). Much more detail on the methods used and results can be found in USFWS (2003).

Table 9B.1 Range of Suitable Habitat Values for Chinook Salmon Spawning in the Sacramento River (USFWS 2003)

Run	Range of Suitable Values Velocity ft/s	Range of Suitable Values Velocity m/s	Range of Suitable Values Depth ft	Range of Suitable Values Depth m	Range of Suitable Values Substrate in	Range of Suitable Values Substrate cm
Fall	0.93 to 2.66	0.28 to 0.81	1–14	0.3–4	1–3 to 3–5	3–8 to 8–13
Late fall	0.90 to 2.82	0.27 to 0.86	1–14	0.3–4	1–3 to 4–5	3–8 to 10–13
Winter	1.54 to 4.10	0.47 to 1.25	3–16	0.9–5	1–3 to 3–5	3–8 to 8–13

9B.5.2.3 Egg Incubation and Alevin Development

Once redd construction is completed, a key determinant of survival from egg incubation through fry emergence is the amount of fine sediment in the gravel (McCuddin 1977; Reiser and White 1988). High concentrations of fine sediment in (or on) a streambed can reduce permeability and intergravel flow within the redd. This can result in reduced delivery rate of oxygen and increasingly elevated metabolic waste levels around incubating eggs, larvae, and sac-fry as they develop within egg pockets (Kondolf 2000), which can in turn lead to high mortality. Several studies have correlated reduced dissolved oxygen levels with mortality, impaired or abnormal development, delayed hatching and emergence, and reduced fry size at emergence in anadromous salmonids (Wickett 1954, Alderdice et al. 1958, Coble 1961, Silver et al. 1963, McNeil 1964a, Cooper 1965, Shumway et al. 1964, Koski 1981). Silver et al. (1963) found that low dissolved oxygen concentrations are related to mortality and reduced size in Chinook Salmon and steelhead embryos. Fine sediments in the gravel interstices can also physically impede fry emergence, trapping (or entombing) them within the redd (Phillips et al. 1975, Hausle and Coble 1976).

The effects of high fine sediment concentrations may be counteracted to a certain extent by the redd construction process itself. As adult salmon build redds, they displace fine material downstream and coarsen the substrate locally (Kondolf et al. 1993, Peterson and Foote 2000, Moore et al. 2004). However, the effects of sediment reduction during redd construction may be rapidly reversed by infiltration of fine sediment into the redds during the incubation period (Kondolf et al. 1993).

Suitable water temperatures are required for proper embryo development and emergence. Incubating Chinook Salmon eggs can withstand constant temperatures between 35.1 (Combs and Burrows 1957) and 62.1°F (1.7 and 16.7°C) (USFWS 1999); however, substantial mortality may occur at the extremes. Myrick and Cech (2004) conclude that temperatures between 43 and 54°F (6 and 12°C) are best for ensuring egg and alevin survival. Sublethal stress and/or mortality of incubating eggs resulting from elevated temperatures would be expected to begin at temperatures of about 58°F (14.4°C) for constant exposures (Combs and Burrows 1957, Combs 1965, Healey 1979).

Some have suggested that the eggs and fry of winter-run Chinook Salmon may be slightly more tolerant of warm water temperatures than those of fall-run Chinook Salmon. One study by USFWS (1999) showed fall-run Chinook Salmon egg mortality increasing at lower temperatures (53.6°F [12°C]) than winter-run (56.0°F [13.3°C]). Greater tolerance to temperature was also observed in the post-hatching period, as was also found by Healey (1979). According to Myrick and Cech (2001), however, temperature tolerances of winter-run eggs and fry generally agree with those found for populations in more northern regions, and there does not appear to be much variation, if any, with regard to egg thermal tolerances between runs of Chinook Salmon (Healey 1979, Myrick and Cech 2001).

9B.5.2.4 Fry Rearing

Following emergence, fry occupy low-velocity, shallow areas near stream margins, including backwater eddies and areas associated with bank cover such as large woody debris (Lister and Genoe 1970, Everest and Chapman 1972, McCain 1992). As the fry grow, they tend to move into deeper and faster water further from banks (Hillman et al. 1987, Everest and Chapman 1972, Lister and Genoe 1970). Everest and Chapman (1972) suggests that habitat with water velocities less than 0.5 ft/s (15 cm/s) and depths less than 24 inches (60 cm) are suitable for newly emerged fry.

Although fry typically drift downstream following emergence (Healey 1991), movement upstream or into cooler tributaries following emergence has also been observed in some systems (Lindsay et al. 1986, Taylor and Larkin 1986). On the Sacramento River, juvenile Chinook Salmon are more commonly found in association with natural banks and shaded riparian cover than banks stabilized with riprap (DFG 1983; Michny and Hampton 1984; Michny and Deibel 1986; Michny 1987, 1988, 1989; Fris and DeHaven 1993). DeHaven (1989) found this association to be weaker at lower water temperatures than at temperatures over 70°F (21°C).

9B.5.2.5 Juvenile Rearing

Little is known regarding habitat selection of juvenile Chinook Salmon in the Sacramento River system specifically. Habitat preferences of Chinook Salmon may vary depending on channel confinement, substrate and bank characteristics, abundance of small and large wood, presence of other salmonids (particularly Coho Salmon), and whether the Chinook display an ocean- or stream-type life history. Juvenile habitat use may also change seasonally, diurnally, or as a function of growth, with larger juveniles tending to occupy habitats with higher water velocities.

Several researchers have shown relationships between velocity and juvenile Chinook Salmon habitat use, with juveniles generally occupying areas with water velocities less than 15 to 30 cm/s (Thompson 1972, Hillman et al. 1987, Steward and Bjornn 1987, Murphy et al. 1989, Beechie et al. 2005), as well as a preference for areas with cover provided by brush, large wood, or undercut banks (Hillman et al. 1987, Johnson et al. 1992, Beechie et al. 2005). Lister and Genoe (1970) found that juvenile Chinook Salmon preferred "slow water adjacent to faster water (40 cm/s)," and Shirvell (1994) suggested that preferred habitat locations vary by activity. For feeding, they are likely to select positions with optimal velocity conditions, whereas for predator avoidance, optimal light conditions are more likely to be important (Shirvell 1994). At night, juvenile Chinook Salmon appear to move to quiet water or pools and settle to the bottom, returning the next day to the riffle and glide habitats they had occupied the previous day (Edmundson et al. 1968, Chelan County Public Utility District 1989).

Although some researchers have found juvenile Chinook Salmon to reside primarily in pools, they may also use glides and runs as well as riffles. Chinook Salmon may prefer deeper pools with low water velocities during spring and summer as well as during winter (Lister and Genoe 1970, Everest and Chapman 1972, Swales et al. 1986, Hillman et al. 1987). In the Elk River in Oregon, Burnett and Reeves (2001) found most juvenile ocean-type Chinook Salmon (in sympatry with Coho Salmon and steelhead) in valley segments with deeper pools, larger volume pools, and pools with greater densities of large wood. In Elk River tributaries, the juveniles were observed almost exclusively in pools. Roper et al. (1994) also found age-0+ Chinook to be strongly associated with pools in the South Umpqua River basin in Oregon. In the Sacramento and American rivers, CDFG (1997) found juvenile Chinook Salmon densities to be highest in runs, closely followed by pools, with fish also occupying riffles and glides.

9B.5.2.6 Summer Rearing
