CEQA Conclusion: The areal extent of lands overlying study area natural gas fields that would be inundated by through restoration actions depends on final footprints for these measures. Most of these natural gas fields would still be accessible from outside the inundated areas using either conventional or directional drilling, although feasibility of access would depend on the exact configuration of inundation and the availability of adjacent drilling sites. Although the overall extent of affected natural gas fields in the region is low to moderate, there is potential for a locally significant impact on access to natural gas fields if they are permanently covered (inundated) such that the resource cannot be recovered. Implementation of Mitigation Measure MIN-6 would reduce this impact, but not to a less-than-significant level. Because implementation of Mitigation Measure MIN-6 cannot assure that all or a substantial portion of existing natural gas fields will remain accessible after implementation of this alternative, this impact is significant and unavoidable.

Mitigation Measure MIN-6: Design Environmental Commitments 4 and 10 to Maintain Drilling Access to Natural Gas Fields to the Extent Feasible

During final design of actions to offset the impacts of constructing and operating the water conveyance facilities, the project proponents will identify means to maintain access to natural gas fields that could be adversely affect by implementing Environmental Commitments 4 and 10 where feasible. These could include preserving non-inundated lands either over or adjacent to natural gas fields adequate in size to allow drilling to occur. These measures will ensure that drilling access to natural gas fields is maintained to the greatest extent practicable.

Impact MIN-7: Loss of Availability of Locally Important Aggregate Resource Sites (Mines and MRZs) as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: Because there are no permitted resource extraction mines (including aggregate mines) and no identified MRZs in the Alternative 4A footprint, including within the footprint for the east-west transmission line alignment option, there would be no effect on the availability of aggregate resources.

CEQA Conclusion: Because there are no permitted mines or MRZs in the construction footprint for Alternative 4A, including within the footprint for the east-west transmission line alignment option, there would be no impact. No mitigation is required.

Impact MIN-8: Loss of Availability of Known Aggregate Resources as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: The demand for construction materials, including aggregates and borrow materials for Alternative 4A would be identical to Alternative 4. The principal demands for construction material would come from the three intakes and associated facilities, the nearly 40 miles of concrete pipeline tunnels, and forebays. This demand would not result in a substantial depletion of construction-grade aggregate within the six regional aggregate production study areas, would not cause remaining supplies to be inadequate for future development, and would not substantially contribute to the need for the development of new aggregate resources. Accordingly, it would not have an adverse effect on the availability of known aggregate resources or borrow materials over the water conveyance facilities construction period.

CEQA Conclusion: The use of large amounts of construction aggregate over the 9-year construction period would not result in a substantial depletion of construction-grade aggregate from the study area, would not cause remaining supplies to be inadequate for future development, and would not contribute to the need for development of new aggregate sources. Consequently, although a substantial amount of available aggregate material may be used under Alternative 4A, the impact on aggregate resources would be less than significant. No mitigation is required.

Borrow is not a defined mineral resource and is usually developed on an as-needed basis. Consequently, the amount of borrow required for this alternative would not be a significant impact. No mitigation is required.

Impact MIN-9: Loss of Availability of Locally Important Aggregate Resource Sites (Mines and MRZs) as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 4A would include moving water, both within infrastructure that would be constructed and the natural channels. Adverse effects would only occur if operations prevented access to a locally important aggregate resource site; this is not expected to occur because there are no aggregate mines or MRZs in the area where the alternative would operate. Accordingly, operation of Alternative 4A would not block access to existing mines or identified MRZs and similar to Alternative 4, there would be no effect. Similarly, routine facilities maintenance activities such as painting, cleaning, and structure repair, landscape maintenance, road work, and periodic replacement of erosion protection on the levees and embankments would not cover or block access to existing mines or identified MRZs because there are no aggregate mines or MRZs in the area where the alternative would operate. Additionally, operations and maintenance would not increase the existing project footprint so they could not have any effect even if aggregate mines or MRZs did exist. Accordingly, the operation and maintenance of the water conveyance facilities under Alternative 4A would not have effects on the availability of aggregate resource sites.

CEQA Conclusion: The operation and maintenance associated with Alternative 4A would have no impact on the availability of aggregate resource sites because none exist within the areas affected by Alternative 4A operations and operations and maintenance would not increase the alternative's footprint. No mitigation is required.

Impact MIN-10: Loss of Availability of Known Aggregate Resources as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 4A would include moving water, both within infrastructure that would be constructed and natural channels. Similar to Alternative 4, no aggregate resources are required for operations so there would be no effect and only small amounts of aggregate and riprap would be required for maintenance of structure foundations, levees, stream banks, and access roads associated with major project features such as intakes, pumping plants, and the head of Old River barrier. As discussed under Alternative 4, the demand for these materials could be easily met locally. Accordingly, operation and the use of a small amount of aggregate material for the maintenance of the water conveyance facilities under Alternative 4A would not result in adverse effects.

CEQA *Conclusion:* Operation of the water conveyance facilities under Alternative 4A would not affect any aggregate resources because operation involves moving water through the conveyance infrastructure and no aggregate resources are required for operations. A small amount of aggregate material would be used for maintenance of Alternative 4A which would be available from local sources. Operation and maintenance would not cause substantial depletion or loss of availability, and would not cause remaining supplies to be inadequate to meet future demands and require developing new sources. Therefore this impact would be less than significant. No mitigation is required.

Impact MIN-11: Loss of Availability of Locally Important Aggregate Resource Sites (Mines and MRZs) as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: The environmental commitments that would have the potential to affect important aggregate resource sites are those that would inundate large areas of land. The loss of important aggregate resource sites under Alternative 4A would be similar to that described under Alternative 4. However, the potential for loss of important aggregate resource sites would be less than Alternative 4 because much less land would be restored within the Plan Area and over a much shorter period. Nevertheless, the potential for inundation and loss of this aggregate resource sites would remain under Alternative 4A and is considered an adverse effect. Mitigation Measure MIN-11 is available to reduce this effect.

CEQA *Conclusion:* As described under Alternative 4, an active mine on Decker Island may fall within the inundation footprints associated with implementing restoration actions associated with tidal natural communities and nontidal marsh. Although less acreage would be restored under Alternative 4A, restoration actions could result in inundation of aggregate resources. Although the impact is expected to be less than under Alternative 4, the potential loss would remain a significant impact because it would eliminate the potential to recover aggregate resources. Mitigation Measure MIN-11 is designed to reduce the impact to less than significant.

Mitigation Measure MIN-11: Purchase Affected Aggregate Materials for Use in Project Construction

The project proponents will purchase the permitted aggregate volume of affected mines for construction use so that the available aggregate will not be lost. The resulting mined site(s) should be considered for integration into the restoration design of any environmental commitment that affects the site(s). For example, the mined site(s) could be reshaped to provide aquatic or intertidal habitat of varying depths and configurations.

Impact MIN-12: Loss of Availability of Known Aggregate Resources as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Restoration actions occurring under Alternative 4A have the potential to reduce the availability of important aggregate resources. When compared to Alternative 4, loss of aggregate resources under Alternative 4A would be less because the total acreage of restoration occurring with the Plan Area would be substantially less. Similar to Alternative 4, aggregate and riprap would be used for levee, berm, access road, and rock revetment construction, and rock would be placed for erosion control and stability at levee breaches and toe drain earthworks. The amounts of aggregate and riprap necessary for these activities cannot be calculated at this time because of the programmatic nature and general design of the restoration actions. However, the amount needed would be used over a period of years and would be expected to be within the available resources of the study area and adjacent aggregate resource study areas discussed in Section 26.1.2.1, *Aggregate Resources* and identified in Table 26-1 of the Draft EIR/EIS. There would be no depletion (loss of availability) of regional aggregate supplies substantial enough to cause remaining supplies to be inadequate for future development or to require development of new aggregate sources to meet future demand. Therefore, the use of aggregate material for the restoration actions under Alternative 4A would not cause an adverse effect on the availability of aggregate resources.

CEQA Conclusion: Restoration actions occurring under Alternative 4A would use small amounts of aggregate for levee, berm, and access road construction, and placement of rock revetments or riprap for erosion control and stability at level breaches and toe drain earthworks. The amounts of aggregate are unknown but would be within the available resources of the study area or adjacent aggregate resource study areas. Because implementing environmental commitments would not use an amount of aggregate that would cause remaining supplies to be inadequate to meet future demands and require developing new sources, this impact would be less than significant. No mitigation is required.

4.3.23 Paleontological Resources

Impact PALEO-1: Destruction of Unique or Significant Paleontological Resources as a Result of Construction of Water Conveyance Facilities

The construction of water conveyance facilities and the extent of destruction of unique or significant paleontological resources under Alternative 4A would be identical to those described under Alternative 4. Construction activities that could result in adverse effects on paleontological resources include excavation for new intakes, pumping plants, new forebays, pipelines and tunnels, canals to the Jones and Banks pumping plants, an operable barrier at the head of Old River, other water facility components, roads, and borrow sites. The depth, extent, and location of excavation and other ground-disturbing activities vary greatly across the Plan Area and are provided in the description of the extent of impacts on paleontological resources in Alternative 4 and summarized in Table 27-14 of the Draft EIR/EIS.

NEPA Effects: The ground-disturbing activities that occur in geologic units sensitive for paleontological resources have the potential to damage or destroy those resources. Direct or indirect destruction of significant paleontological resources as defined by the Society of Vertebrate Paleontology (SVP) (2010) would represent an adverse effect because conveyance facility construction could directly or indirectly destroy unknown paleontological resources in geologic units known to be sensitive for these resources.

The shallow excavation and grading in surficial Holocene deposits that would take place for the construction of roads could be addressed through implementation of Mitigation Measures PALEO-1b and PALEO-1d.

Mitigation Measures PALEO-1a through PALEO-1d are available to mitigate the effects of the surface-related ground disturbance activities associated with Alternative 4A. However, while these measures could be applied to the excavation of the tunnel shafts, no mitigation is available for the boring activities because they would be conducted deep underground and could not be monitored. Moreover, although boring material could be examined by monitors, such work would be subsequent to boring, and the boring area could not be accessed even if fossils were encountered.

Excavation for new intakes, pumping plants, new/expanded forebays, pipelines and tunnels, canals to Jones and Banks pumping plants, and other water facility components necessary for Alternative 4A would most likely destroy unique or significant paleontological resources and would constitute an adverse effect under NEPA.

CEQA Conclusion: Construction of water conveyance facilities proposed under Alternative 4A could cause the destruction of unique paleontological resources. The ground-disturbing activities associated with Alternative 4A would occur in geologic units sensitive for paleontological resources and could therefore have the potential to damage or destroy those resources. Direct or indirect destruction of significant paleontological resources as defined by the SVP (2010) would constitute a significant impact under CEQA.

Implementation of Mitigation Measures PALEO-1a through PALEO-1d would reduce the effects of surface-related ground disturbance to a less-than-significant level, but excavation for the tunnels necessary for Alternative 4A would most likely destroy unique or significant paleontological resources in the Plan Area and would potentially cause a significant and unavoidable impact.

Mitigation Measure PALEO-1a: Prepare a Monitoring and Mitigation Plan for Paleontological Resources

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Mitigation Measure PALEO-1b: Review 90% Design Submittal and Develop Specific Language Identifying How the Mitigation Measures Will Be Implemented along the Alignment

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Mitigation Measure PALEO-1c: Educate Construction Personnel in Recognizing Fossil Material

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Mitigation Measure PALEO-1d: Collect and Preserve Substantial Potentially Unique or Significant Fossil Remains When Encountered

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Impact PALEO-2: Destruction of Unique or Significant Paleontological Resources Associated with the Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Ground-disturbing activities associated with restoration actions under Alternative 4A would result in impacts that would be similar in nature to those described under Alternative 4. However, the extent of these impacts would be much less under Alternative 4A because less ground-disturbing activity would occur. The environmental committments are described in Section 4.1.2.3, *Environmental Commitments*, of this RDEIR/SDEIS and include natural communities protection and restoration, tidal natural communities restoration, channel margin enhancement, riparian natural community restoration, vernal pool and alkali seasonal wetland complex restoration, and nontidal marsh restoration. Land-disturbing activities would be required to implement each of the conservation and stressor reduction measures.

NEPA Effects: If fossils are present in the Plan Area, they could be damaged during excavation required to implement the conservation and stressor reduction components. The greater the extent of excavation, the greater the potential effect, although even localized excavation could damage or destroy paleontological resources. Direct or indirect destruction of vertebrate or otherwise scientifically significant paleontological resources as defined by the SVP (2010) would be an adverse effect.

Mitigation Measures PALEO-1b and PALEO-1d are available to mitigate all shallow ground-disturbing environmental commitments. Mitigation Measures PALEO-1a through PALEO-1d would address all deeper ground-disturbing environmental commitments.

CEQA Conclusion: Ground-disturbing activities associated with implementing the conservation and stressor reduction components under Alternative 4A could affect paleontological resources. If fossils are present in the Plan Area, they could be damaged during excavation associated with these environmental commitments. The greater the extent of excavation, the greater the potential impact, although even localized excavation could damage or destroy paleontological resources. Direct or indirect destruction of significant paleontological resources as defined by the SVP (2010) would constitute a significant impact.

Implementation of Mitigation Measures PALEO-1b and PALEO-1d for all shallow ground-disturbing environmental commitments and Mitigation Measures PALEO-1a through PALEO-1d for all deeper ground-disturbing environmental commitments ensure that unique or significant paleontological resources in the alternative footprint are systematically identified, documented, avoided or protected from damage where feasible, or recovered and curated so they remain available for scientific study and would reduce these impacts to a less-than-significant level.

Mitigation Measure PALEO-1a: Prepare a Monitoring and Mitigation Plan for Paleontological Resources

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Mitigation Measure PALEO-1b: Review 90% Design Submittal and Develop Specific Language Identifying How the Mitigation Measures Will Be Implemented along the Alignment

Please see Mitigation Measure PALEO-1b under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Mitigation Measure PALEO-1c: Educate Construction Personnel in Recognizing Fossil Material

Please see Mitigation Measure PALEO-1c under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

Mitigation Measure PALEO-1d: Collect and Preserve Substantial Potentially Unique or Significant Fossil Remains When Encountered

Please see Mitigation Measure PALEO-1d under Impact Paleo-1 in the discussion of Alternative 4 in Chapter 27, *Paleontological Resources*, of the Draft EIR/EIS.

4.3.24 Environmental Justice

As described in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS some of the resource topics were not considered in the assessment of disproportionate impacts on minority or low-income populations. For the reasons described in Section 28.5.3.1, *Issues Not Analyzed in Detail*, of the Draft EIR/EIS, these resources were also not evaluated as part of the Alternative 4A environmental justice impact assessment. The resource topics not evaluated for a disproportionate impact on minority or low income populations are geology and seismicity, hazards and hazardous materials, mineral resources, water supply, surface water, groundwater, water quality, soils, fish and aquatic resources, terrestrial biological resources, agricultural resources, recreation, transportation, energy, air quality, and paleontological resources.

4.3.24.1 Land Use

The potential impact on minority and low-income populations resulting from changes in land use for Alternative 4A would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 13.3.3.9 of the Draft EIR/EIS identifies effects caused by incompatibility with local land uses, potential for physical division of established communities, and incompatibility with land use policies, By itself, incompatibility with land use policies is not a physical effect on the environment, and, therefore, does not have the potential to result in a disproportionate effect on a minority or low-income populations. Chapter 13, *Land Use*, Section 13.3.3.9, of the Draft EIR/EIS also addresses the potential for an alternative to result in the relocation of residents, or a physical effect on existing structures, with the consequence that adverse effects on the physical environment would result. The following adverse effects are relevant to this analysis:

Impact LU-2: Conflicts with Existing Land Uses as a Result of Constructing the Proposed Water Conveyance Facility

Impact LU-3: Create Physical Structures Adjacent to and through a Portion of an Existing Community as a Result of Constructing the Proposed Water Conveyance Facility

The extent of land use changes attributable to construction of Alternative 4A that could affect minority and low-income populations would be the same as disclosed for Alternative 4 because the period of construction, construction methods, and design of the water conveyance facility would be identical between the two alternatives. As discussed in detail under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS, a disproportionate effect on minority populations would occur because construction of Intakes 2, 3, and 5 would result in the displacement of residential structures and permanent structures within census blocks where the minority population is greater than 50%.

4.3.24.2 Socioeconomics

The potential impact on minority and low-income communities associated with changes in socioeconomic conditions for Alternative 4A would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 13.3.3.9 of the Draft EIR/EIS identified effects on agricultural economics and local employment conditions associated with constructing and operating the water conveyance facility and implementing environmental commitments. These impacts have the potential to disproportionately affect environmental justice populations. The following adverse effects are relevant to this analysis:

Impact ECON-1: Temporary Effects on Regional Economics in the Delta Region during Construction of the Proposed Water Conveyance Facilities

Impact ECON-7: Permanent Regional Economic Effects in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

Land use changes that could affect minority and low-income populations for Alternative 4A would be the same as indicated for Alternative 4 because the period of construction, construction methods, and design of the water conveyance facility would be identical between the two alternatives. As discussed in greater detail under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the majority of farm-related employment is represented by minority populations, including those of Hispanic origin, and potentially low-income, loss of agriculture land and loses of associated employment is expected to result in a disproportionate effect on minority populations. While a net increase in employment would occur during construction of the water conveyance facility, it is expected that most new construction jobs would not likely be filled by displaced agricultural workers because the skills required are not comparable. This effect would, therefore, remain adverse because job losses would disproportionately accrue to a minority population.

4.3.24.3 Aesthetics and Visual Resources

The potential impact on minority and low-income communities associated with changes in visual resources for Alternative 4A would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 17.3.3.9 in the Draft EIR/EIS addresses impacts on aesthetics and visual resources in the study area. The impacts on aesthetics and visual resources have the potential to disproportionately affect environmental justice populations. The following adverse effects and mitigation measures are relevant to this analysis:

Impact AES-1: Substantial Alteration in Existing Visual Quality or Character during Construction of Conveyance Facilities

Impact AES-2: Permanent Effects on a Scenic Vista from Presence of Conveyance Facilities

Impact AES-3: Permanent Damage to Scenic Resources along a State Scenic Highway from Construction of Conveyance Facilities

Impact AES-4: Creation of a New Source of Light or Glare That Would Adversely Affect Views in the Area as a Result of Construction and Operation of Conveyance Facilities

Impact AES-6: Substantial Alteration in Existing Visual Quality or Character during Implementation of CM2–CM21

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Mitigation Measure AES-4a: Limit Construction to Daylight Hours within 0.25 Mile of Residents

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Mitigation Measure AES-6a: Underground New or Relocated Utility Lines Where Feasible

Mitigation Measure AES-6b: Develop and Implement an Afterhours Low-intensity and Lights off Policy

Mitigation Measure AES-6c: Implement a Comprehensive Visual Resources Management Plan for the Delta and Study Area

The changes in the visual character of the study area that could affect minority and low-income communities under Alternative 4A would be the same as indicated under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be identical between the two alternatives. As described in detail under Alternative 4, changes in the visual character of the study area would occur as a result of the following:

- Landscape scars left behind from spoil borrow and RTM areas, transmission lines, concrete batch plants and fuel stations, and launching, retrieval, ventilation shafts sites.
- Constructing industrial facilities (i.e., Sacramento River intakes, intermediate forebay, expanded Clifton Court Forebay and pumping plant) in the study area.

The change in visual character as a result of the construction of the water conveyance facilities would be evident from the communities of Walnut Grove, Clarksburg, and Hood as well as rural residences located along the entire alignment. Because of the concentration of minority and low income populations in these communities as well as along the entire alignment, a change in visual character of the study area would disproportionately affect these populations. For these reasons, although mitigation is available to reduce the severity of these effects, this effect would be adverse.

Similar to Alternative 4, implementing conservation and stressor reduction measures as part of Alternative 4A, would result in impacts on the study area's visual quality and character. However because the precise location of the conservation and stressor reduction measures are unknown, this impact is not carried forward for further analysis of environmental justice effects.

4.3.24.4 Cultural Resources

The potential impact on minority and low-income communities associated with changes to cultural resources Alternative 4A would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 18.3.5.9 of the Draft EIR/EIS addresses cultural resources in the study area. The impacts on cultural resources have the potential to disproportionately affect minority or low-income populations. The following adverse effects and mitigation measures are relevant to this analysis:

Impact CUL-1: Effects on Identified Archaeological Sites Resulting from Construction of Conveyance Facilities

Impact CUL-2: Effects on Archaeological Sites to Be Identified through Future Inventory Efforts

Impact CUL-3: Effects on Archaeological Sites That May Not Be Identified through Inventory Efforts

Impact CUL-4: Effects on Buried Human Remains Damaged during Construction

Impact CUL-5: Direct and Indirect Effects on Eligible and Potentially Eligible Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Impact CUL-6: Direct and Indirect Effects on Unidentified and Unevaluated Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Impact CUL-7: Effects of Environmental Commitments on Cultural Resources

Mitigation Measure CUL-1: Prepare a Data Recovery Plan and Perform Data Recovery Excavations on the Affected Portion of the Deposits of Identified and Significant Archaeological Sites

Mitigation Measure CUL-2: Conduct Inventory, Evaluation, and Treatment of Archaeological Resources

Mitigation Measure CUL-3: Implement an Archaeological Cultural Resources Discovery Plan, Perform Training of Construction Workers, and Conduct Construction Monitoring

Mitigation Measure CUL-4: Follow State and Federal Law Governing Human Remains If Such Resources Are Discovered during Construction

Mitigation Measure CUL-5: Consult with Relevant Parties, Prepare and Implement a Built Environment Treatment Plan

Mitigation Measure CUL-6: Conduct a Survey of Inaccessible Properties to Assess Eligibility, Determine if These Properties Will Be Adversely Impacted by the Project, and Develop Treatment to Resolve or Mitigate Adverse Impacts

Mitigation Measure CUL-7: Conduct Cultural Resource Studies and Adopt Cultural Resource Mitigation Measures for Cultural Resource Impacts Associated with Implementation of CM2–CM21

The impact that the loss of cultural resources from within the study area could have on minority and low-income populations under Alternative 4A would be the same as indicated under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be identical between the two alternatives. As discussed in greater detail under Alternative 4, the loss or damage to prehistoric cultural resources would result in a disproportionate effect on Native American populations and potentially other minorities. Despite the required mitigation measures and Native Consultation processes, construction of Alternative 4A is likely to result in adverse effects on prehistoric archaeological resources and human remains because the scale of the construction activities makes avoidance of all eligible resources infeasible. The effect on minority populations that may ascribe significance to cultural resources in the Delta would remain disproportionate even after mitigation because mitigation cannot guarantee that all resources would be avoided, or that effects on affected resources would be reduced. For these reasons this effect would be adverse because the effect would disproportionately accrue to a minority population.

4.3.24.5 Public Services and Utilities

The potential impact on minority and low-income communities associated with changes to the availability of public services and utilities under Alternative 4A would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 20.3.3.9 of the Draft EIR/EIS addresses potential effects on utility infrastructure and public service providers, such as fire stations and police facilities. The following adverse effects on public services and utilities are relevant to the analysis:

Impact UT-6: Effects on Regional or Local Utilities as a Result of Constructing the Proposed Water Conveyance Facilities

Impact UT-8: Effects on Public Services and Utilities as a Result of Implementing the Proposed CM2–CM11

The impacts on public services and utilities located within the study area that could disproportionately affect minority and low-income populations under Alternative 4A would be the same as indicated disclosed under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be identical between the two alternatives. As discussed in greater detail under Alternative 4, the impact of constructing the proposed water conveyance facilities on public services and utilities would not result in a disproportionate effect on minority or low income populations because relocation of an existing known utility would affect the entire service area of that utility. This effect would not be anticipated to result in a disproportionate effect on a minority or low-income population.

4.3.24.6 Noise

The potential impact on minority and low-income communities associated with noise occurring under Alternative 4A would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 23.4.3.9 of the Draft EIR/EIS identifies the following adverse effects associated with new sources of noise and vibration that would be introduced into the study area under Alternative 4. The following adverse effects and mitigation measure are relevant to this analysis.

Impact NOI-1: Exposure of Noise-Sensitive Land Uses to Noise from Construction of Water Conveyance Facilities

Impact NOI-2: Exposure of Sensitive Receptors to Vibration or Groundborne Noise from Construction of Water Conveyance Facilities

Impact NOI-4: Exposure of Noise-Sensitive Land Uses to Noise from Implementation of Proposed CM2–CM21

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Mitigation Measure NOI-2: Employ Vibration-Reducing Construction Practices during Construction of Water Conveyance Facilities

The impacts of noise and vibration generated during construction of the water conveyance facilities and resulting effects on minority and low-income communities occurring under Alternative 4A would be the same as indicated under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be identical between the two alternatives. As discussed in greater detail under Alternative 4, constructing the water conveyance facilities would generate nose in exceedance of daytime and nighttime noise standards in areas zoned as sensitive land uses including residential, natural/recreational, agricultural residential, and schools. Similarly, ground borne vibration from impact pile driving would exceed vibration thresholds in areas zoned for residential, including agricultural residential. This effect of noise and vibration generated during construction would remain adverse after application of mitigation. Because the alignment of the water conveyance facility is proximate to census blocks and block groups where meaningfully greater minority and low-income populations occur it is expected that generation of noise and vibration in exceedance of thresholds would result in a potentially disproportionate effect on minority and low-income populations.

Impacts of implementing conservation and stressor reduction components (Environmental Commitments 3, 4, 6–12, 15, and 16) under Alternative 4A would be expected to be similar to impacts of implementing CM2–CM11 under Alternative 4. However, because fewer acres would be restored under Alternative 4A, it is expected that noise and vibration generated would be less when compared to Alternative 4. Nevertheless, it would be difficult to analyze potential disproportionate effects on environmental justice population because similar to CM3–CM11, the location of the conservation and stressor reduction components are not known. However, because of the distribution of minority and low-income populations in the study area, there is a potential for noise and vibration impacts to disproportionately affect these populations.

4.3.24.7 Public Health

Section 4.3.21, *Public Health*, of this RDEIR/EIS, identifies the potential for construction, operation, and maintenance of Alternative 4A to mobilize or increase constituents known to bioaccumulate. The following adverse effects are relevant to this analysis.

Impact PH-3: Substantial Mobilization of or Increase in Constituents Known to Bioaccumulate as a Result of Construction, Operation or Maintenance of the Water Conveyance Facilities

The amount of tidal habitat restoration completed under Alternative 4A (Environmental Commitment 4) would be substantially less than under Alternative 4 CM4. To the extent that restoration actions alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of operations-related water quality changes due to operation of the water conveyance facilities. Three intakes would be constructed and operated under Alternative 4A, similar to Alternative 4. Sediment-disturbing activities during construction and maintenance of the intake and other water conveyance facilities proposed near or in surface waters under this alternative could result in the disturbance of existing constituents in sediment, such as pesticides or methylmercury. The effects of Alternative 4A on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be similar to or slightly less than those described for the Alternative 4. Alternative 4A would not result in increased tributary flows that would mobilize organochlorine pesticides in sediments.

If mercury is sequestered in sediments at water facility construction sites, it could become suspended in the water column during construction activities, opening up a new pathway into the food chain. Construction activities (e.g., pile driving and cofferdam installation) at intake sites or barge landing locations would result in a localized, short-term resuspension of sediment and an increase in turbidity that may contain elemental or methylated forms of mercury. Please see Chapter 8, Section 8.1.3.9, *Mercury,* in Appendix A of the RDEIR/SDEIS for a discussion of methylmercury concentrations in sediments.

Changes in methylmercury concentrations under Alternative 4A are expected to be small. The greatest annual average methylmercury concentration for drought conditions would be 0.166 ng/L for the San Joaquin River at Buckley Cove (all scenarios) which was slightly lower than the No Action Alternative (ELT) (0.168 ng/L). Fish tissue estimates show only small or no increases in mercury concentrations based on long-term annual average concentrations for mercury at the Delta locations, but they would be different relative to the No Action Alternative (ELT). Under Operational Scenario H3 (Equation 2—see Chapter 8, *Water Quality*, of the Draft EIR/EIS) there would be 11% to 12% percent increases at Staten Island and Rock Slough relative to the No Action Alternative (ELT) in all modeled years. Under Operational Scenario H4 there would be an 11% decrease relative to the No Action Alternative (ELT) for drought years. These changes are expected to be within the uncertainty inherent in the modeling approach (see Section 4.3.4, *Water Quality*, of this RDEIR/SDEIS for a discussion of the uncertainty associated with bioaccumulation models), and would likely not be measurable in the environment. In the LLT, the primary difference would be changes in the Delta source water fractions to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of Alternative 4A and, therefore, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

> Because some of the affected species of fish in the Delta are pursued during subsistence fishing by minority and low-income populations, this increase creates the potential for mercury-related health effects on these populations. Asian, African-American, and Hispanic subsistence fishers pursuing fish in the Delta already consume fish in quantities that exceed the US Environmental Protection Agency reference dose of 7 micrograms (μg) per day total (Shilling et al. 2010:5). This reference dose is set at 1/10 of the dose associated with measurable health impacts (Shilling et al. 2010:6). The highest rates of mercury intake from Delta fish occur among Lao fishers (26.5 μg per day, Shilling et al. 2010:6). Increased mercury was modeled based upon increases modeled for one species: largemouth bass. These effects are considered unmitigable (see Chapter 8, *Water Quality,* Mitigation Measure WQ-13).

> The associated increase in human consumption of mercury caused by these alternatives would depend upon the selection of the fishing location (and associated local fish body burdens), and the relative proportion of different Delta fish consumed. Different fish species would suffer bioaccumulation at different rates associated with the specific species, therefore the specific spectrum of fish consumed by a population would determine the effect of increased mercury body burdens in individual fish species. These confounding factors make demonstration of precise impacts on human populations infeasible. However, because minority populations are known to practice subsistence fishing and consume fish exceeding US EPA reference doses, any increase in the fish body burden of mercury may contribute to an existing adverse effect. Because subsistence fishing is specifically associated with minority populations in the Delta compared to the population at large this effect would be disproportionate on those populations for Alternative 4A. This effect would be adverse.

4.3.24.8 Summary of Environmental Justice Effects under Alternative 4A

Alternative 4A would result in disproportionate effects on minority and low-income communities resulting from land use, socioeconomics, aesthetics and visual resources, cultural resources, noise, and public health effects. Mitigation and environmental commitments are available to reduce these effects; however, effects would remain adverse. For these reasons, effects on minority and low-income populations would be disproportionate and adverse.

4.3.25 Climate Change

This section is organized differently from the other sections above because analyzing how Alternative 4A would affect the Delta's resiliency and adaptability to climate change is a fundamentally different analysis than those presented in other resource analyses. Whereas the other sections are organized to identify effects of Alternative 4A and how to mitigate any significant impacts, this section's function is to analyze and disclose how Alternative 4A would affect the Delta's resiliency and adaptability to expected climate change. While climate change is already ongoing and would occur under the ELT timeframe, effects of Alternative 4A on the resiliency and adaptability would be greater under LLT conditions as climate change effects are expected to be more pronounced[6]. Nevertheless, an assessment of conditions under the ELT timeframe is provided below.

[6] The ELT timeframe is modeled at 2025. The LLT timeframe is modeled at 2060.

As described in Draft EIR/EIS Chapter 29, *Climate Change,* Section 29.6.1.1, impact analyses evaluated potential sea level increases of 6 inches (15 centimeters) in 2025, which is relevant to the early long-term timeframe considered for the purposes of Alternative 4A. Expected changes in precipitation and hydrology were also evaluated including earlier runoff as a result of warmer temperatures causing more precipitation to fall as rain instead of snow and the remaining snow melting earlier. These hydrologic changes will make water management more challenging and more constrained in the future and are expected to result in more years of critical dryness. DWR's modeling of future conditions suggests that with current management and operations, level of demand, and current climate, major CVP and SWP reservoirs could reach dead storage levels (the level below which water cannot be released) and that the likelihood of these critical conditions will increase substantially as the climate warms. In these instances, there would be critical water shortages leading to potentially extreme impacts on agriculture, municipal, industrial, and ecological water uses.

Alternative 4A would provide resiliency and adaptation benefits over the No Action/No Project alternative for dealing with the combined effect of increases in sea level rise and changes in upstream hydrology. As shown in Table B.1-3 in Appendix B of this RDEIR/SDEIS, implementation of this alternative would result in Delta exports that could range from slightly lower (less than 1% decrease under Scenario H3) to somewhat higher (11% increase under Scenario H4) than those under the No Action Alternative (ELT). Alternative 4A includes dual conveyance facilities, allowing water to be moved through the Delta when conditions permit and allowing water to be diverted from the Sacramento River in the northern Delta when conditions do not permit through Delta conveyance. The location of the north Delta diversion facility is further inland making it less vulnerable to salinity intrusion. Even with substantial sea level rise and critically dry upstream conditions, salinity could be repelled from this location. By establishing an alternative diversion point for Delta exports, a great deal of Delta management flexibility is added. Currently, management of the Delta is constrained by requirements to maintain X2 at specific locations during certain times of the year to ensure water diversions have low salinity and to ensure that critical fish populations stay outside of the entrapment zone. Alternative 4A would allow the Delta to be managed in a number of different ways, including maintaining salinity as it is currently managed or allowing salinity to fluctuate more freely in the Delta as it did prior to the development of upstream reservoirs. This added flexibility would allow managers more options for adaptively managing the Delta so that conditions can be optimized to provide benefits across all Delta water uses and habitat conditions. Alternative 4A would also provide more reliable water supplies, which will provide additional resilience and adaptability to increases in water demand as a result of higher temperatures and increased evapotranspiration and evaporation.

In addition to added water management flexibility created by proposed water conveyance facilities, Alternative 4A includes Environmental Commitments 3, 4, 12, 15, and 16 that provide for actions that will improve habitat in certain areas and reduce the effects of stressors, though to a substantially smaller geographic extent than proposed under Alternative 4. By enhancing, restoring, and protecting habitat, Alternative 4A would increase resilience and adaptability to the climate changes described above by increasing the amount of habitat that is available during periods of high stress such as very high or low freshwater inflow or very high salinity intrusion. By creating a wider variety of water management options and restoring habitat, Alternative 4A can also help buffer potential negative effects of increased water temperatures thereby adding resiliency to increased water temperatures. More detail on existing temperature conditions in watersheds within the Delta and water temperature effects on aquatic habitat as well as biological and biochemical processes, and how managed flows influence water temperatures can be found in Chapter 11, Fish and Aquatic Resources.

Similarly, in consideration of terrestrial species, protection and restoration of a variety of natural communities will increase the patch size and connectivity of habitats. Increasing patch size will tend to increase population sizes of native species, which provides more resilience against a changing climate. Increasing connectivity allows more genetic exchange among populations and movement to more suitable habitats as environmental conditions change. By reducing stressors on the Delta ecosystem through predator control at the north Delta intakes and Clifton Court Forebay and installation of a nonphysical fish barrier at Georgiana Slough, Alternative 4A will contribute to the health of the ecosystem and of individual species populations making them stronger and more resilient to the potential variability and extremes caused by climate change.

As described for Alternative 4, Alternative 4A would not be anticipated to add resiliency to existing levees; levee fragility would remain high and increase with time as in the No Action/No Project Alternative. However, Alternative 4A would provide additional adaptability to catastrophic failure of Delta levees. By providing an alternate conveyance route around the Delta, this alternative provides a mechanism to continue making water deliveries to SWP/CVP contractors and local and in-Delta water users with conveyance interties even if the Delta were temporarily disrupted by a catastrophic levee failure.

Construction and operation of the proposed water conveyance facilities and implementation of environmental commitments under Alternative 4A would not affect the ability of agencies to implement plans and proactive measures associated with climate change resiliency (see Draft EIR/EIS Chapter 29, *Climate Change,* Section 29.7 for a discussion of individual plans and policies). Accordingly, the project would be compatible with these federal and state plans to address climate change.

4.3.26 Growth Inducement and Other Indirect Effects

4.3.26.1 Direct Growth Inducement

Construction Jobs

Construction of Alternative 4A would require a peak of approximately 2,278[7] construction workers over a fourteen-year period. It is estimated that approximately 30 percent of these workers would come from out of state (due to the specialized nature of some of the jobs) and reside temporarily in the vicinity. Assuming the peak number of construction jobs (assumed to occur in year four of the eight-year period, as discussed in Chapter 16, *Socioeconomics*), this would mean approximately 752 workers coming from out of state. Construction would occur in the Delta area roughly between Sacramento and Stockton, and it is expected that the remaining approximately 3,100 workers would be drawn from the labor force of the five Delta counties in the project vicinity—Contra Costa, Sacramento, San Joaquin, Solano, and Yolo. The 1,526 jobs expected to be drawn from the local labor pool represents approximately 7% of the number of construction jobs in four of the five counties (Sacramento, San Joaquin, Solano, and Yolo)[8] in 2009, according to the California Department of Employment (California Employment Development Department 2011). While this is not an inconsequential percentage of construction jobs in 2009, the 1,526 project construction jobs is substantially less than the 13,000 construction jobs that were *lost* in the previous year (from 2008 to 2009) (California Employment Development Department 2011), due to the ongoing economic downturn.

With respect to the 752 workers who are assumed would be from out of state, according to the 2010 decennial census, there were almost 20,000 vacant residential units for rent in the five Delta counties in 2010 and, in the cities of Sacramento and Stockton alone, there were 4,052 vacant residential units for rent (U.S. Census Bureau 2011). All these jurisdictions except Yolo County had residential rental vacancy rates higher than the 5% rate considered optimal to allow normal turnover and renter mobility.[9] The cities of Sacramento and Stockton alone had a combined total of 12,591 vacant residential units for rent and rental vacancy rates of 8.3% and 9.4%, respectively. In addition to the available rental housing units, there are recreational vehicle and mobile home parks and numerous hotels and motels within the five-county region to accommodate any construction workers. Given the availability of housing in the project vicinity, out-of-state workers would be readily accommodated by existing housing; therefore the influx of these workers during project construction would not induce substantial new housing development.

---

[7] Based on the estimated construction workforce presented in Chapter 16, *Socioeconomics*, Table 16-19.

[8] Information on construction employment for Contra Costa County is not included in the industry employment by county data provided by the California Employment Development Department; therefore the construction employment numbers discussed here do not include Contra Costa County. In addition the only annual average industry employment data provided for San Joaquin and Solano counties is for the Stockton Metropolitan Statistical Area (MSA) and the Vallejo-Fairfield MSA, respectively; consequently the job information for the four counties presented here is likely to be understated to some degree, although it is assumed the MSAs reflect county employment trends and are the major employment centers in their respective counties.

[9] According to the Association of Bay Area Governments (ABAG), in the Bay Area a 5% vacancy rate is considered necessary to permit ordinary mobility in rental housing (i.e., normal housing turnover and mobility on the part of renters), and a 2% vacancy rate is considered necessary to permit ordinary mobility in for-sale housing (Association of Bay Area Governments ND:1-18.) Rental vacancy rates in four of the five Delta counties ranged from 6.8% to 8.3%; Yolo County's rental vacancy rate was 5%.

Permanent Jobs

Alternative 4A would require approximately 129 permanent operations and maintenance workers, who would be anticipated to live in the Delta region. This number represents about 0.02% of the total nonfarm jobs and 0.4% of the transportation, warehousing, and utilities jobs in the five Delta counties (California Employment Development Department 2011). It is therefore likely that this small number of new jobs would readily be filled by the local labor force and would not induce additional growth in the area. Assuming some or all of the jobs were specialized and required workers from outside the local labor pool, given the availability of housing in the project vicinity, these workers would be readily accommodated by existing housing; therefore the influx of these workers during project operation would not induce substantial new housing development.

4.3.26.2 Indirect Growth Inducement Associated with Facility Construction and Operation

Access Roads within the Plan Area

Construction of Alternative 4A water conveyance facilities will be identical to Alternative 4. In general, construction of roads in relatively undeveloped areas has the potential to induce growth by facilitating access to such areas by removing lack of roadway infrastructure as an obstacle to growth. The temporary access roads would be removed following construction and the land would be returned to its pre-project conditions; therefore temporary roads would not have the potential to induce future development. The permanent access roads would remain and, given the nature of the Plan Area, would largely be located on agricultural or open space lands. However, existing roads, including Highways 84, 160, and 4, are located close to much of the proposed alignments and facility sites, and the majority of the permanent access roads would be short segments providing a direct route between an existing road and a given project facility; therefore the new permanent roads would not provide access to substantial areas of agricultural or undeveloped lands not already served by area roads. No changes are proposed to the land use or zoning designations of land within the Plan Area; although the construction of proposed project facilities (including the permanent access roads) would remove the specific facility sites from agricultural production or other current land use, as discussed in Chapters 13 and 14, adjacent lands would continue to be designated for their current land uses. Therefore, the construction of the relatively limited segments of permanent access roads would not induce urban development.

Flood Risk Reduction

Actions under Alternative 4A are not anticipated to have any substantial impact or change on potential for flooding within the Plan Area and downstream areas (RDEIR/SDEIS Section 4.3.2 *Surface Water*). Alternative 4A would not result in an increase in potential risk for flood management compared to Existing Conditions when the changes due to sea level rise and climate change are eliminated from the analysis. Peak monthly flows under Alternative 4A in the locations considered in the analysis done were similar to or less than those that would occur under Existing Conditions without the changes in sea level rise and climate change; or the increased peak monthly flows would not exceed the flood capacity of the channels at these locations. It is not expected that there will be changes to land use or zoning designations within the Plan Area and therefore, no large-scale or substantial development would be expected to occur. There is not anticipated to have any indirect effect on growth.

4.3.26.3 Indirect Growth Inducement Potential: Summary of Modeling Results

The following sections highlight changes in SWP and CVP deliveries associated with the project alternatives based on modeling conducted using CALSIM II, focusing on changes in municipal and industrial (M&I) deliveries (also referred to as urban deliveries). Figure 4.3.1-26 summarizes overall changes in SWP deliveries to both agricultural and M&I contractors for Alternative 4A (H3 and H4) relative to Existing Conditions (the CEQA baseline) and the No Action Alternative (ELT) (which reflects with sea level rise and climate change (i.e., effects of precipitation and snowpack). Figure 4.3.1-25 summarizes changes in CVP deliveries under Alternative 4A (H3 and H4) relative to Existing Conditions as well as the No Action Alternative (ELT).

Note that the CALSIM II model was designed to evaluate water deliveries for the project as a whole, and was not designed to provide delivery allocation at the contractor level. Under circumstances of reduced SWP and CVP deliveries, CALSIM II tends to allocate water first to contractors in the northern portion of the project and then to contractors in the south. This results in an uneven distribution of reductions, with contractors in the south receiving larger reductions than contractors in the north. Consequently, where reduced deliveries are projected (Alternative 4A (Scenario H4)), some contractors (and therefore hydrologic regions) are projected to experience much larger decreases than others. This discrepancy is for the most part an artifact of the algorithm used in the model. Although system constraints may still lead to differences in distribution of reductions, these reductions in deliveries are likely to be more evenly distributed across the regions than CALSIM II has predicted. For more information on the modeling of water deliveries using the CALSIM II model, see Chapter 5, *Water Supply*, and Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS.

For purposes of analyzing the project's potential to induce growth, this analysis focuses on the net increase in annual average deliveries; all information on water deliveries presented below is for average annual deliveries in normal hydrologic years. The SWP modeling results reflected in the tables and figures presented in this section include Table A water as well as Article 21 water.[10]

This analysis does not address potential effects of redistribution of SWP water supply among SWP water contractors that might occur from an SWP contract amendment or funding agreements for implementing the project, other than as possible multi-year or permanent agricultural to urban water transfer of SWP water. A SWP contract amendment or funding agreement could include provisions for allocating benefits, such as a more reliable water supply, to contractors who pay for the project and could create the potential for redistributing SWP water. At this time, because a specific SWP amendment or funding agreement has not been developed, it would be too speculative pursuant to Section 15145 of the State CEQA Guidelines to evaluate changes in SWP water

[10] Article 21 water is interruptible water allocated under certain conditions. Water supply under Article 21 becomes available only during wet months of the year (December through March). A SWP contractor must have an immediate use for Article 21 supply or a place to store it outside of SWP; therefore not all SWP contractors can take advantage of this additional supply. Article 21 is a section of the contract between DWR and the water contractor that permits delivery of water in excess of delivery of SWP Table A. It is apportioned to contractors that request it in the same proportion as their SWP Table A water. Article 21 water is allocated under certain conditions: (a) SWP's share of San Luis Reservoir is full or projected to fill in the near term; (b) other SWP reservoirs are full or at their storage targets, or conveyance capacity to fill these reservoirs is maximized; (c) releases from upstream reservoirs plus unregulated inflow exceed the water supply needed to meet Sacramento Valley in-basin uses; (d) SWP Table A deliveries are being fully met; and (e) Banks Pumping Plant has spare capacity (California Department of Water Resources 2008b:32,39).

distribution at this time. If the SWP amendment or agreement, after it is developed, may have potential to have an environmental effect not already contemplated in the BDCP EIR/EIS, DWR would prepare additional analysis.

Alternative 4A

As described in Section 4.1, *Introduction*, of this RDEIR/SDEIS, facility construction under Alternative 4A would be identical to Alternative 4 and operational criteria would be similar. The addition of new north Delta intakes as well as changes to Delta regulatory requirements under Alternative 4A would provide operational flexibility that would allow the SWP and CVP to increase Delta exports compared to operations under existing conditions, and the Early Long Term. Water supply and conveyance operations would follow the guidelines described as Scenario H3 or H4, which variously include or exclude implementation of fall X2 and/or enhanced spring outflow. Alternative 4A and the Early Long Term also assume that there would be an increase in M&I water rights demands north of the Delta, which would increase overall system demands and reduce the amount of CVP water available for export south of the Delta.

Consequently, SWP M&I deliveries under Alternative 4A are projected to increase due to increased capacity for Delta exports, while in some cases CVP deliveries south of Delta are projected to decrease due to increased water rights demands north of Delta. Consequently, SWP M&I deliveries under Alternative 4 are projected to increase due to increased Delta exports, while in some cases CVP deliveries are projected to decrease due to increased water rights demands. See Section 4.3.1., *Water Supply*, of this RDEIR/SDEIS for more detail on changes in Delta exports and SWP and CVP deliveries under Alternative 4A.

Changes in Deliveries to the Hydrologic Regions

SWP. Compared to Existing Conditions, Alternative 4A would increase (H3) or decrease (H4) deliveries to all hydrologic regions depending on the range of spring outflow requirements. Exceptions would be the San Joaquin River region, which would experience an increase (H4) or no change in deliveries (H3). South Coast would either receive the largest net increase in deliveries (up to 87 TAF of Table A deliveries under H3) or the largest net decrease in deliveries (a decrease of up to 170 TAF of Table A deliveries under H4) among the regions.

Compared to the No Action Alternative ELT, Alternative 4A is expected to show less extreme of an effect (less increase or less decrease) than the results shown in Table 30-16 in the Public Draft EIR/EIS at the No Action Alternative (2060). Alternative 4A would be expected to increase (H3) or decrease (H4) deliveries to all hydrologic regions depending on the range of spring outflow requirements. Exceptions would be for the San Joaquin River region, which would experience no change in deliveries (H3 and H4) and the Tulare Lake region which could possibly receive an increase (H4). Compared to No Action Alternative ELT, under Scenario H3 and H4, South Coast would receive the largest net increase in deliveries (Table A deliveries) among the regions.

CVP. The operational scenarios under Alternative 4A would not change M&I deliveries for the Sacramento River, South Coast, South Lahontan and Colorado River regions because there are no affected CVP contractors located in these regions. Compared to Existing Conditions, Scenarios H3 and H4 would decrease deliveries to the other hydrologic regions; San Francisco Bay is projected to receive the largest potential decrease (5 TAF) among the affected hydrologic regions. For more information, refer to Table 30-17 in the Public Draft EIR/EIS.

Compared to the No Action Alternative ELT, Alternative 4A is expected to show less extreme of an effect (less increase or less decrease) than the results shown in Table 30-17 in the Public Draft EIR/EIS at the No Action Alternative (2060). Scenario H3 and H4 would increase deliveries to the other hydrologic regions. San Francisco Bay is projected to receive the largest potential increase among the affected hydrologic regions.

Alternative 4A Compared to Existing Conditions, Early Long Term.

SWP. Compared to the Existing Conditions ELT, Alternative 4A is expected to show less extreme of an effect (less increase or less decrease) than the results contained in the Alternative 4 discussion which looks at Alternative 4A conditions at 2060. By 2025, total deliveries to all SWP contractors are projected to decrease by 9% or increase by 5% at ELT and would remain similar or decrease by 13% at LLT relative to Existing Conditions depending upon the range of spring Delta outflow requirements. Under Alternative 4A, by 2025, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would decrease (11%) and increase (8%) at ELT and would decrease (17%) and increase (3%) at LLT depending upon range of spring outflow requirements, relative to Existing Conditions. Under Alternative 4A, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would decrease (12%) and increase (8%) at ELT and would decrease (17%) and increase (2%) at LLT depending upon range of spring outflow requirements. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

CVP. By 2025, total deliveries to all CVP contractors are projected to increase by up to 3% relative to Existing Conditions at ELT and up to 2% at LLT. Under Alternative 4A, average annual total south of Delta CVP deliveries as compared to Existing Conditions, would decrease by up to 4% at ELT and by up to 9% at LLT.

Alternative 4 Compared to No Action Alternative Early Long Term

SWP. Compared to the No Action Alternative ELT, Alternative 4A is expected to show less extreme of an effect (less increase or less decrease) than the results contained in the Alternative 4 discussion which looks at Alternative 4A conditions at 2060. By 2025, under average annual total SWP deliveries to all SWP contractors are projected to increase by 12% (H3) or decrease by about 3% (H4) relative to the No Action Alternative ELT depending upon the range of spring outflow requirements. Under Alternative 4A, average annual total south of Delta SWP deliveries as compared to No Action Alternative (ELT), would decrease (by about 4%) or increase (by about 16%) depending upon range of spring outflow requirements.

CVP. By 2025, deliveries under Scenarios H3 and H4 to all CVP M&I contractors are projected to increase by up to 3% relative to the No Action Alternative ELT and up to 2% at LLT. Under Alternative 4A, average annual total south of Delta CVP deliveries as compared to No Action Alternative (ELT), would increase by about 5%.

Comparison of Water Deliveries with California Water Plan Projected Demand [11]

As explained in Section 4.1.2.2, *Water Conveyance Facility Operations*, of this RDEIR/SDEIS, operational components of the water conveyance facilities under Alternative 4A would be similar, but not identical, to those described under Scenario H in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. However, Alternative 4A is analyzed at a shorter timeframe. Anticipated water deliveries would also be similar as those observed under Alternative 4. Under Alternative 4, total SWP deliveries to all regions would increase under two scenarios and would decrease under two other scenarios compared to Existing Conditions. Under Scenario H3, total SWP deliveries to all regions would increase by approximately 201 TAF, and under Scenario H4, total SWP deliveries to all regions would decrease by approximately 295 TAF. Total CVP M&I deliveries to all regions would decrease under both Alternative 4A scenarios: under Scenario H3 they would decrease by 10 TAF, and under Scenario H4 CVP M&I deliveries would decrease by 10 TAF compared to Existing Conditions. CVP agricultural deliveries would decrease by 215 TAF under Scenario H3, and would decrease by 243 TAF under Scenario H4.

Based on the information above, under Alternative 4A Scenario H3, net SWP and CVP deliveries would decrease by 2025. This decrease in supply is in contrast to projected increases in demand for the hydrologic regions assuming the Current Trends demand scenario. Under Alternative 4A Scenario H4, net SWP and CVP deliveries would decrease by 2025 compared to Existing Conditions. This decrease in supply is in contrast to projected increases in demand for the hydrologic regions assuming the Current Trends demand scenario.

4.3.26.4 Potential for Increases in Water Deliveries to Agricultural Contractors to Remove Obstacles to Growth

Alternative 4A would have a similar effect as Alternatives 1A through 9. However, since Alternative 4A includes a smaller package of habitat restoration as part of its environmental commitment, significantly more agricultural land would continue to be used for agricultural purposes. As described in Chapter 5, *Water Supply*, and shown in Table 30-14, deliveries to agricultural contractors are projected to increase under some alternatives. To the extent that the lack of sufficient, reliable water supplies currently poses a constraint to agricultural production, then increased reliable supplies have the potential to support increased agricultural production. Increased reliability of supplies (e.g., increased supplies to agricultural contractors during dry years) may support additional agricultural production. Where and how such increases would occur likely could vary from one farming interest to another. Increased agricultural production could support an increase in seasonal and permanent on-farm employment as well as increased economic activity in the larger agricultural industry (associated with agricultural inputs, processing, transport, etc.). The ability of local labor pools to support seasonal and permanent increases in employment would likely vary from region to region.

[11] As described in Section 30.1.1.3, of the Draft EIR/EIS, the California Water Plan is updated every five years. The latest California Water Plan was released in 2009 and contains projections to the year 2050. It is not expected that there will be substantial changes in demand trends between 2050 and 2060 that would impact the comparison of the year 2050 projections from the California Water Plan with modeling projections for the BDCP at the "Late Long Term" BDCP planning horizon (year 2060).

4.3.26.5 Potential for Increases in Water Deliveries to Urban Contractors to Remove Obstacles to Growth

Operations under Alternative 4A would be identical to those analyzed under Alternative 4. However, Alternative 4A is analyzed at a shorter timeframe. Anticipated water deliveries would also be similar as those observed under Alternative 4.

For Alternative 4, Scenarios H3 and H4, growth potential supported by the project in the South Coast region represents the largest percentage of projected increase in population from 2010 to 2060 among the regions: 5.3% compared to Existing Conditions and 10.1% compared to the No Action Alternative for Scenario H3; and 6.2% compared to Existing Conditions and 7.5% compared to the No Action Alternative for Scenario H4.

The South Coast, San Francisco Bay, South Lahontan, and Colorado River regions are the regions that could realize the largest increases in population due to increases in M&I deliveries (Tables 30-20 and 30-21). However, Alternative 4A (Scenarios H3 and H4) are unlikely to result in an increase of deliveries significant enough that it would foster additional growth in these areas.

It is anticipated that Alternative 4A would create a similar effect.

Comparison of Project Growth Potential with Growth Forecasts from Regional Planning Agencies

This section compares the population growth potentially supported by M&I deliveries in these regions to the growth forecasts of the respective regional planning agencies. These four regions account for 93 to 99% of the potential population supported by deliveries in 2060 compared to Existing Conditions, and 89 to 90% of the potential population supported by deliveries in 2060 compared to the No Action Alternative for five of the six alternatives[12] that provide increased deliveries. Because deliveries to the other regions that would receive increases (Sacramento River, Central Coast, and Tulare Lake) would not support substantial potential population overall or compared to the population increases projected for each region, the growth potential of the project in these regions is limited. Therefore, this discussion focuses on the four regions that would receive the largest M&I increase.

[12] Under Alternative 9 these four regions account for 59% of total deliveries compared to the No Action Alternative (2060). However, because deliveries under this alternative are relatively small its potential to support population growth in any region receiving deliveries is limited: Alternative 9 would support less than 1% of the population increase projected to occur in the eight hydrologic regions between 2010 and 2060 and no more than 3% of the projected population increase in any particular hydrologic region.

4.4 Impacts of Alternative 2D

4.4.1 Water Supply

Facilities construction under Alternative 2D would be identical to that described under Alternative 4, except this alternative would include two additional intakes. Alternative 2D water conveyance operations would be similar to the operations that would occur under Alternative 2A.

Model simulation results for Alternative 2A Early Long-Term (ELT) are summarized in Tables B.1-4 and B.1-5 in Appendix B of the RDEIR/SDEIS. Model simulation results for Alternative 2D at Late Long-term (LLT) which are similar to the Alternative 2A (LLT), are summarized in Tables 5-7 through 5-9 in the Draft EIR/EIS.

As indicated in Section 5.3.2, *Determination of Effects*, of Draft EIR/EIS, NEPA adverse effect and CEQA significant impact conclusions are not provided for the impacts discussed in this water supply section.

4.4.1.1 Summary of Water Supply Operations under Alternative 2D

Change in Delta Outflow

Changes in long-term average Delta outflow under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-4 and B.1-5 in Appendix B and Figures 4.4.1-1 through 4.4.1-3 in this RDEIR/SDEIS.

Changes in long-term average Delta outflow under Alternative 2D (LLT) (similar to Alternative 2A [LLT]) as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-3 through 5-5 and Tables 5-7 through 5-9 of the Draft EIR/EIS.

Late-fall and winter outflows remain similar or show minor reductions in Alternative 2D compared to No Action Alternative. In the spring months, outflow would decrease under Alternative 2D as compared to No Action Alternative. SWP and CVP exports in summer months would increase and result in lower outflow as compared to No Action Alternative. In the fall months, outflow under Alternative 2D as compared to No Action Alternative would be similar because of the Fall X2 requirement in wet and above-normal years, and increased or similar outflow in September and October months of all year types because of OMR flow requirements and export reductions.

Long-term average and wet year peak outflows would increase in winter months with a corresponding decrease in spring months because of the shift in system inflows caused by climate change and increased Delta exports as compared to Existing Conditions. In other year types, Alternative 2D would result in higher or similar outflow because of the spring outflow requirements. In summer and fall months, Alternative 2D would result in similar or higher outflow because of changes in export patterns and OMR flow requirements and export reductions in fall months, and also because of the Fall X2 requirements in wet and above normal years. The incremental changes in Delta outflow between Alternative 2D and Existing Conditions would be a function of both the facility and operations assumptions (including north Delta intakes capacity of 15,000 cfs, less negative OMR flow requirements, enhanced spring outflow and/or Fall X2 requirements) and the reduction in water supply availability due to increased north of Delta urban demands, sea level rise and climate change.

Delta outflow under Alternative 2D would likely decrease in winter, spring and summer months, and remain similar or increase in other months, compared to the conditions without the project.

Results for the range of changes in Delta Outflow under Alternative 2D (LLT), which are similar to Alternative 2A (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS.

Change in SWP and CVP Reservoir Storage

Changes in May and September reservoir storage under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Figures 4.4.1-4 through 4.4.1-10 and Tables B.1-4 and B.1-5 in Appendix B of this RDEIR/SDEIS for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis Reservoir storages are presented in Figures 4.4.1-11 through 4.4.1-14 for completeness.

Changes in May and September reservoir storage under Alternative 2D (LLT) [similar to Alternative 2A (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables 5-7 through 5-9 of Draft EIR/EIS for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis Reservoir storages are presented in Figures 5-13 through 5-16 of Draft EIR/EIS for completeness.

Results for changes in SWP and CVP reservoir storages under Alternative 2D at LLT, which are similar to Alternative 2A (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS.

Trinity Lake

Under Alternative 2D, average annual end of September Trinity Lake storage as compared to No Action Alternative would remain similar in most years at ELT, and decrease (3%) at LLT.

Under Alternative 2D, average annual end of September Trinity Lake storage as compared to Existing Conditions would decrease by 9% at ELT and 19% at LLT. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 2D and the results show that average annual end of September Trinity Lake storage could remain similar or decrease under Alternative 2D as compared to the conditions without the project.

Shasta Lake

Under Alternative 2D, average annual end of September Shasta Lake storage as compared to No Action Alternative would remain similar in most of the years at ELT, and decrease (3%) at LLT.

Under Alternative 2D, average annual end of September Shasta Lake storage as compared to Existing Conditions would decrease by 9% at ELT and 20% at LLT. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 2D and the results show that average annual end of September Shasta Lake storage could remain similar or decrease under Alternative 2D as compared to the conditions without the project.

Lake Oroville

Under Alternative 2D, average annual end of September Lake Oroville storage as compared to No Action Alternative would increase by up to 4% at ELT and 6% at LLT.

Under Alternative 2D, average annual end of September Lake Oroville storage as compared to Existing Conditions would decrease by 18% at ELT and 28% at LLT. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 2D and the results show that average annual end of September Lake Oroville storage could increase under Alternative 2D as compared to the conditions without the project.

Folsom Lake

Under Alternative 2D, average annual end of September Folsom Lake storage as compared to No Action Alternative would decrease by about 2%.

Under Alternative 2D, average annual end of September Folsom Lake storage as compared to Existing Conditions decrease by up to 17% at ELT and 29% at LLT. This decrease primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 2D and the results show that average annual end of September Folsom Lake storage could decrease under Alternative 2D as compared to the conditions without the project.

San Luis Reservoir

Under Alternative 2D, average annual end of September San Luis Reservoir storage as compared to the No Action Alternative would mostly decrease, due to changes in export patterns.

Under Alternative 2D, average annual end of September San Luis Reservoir storage as compared to Existing Conditions would decrease. This decrease primarily would occur due to changes in export patterns, sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 2D and the results show that average annual end of September San Luis Reservoir storage would generally decrease under Alternative 2D as compared to the conditions without the project.

Change in Delta Exports

Changes in average annual Delta exports under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Figures 4.4.1-15 through 4.4.1-18 and Tables B.1-4 and B.1-5 in Appendix B of this RDEIR/SDEIS.

Changes in average annual Delta exports under Alternative 2D (LLT) [similar to Alternative 2A (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-17 through 5-20 and Tables 5-7 through 5-9, of Draft EIR/EIS.

The addition of the north Delta intakes and changes to Delta regulatory requirements under Alternative 2D change SWP and CVP Delta exports as compared to Delta exports under Existing Conditions and the No Action Alternative.

Delta exports would increase in wetter years and either remain similar or decrease in drier years under Alternative 2D as compared to exports under No Action Alternative because of the additional capability to divert water at the north Delta intakes.

Total long-term average annual Delta exports under Alternative 2D would increase at ELT and decrease by up to 1% at LLT as compared to exports under Existing Conditions reflecting changes in operations due to less negative OMR flows, implementation of Fall X2 and/or spring outflow under Alternative 2D, and sea level rise and climate change.

The incremental change in Delta exports under Alternative 2D as compared to No Action Alternative would be caused by the facility and operations assumptions of Alternative 2D. Delta exports would increase in wetter years and remain similar or decrease in the drier years under Alternative 2D as compared to the conditions without the project.

Change in SWP and CVP Deliveries

Impact WS-1: Changes in SWP CVP Water Deliveries during Construction

NEPA Effects: During construction of water conveyance facilities associated with Alternative 2D, operation of existing SWP and CVP water conveyance would continue. Construction would not affect the timing or amount of water exported from the Delta through SWP and CVP facilities.

***CEQA Conclusion*:** Constructing Alternative 2D water conveyance facilities would not impact operation of existing SWP or CVP facilities.

Impact WS-2: Change in SWP and CVP Deliveries

The addition of the north Delta intakes under Alternative 2D provides operational flexibility compared to deliveries under Existing Conditions and the No Action Alternative.

Changes in SWP and CVP Deliveries under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-4 and B.1-5 in Appendix B and Figures 4.4.1-22 through 4.4.1-28.

Changes in SWP and CVP Deliveries under Alternative 2D (LLT) [similar to Alternative 2A (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables 5-7 through 5-9 of Draft EIR/EIS.

Results for SWP and CVP deliveries under Alternative 2D (LLT), which are similar to Alternative 2A (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS.

Total CVP Deliveries

Under Alternative 2D, average annual total CVP deliveries as compared to No Action Alternative, would increase by up to 3% at ELT and by up to 2% at LLT. Under Alternative 2D, average annual total south of Delta CVP deliveries as compared to No Action Alternative, would increase by up to 5%.

Under Alternative 2D, average annual total CVP deliveries as compared to Existing Conditions, would increase by up to 2% at ELT and decrease by up to 1% at LLT. Under Alternative 2D, average annual total south of Delta CVP deliveries as compared to Existing Conditions, would decrease by up to 2% at ELT and by up to 6% at LLT.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change. Therefore, average annual total CVP deliveries and average annual total CVP south of Delta deliveries would increase under Alternative 2D scenarios as compared to the conditions without the project.

CVP North of Delta Agricultural Deliveries

Under Alternative 2D, average annual CVP north of Delta agricultural deliveries would increase by up to 4% at ELT and by up to 2% at LLT as compared to No Action Alternative.

Under Alternative 2D, average annual CVP north of Delta agricultural deliveries as compared to Existing Conditions, would decrease by up to 17% at ELT and by up to 30% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP north of Delta agricultural deliveries as compared to No Action Alternative would generally increase. Therefore, average annual CVP north of Delta agricultural deliveries would generally increase under Alternative 2D as compared to the conditions without the project.

CVP South of Delta Agricultural Deliveries

Under Alternative 2D, average annual CVP south of Delta agricultural deliveries as compared to No Action Alternative would increase by up to 13% at ELT and by up to 14% at LLT.

Under Alternative 2D, average annual CVP south of Delta agricultural deliveries as compared to Existing Conditions would decrease by up to 1% at ELT and 14% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP south of Delta agricultural deliveries as compared to No Action Alternative would generally increase. Therefore, average annual CVP south of Delta agricultural deliveries would increase under Alternative 2D as compared to the conditions without the project.

CVP Settlement and Exchange Contract Deliveries

There would be negligible change to CVP Settlement Contract deliveries during dry and critical years under Alternative 2D as compared to deliveries under the No Action Alternative.

There would be negligible change to CVP Settlement Contract deliveries during dry and critical years under Alternative 2D at ELT as compared to deliveries under the Existing Conditions. Under Alternative 2D at LLT, CVP Settlement Contract deliveries during dry and critical years as compared to Existing Conditions would decrease. This is due to Shasta Lake storage declining to dead pool more frequently, as described previously, under increased north-of Delta demands and climate change and sea level rise conditions. As described in the methods section of Chapter 5, *Water Supply*, in the Draft EIR/EIS, model results and potential changes under these extreme reservoir storage conditions may not be representative of actual future conditions because changes in assumed operations may be implemented to avoid these conditions.

There would be no changes in deliveries to CVP Exchange Contractors under Alternative 2D.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that CVP Settlement Contract and CVP Exchange Contractors deliveries during dry and critical years would remain similar. Therefore, CVP Settlement Contract and CVP Exchange Contractors deliveries during dry and critical years under Alternative 2D would be similar to the deliveries under the conditions without the project.

CVP North of Delta Municipal and Industrial Deliveries

Under Alternative 2D, average CVP north of Delta M&I deliveries as compared to No Action Alternative would remain similar of result in minor increase.

Under Alternative 2D, average annual CVP north of Delta M&I deliveries as compared to Existing Conditions would increase by up to 88% at ELT and 82% at LLT. However, this increase primarily would occur because there would be an increase in north of Delta M&I water rights demands under Alternative 2D and No Action Alternative as compared to demands under Existing Conditions.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP north of Delta M&I deliveries would remain similar or show minor increase under Alternative 2D as compared to the deliveries under the No Action Alternative. Therefore, average annual CVP north of Delta M&I deliveries would remain similar or increase under Alternative 2D as compared to the conditions without the project.

CVP South of Delta Municipal and Industrial Deliveries

Under Alternative 2D, average CVP south of Delta M&I deliveries as compared to No Action Alternative, would increase by about 4%.

Under Alternative 2D, average annual CVP south of Delta M&I deliveries as compared to Existing Conditions would decrease by up to 1% at ELT and by up to 7% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP south of Delta M&I deliveries would remain similar or increase under Alternative 2D as compared to the deliveries under the No Action Alternative. Therefore, average annual CVP south of Delta M&I deliveries would increase under Alternative 2D as compared to the conditions without the project.

Total SWP Deliveries

Under Alternative 2D, average annual total SWP deliveries as compared to No Action Alternative, would increase (by about 15%). Under Alternative 2D, average annual total south of Delta SWP deliveries as compared to No Action Alternative, would increase (by about 21%).

Under Alternative 2D, average annual total SWP deliveries as compared to Existing Conditions, would increase (8%) at ELT and increase (3%) at LLT. Under Alternative 2D, average annual total south of Delta SWP deliveries as compared to Existing Conditions, would increase (11%) at ELT and would increase (5%) at LLT. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that under Alternative 2D average annual total SWP deliveries would increase. Therefore, average annual total SWP deliveries and average annual total SWP south of Delta deliveries under Alternative 2D would show an increase as compared to the conditions without the project.

SWP Table A Deliveries

Under Alternative 2D, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to No Action Alternative (ELT), would increase (by about 16%). Under Alternative 2D, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to No Action Alternative (ELT), would increase (by about 16%).

Under Alternative 2D, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would increase (11%) at ELT and would increase (5%) at LLT. Under Alternative 2D, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would increase (10%) at ELT and would increase (4%) at LLT. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

Deliveries under the No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that under Alternative 2D average annual total SWP Table A deliveries with Article 56 (without Article 21) would increase.

SWP Article 21 Deliveries

Under Alternative 2D, average annual total SWP Article 21 deliveries as compared to No Action Alternative, would increase by about 231%.

Under Alternative 2D, average annual total SWP Article 21 deliveries as compared to Existing Conditions, would increase by up to 10% at ELT and by up to 1% at LLT. However, this decrease primarily would occur due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual Article 21 deliveries would increase under Alternative 2D as compared to the deliveries under the No Action Alternative. Therefore, average annual Article 21 deliveries would increase under Alternative 2D as compared to the conditions without the project.

SWP Feather River Service Area

Under Alternative 2D, average annual total SWP Feather River Service Area deliveries during dry and critical years as compared to No Action Alternative would increase or remain similar.

Under Alternative 2D, average annual total SWP Feather River Service Area deliveries during dry and critical years as compared to Existing Conditions, would decrease by up to 4% at ELT and by up to 5% at LLT. The primary cause of this reduction would be change in SWP operations due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 2D in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual SWP Feather River Service Area deliveries would increase or remain similar under Alternative 2D as compared to the deliveries under No Action Alternative. Therefore, average annual SWP Feather River Service Area deliveries would remain similar under Alternative 2D as compared to the conditions without the project.

NEPA Effects: SWP and CVP deliveries under Alternative 2D as compared to deliveries under No Action Alternative would increase or remain similar. Indirect effects of changes in water deliveries in addition to potential effects on urban areas caused by changes in SWP and CVP water supply deliveries under Alternative 2D, are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects,* and other sections addressing specific resources.

CEQA Conclusion: SWP and CVP deliveries under Alternative 2D would decline as compared to deliveries under Existing Conditions. The primary cause of the reduction is increased north of Delta water demands that would occur under No Action Alternative and Alternative 2D and changes in SWP and CVP operations due to sea level rise and climate change. As shown above in the NEPA analysis, SWP and CVP deliveries would generally increase or remain similar under Alternative 2D as compared to deliveries under conditions in 2025 and 2060 without Alternative 2D if sea level rise and climate change conditions are considered the same under both scenarios (Alternative 2D and No Action Alternative). SWP and CVP deliveries under Alternative 2D would generally increase or remain similar as compared to deliveries under Existing Conditions without the effects of increased north of Delta water demands, sea level rise, and climate change. Some reductions in the SWP south of Delta deliveries could occur under Alternative 2D with higher spring outflow requirements. Indirect effects of changes in water deliveries including potential effects on urban areas caused by changes in SWP and CVP water supply deliveries are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects,* and other sections addressing specific resources.

Impact WS-3: Effects of Water Transfers on Water Supply

Alternative 2D increases project water supply allocations as compared to the No Action Alternative, and consequently will decrease cross-Delta water transfer demand compared to the No Action Alternative. Alternative 2D would change the combined SWP Table A and CVP south-of-Delta agricultural water supply allocations as compared to Existing Conditions, and the frequency of years in which cross-Delta transfers are assumed to be triggered would change as well, assuming an estimated cross-Delta transfer supply of 600,000 acre-feet in any one year.

Under Alternative 2D as compared to Existing Conditions, the frequency of years in which cross-Delta transfers would increase, and the average annual volume of those transfers would increase. Under Alternative 2D as compared to the No Action Alternative, the frequency of years in which cross-Delta transfers would occur would decrease.

Alternative 2D provides a separate cross-Delta facility with additional capacity to move transfer water from areas upstream of the Delta to export service areas and provides a longer transfer window than allowed under current regulatory constraints. In addition, the facility provides conveyance that would not be restricted by Delta reverse flow concerns or south Delta water level concerns. As a result of avoiding those restrictions, transfer water could be moved at any time of the year that capacity exists in the combined cross-Delta channels, the new cross-Delta facility, and the export pumps, depending on operational and regulatory constraints, including criteria guiding the operation of water conveyance facilities under Alternative 2D.

NEPA Effects: Alternative 2D would decrease water transfer demand compared to existing conditions. Alternative 2D would decrease conveyance capacity, enabling additional cross-Delta water transfers that could lead to increases in Delta exports when compared to No Action Alternative. Prior to approval, each transfer must go through NEPA review and be evaluated by the export facility agency, and may also be subject to CEQA review and/or SWRCB process. Indirect effects of changes in Delta exports or water deliveries are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, and other sections addressing specific resources.

CEQA Conclusion: Alternative 2D would increase water transfer demand compared to existing conditions. Alternative 2D would increase conveyance capacity, enabling additional cross-Delta water transfers that could lead to increases in Delta exports when compared to existing conditions. Prior to approval, each transfer must go through the CEQA and/or SWRCB process and be evaluated by the export facility agency, and may also be subject to NEPA review. Indirect effects of changes in Delta exports or water deliveries are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, and other sections addressing specific resources.

4.4.2 Surface Water

Facilities construction under Alternative 2D would be identical to those described under Alternative 4. Except this alternative would include two additional intakes. Alternative 2D water conveyance operations would be similar to the operations that would occur under Alternative 2A.

Model simulation results for Alternative 2D Early Long-term (ELT), which are represented by Alternative 2A (ELT), are summarized in Tables B.2-7 through B.2-12 in Appendix B of the RDEIR/SDEIS. Model simulation results for Alternative 2D at Late Long-term (LLT) which are similar to Alternative 2A (LLT), are summarized in Tables 6-2 through 6-9 in the Draft EIR/EIS.

Section 6.3.2, *Determination of Effects*, of Draft EIR/EIS describes criteria used for the NEPA adverse effect and CEQA significant impact determinations.

SWP CVP Reservoir Storage and Related Changes to Flood Potential

Impact SW-1: Changes in SWP or CVP Reservoir Flood Storage Capacity

Reservoir storage in Shasta Lake, Folsom Lake, and Lake Oroville during the October through June period is compared to the flood storage capacity of each reservoir to identify the number of months where the reservoir storage is close to the flood storage capacity.

Changes in the number of months where the reservoir storage is close to the flood storage capacity under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-7 through B.2-12 in Appendix B of this RDEIR/SDEIS.

Changes in the number of months where the reservoir storage is close to the flood storage capacity under Alternative 2D (LLT) [similar to Alternative 2A (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Tables 6-2 through 6-7 of Draft EIR/EIS.

NEPA Effects: Under Alternative 2D, the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be similar (or show no more than 10% increase) under the No Action Alternative.

A comparison with storage conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that reservoir storages would not be consistently high during October through June under Alternative 2D as compared to the conditions under the No Action Alternative. Therefore, Alternative 2D would not result in adverse effects on reservoir flood storage capacity as compared to the conditions without the project.

CEQA Conclusion: Under Alternative 2D, the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be less than under Existing Conditions. These differences represent changes under Alternative 2D, increased demands from Existing Conditions to No Action Alternative, and changes due to sea level rise and climate change. Alternative 2D would not cause consistently higher storages in the upper Sacramento River watershed during the October through June period. Accordingly, Alternative 2D would result in a less-than-significant impact on flood management. No mitigation is required.

Highest Monthly Flows in Sacramento and San Joaquin Rivers and Related Changes to Flood Potential

Impact SW-2: Changes in Sacramento and San Joaquin River Flood Flows

Changes in highest monthly flows under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-7 through B.2-9 in Appendix B and Figures 4.4.2-1 through 4.4.2-15 of this RDEIR/SDEIS.

Changes in highest monthly flows under Alternative 2D (LLT) [similar to Alternative 2A (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 6-8 through 6-22 and Tables 6-2 through 6-4 of the Draft EIR/EIS.

Sacramento River at Bend Bridge

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would increase by about 2% of the channel capacity (100,000 cfs) as compared to the flows under Existing Conditions. The increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the Sacramento River at Bend Bridge as compared to the conditions without the project.

Sacramento River at Freeport

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would decrease by about 1% of the channel capacity (110,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the Sacramento River at Freeport as compared to the conditions without the project.

San Joaquin River at Vernalis

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar to (or show less than 1% change with respect to the channel capacity: 52,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar (or show less than 1% change with respect to the channel capacity: 52,000 cfs) as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the San Joaquin River at Vernalis as compared to the conditions without the project.

Sacramento River at Location Upstream of Walnut Grove (downstream of north Delta intakes)

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would decrease by about 12% of channel capacity (110,000 cfs) as compared to the flows under the No Action Alternative. This decrease primarily would occur due to the diversion of Sacramento River flow at the north Delta intakes under Alternative 2D.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would decrease by about 12% of channel capacity (110,000 cfs) as compared to the flows under Existing Conditions. This decrease primarily would occur due to the diversion of Sacramento River flow at the north Delta intakes under Alternative 2D.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the Sacramento River upstream of Walnut Grove as compared to the conditions without the project.

Trinity River Downstream of Lewiston Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would increase by about 4% of channel capacity (6,000 cfs) as compared to the flows under Existing Conditions. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the Trinity River downstream of Lewiston Lake as compared to the conditions without the project.

American River Downstream of Nimbus Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar to (or show less than 1% change with respect to the channel capacity: 152,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would increase by no more than approximately 1% of the channel capacity (152,000 cfs) as compared to the flows under Existing Conditions. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the American River at Nimbus Dam as compared to the conditions without the project.

Feather River Downstream of Thermalito Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would remain similar as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would increase by about 1% of channel capacity (210,000 cfs) or remain similar as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the Feather River at Thermalito Dam as compared to the conditions without the project.

Yolo Bypass at Fremont Weir

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D would increase no more than approximately 1% of the channel capacity (343,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 2D at ELT would increase no more than 1% of the channel capacity (343,000 cfs) and at LLT would increase no more than 2% of the channel capacity (343,000 cfs) as compared to the flows under the Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 2D as compared to the No Action Alternative. Therefore, Alternative 2D would not result in adverse impacts on flow conditions in the Yolo Bypass at Fremont Weir as compared to the conditions without the project.

NEPA Effects: Overall, Alternative 2D would not result in an increase in potential risk for flood management compared to the No Action Alternative. Highest monthly flows under Alternative 2D in the locations considered in this analysis either were similar to or less than the highest monthly flows that would occur under the No Action Alternative; or the increase in highest monthly flows would be less than the flood capacity for the channels at these locations.

Therefore, Alternative 2D would not result in adverse effects on flood management.

***CEQA Conclusion*:** Alternative 2D would not result in an increase in potential risk for flood management compared to Existing Conditions when the changes due to sea level rise and climate change are eliminated from the analysis. Highest monthly flows under Alternative 2D in the locations considered in this analysis either were similar to or less than those that would occur under Existing Conditions without the changes in sea level rise and climate change; or the increased highest monthly flows would not exceed the flood capacity of the channels at these locations. Accordingly, Alternative 2D would result in a less-than-significant impact on flood management. No mitigation is required.

Reverse Flows in Old and Middle River

Impact SW-3: Change in Reverse Flow Conditions in Old and Middle Rivers

Changes in average monthly reverse flow conditions for Old and Middle River flows under Alternative 2D (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-7 through B.2-9 in Appendix B and Figure 4.3.2-16 in this RDEIS/SDEIS.

Changes in average monthly reverse flow conditions for Old and Middle River flows under Alternative 2D (LLT) [similar to Alternative 2A (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figure 6-23 and Tables 6-2 through 6-4 of Draft EIR/EIS.

Reverse flow conditions for Old and Middle River flows would be reduced in all months under Alternative 2D on a long-term average basis except in April, compared to reverse flows under both Existing Conditions and the No Action Alternative. Compared to flows under the No Action Alternative, Old and Middle River flows would be generally less positive in April.

NEPA Effects: A comparison with reverse flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 2D without the effects of sea level rise and climate change. The results show that reverse flow conditions under Alternative 2D would be reduced in all months on a long-term average basis except in April as compared to No Action Alternative. In April the reverse flow conditions would be generally greater than 1% under Alternative 2D as compared to No Action Alternative. The effects to beneficial use of the surface water for water supplies and aquatic resources, is described in Section 4.3.4, *Water Quality* and Section 4.3.7, *Fish and Aquatic Resources*.

***CEQA Conclusion*:** Alternative 2D would provide positive changes related to reducing reverse flows in Old and Middle Rivers in May through March and negative changes in the form of increased reverse flow conditions in April, compared to Existing Conditions. The increase (more negative) in reverse flow conditions is generally greater than 1% as compared to Existing Conditions. The significance of the impact to beneficial use of the surface water for water supplies and aquatic resources, and appropriate Mitigation Measures for those impacts to beneficial uses is described in Section 4.3.4, *Water Quality* and Section 4.3.7, *Fish and Aquatic Resources*.

Impact SW-4: Substantially Alter the Existing Drainage Pattern or Substantially Increase the Rate or Amount of Surface Runoff in a Manner That Would Result in Flooding during Construction of Conveyance Facilities

NEPA Effects: Effects associated with construction and operations of facilities under Alternative 2D would be similar to those described under Alternative 1A with the exception of elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 2D as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. However, the measures included in Alternative 1A to avoid adverse effects would be included in Alternative 2D.

Alternative 2D would involve excavation, grading, stockpiling, soil compaction, and dewatering that would result in temporary and long-term changes to drainage patterns, drainage paths, and facilities that would in turn, cause changes in drainage flow rates, directions, and velocities. Construction of cofferdams could impede river flows at the intake locations, but would not increase water surface elevations upstream by more than 0.10 feet during flood events. Potential adverse effects could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages; and changes in sediment accumulation near the intakes. Mitigation Measure SW-4 is available to address effects of runoff and sedimentation.

***CEQA Conclusion*:** Alternative 2D could result in alterations to drainage patterns, stream courses, and runoff; and potential for slightly increased surface water elevations in the rivers and streams during construction and operations of facilities located within the waterway. Although intakes have been designed and located on-bank to minimize changes to river flow characteristics, some localized water elevation changes would occur upstream and adjacent to each cofferdam at the intake sites due to facility location within the river. These localized surface elevation changes would not exceed an increase of 0.10 feet at any intake location even under flood flow conditions. Potential impacts could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages, and from changes in sediment accumulation near the intakes. These impacts are considered significant. Mitigation Measure SW-4 would reduce this impact to a less-than-significant level

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A

Impact SW-5: Substantially Alter the Existing Drainage Pattern or Substantially Increase the Rate or Amount of Surface Runoff in a Manner That Would Result in Flooding during Construction of Habitat Restoration Area Facilities under Environmental Commitments 3, 4, and 6–11

NEPA Effects: Alternative 2D would include construction of the restoration area facilities under Environmental Commitments 3, 4, 6, 7, 8, 9, 10, and 11.

Riparian habitat restoration is anticipated to occur primarily in association with the restoration of tidal marsh habitat, and channel margin habitat. The restored vegetation has the potential of increasing channel roughness, which could result in increases in channel water surface elevations, including under flood flow conditions, and in decreased velocities. Modified channel geometries could increase or decrease channel velocities and/or channel water surface elevations, including under flood flow conditions. Under existing regulations, the USACE, CVFPB, and DWR would require the habitat restoration projects to be flood neutral. The specific permits/decisions/approvals required are included in Table 1-1 of this RDEIR/SDEIS, and in Table 1-2 of the Draft EIR/EIS. Measures to reduce flood potential could include channel dredging to increase channel capacities and decrease channel velocities and/or water surface elevations.

CEQA Conclusion**:** Alternative 2D would include construction of the restoration area facilities under Environmental Commitments 3, 4, and 6–11. Alternative 2D could result in alterations to drainage patterns, stream courses, and runoff; and potential for increased surface water elevations in the rivers and streams during construction and operations of facilities located within the waterway. These impacts are considered significant. Under existing regulations, the USACE, CVFPB, and DWR would require the habitat restoration projects to be flood neutral. The specific permits/decisions/ approvals required are included in Table 1-1 of this RDEIR/SDEIS, and in Table 1-2 of the Draft EIR/EIS. Measures to reduce flood potential could include channel dredging to increase channel capacities and decrease channel velocities and/or water surface elevations. Mitigation Measure SW-4 would reduce this impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A

Impact SW-6: Create or Contribute Runoff Water Which Would Exceed the Capacity of Existing or Planned Stormwater Drainage Systems or Provide Substantial Additional Sources of Polluted Runoff

Effects associated with construction and operations of facilities under Alternative 2D would be similar to those described under Alternative 1A with the exception of elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 2D as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A.

NEPA Effects: Paving, soil compaction, and other activities would increase runoff during facilities construction and operations. Construction and operation of dewatering facilities and associated discharge of water would result in localized increases in flows and water surface elevations in receiving channels. These activities could result in adverse effects if the runoff volume exceeds the capacities of local drainages. As noted below in the CEQA Conclusion section, compliance with permit design requirements would avoid adverse effects on surface water quality and flows from dewatering activities. The use of dispersion facilities would reduce the potential for channel erosion. Mitigation Measure SW-4 is available to address adverse effects.

CEQA Conclusion**:** Alternative 2D actions would include installation of dewatering facilities in accordance with permits issued by the Regional Water Quality Control Board and CVFPB (See Section 6.2.2.4 of the Draft EIR/EIS). Alternative 2D would include provisions to design the dewatering system in accordance with these permits to avoid significant impacts on surface water quality and flows. However, increased runoff could occur from facilities sites during construction or operations and could result in significant impacts if the runoff volume exceeds the capacities of local drainages. These impacts are considered significant. Mitigation Measure SW-4 would reduce this potential impact to a less-than-significant level.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A

Impact SW-7: Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding Due to the Construction of New Conveyance Facilities

NEPA Effects: Effects associated with construction of conveyance facilities under Alternative 2D would be identical to those described under Alternative 1A with the exception of elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 2D as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. However, the measures included in Alternative 1A to avoid adverse effects would be included in Alternative 2D.

Alternative 2D would not result in an increase to exposure of people or structures to flooding due to construction of the conveyance facilities because the project proponents would be required to comply with USACE CVFPB, and DWR requirements to avoid increased flood potential and levee failure due to construction and operation of the facilities as described in Section 6.2.2.4 of the Draft EIR/EIS. Additionally, DWR would consult with local reclamation districts to ensure that construction activities would not conflict with reclamation district flood protection measures. Determination of design flood elevations would need to consider sea level rise to reduce impacts.

***CEQA Conclusion*:** Alternative 2D would not result in an increase to exposure of people or structures to flooding due to construction of the conveyance facilities because the project proponents would be required to comply with the requirements of USACE, CVFPB, and DWR to avoid increased flood potential and levee failure due to construction and operation of the facilities as described in Section 6.2.2.4 of the Draft EIR/EIS. If the design flood elevations did not consider sea level rise to reduce impacts, these impacts are considered significant. Mitigation Measure SW-7 would reduce this impact to a less-than-significant level.

Mitigation Measure SW-7: Implement Measures to Reduce Flood Damage

Please see Mitigation Measure SW-7 under Impact SW-7 in the discussion of Alternative 1A

Impact SW-8: Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding Due to Habitat Restoration under Environmental Commitments 3, 4, and 6–11

Tidal marsh habitat, and channel margin habitat could increase flood potential due to impacts on adjacent levees. The newly flooded areas would have larger wind fetch lengths (unobstructed distance which wind can travel over water and potentially develop large waves caused by wind force not tidal force) compared to the existing fetch lengths of the adjacent leveed channels. An increase in fetch length would result in increases in wave height and velocities that reach the existing levees along adjacent islands and floodplains. These potential increases in wave action could also reach the land-side of the remaining existing levees around the restoration area. In accordance with existing requirements of the USACE, CVFPB, and DWR, Alternative 2D would be designed to avoid increased flood potential as compared to Existing Conditions or No Action Alternative.

NEPA Effects: Alternative 2D would not result in an increase to exposure of people or structures to flooding due to the operation of the Environmental Commitments because the facilities would be required to comply with the requirements of the USACE, CVFPB, and DWR to avoid increased flood potential. However, increased wind fetch near open water areas of habitat restoration could cause potential damage to adjacent levees, which would be considered an adverse effect. This impact could become more substantial with sea level rise and climate change. Mitigation Measure SW-8 would reduce this potential adverse effect.

***CEQA Conclusion*:** Alternative 2D would not result in an increase to exposure of people or structures to flooding due to the construction or operations of Environmental Commitments because the facilities would be required to comply with the requirements of the USACE, CVFPB, and DWR to avoid increased flood potential. However, increased wind fetch near open water areas of habitat restoration could cause potential damage to adjacent levees. These impacts are considered significant. Mitigation Measure SW-8 would reduce this potential impact to a level of less than significant.

Mitigation Measure SW-8: Implement Measures to Address Potential Wind Fetch Issues

Please see Mitigation Measure SW-8 under Impact SW-8 in the discussion of Alternative 1A

Impact SW-9: Place within a 100-Year Flood Hazard Area Structures Which Would Impede or Redirect Flood Flows, or Be Subject to Inundation by Mudflow

Effects associated with construction and operations of facilities under Alternative 2D would be identical those described under Alternative 1A with the exception of elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 2D as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. The measures included in Alternative 1A to avoid adverse effects would be included in Alternative 2D. As described under Impact SW-1, Alternative 2D would not increase flood potential on the Sacramento River, San Joaquin River, Trinity River, American River, or Feather River, or Yolo Bypass as described under Impact SW-2. Alternative 2D would include measures, including Mitigation Measure SW-4, to address potential issues associated with alterations to drainage patterns, stream courses, and runoff and potential for increased surface water elevations in the rivers and streams during construction and operations of facilities.

NEPA Effects: Potential adverse effects could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages; and changes in sediment accumulation near the intakes. These effects are considered adverse. Mitigation Measure SW-4 is available to address these potential effects.

***CEQA Conclusion*:** Alternative 2D would not result in an impedance or redirection of flood flows or conditions that would cause inundation by mudflow due to construction or operations of the conveyance facilities or construction of the Environmental Commitments because the project proponents would be required to comply with the requirements of USACE CVFPB, and DWR to avoid increased flood potential as described in Section 6.2.2.4 of the Draft EIR/EIS. Potential adverse impacts could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages, as well as changes in sediment accumulation near the intakes. These impacts are considered significant. Mitigation Measure SW-4 would reduce this potential impact to a less-than-significant level.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

4.4.3 Groundwater

4.4.3.1 Delta Region

Alternative 2D would include the same physical/structural components as Alternative 4 but would include two additional intakes. Facilities construction under Alternative 2D would be similar to those described for Alternative 4, but with a larger footprint due to two additional intakes.

Impact GW-1: During Construction, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Local Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

Construction activities under Alternative 2D would be similar to those under Alternative 4. The impacts on groundwater levels resulting from dewatering activities are dependent on the local hydrogeology and the depth and duration of dewatering required. Because all of the pump stations associated with the intakes are located in areas of similar geology and hydrogeology, and the dewatering configurations are identical for each of the facilities, it would be expected that the impacts of construction activities on local groundwater levels and associated well yields would be similar. The only difference would be associated with the number of intakes used. This alternative would use five intakes instead of only three intakes used in Alternative 4. Dewatering activities would result in increased groundwater level impacts and potentially more wells being affected.

NEPA Effects: Similarly to the impacts described under Alternative 4, the sustainable yield of some wells might temporarily be affected by the lower water levels resulting from construction dewatering under Alternative 2D, such that they are not able to support existing land uses. The construction of conveyance features would result in effects on groundwater levels and associated well yields that would be temporary. These effects are considered adverse. It should be noted that these estimated impacts reflect a worst-case scenario as the option of installing seepage cutoff walls during dewatering was not considered in the analysis.

CEQA Conclusion: Similarly to the impacts described under Alternative 4, wells in the vicinity of the construction dewatering areas under Alternative 2D could experience significant reductions in yield, if they are shallow wells and may not be able to support existing land uses. The temporary impact on groundwater levels and associated well yields is considered significant because construction-related dewatering might affect the amount of water supplied by shallow wells located near the construction sites. Mitigation Measure GW-1 identifies a monitoring procedure and options for maintaining an adequate water supply for land owners that experience a reduction in groundwater production from wells within the impacted areas due to construction-related dewatering activities. It should be noted that these estimated impacts reflect a worst-case scenario as the option of installing seepage cutoff walls during dewatering was not considered in the analysis. Implementing Mitigation Measure GW-1 would help address these effects; however, the impact may remain significant because replacement water supplies may not meet the preexisting demands or planned land use demands of the affected party. In some cases this impact might temporarily be significant and unavoidable until groundwater elevations recover to pre-construction conditions which could require several months after dewatering operations cease.

Mitigation Measure GW-1: Maintain Water Supplies in Areas Affected by Construction Dewatering

Please see Mitigation Measure GW-1 under Impact GW-1 in the discussion of Alternative 1A.

Impact GW-2: During Operations, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Local Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

See Impact GW-2 under Alternative 4; operations under Alternative 2D would be similar to those under Alternative 4.

NEPA Effects: The new Intermediate Forebay and the expanded Clifton Court Forebay would be constructed to comply with the requirements of the DSD which include design features intended to minimize seepage under the embankments. In addition, the forebays will include a seepage cutoff wall installed to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. Any potential vertical seepage under the smaller Intermediate Forebay would also be captured by the toe drain. However, operation of Alternative 2D would result in groundwater level increases in the vicinity of the expanded Clifton Court Forebay portion at Byron Tract due to groundwater recharge, similar to Alternative 4.

Operation of the tunnel would have no impact on existing wells or yields given the facilities would be located more than 100 feet underground and would not substantially alter groundwater levels in the vicinity.

CEQA Conclusion: The new Intermediate Forebay and the expanded Clifton Court Forebay will include design features intended to minimize seepage under the embankments and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. Any potential vertical seepage under the smaller Intermediate Forebay would also be captured by the toe drain. However, operation of Alternative 2D would result in groundwater level increases in the vicinity of the expanded Clifton Court Forebay portion at Byron Tract due to groundwater recharge, similar to Alternative 4, which would not reduce the yields of nearby wells.

Operation of the tunnel would have no impact on existing wells or yields given these facilities would be located over 100 feet underground and would not substantially alter groundwater levels in the vicinity.

Therefore, this impact would be less than significant. No mitigation is required.

Impact GW-3: Degrade Groundwater Quality during Construction and Operation of Conveyance Facilities

See Impact GW-3 under Alternative 4; the construction and operations activities under Alternative 2D would be similar to those under Alternative 4, with potentially a higher magnitude, because five intakes would be constructed (instead of three).

NEPA Effects: Dewatering would temporarily lower groundwater levels and cause small changes in groundwater flow patterns near the intake pump stations along the Sacramento River, Intermediate Forebay, and Clifton Court Forebay. Since no significant regional changes in groundwater flow directions are anticipated, and the inducement of poor-quality groundwater into areas of better quality is unlikely, it is anticipated that there would be no change in groundwater quality for

Alternative 2D. Further, the planned treatment of extracted groundwater prior to discharge into adjacent surface waters would prevent significant impacts on groundwater quality. There would be no adverse effect.

CEQA Conclusion: No significant groundwater quality impacts are anticipated during construction activities. Because of the temporary and localized nature of construction dewatering, the potential for the inducement of the migration of poor-quality groundwater into areas of higher quality groundwater will be low. Further, the planned treatment of extracted groundwater prior to discharge into adjacent surface waters would prevent significant impacts on groundwater quality.

No significant groundwater quality impacts are anticipated in most areas of the Delta during the implementation of Alternative 2D, because changes to regional patterns of groundwater flow are not anticipated. However, degradation of groundwater quality near the Suisun Marsh area are likely, due to the effects of saline water intrusion caused by slightly rising sea levels. Effects due to climate change are provided for informational purposes only and do not lead to mitigation. This impact would be less than significant. No mitigation is required.

Impact GW-4: During Construction of Conveyance Facilities, Interfere with Agricultural Drainage in the Delta

See Impact GW-4 under Alternative 4; construction activities under Alternative 2D would be similar to those under Alternative 4, with a higher magnitude, because five intakes would be constructed (instead of three).

NEPA Effects: In the absence of seepage cutoff walls intended to minimize local changes to groundwater flow, the lowering of groundwater levels due to construction dewatering would temporarily affect localized shallow groundwater flow patterns during and immediately after the construction dewatering period. For the Byron Tract Forebay site, only a portion of the shallow groundwater flow will be directed inward toward the dewatering operations. Forecasted temporary changes in shallow groundwater flow directions and areas of impacts are minor near the intakes. Therefore, agricultural drainage during construction of conveyance features is not forecasted to result in adverse effects under Alternative 2D. In some instances, the lowering of groundwater levels in areas that experience near-surface water level conditions (or near-saturated root zones) would be beneficial. There would be no adverse effect.

CEQA Conclusion: The forecasted changes in shallow groundwater flow patterns due to construction dewatering activities in the Delta are localized and temporary and are not anticipated to cause significant impacts on agricultural drainage. This impact would be less than significant. No mitigation is required.

Impact GW-5: During Operations of New Facilities, Interfere with Agricultural Drainage in the Delta

See Impact GW-5 under Alternative 4; operations under Alternative 2D would be similar to those under Alternative 4.

NEPA Effects: The Intermediate Forebay and the expanded Clifton Court Forebay will include a seepage cutoff wall to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. These design measures will greatly reduce any potential for seepage onto adjacent lands and avoid interference with agricultural drainage in the vicinity of the Intermediate Forebay. Once constructed, the operation of the forebay would be monitored to ensure seepage does not exceed performance requirements.

However, operation of Alternative 2D would result in local changes in shallow groundwater flow patterns adjacent to the expanded Clifton Court Forebay portion at Byron Tract, where groundwater recharge from surface water would result in groundwater level increases, similar to Alternative 4. If existing agricultural drainage systems adjacent to the forebay are not adequate to accommodate the additional drainage requirements, operation of the forebay could interfere with agricultural drainage in the Delta.

CEQA Conclusion: The Intermediate Forebay and the expanded Clifton Court Forebay will include a seepage cutoff wall to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. These design measures will greatly reduce any potential for seepage onto adjacent lands and avoid interference with agricultural drainage in the vicinity of the Intermediate Forebay. Once constructed, the operation of the forebay would be monitored to ensure seepage does not exceed performance requirements.

However, operation of Alternative 2D would result in local changes in shallow groundwater flow patterns adjacent to the expanded Clifton Court Forebay portion at Byron Tract, caused by groundwater recharge from surface water, and could cause significant impacts to agricultural drainage where existing systems are not adequate to accommodate the additional drainage requirements, similar to Alternative 4. Implementation of Mitigation Measure GW-5 is anticipated to reduce this impact to a less-than-significant level in most instances, though in some instances mitigation may be infeasible due to factors such as costs that would be imprudent to bear in light of the fair market value of the affected land. The impact is therefore significant and unavoidable as applied to such latter properties.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A.

Impact GW-6: Deplete Groundwater Supplies or Interfere with Groundwater Recharge Alter Local Groundwater Levels Reduce the Production Capacity of Preexisting Nearby Wells, or Interfere with Agricultural Drainage as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: Implementation of the environmental commitments under Alternative 2D could result in additional increased frequency of inundation of areas associated with the proposed tidal habitat, channel margin habitat, and seasonally inundated floodplain restoration actions, which would result in increased groundwater recharge. Such increased recharge could result in groundwater level rises in some areas. More frequent inundation would also increase seepage, which is already difficult and expensive to control in most agricultural lands in the Delta (see Chapter 14, *Agricultural Resources*). Effects associated with the implementation of those environmental commitments be considered adverse. The implementation of Mitigation Measure GW-5 would help address these effects by identifying areas where seepage conditions have worsened and installing additional subsurface drainage measures, as needed.

CEQA Conclusion: Implementation of the environmental commitments under Alternative 2D could result in additional increased frequency of inundation of areas associated with the proposed tidal habitat, channel margin habitat, and seasonally inundated floodplain restoration actions, which would result in increased groundwater recharge. Such increased recharge could result in groundwater level rises in some areas. More frequent inundation would also increase seepage, which is already difficult and expensive to control in most agricultural lands in the Delta (see Chapter 14, *Agricultural Resources*). Impacts associated with the implementation of those environmental commitments would result in significant impacts. This impact would be reduced to a less-than-significant level in most instances, with the implementation of Mitigation Measure GW-5 by identifying areas where seepage conditions have worsened and installing additional subsurface drainage measures, as needed.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A.

Impact GW-7: Degrade Groundwater Quality as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: The increased inundation frequency in restoration areas from the environmental commitments under Alternative 2D would increase the localized areas exposed to saline and brackish surface water, which would result in increased groundwater salinity beneath such areas. The flooding of large areas with saline or brackish water would result in an adverse effect on groundwater quality beneath or adjacent to flooded areas. It would not be possible to completely avoid this effect. However, if water supply wells in the vicinity of these areas are not useable because of water quality issues, Mitigation Measure GW-7 would help reduce this impact, but the impact would remain significant and unavoidable.

CEQA Conclusion: The increased inundation frequency in restoration areas from the environmental commitments under Alternative 2D would increase the localized areas exposed to saline and brackish surface water, which would result in increased groundwater salinity beneath such areas. The flooding of large areas with saline or brackish water would result in significant impacts on groundwater quality beneath or adjacent to flooded areas. It would not be possible to completely avoid this effect. However, if water supply wells in the vicinity of these areas are not useable because of water quality issues, Mitigation Measure GW-7 is available to address this effect. Nonetheless, because it is not possible to completely avoid this impact, it is considered significant and unavoidable.

Mitigation Measure GW-7: Provide an Alternate Source of Water

Please see Mitigation Measure GW-7 under Impact GW-7 in the discussion of Alternative 1A.

4.4.3.2 SWP/CVP Export Service Areas

Impact GW-8: During Operations, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

The groundwater resource impacts of Alternative 2D will be similar to those under Alternative 2A, but with the magnitude of the impacts proportional to the change in the quantity of CVP and SWP surface water supplies delivered to the SWP/CVP Export Service Areas compared to the No Action Alternative at ELT.

Table 4.3.3-1 below shows the long-term average SWP and CVP deliveries for Alternative 2D compared to existing conditions and the No Action Alternative at early long-term. See Table 7-7 in Chapter 7, *Groundwater* of the Draft EIR/EIS for long-term average SWP and CVP surface water deliveries at LLT.

Table 4.3.3-1. Long-Term State Water Project and Central Valley Project Deliveries to Hydrologic Regions Located South of the Delta at Early Long-Term

	Long-Term Average State Water Project and Central Valley Project Deliveries at Early Long Term(TAF/year)		
Alternative	San Joaquin and Tulare Hydrologic Region	Central Coast Hydrologic Region	Southern California Hydrologic Region
Existing Conditions	2,964	47	1,647
No Action Alternative (ELT)	2,682	43	1,580
Alternative 2D ELT	3,025	51	1,813

NEPA Effects: In the San Joaquin and Tulare Hydrologic Region, total long-term average annual water deliveries to the CVP and SWP Service Areas under Alternative 2D at ELT are expected to be higher than the exports under the No Action Alternative at early long-term. Increases in surface water deliveries attributable to project operations from the implementation of Alternative 2D are anticipated to result in a corresponding decrease in groundwater use in the San Joaquin and Tulare Export Service Areas as compared to the No Action Alternative (ELT), as discussed in Section 4.2.4 of this RDEIR/SDEIS. Higher groundwater levels associated with reduced overall groundwater use would result in a beneficial effect on groundwater levels. Similarly, total long-term average annual water deliveries to the CVP and SWP Service Areas under Alternative 2D at LLT are expected to be higher than the exports under the No Action Alternative at late long-term.

The total long-term average annual SWP deliveries to Southern California areas under Alternative 2D would be greater than those under the No Action Alternative (ELT) as well as at LLT. Therefore, implementation of Alternative 2D would result in a corresponding decrease in groundwater use. There would be no adverse effects on groundwater levels because of the anticipated decreases in groundwater pumping due to an increase in surface water deliveries.

***CEQA Conclusion**:* For the San Joaquin and Tulare Service Areas, total long-term average surface water deliveries under Alternative 2D at ELT would be higher compared to Existing Conditions. Increases in surface water deliveries attributable to project operations from the implementation of Alternative 2D are anticipated to result in a corresponding decrease in groundwater use in the San Joaquin and Tulare Export Service Areas as compared to the Existing Conditions. Higher groundwater levels associated with reduced overall groundwater use would result in less-than-significant impacts on groundwater levels. Total long-term average surface water deliveries under Alternative 2D at LLT in the San Joaquin Valley and Tulare Basin would be lower compared to Existing Conditions, largely because of effects due to climate change, sea level rise, and increased water demand north of the Delta.

The total long-term average annual SWP deliveries to Southern California areas under Alternative 2D at ELT and at LLT would be greater than those under Existing Conditions. Therefore, implementation of Alternative 2D would result in a corresponding decrease in groundwater use.

Impacts on groundwater levels would be less than significant because of the anticipated decreases in groundwater pumping due to an increase in surface water deliveries.

Impact GW-9: Degrade Groundwater Quality

NEPA Effects: As discussed under Impact GW-8, surface water deliveries to the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin under Alternative 2D are expected to increase as compared to the No Action Alternative (ELT) and at LLT. Increased surface water deliveries could result in a decrease in groundwater use. The decreased groundwater use is not anticipated to alter regional patterns of groundwater flow in these service areas. Therefore, it is not anticipated this would result in an adverse effect on groundwater quality in these areas because similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater as might occur with increased pumping. Similarly, long-term average annual SWP supplies to Southern California are anticipated to increase under Alternative 2D compared to the No Action Alternative at ELT and at LLT, and therefore, groundwater pumping is anticipated to decrease, which would not alter regional groundwater flow patterns. As a result, adverse effects on groundwater quality are not anticipated in this region because similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater.

CEQA Conclusion: As discussed under Impact GW-8 above, the impacts of Alternative 2D with respect to groundwater levels are considered to be less than significant in the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin and in Southern California. Therefore, no significant groundwater quality impacts are anticipated in these areas during the implementation of Alternative 2D because it is not anticipated to alter regional groundwater flow patterns. Therefore, this impact is considered less than significant because groundwater levels and flow patterns would not change compared to Existing Conditions, and similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater.

Impact GW-10: Result in Groundwater Level–Induced Land Subsidence

Groundwater level-induced land subsidence has the highest potential to occur in the San Joaquin and Tulare Export Service Areas, based on historical data, if groundwater pumping substantially increases due to the Alternatives.

NEPA Effects: As discussed under Impact GW-8, surface water deliveries to the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin under Alternative 2D are expected to increase as compared to the No Action Alternative (ELT) as well as at LLT. Increased surface water deliveries could result in a decrease in groundwater pumping. The decreased groundwater pumping would result in higher groundwater levels, and therefore, the potential for groundwater level-induced land subsidence is reduced under Alternative 2D. Operations under Alternative 2D would not result in an adverse effect on the potential for groundwater level-induced land subsidence in these areas because groundwater levels would not decline such that compaction of unconsolidated materials in the unconfined aquifer would occur.

CEQA Conclusion: As discussed under Impact GW-8 above, the impacts of Alternative 2D with respect to groundwater levels are considered to be less than significant in the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin. Therefore, the potential for groundwater level-induced land subsidence is anticipated to be less than significant in these areas during the implementation of Alternative 2D because it is not anticipated to result in a decline in groundwater levels such that compaction of unconsolidated materials in the unconfined aquifer would occur.

4.4.4 Water Quality

The water quality changes described for Alternative 2D reflect assumed water conveyance facilities operations. The water quality changes described for Alternative 2D are also affected by assumptions regarding the extent of habitat restoration to be implemented. As described in Section 4.1.3 of this RDEIR/SDEIS, Alternative 2D does not include the full suite of conservation actions included in Alternative 4. Aside from the water conveyance facilities, the most important differences from a water quality perspective are:

- CM2 – Yolo Bypass Improvements: this is included in Alternative 4, but not included in Alternative 2D; and
- CM4 – Tidal Natural Communities Restoration: includes 65,000 acres in Alternative 4, but would be significantly less under Alternative 2D.

This results in somewhat different patterns of water withdrawals from the Delta, and potentially somewhat different effects on water quality and aquatic habitat conditions in the Plan Area than analyzed for Alternative 4. As described in Section 4.1.3, *Description of Alternative 2D*, of this RDEIR/SDEIS, actions associated with Alternative 4 that are not proposed to be implemented under Alternative 2D would continue to be pursued as part of existing, but separate, projects and programs associated with the 2008 USFWS and 2009 NMFS BiOps (e.g., 8,000 acres of tidal habitat restoration and Yolo Bypass improvements), California EcoRestore and the 2014 California Water Action Plan.

The analysis of boron, bromide, chloride, DOC, EC, and nitrate under Alternative 2D in the ELT is based on modeling conducted for Alternative 2 in the ELT, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. As described above, Yolo Bypass Improvements are not a component of Alternative 2D and the amount of tidal habitat restoration (i.e., Environmental Commitment 4) would be significantly less than that represented in the modeling. In general, the significance of this difference is that the assessment of bromide, chloride, and EC for Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT), likely overestimates increases in bromide, EC, and chloride that could occur, particularly in the west Delta. Nevertheless, there is notable uncertainty in the results of all quantitative assessments that refer to modeling results, due to the differing assumptions used in the modeling and the description of Alternative 2D and the No Action Alternative (ELT).

Due to the reduced suite of environmental commitments in Alternative 2D compared to Alternative 4 (in particular, significantly less tidal restoration), there generally are fewer significant impacts identified for Alternative 2D than for Alternative 4.

Impact WQ-1: Effects on Ammonia Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), substantial point and non-point sources of ammonia-N do not exist upstream of the SRWTP at Freeport in the Sacramento River watershed, in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), or upstream of the Delta in the San Joaquin River watershed. Thus, like Alternative 4, operation of the water conveyance facilities under Alternative 2D would have negligible, if any, effect on ammonia concentrations in the rivers and reservoirs upstream of the Delta relative to Existing Conditions and the No Action Alternative (ELT and LLT). Any negligible increases in ammonia-N concentrations that could occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies, with regard to ammonia.

Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), a substantial decrease in Sacramento River ammonia concentrations is expected under Alternative 2D relative to Existing Conditions, due to planned lowering of ammonia in the SRWTP effluent discharge, and this is expected to decrease ammonia concentrations for all areas of the Delta that are influenced by Sacramento River water. Concentrations of ammonia at locations not influenced notably by Sacramento River water would change little relative to Existing Conditions, due to the similarity in San Joaquin River and San Francisco Bay concentrations and the lack of expected changes in either of these concentrations. Thus, Alternative 2D would not result in substantial increases in ammonia concentrations in the Plan Area, relative to Existing Conditions.

Relative to the No Action Alternative (ELT and LLT), the primary mechanism that could potentially alter ammonia concentrations under Alternative 2D is decreased flows in the Sacramento River, which would lower dilution available to the SRWTP discharge. This flow change would be attributable only to operations of the water conveyance facilities, since the same assumptions regarding SRWTP discharge ammonia concentrations, water demands, climate change, and sea level rise apply to both Alternative 2D and the No Action Alternative (ELT and LLT). A simple mass balance calculation was performed to calculate ammonia concentrations downstream of the SRWTP discharge (i.e., downstream of Freeport) under Alternative 2D and the No Action Alternative (ELT) to assess the effects of the flow changes. Monthly average CALSIM II flows at Freeport and the upstream ammonia concentration (0.04 mg/L-N; Central Valley Water Board 2010a:5) were used, together with the SRWTP permitted average dry weather flow (181 mgd) and seasonal ammonia limitations (1.5 mg/L-N in Apr–Oct, 2.4 mg/L-N in Nov–Mar), to estimate the average change in ammonia concentrations downstream of the SRWTP. Table 4.4.4-1 in this RDEIR/SDEIS shows monthly average and long-term annual average predicted concentrations under Alternative 2D. As Table 4.4.4-1 shows, average monthly ammonia concentrations in the Sacramento River downstream of Freeport (upon full mixing of the SRWTP discharge with river water) under Alternative 2D and the No Action Alternative (ELT) are expected to be similar. In comparison to the No Action Alternative (ELT), minor increases in monthly average ammonia concentrations would occur during January through March, July through September, and November under Alternative 2D. Minor decreases in ammonia concentrations are expected for Alternative 2D in June and October. A minor increase in the annual average concentration would occur under Alternative 2D, compared to the No Action Alternative (ELT). Relative to the No Action Alternative (LLT), Alternative 2D is expected to result in similar minor increases in Sacramento River ammonia concentration, because the increased water demands, climate change, and sea level rise in the LLT would occur under both alternatives, and neither would affect ammonia sources or loading. The estimated concentrations in the Sacramento River downstream of Freeport under Alternative 2D would be similar to existing source water concentrations for the San Francisco Bay and San Joaquin River. Consequently, changes in source water fraction anticipated under Alternative 2D, relative to the No Action Alternative (ELT and LLT), are not expected to substantially increase ammonia concentrations at any Delta locations.

Ammonia concentrations downstream of Freeport in the Sacramento River under Alternative 2D would be similar to those under Alternative 4 (see Table 8-67 in Appendix A of the RDEIR/SDEIS). As stated for Alternative 4, any negligible increases in ammonia concentrations that could occur at certain locations in the Delta under Alternative 2D would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the water quality at these locations, with regard to ammonia.

Table 4.4.4-1. Estimated Ammonia (mg/L as N) Concentrations in the Sacramento River Downstream of the Sacramento Regional Wastewater Treatment Plant for the No Action Alternative Early Long-term (ELT) and Alternative 2D

	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Annual Average
No Action Alternative (ELT)	0.076	0.082	0.068	0.060	0.057	0.060	0.058	0.062	0.067	0.060	0.067	0.063	0.065
Alternative 2D	0.075	0.086	0.068	0.061	0.058	0.061	0.058	0.062	0.062	0.062	0.070	0.067	0.066

SWP CVP Export Service Areas

As discussed above, for areas of the Delta that are influenced by Sacramento River water, including Banks and Jones pumping plants, ammonia-N concentrations are expected to decrease under Alternative 2D, relative to Existing Conditions (in association with less diversion of water influenced by the SRWTP). Like Alternative 4, this decrease in ammonia-N concentrations for water exported via the south Delta pumps is not expected to result in an adverse effect on beneficial uses or substantially degrade water quality of exported water, with regard to ammonia. Furthermore, as discussed above, for all areas of the Delta, including Banks and Jones pumping plants, ammonia concentrations are not expected to be substantially different under Alternative 2D relative to the No Action Alternative (ELT and LLT). Thus, any negligible increases in ammonia concentrations that could occur at Banks and Jones pumping plants would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade water quality at these locations, with regard to ammonia.

NEPA Effects: In summary, ammonia concentrations in water bodies upstream of the Delta, in the Plan Area, and the waters exported to the SWP/CVP Export Service Areas are not expected to be substantially different under Alternative 2D relative to the No Action Alternative (ELT and LLT). Thus, effects of the water conveyance facilities on ammonia are considered to be not adverse.

CEQA Conclusion: The magnitude and direction of changes in ammonia concentrations in water bodies upstream of the Delta, in the Plan Area, or the waters exported to the SWP/CVP Export Service Areas would be approximately the same as expected under Alternative 4, relative to Existing Conditions. There would be no substantial, long-term increase in ammonia concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the CVP and SWP service areas under Alternative 2D relative to Existing Conditions. As such, Alternative 2D is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because ammonia concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects on beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that could occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-2: Effects on Ammonia Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Some habitat restoration activities would occur on lands in the Delta formerly used for irrigated agriculture. Although this may decrease ammonia loading to the Delta from agriculture, increased biota in those areas as a result of restored habitat may increase ammonia loading originating from flora and fauna. Ammonia loaded from organisms is expected to be converted rapidly to nitrate by established microbial communities. Thus, these land use changes would not be expected to substantially increase ammonia concentrations in the Delta. Implementation of Environmental Commitments 12, 15, and 16 do not include actions that would affect ammonia sources or loading. Based on these findings, the effects on ammonia from the implementation Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D are determined to not be adverse.

CEQA Conclusion**:** Land use changes that would occur from the environmental commitments are not expected to contribute substantially increase ammonia concentrations, because the amount of area to be converted would be small relative to existing habitat, and any resulting ammonia would likely be rapidly converted to nitrate. Thus, there would be no substantial, long-term increase in ammonia concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 relative to Existing Conditions. As such, implementation of these environmental commitments would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Because ammonia concentrations would not be expected to increase substantially from implementation of these environmental commitments, no long-term water quality degradation would be expected to occur and, thus, no significant impact on beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that could occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-3: Effects on Boron Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), under Alternative 2D there would be no expected change to the sources of boron in the Sacramento River and east-side tributary watersheds and, thus, resultant changes in flows from altered system-wide operations would have negligible, if any, effects on the concentration of boron in the rivers and reservoirs of these watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease by 1%, relative to Existing Conditions (in association with the different operational components of Alternative 2D in the ELT, climate change, and increased water demands) (Table Bo-1 in Appendix B of this RDEIR/SDEIS). The reduced flow relative to Existing Conditions would result in possible increases in long-term average boron concentrations of up to about 0.5% relative to the Existing Conditions. Flows would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial boron increases relative to the No Action Alternative (ELT). The increased boron concentrations, relative to Existing Conditions, under Alternative 2D in the ELT would not increase the frequency of exceedances of any applicable objectives or criteria and would not be expected to cause further degradation at measurable levels in the lower San Joaquin River, and thus would not cause the existing impairment there to be discernibly worse. Consequently, Alternative 2D in the ELT would not be expected to cause exceedance of boron objectives/criteria or substantially degrade water quality with respect to boron, and thus would not adversely affect any beneficial uses of the Sacramento River, the east-side tributaries, associated reservoirs upstream of the Delta, or the San Joaquin River.

Effects of Alternative 2D in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect boron sources in these areas.

Delta

Effects of water conveyance facilities on boron under Alternative 2D in the Delta would be similar to the effects discussed for Alternative 4. To the extent that habitat restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. However, there would be less potential for increased boron concentrations at western Delta locations associated with restoration Environmental Commitments under Alternative 2D because very little would occur relative to Alternative 4. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-4. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

The effects of Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT) are discussed together because the direction and magnitude of predicted change are similar. Relative to the Existing Conditions and No Action Alternative (ELT), Alternative 2D would result in increased long-term average boron concentrations for the 16-year period modeled at most of the interior Delta locations (increases up to 9% at the S. Fork Mokelumne River at Staten Island, 12% at Franks Tract, and 14% at Old River at Rock Slough) (Table Bo-9 in Appendix B of this RDEIR/SDEIS). The long-term average boron concentrations at most of the western Delta assessment locations would not change measurably. The long-term annual average and monthly average boron concentrations, for either the 16-year period or drought period modeled, would never exceed the 2,000 μg/L human health advisory objective (i.e., for children) or the 500 μg/L agricultural objective at the majority of assessment locations, which represents no change from the Existing Conditions and No Action Alternative (ELT) (Table Bo-8 in Appendix B of this RDEIR/SDEIS). A small increase in the frequency of exceedances 500 μg/L agricultural objective at the Sacramento River at Mallard Island (i.e., as much as 4% in the drought period relative to the No Action Alternative [ELT]) would not be anticipated to substantially affect agricultural diversions which occur primarily at interior Delta locations. Minor reductions in long-term average assimilative capacity of up to 1% at interior Delta locations (i.e., Old River at Rock Slough) would occur with respect to the 500 μg/L agricultural objective (Table Bo-11 in Appendix B of this RDEIR/SDEIS). However, because the absolute boron concentrations would still be well below the lowest 500 μg/L objective for the protection of the agricultural beneficial use under Alternative 2D, the levels of boron degradation would not be of sufficient magnitude to substantially increase the risk of exceeding objectives or cause adverse effects to municipal and agricultural water supply beneficial uses, or any other beneficial uses, in the Delta (Figure Bo-2 in Appendix B of this RDEIR/SDEIS).

Effects of Alternative 2D in the Delta in the LLT, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to those described above for the ELT. Boron concentrations may be higher at western Delta locations due to greater effects of climate change on sea level rise that would occur in the LLT; however, these effects are independent of the alternative. Further, boron is of concern in waters diverted for agricultural use, which primarily occurs in the interior Delta, and based on Delta source water characteristics (see Table 8-42 in Appendix A of the RDEIR/SDEIS), boron concentrations in the interior Delta would be expected to remain suitable for agricultural use.

SWP/CVP Export Service Areas

Under the Alternative 2D, long-term average boron concentrations would decrease at the Banks pumping plant (as much as 24%) and at Jones pumping plant (as much as 27%) relative to Existing Conditions, and the reductions would be similar compared to No Action Alternative (ELT) (Table Bo-9 in Appendix B of this RDEIR/SDEIS) as a result of export of a greater proportion of low-boron Sacramento River water. Commensurate with the decrease in exported boron concentrations, boron concentrations in the lower San Joaquin River may be reduced and would likely alleviate or lessen any expected increase in boron concentrations at Vernalis associated with flow reductions (see discussion of Upstream of the Delta), as well as locations in the Delta receiving a large fraction of San Joaquin River water. Reduced export boron concentrations also may contribute to reducing the existing CWA Section 303(d) impairment in the lower San Joaquin River and associated TMDL actions for reducing boron loading. These same effects on boron at the Banks and Jones pumping plants would be expected in the LLT, because the primary effect of climate change on sea level rise and boron concentrations is expected in the western Delta.

Maintenance of SWP and CVP facilities under Alternative 2D would not be expected to create new sources of boron or contribute towards a substantial change in existing sources of boron in the affected environment.

NEPA Effects: In summary, relative to the No Action Alternative (ELT and LLT), Alternative 2D would result in relatively small increases in long-term average boron concentrations in the Delta, not measurably increase boron levels in the lower San Joaquin River, and reduce boron levels in water exported to the SWP/CVP export service areas. However, the predicted changes would not be expected to cause exceedances of applicable objectives or further measurable water quality degradation, and thus would not constitute an adverse effect on water quality.

CEQA Conclusion: Based on the above assessment, any modified reservoir operations and subsequent changes in river flows under Alternative 2D, relative to Existing Conditions, would not be expected to result in a substantial adverse change in boron levels upstream of the Delta. Small increases in boron levels predicted for interior Delta locations in response to a shift in the Delta source water percentages would not be expected to cause exceedances of objectives, or substantial degradation of these water bodies. Alternative 2D maintenance also would not result in any substantial increases in boron concentrations in the affected environment. Boron concentrations would be reduced in water exported from the Delta to the CVP/SWP Export Service Areas, thus reflecting a potential improvement to boron loading in the lower San Joaquin River.

Boron is not a bioaccumulative constituent, thus any increased concentrations under Alternative 2D would not result in adverse boron bioaccumulation effects to aquatic life or humans. Relative to Existing Conditions, Alternative 2D would not result in substantially increased boron concentrations such that frequency of exceedances of municipal and agricultural water supply objectives would increase. The levels of boron degradation that may occur under Alternative 2D would not be of sufficient magnitude to cause substantially increased risk for adverse effects to municipal or agricultural beneficial uses within the affected environment. Long-term average boron concentrations would decrease in Delta water exports to the SWP and CVP service area, which may contribute to reducing the existing CWA Section 303(d) impairment of agricultural beneficial uses in the lower San Joaquin River. Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-4: Effects on Boron Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Effects on boron from implementation of environmental commitments under Alternative 2D would be the same as those described for Alternative 4A.

NEPA Effects: The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 for Alternative 2D present no new direct sources of boron to the affected environment, including areas upstream of the Delta, within the Delta region, and in the SWP/CVP Export Service Areas. Habitat restoration activities in the Delta, while involving increased land and water interaction within these habitats, would not be anticipated to contribute boron which is primarily associated with source water inflows to the Delta (i.e., San Joaquin River, agricultural drainage, and Bay source water). Moreover, some habitat restoration would occur on lands within the Delta currently used for irrigated agriculture, thus replacing agricultural land uses with restored habitats. The potential reduction in irrigated lands within the Delta may result in reduced discharges of agricultural field drainage with elevated boron concentrations, which would be considered an improvement compared to the No Action Alternative (ELT and LLT). Consequently, as they pertain to boron, implementation of the environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 for Alternative 2D would not present new or substantially changed sources of boron to the affected environment upstream of the Delta, within Delta, or in the SWP/CVP Export Service Areas. As such, their implementation would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or other criteria would be exceeded in water bodies of the affected environment located upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas or substantially degrade the quality of these water bodies, with regard to boron. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-5: Effects on Bromide Concentrations Resulting from Facilities Operations and Maintenance Upstream of the Delta

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), under Alternative 2D in the ELT there would be no expected change to the sources of bromide in the Sacramento River and east-side tributary watersheds. Thus, changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of bromide in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions and would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial bromide increases. Moreover, there are no existing municipal intakes on the lower San Joaquin River, which is the beneficial use most sensitive to elevated bromide concentrations. Consequently, Alternative 2D in the ELT would not be expected to adversely affect the MUN beneficial use, or any other beneficial uses, of the Sacramento River, the San Joaquin River, the eastside tributaries, or their associated reservoirs upstream of the Delta due to changes in bromide concentrations.

Effects of Alternative 2D in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect bromide sources in these areas.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-6. See Chapter 8, Section 8.3.1.3, *Plan Area* in Appendix A of the RDEIR/SDEIS for more information regarding the modeling methodology.

Estimates of bromide concentrations at Delta assessment locations were generated using a mass balance approach, and using relationships between EC and chloride and between chloride and bromide and DSM2 EC output. See Chapter 8, Section 8.3.1.3, *Plan Area* in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in bromide at Delta assessment locations based on both approaches.

Based on the mass balance modeling approach for bromide, relative to Existing Conditions, Alternative 2D long-term average bromide concentrations would increase in the S. Fork Mokelumne River at Staten Island, and decrease at all other assessment locations (Table Br-3 in Appendix B of this RDEIR/SDEIS). Average bromide concentrations at Staten Island would increase from 50 µg/L under Existing Conditions to 64 µg/L (28% increase) for the modeled 16-year hydrologic period (1976–1991). However, multiple interior and western Delta assessment locations would have an increased frequency of exceedance of 50 µg/L, which is the CALFED Drinking Water Program goal for bromide as a long-term average applied to drinking water intakes (Table Br-3 in Appendix B of this RDEIR/SDEIS). These locations are the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. The greatest increase in frequency of exceedance of the CALFED Drinking Water Program long-term goal of 50 μg/L would occur in the S. Fork Mokelumne River (26% increase) and Sacramento River at Emmaton (6% increase). The increase in frequency of exceedance of the 50 μg/L threshold at the other locations would be 2% or less. Similarly, these locations would have an increased frequency of exceedance of 100 μg/L, which is the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts (Table Br-3 in Appendix B of this RDEIR/SDEIS). The greatest increase in frequency of exceedance of 100 μg/L would occur at Franks Tract (7% increase). The increase in frequency of exceedance of the 100 μg/L threshold at the other locations would be 4% or less.

Changes in long-term average bromide concentrations and changes in threshold exceedance frequencies relative to the No Action Alternative (ELT) are generally of similar magnitude to those previously described relative to Existing Conditions (Table Br-3 in Appendix B of this RDEIR/SDEIS). However, unlike the Existing Conditions comparison, relative to the No Action Alternative (ELT), long-term average bromide concentrations at Buckley Cove would increase under Alternative 2D, although the increases would be relatively small (<1%).

Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide were consistent with the discussion above, and assessment of bromide using these modeling results lead to the same conclusions as are presented above for the mass balance approach (Tables Br-4 in Appendix B of this RDEIR/SDEIS).

Unlike Alternative 4, there would be no increased bromide concentration or frequency of exceedance of bromide thresholds in Barker Slough at the North Bay Aqueduct under Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT). Also, the magnitude of bromide concentration increases at Mallard Slough and in the San Joaquin River at Antioch during their historical months of use, relative to Existing Conditions and the No Action Alternative (ELT), would be generally similar to those described for Alternative 4 (Tables Br-5 and Br-6 in Appendix B of this RDEIR/SDEIS), and the frequency of exceedance of bromide thresholds would be similar (Tables Br-3 and Br-4 in Appendix B of this RDEIR/SDEIS). As described for Alternative 4, the use of seasonal intakes at these locations is largely driven by acceptable water quality, and thus has historically been opportunistic. Opportunity to use these intakes would remain, and the predicted increases in bromide concentrations at Antioch and Mallard Slough would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, at these locations.

The effects of Alternative 2D in the LLT in the Delta region, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to that described above. There may be higher bromide concentrations in the LLT in the western Delta, but this would be associated with sea level rise, not the project alternative, because the primary source of bromide to the Delta is sea water intrusion.

SWP/CVP Export Service Areas

Under Alternative 2D, long-term average bromide concentrations at the Banks and Jones pumping plants, based on the mass balance modeling approach, would decrease. Long-term average bromide concentrations for the modeled 16-year hydrologic period at the pumping plants would decrease by as much as 46% relative to Existing Conditions and 42% relative to the No Action Alternative (ELT) (Table Br-3 in Appendix B of this RDEIR/SDEIS). As a result, less frequent exceedances of the 50 μg/L and 100 μg/L assessment thresholds would occur and an overall improvement in SWP/CVP

Export Service Areas water quality would occur respective to bromide. Commensurate with the decrease in exported bromide, an improvement in lower San Joaquin River bromide would also occur since bromide in the lower San Joaquin River is principally related to irrigation water deliveries from the Delta. Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide are consistent with the mass balance results, and assessment of bromide using these modeling results leads to the same conclusions (Table Br-4 in Appendix B of this RDEIR/SDEIS).

The effects of Alternative 2D in the LLT in the SWP/CVP Export Service Areas, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to that described above, because the sea level rise that could occur in the LLT would not be expected to result in substantial bromide contributions to the water exported at Banks and Jones pumping plants.

Maintenance of SWP and CVP facilities under Alternative 2D would not be expected to create new sources of bromide or contribute towards a substantial change in existing sources of bromide in the affected environment. Maintenance activities would not be expected to cause any substantial change in bromide such that MUN beneficial uses, or any other beneficial use, would be adversely affected anywhere in the affected environment.

NEPA Effects**:** In summary, the operations and maintenance activities under Alternative 2D, relative to the No Action Alternative (ELT and LLT) would result in an increased frequency of exceedance of the 50 μg/L and 100 μg/L bromide thresholds for protecting against the formation of disinfection byproducts in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. However, long-term average bromide concentrations would increase only in the S. Fork Mokelumne River at Staten Island and San Joaquin River at Buckley Cove; there would be decreases in long-term average bromide concentrations at the other assessment locations. The long-term bromide concentration in the S. Fork Mokelumne River at Staten Island would be less than the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts, and the increase in the San Joaquin River at Buckley Cove would be minimal (<1%). Thus, these increased bromide concentrations are not expected to result in adverse affects to MUN beneficial uses, or any other beneficial use, at these locations. Based on these findings, this effect is determined to not be adverse.

CEQA Conclusion**:** While greater water demands under Alternative 2D would alter the magnitude and timing of reservoir releases north and east of the Delta, these activities would have negligible, if any, effect on the sources of bromide, and ultimately the concentration of bromide in the Sacramento River, the San Joaquin River, the eastside tributaries, and the various reservoirs of the related watersheds, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS).

Under Alternative 2D there would be an increased frequency of exceedance of the 50 μg/L and 100 μg/L bromide thresholds for protecting against the formation of disinfection byproducts in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. However, long-term average bromide concentrations would increase only in the S. Fork Mokelumne River at Staten Island and decrease at all other assessment locations. The long-term bromide concentration in the S. Fork Mokelumne River at Staten Island (64 μg/L) would be less than the 100 μg/L believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts. Further, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), the use of seasonal intakes at Antioch and Mallard Island is largely driven by acceptable water quality, and thus has historically been opportunistic and opportunity to use these intakes would remain. Thus, these increased bromide concentrations would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, at these locations.

The assessment of effects on bromide in the SWP/CVP Export Service Areas is based on assessment of changes in bromide concentrations at Banks and Jones pumping plants. Long-term average bromide concentrations at the Banks and Jones pumping plants are predicted to decrease by as much as 46% relative to Existing Conditions and there would be less frequent exceedance of bromide concentration thresholds.

Based on the above, Alternative 2D would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide. Alternative 2D would not result in any substantial change in long-term average bromide concentration or exceed 50 and 100 µg/L assessment threshold concentrations by frequency, magnitude, and geographic extent that would result in adverse effects on any beneficial uses within affected water bodies. Bromide is not a bioaccumulative constituent and thus concentrations under this alternative would not result in bromide bioaccumulating in aquatic organisms. Increases in exceedances of the 100 µg/L assessment threshold concentration would be 7% or less at all locations assessed, which is considered to be less than substantial long-term degradation of water quality. The levels of bromide degradation that may occur under the Alternative 2D would not be of sufficient magnitude to cause substantially increased risk for adverse effects on any beneficial uses of water bodies within the affected environment. Bromide is not CWA Section 303(d) listed and thus the minor increases in long-term average bromide concentrations would not affect existing beneficial use impairment because no such use impairment currently exists for bromide. Based on these findings, this impact is less than significant. No mitigation is required.

Impact WQ-6: Effects on Bromide Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would present no new sources of bromide to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Areas. Some habitat restoration activities would occur on lands in the Delta formerly used for irrigated agriculture. Such replacement or substitution of land use activity would not be expected to result in new or increased sources of bromide to the Delta. Therefore, as they pertain to bromide, implementation of these environmental commitments would not be expected to adversely affect MUN beneficial use, or any other beneficial uses, of the affected environment.

Environmental Commitment 4 would result in some tidal habitat restoration, however, the areal extent would be small relative to the existing and No Action Alternative tidal area and, thus not expected to appreciably affect the magnitude of daily tidal water exchange at the restoration areas or alter other hydrodynamic conditions in adjacent Delta channels that would result in measurable bromide concentration changes.

In summary, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D relative to the No Action Alternative (ELT and LLT), would have negligible, if any, effects on bromide concentrations. Therefore, the effects on bromide from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D would not present new or substantially changed sources of bromide to the affected environment. Some environmental commitments may replace or substitute for existing irrigated agriculture in the Delta. This replacement or substitution would not be expected to substantially increase or present new sources of bromide. Thus, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would have negligible, if any, effects on bromide concentrations throughout the affected environment, would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide, and would not cause changes in bromide concentrations that would result in significant impacts on any beneficial uses within affected water bodies. Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause significant long-term water quality degradation such that there would be greater risk of significant impacts on beneficial uses, would not cause greater bioaccumulation of bromide, and would not further impair any beneficial uses due to bromide concentrations because no uses are currently impaired due to bromide levels. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-7: Effects on Chloride Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 2D on chloride concentrations in reservoirs and rivers upstream of the Delta would be the similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). Chloride loading in these watersheds would remain unchanged and resultant changes in flows from altered system-wide operations would have negligible, if any, effects on the concentration of chloride in the rivers and reservoirs of these watersheds. There would be no expected change to the sources of chloride in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of chloride in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions and would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial chloride increases. Moreover, there are no existing municipal intakes on the lower San Joaquin River. Consequently, Alternative 2D in the ELT would not be expected to cause exceedances of chloride objectives/criteria or substantially degrade water quality with respect to chloride, and thus would not adversely affect any beneficial uses of the Sacramento River, the eastside tributaries, associated reservoirs upstream of the Delta, or the San Joaquin River.

Effects of Alternative 2D in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect chloride sources in these areas.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 2D would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-8. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Estimates of chloride concentrations at Delta assessment locations were generated using a mass balance approach and EC-chloride relationships and DSM2 EC output. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in chloride at Delta assessment locations based on both approaches.

Modeling of chloride using both the mass balance approach and EC-chloride relationship predicts that Alternative 2D in the ELT would result in similar or reduced long-term average chloride concentrations, relative to Existing Conditions, for the 16-year period modeled at all assessment locations except for the S. Fork Mokelumne River at Staten Island. The increase in long-term average chloride concentration at Staten Island would be 4 mg/L (25%) based on the mass balance modeling and 2 mg/L (10%) based on the EC-chloride relationship (Tables Cl-16 and Cl-17 in Appendix B of this RDEIR/SDEIS). These increases are extremely small in absolute terms and relative to applicable water quality objectives, and are within the estimated modeling uncertainty. The results differ from Alternative 4, under which there would be increased long-term average chloride concentrations also at the North Bay Aqueduct at Barker Slough. The change in long-term average chloride concentrations relative to the No Action Alternative (ELT) would be similar to those relative to Existing Conditions.

The following outlines the modeled chloride changes relative to the applicable objectives and beneficial uses of Delta waters.

Municipal Beneficial Uses Relative to Existing Conditions

Estimates of chloride concentrations generated using EC-chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses on a basis of the percent of years the chloride objective is exceeded for the modeled 16-year period. The objective is exceeded if chloride concentrations exceed 150 mg/L for a specified number of days in a given water year at Antioch and Contra Costa Pumping Plant #1. The modeled frequency of objective exceedance would decrease at the Contra Costa Pumping Plant #1 from 6.7% of years under Existing Conditions to 0% of years under Alternative 2D in the ELT (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Evaluation of the 250 mg/L Bay-Delta WQCP objective for chloride utilized results from both the mass balance approach and EC-chloride relationship. The basis for the evaluation was the predicted number of days the objective would be exceeded for the modeled 16-year period.

Based on the mass balance approach, there would be a decreased frequency of exceedance of the 250 mg/L objective under Alternative 2D, relative to Existing Conditions, at all locations except in the Sacramento River at Mallard Island and the Sacramento River at Emmaton. In the Sacramento River at Mallard Island, the frequency of objective exceedance would increase from 85% under Existing Conditions to 86% under Alternative 2D for the entire period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). In the Sacramento River at Emmaton, there would be an increase in chloride objective exceedance during the drought period modeled, from 55% to 57%.

The mass balance results also indicate reduced assimilative capacity with respect to the 250 mg/L objective during certain months and at certain locations. In the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in March and April of up to 17% for the 16-year period modeled, and 55% for the drought period modeled (Table Cl-18 in Appendix B of this RDEIR/SDEIS). Assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced, in February through June, by up to 4% for the entire period modeled and 6% for the drought period modeled. These estimates include the effect of climate change and sea level rise, as well as the alternative. Comparisons to the No Action Alternative (ELT) below provide an assessment of the effect of the alternative alone.

When utilizing the EC-chloride relationship to model chloride concentrations for the 16-year period, trends in frequency of exceedance and use of assimilative capacity would be similar to that discussed when utilizing the mass balance modeling approach (Tables Cl-3 and Cl-19 in Appendix B of this RDEIR/SDEIS). However, the EC-chloride relationships generally predicted changes of lesser magnitude, where predictions of change utilizing the mass balance approach were generally of greater magnitude, and thus more conservative. As discussed in Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS, in cases of such disagreement, the approach that yielded the more conservative predictions was used as the basis for determining adverse impacts.

CWA Section 303(d) Listed Water Bodies–Relative to Existing Conditions

Tom Paine Slough in the southern Delta is on the state's CWA Section 303(d) list for chloride with respect to the secondary MCL of 250 mg/L. Monthly average chloride concentrations at the Old River at Tracy Road for the 16-year period modeled, which represents the nearest DSM2-modeled location to Tom Paine Slough, would be generally similar under Alternative 2D in the ELT relative to Existing Conditions, and thus, would not be further degraded on a long-term basis (Figure Cl-5 in Appendix B of this RDEIR/SDEIS).

Suisun Marsh also is on the state's CWA Section 303(d) list for chloride in association with the Bay-Delta WQCP objectives for maximum allowable salinity during the months of October through May, which establish appropriate seasonal salinity conditions for fish and wildlife beneficial uses. With respect to Suisun Marsh, the monthly average chloride concentrations for the 16-year period modeled would generally increase under Alternative 2D in the ELT relative to Existing Conditions in March through May at the Sacramento River at Mallard Island (Figure Cl-6 in Appendix B of this RDEIR/SDEIS) and at Collinsville (Figure Cl-7 in Appendix B of this RDEIR/SDEIS), and increase substantially in October through May at Montezuma Slough at Beldon's Landing (i.e., over a doubling of concentration in December through February) (Figure Cl-8 in Appendix B of this RDEIR/SDEIS). However, modeling of Alternative 2D assumed no operation of the Montezuma Slough Salinity Control Gates, but the project description assumes continued operation of the Salinity Control Gates, consistent with assumptions included in the No Action Alternative. A sensitivity analysis modeling run conducted for Alternative 4 scenario H3 at the LLT with the gates operational consistent with the No Action Alternative resulted in substantially lower EC levels than indicated in the original Alternative 4 modeling results for Suisun Marsh, but EC levels were still somewhat higher than EC levels under Existing Conditions for several locations and months. Although chloride was not specifically modeled in these sensitivity analyses, it is expected that chloride concentrations would be nearly proportional to EC levels in Suisun Marsh. Additionally, although these analyses were only conducted at the LLT, they are expected to generally also apply to the ELT. Another modeling run with the gates operational and restoration areas removed resulted in EC levels nearly equivalent to Existing Conditions (see Appendix 8H, Attachment 1 in Appendix A of the RDEIR/SDEIS for more information on these sensitivity analyses). Since Alternative 2D in the ELT includes operation of the gates, and includes very little tidal restoration area, it is anticipated that chloride increases in Suisun Marsh predicted via the modeling would not occur, and that chloride in Suisun Marsh under Alternative 2D in the ELT would be very similar to Existing Conditions. For these reasons, any changes in chloride in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

Municipal Beneficial Uses Relative to No Action Alternative (ELT)

Similar to the assessment conducted for Existing Conditions, estimates of chloride concentrations generated from EC-chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses. For Alternative 2D in the ELT, the modeled frequency of objective exceedance would not change at the Contra Costa Pumping Plant #1--the No Action Alternative (ELT) and Alternative 2D in the ELT all would have 0% exceedance (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Based on the mass balance approach, the frequency of exceedance of the 250 mg/L objective under Alternative 2D in the ELT would be the same, or would decrease, at all locations relative to the No Action Alternative (ELT) (Table Cl-2 in Appendix B of this RDEIR/SDEIS). Estimates of long-term use of assimilative capacity using the mass balance results indicated the potential for reduced assimilative capacity with respect to the 250 mg/L objective for certain months and locations. Calculations using the long-term monthly and annual average concentrations showed that in the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in April of 20% for the drought period modeled (Table Cl-18 in Appendix B of this RDEIR/SDEIS). The same approach showed that assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced in March through June, by up to 4%, and in October by 13%, for the entire period modeled. During the drought period modeled, there would be reductions of assimilative capacity of 2% in June and 61% in September (Table Cl-18 in Appendix B of this RDEIR/SDEIS). However, this approach used long-term average chloride concentrations, which can be heavily influenced by changes in a small number of years when chloride concentrations would already be very high. Additionally, when long term averages are just below the objective, very small changes in chloride that are within the modeling uncertainty can result in very high estimates of use of assimilative capacity. To further investigate the potential for water quality degradation with respect to chloride, the concentrations of chloride during individual water years was examined.

This further examination was limited to the mass balance approach, since when utilizing the EC-chloride relationship to model monthly average chloride concentrations for the 16-year period, trends in frequency of exceedance and use of assimilative capacity were similar to that discussed for the mass balance modeling approach (Tables Cl-3 and Cl-19 in Appendix B of this RDEIR/SDEIS). However, utilizing the EC-chloride relationships generally predicted changes of lesser magnitude, where predictions of change utilizing the mass balance approach were generally of greater magnitude, and thus more conservative. As discussed in Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS, in cases of such disagreement, the approach that yielded the more conservative predictions was used as the basis for determining adverse impacts.

Figure Cl-18 shows chloride concentrations in April during the five-year drought period (1987–1991) at Antioch, where Table Cl-18 in Appendix B of this RDEIR/SDEIS indicated 20% use of assimilative capacity. The figure shows that during three of the five years, chloride concentrations increased relative to the No Action Alternative (ELT) and decreased in the other two years. The absolute differences estimated are fairly small and may be within modeling uncertainty. Figures Cl-

19 and Cl-20 show a box and whisker plot and exceedance plot for April at Antioch for all dry and critical water years modeled (not just the 1987–1991 drought period). These graphs show that while the median chloride concentration is slightly increased relative to the No Action Alternative (ELT), the maximum, 25th percentile, and 75th percentile values are all decreased. Based on this analysis, long-term degradation is not expected at Antioch in April during drought years.

Figure Cl-21 shows chloride levels in September at Contra Costa Pumping Plant #1 during the drought period (1987–1991), where Table Cl-18 in Appendix B of this RDEIR/SDEIS indicated 61% use of assimilative capacity. In general, changes in chloride concentrations relative to the No Action Alternative (ELT) are fairly small, and may be within modeling uncertainty. Figures Cl-22 and Cl-23 show a box and whisker plot and exceedance plot for September at Contra Costa Pumping Plant #1 for all dry and critical water years modeled (not just the 1987–1991 drought period). These graphs show that the median chloride concentration is slightly decreased relative to the No Action Alternative (ELT), and chloride concentrations are generally similar to the No Action Alternative (ELT) throughout the range seen. The 61% use of assimilative capacity was shown because long term averages were just below the criterion, so a very small increase in chloride (that is probably within the modeling uncertainty) resulted in a very high estimate of use of assimilative capacity. Similar results are shown in Figure Cl-24, Cl-25, and Cl-26 for October at Contra Costa Pumping Plant #1. Median concentrations decreased slightly, and the exceedance plot shows generally similar concentrations throughout the range seen. Figure Cl-24 shows that while some years see increased concentrations (e.g., 1978, 1989), other years see decreased concentrations (e.g., 1980, 1982). Based on this analysis, long-term degradation is not expected at Contra Costa Pumping Plant #1 in September during drought years, or October on a long-term average basis.

Furthermore, sensitivity analyses conducted of Alternative 4 Scenario H3 without restoration areas indicated lower chloride levels in the western Delta than with the restoration areas. It is thus likely that modeling of Alternative 2D that does not include restoration areas would show lower levels of chloride at Antioch in April, and at Contra Costa Pumping Plant #1 in September and October than is shown herein using the Alternative 2 (ELT) modeling.

Based on the low level of water quality degradation estimated for the western Delta, and the lack of exceedance of water quality objectives, Alternative 2D is not expected to have substantial adverse effects on municipal and industrial beneficial uses in the western Delta.

CWA Section 303(d) Listed Water Bodies–Relative to No Action Alternative (ELT)

With respect to the state's CWA Section 303(d) listing for chloride, Alternative 2D would generally result in similar changes to those discussed for the comparison to Existing Conditions. Monthly average chloride concentrations at Tom Paine Slough would not be further degraded on a long-term basis, based on changes that would occur in Old River at Tracy Road (Figure Cl-5 in Appendix B of this RDEIR/SDEIS). Modeling indicated that monthly average chloride concentrations at source water channel locations for the Suisun Marsh would increase substantially in some months during October through May relative to the No Action Alternative (ELT) (Figures Cl-6, Cl-7, and Cl-8 in Appendix B of this RDEIR/SDEIS), but the results of sensitivity analyses performed indicate that chloride increases in Suisun Marsh predicted via the modeling would not occur, and that chloride in Suisun Marsh under Alternative 2D in the ELT would be very similar to the No Action Alternative (ELT). Depending on where tidal restoration areas assumed to be included in the No Action Alternative are located, chloride concentrations under Alternative 2D could be less than under the

No Action Alternative (ELT). For these reasons, any changes in chloride in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

The effects of Alternative 2D in the LLT in the Delta region, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to effects in the ELT. With greater climate change and sea level rise, additional outflow may be required at certain times to prevent increases in chloride in the west Delta. Small increases in chloride concentrations may occur in some areas, but it is not expected that these increases would cause exceedance of Bay-Delta WQCP objectives of cause substantial long-term degradation that would impact municipal and industrial beneficial uses.

SWP/CVP Export Service Areas

Under Alternative 2D in the ELT, long-term average chloride concentrations at the Banks and Jones pumping plants, based on the mass balance analysis of modeling results for the 16-year period, would decrease relative to Existing Conditions. Chloride concentrations would be reduced by 45% at Banks pumping plant (Table Cl-16 in Appendix B of this RDEIR/SDEIS). At Jones pumping plant, chloride concentrations would be reduced 43% (Table Cl-16 in Appendix B of this RDEIR/SDEIS). The frequency of exceedances of applicable water quality objectives would decrease relative to Existing Conditions, for both the 16-year period and the drought period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). The chloride concentration changes relative to the No Action Alternative (ELT) would be similar. Consequently, water exported into the SWP/CVP Export Service Areas would generally be of similar or better quality with regard to chloride relative to Existing Conditions and the No Action Alternative (ELT). Results of the modeling approach which utilized a EC-chloride relationship are consistent these results, and assessment of chloride using these modeling output results in the same conclusions as for the mass balance approach (Tables Cl-3 and Cl-17 in Appendix B of this RDEIR/SDEIS).

Commensurate with the reduced chloride concentrations in water exported to the SWP/CVP Export Service Area, reduced chloride loading in the lower San Joaquin River would be anticipated which would likely alleviate chloride concentrations at Vernalis.

The effects of Alternative 2D in the LLT in the SWP/CVP Export Service Areas, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be very similar to effects in the ELT.

Maintenance of SWP and CVP facilities would not be expected to create new sources of chloride or contribute towards a substantial change in existing sources of chloride in the affected environment. Maintenance activities would not be expected to cause any substantial change in chloride such that any long-term water quality degradation would occur, thus, beneficial uses would not be adversely affected anywhere in the affected environment.

NEPA Effects**:** In summary, relative to the No Action Alternative (ELT and LLT), Alternative 2D would not result in substantially increased chloride concentrations in the Delta on a long-term average that would result in adverse effects on the municipal and industrial water supply beneficial use, or any other beneficial use. Additional exceedance of the 150 mg/L and 250 mg/L objectives is not expected, and substantial long-term degradation is not expected that would result in adverse effects on the municipal and industrial water supply beneficial use, or any other beneficial use. Based on these findings, this effect is determined to not be adverse.

CEQA Conclusion: Chloride is not a constituent of concern in the Sacramento River watershed upstream of the Delta, thus river flow rate and reservoir storage reductions that would occur under Alternative 2D relative to Existing Conditions, would not be expected to result in a substantial adverse change in chloride levels. Additionally, relative to Existing Conditions, Alternative 2D would not result in reductions in river flow rates (i.e., less dilution) or increased chloride loading such that there would be any substantial increase in chloride concentrations upstream of the Delta in the San Joaquin River watershed.

Relative to Existing Conditions, Alternative 2D would not result in substantially increased chloride concentrations in the Delta on a long-term average basis that would result in adverse effects on the municipal and industrial water supply beneficial use. Additional exceedance of the 150 mg/L and 250 mg/L objectives is not expected, and substantial long-term degradation is not expected that would result in adverse effects on the municipal and industrial water supply beneficial use.

Chloride concentrations would be reduced under Alternative 2D in water exported from the Delta to the SWP/CVP Export Service Areas thus reflecting a potential improvement to chloride loading in the lower San Joaquin River.

Chloride is not a bioaccumulative constituent, thus any increased concentrations under the Alternative 2D would not result in substantial chloride bioaccumulation impacts on aquatic life or humans. Alternative 2D maintenance would not result in any substantial changes in chloride concentration upstream of the Delta or in the SWP/CVP Export Service Areas

Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-8: Effects on Chloride Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D would present no new direct sources of chloride to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Areas. Consequently, as they pertain to chloride, implementation of these environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment. Moreover, some habitat restoration activities would occur on lands within the Delta currently used for irrigated agriculture. The potential reduction in irrigated lands within the Delta may result in reduced discharges of agricultural field drainage with elevated chloride concentrations, which would be considered an improvement relative to the No Action Alternative (ELT and LLT). Therefore, the effects on chloride from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion: Implementation of the Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D would not present new or substantially changed sources of chloride to the affected environment upstream of the Delta, within Delta, or in the SWP/CVP Export Service Areas. Replacement of irrigated agricultural land uses in the Delta with habitat restoration may result in some reduction in discharge of agricultural field drainage with elevated chloride concentrations, thus resulting in improved water quality conditions. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-9: Effects on Dissolved Oxygen Resulting from Facilities Operations and Maintenance

As described in detail for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), DO levels are primarily affected by water temperature, flow velocity, turbulence, amounts of oxygen demanding substances present (e.g., ammonia, organics), and rates of photosynthesis (which is influenced by nutrient levels), respiration, and decomposition. Water temperature and salinity affect the maximum DO saturation level (i.e., the highest amount of oxygen the water can dissolve). Flow velocity affects the turbulence and re-aeration of the water (i.e., the rate at which oxygen from the atmosphere can be dissolved in water). High nutrient content can support aquatic plant and algae growth, which in turn generates oxygen through photosynthesis and consumes oxygen through respiration and decomposition.

As described for Alternative 4, amounts of oxygen demanding substances present (e.g., ammonia, organics) in the reservoirs and rivers upstream of the Delta, rates of photosynthesis (which is influenced by nutrient levels/loading), and respiration and decomposition of aquatic life is not expected to change sufficiently under Alternative 2D to substantially alter DO levels relative to Existing Conditions or the No Action Alternative (ELT and LLT). Further, the rivers upstream of the Delta are well oxygenated and experience periods of supersaturation (i.e., when DO level exceeds the saturation concentration). Because these are large, turbulent rivers, any reduced DO saturation level that would be caused by an increase in temperature under Alternative 2D would not be expected to cause DO levels to be outside of the range seen historically. Flow changes that would occur under Alternative 2D would not be expected to have substantial effects on river DO levels; likely, the changes would be immeasurable. This is because sufficient turbulence and interaction of river water with the atmosphere would continue to occur to maintain water saturation levels (due to these factors) at levels similar to that of Existing Conditions and the No Action Alternative (ELT and LLT).

Also as described for Alternative 4, salinity changes would generally have relatively minor effects on Delta DO levels. Further, the relative degree of tidal exchange of flows and turbulence, which contributes to exposure of Delta waters to the atmosphere for reaeration, would not be expected to substantially change relative to Existing Conditions or the No Action Alternative (ELT and LLT), such that these factors would reduce Delta DO levels below objectives or levels that protect beneficial uses. Similarly, increased temperature under Alternative 2D would generally have relatively minor effects on Delta DO levels, relative to Existing Conditions.

Similar to Alternative 4, flows in the San Joaquin River at Stockton were evaluated, and are shown in Figure DO-1 in Appendix B of this RDEIR/SDEIS. The figure shows that while flows do would change somewhat, they are would generally be within the range of flows seen under Existing Conditions and the No Action Alternative. Reports indicate that the aeration facility performs adequately under the range of flows from 250–1,000 cfs (ICF International 2010). Based on the above, the expected changes in flows in the San Joaquin River at Stockton are not expected to substantially move the point of minimum DO, and therefore the aeration facility will would likely still be located appropriately to keep DO levels above Basin Plan objectives.

Overall, assuming continued operation of the aerators, the alternative is not expected to have a substantial impact adverse effect on DO in the Deep Water Ship Channel. It is expected that DO levels in the Deep Water Ship Channel, which is CWA Section 303(d) listed as impaired due to low DO, would remain similar to those under Existing Conditions and the No Action Alternative (ELT and

LLT) or improve as TMDL-required studies are completed and actions are implemented to improve DO levels. DO levels in other Clean Water Act Section 303(d)-listed waterways would not be expected to change relative to Existing Conditions or the No Action Alternative (ELT and LLT), as the circulation of flows, tidal flow exchange, and re-aeration would continue to occur.

In the SWP/CVP Export Service Areas, the primary factor that would affect DO in the conveyance channels and ultimately the receiving reservoirs would be changes in the levels of nutrients and oxygen-demanding substances and DO levels in the exported water. As described above and for Alternative 4, exported water could potentially be warmer and have higher salinity relative to Existing Conditions and the No Action Alternative (ELT and LLT). Nevertheless, because the biochemical oxygen demand of the exported water would not be expected to substantially differ from that under Existing Conditions or the No Action Alternative (ELT and LLT) due to water quality regulations, canal turbulence, exposure of the water to the atmosphere, and the algal communities that exist within the canals that would establish an equilibrium for DO levels within the canals. The same would occur in downstream reservoirs.

NEPA Effects: Because DO levels are not expected to change substantially relative to the No Action Alternative (ELT and LLT), the effects on DO from implementing Alternative 2D are determined to not be adverse.

CEQA Conclusion: The effects of Alternative 2D on DO levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). Reservoir storage reductions that would occur under Alternative 2D, relative to Existing Conditions, would not be expected to result in a substantial adverse change in DO levels in the reservoirs, because oxygen sources (surface water aeration, aerated inflows, vertical mixing) would remain. Similarly, river flow rate reductions would not be expected to result in a substantial adverse change in DO levels in the rivers upstream of the Delta, given that mean monthly flows would remain within the ranges historically seen under Existing Conditions and the affected river are large and turbulent. Any reduced DO saturation level that may be caused by increased water temperature would not be expected to cause DO levels to be outside of the range seen historically. Finally, amounts of oxygen demanding substances and salinity would not be expected to change sufficiently to affect DO levels.

It is expected there would be no substantial change in Delta DO levels in response to a shift in the Delta source water percentages under this alternative or substantial degradation of these water bodies, with regard to DO. DO levels would be affected by nutrient loading, which the state regulates the discharges of, and this loading would not be expected to lower DO levels relative to Existing Conditions based on historical DO levels. Further, the anticipated changes in salinity would have relatively minor effects on DO levels, and tidal exchange, which contribute to the reaeration of Delta waters would not be expected to change substantially.

There is not expected to be substantial, if even measurable, changes in DO levels in the SWP/CVP Export Service Areas waters, relative to Existing Conditions, because the biochemical oxygen demand of the exported water would not be expected to substantially differ from that under Existing Conditions (due to water quality regulations), canal turbulence and exposure of the water to the atmosphere and the algal communities that exist within the canals that would establish an equilibrium for DO levels within the canals. The same would occur in downstream reservoirs.

Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would result in significant impacts on any beneficial uses within affected water bodies. Because no substantial changes in DO levels are expected, long-term water quality degradation would not be expected to occur, and, thus, beneficial uses would not be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels would be expected, greater degradation and DO-related impairment of these areas would not be expected. Based on these findings, this impact would be less than significant. No mitigation is required.

Impact WQ-10: Effects on Dissolved Oxygen Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Environmental Commitments 3, 4, and 6–11 would involve habitat restoration actions. The increased habitat provided by these environmental commitments could contribute to an increased biochemical or sediment demand, through contribution of organic carbon and plants decaying. However, the areal extent of new habitat would be small relative to existing and No Action Alternative habitat areas, and similar habitat existing in the Delta is not identified as contributing to adverse DO conditions. The remaining environmental commitments would not be expected to affect DO levels because they are actions that do not affect the presence of oxygen-demanding substances. Therefore, the effects on DO from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

***CEQA Conclusion*:** It is expected that DO levels in the Upstream of the Delta Region, in the Plan Area, or in the SWP/CVP Export Service Areas following implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D would not be substantially different from existing DO conditions, because these would contribute to a minimal, localized change in oxygen-demanding substances associated with habitat restoration, if at all. Therefore, these environmental commitments are not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would result in significant impacts on any beneficial uses within affected water bodies. Because no substantial changes in DO levels would be expected, long-term water quality degradation would not be expected, and, thus, beneficial uses would not be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels would be expected, greater degradation and impairment of these areas would not be expected. Based on these findings, this impact would be less than significant. No mitigation is required.

Impact WQ-11: Effects on Electrical Conductivity Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 2D on EC levels in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). The extent of new urban growth would be less in the ELT, thus discharges of EC-elevating parameters in runoff and wastewater discharges to water bodies upstream of the Delta would be expected to be less than in the LLT. However, the state is regulating point source discharges of EC-related parameters and implementing a program to further decrease loading of EC-related parameters to tributaries. Based on these considerations, and those described in Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS, EC levels (highs, lows, typical conditions) in the

Sacramento River and its tributaries, the eastside tributaries, or their associated reservoirs upstream of the Delta would not be expected to be outside the ranges occurring under Existing Conditions.

For the San Joaquin River, increases in EC levels under Alternative 2D could occur, but would be slightly less than those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). This is because the effects of climate change and increase water demands on flows, which could effect dilution of high EC discharges, would be less in the ELT. The implementation of the adopted TMDL for the San Joaquin River at Vernalis and the ongoing development of the TMDL for the San Joaquin River upstream of Vernalis are expected to contribute to improved EC levels. Based on these considerations, substantial changes in EC levels in the San Joaquin River relative to Existing Conditions would not be expected to be of sufficient magnitude and geographic extent that would result in adverse effects on any beneficial uses, or substantially degrade the quality of these water bodies, with regard to EC.

Delta

As mentioned at the beginning of Section 4.4.4 of the RDEIR/SDEIS, the analysis of EC under Alternative 2D is based on modeling conducted for Alternative 2 in the ELT, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. Also, the modeling was originally performed assuming the Emmaton compliance point shifted to Threemile Slough. However, Yolo Bypass Improvements are not a component of Alternative 2D and the amount of tidal habitat restoration (i.e., Environmental Commitment 4) would be significantly less than that represented in the Alternative 2 modeling. Also, Alternative 2D does not include a change in compliance point from Emmaton to Threemile Slough. Furthermore, there are several factors related to the modeling approach that may result in modeling artifacts that show objective exceedance, when in reality no such exceedance would occur. The result of all of these factors is that the quantitative modeling results presented in this assessment is not entirely predictive of actual effects under Alternative 2D, and the results should be interpreted with caution. In order to understand the significance of all of these factors on the results, sensitivity analyses and further other analyses were performed to evaluate the impact of maintaining the compliance point at Emmaton, the impact of having substantially less restoration than included in the modeling that was analyzed, and whether exceedances were indeed modeling artifacts or were potential alternative-related effects that may actually occur. For more information on these sensitivity analyses, refer to Chapter 8, Section 8.3.1.7, *Electrical Conductivity*, and Appendix 8H, Attachment 1, both in Appendix A of the RDEIR/SDEIS.

In this assessment, the modeling results are described and then in most cases are qualified in light of findings from the sensitivity analyses. Conclusions thus represent assessment of the combination of the modeling results and sensitivity analysis findings.

The modeling of EC under Alternative 2D included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 2D would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of operations-related water quality changes (i.e., water conveyance facilities). Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-12. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Relative to Existing Conditions and the No Action Alternative (ELT), initial review of modeling results indicated that Alternative 2D would potentially result in an increase in the number of days the Bay-Delta WQCP EC objectives would be exceeded in the Sacramento River at Emmaton, and San Joaquin River at San Andreas Landing and Prisoners Point (Table EC-9 in Appendix B of this RDEIR/SDEIS). Additionally, the modeling results indicated potentially large increases in EC in Suisun Marsh. However, to understand and interpret these results, considerations must be made regarding uncertainty in the modeling, differing assumptions between the modeling and the alternative, and sensitivity analyses. These objectives and locations are addressed in the context of these considerations in detail below. At all other locations, the level of exceedance and EC in the modeling results was approximately equivalent or lower than under Existing Conditions and the No Action Alternative (ELT).

Sacramento River at Emmaton

Modeling results indicated that the Emmaton EC objective would be exceeded more often under Alternative 2D than under Existing Conditions and the No Action Alternative (ELT), and that increases in EC could cause substantial water quality degradation in summer months of dry and critical water years. However, sensitivity analyses have shown that the level of effect would be less than presented in the modeling. Remaining increases in exceedance of the objective and degradation are expected to be addressed via real-time operations, including real time management of the north Delta and south Delta intakes, as well as Delta Cross Channel operation. Further discussion is provided below.

Modeling results indicated that the percent of days the Emmaton EC objective would be exceeded for the entire period modeled (1976–1991) would increase from 6% under Existing Conditions, or 13% under the No Action Alternative (ELT), to 16% and the percent of days out of compliance would increase from 11% under Existing Conditions, or 21% under the No Action Alternative (ELT), to 25%. Although these results are for modeling that was originally performed for Alternative 2 at the ELT assuming the Emmaton compliance point shifted to Threemile Slough, Alternative 2D does not include a change in compliance point from Emmaton to Threemile Slough. Sensitivity analyses were performed that modeled Alternative 4 scenario H3 at the LLT with Emmaton as the compliance point. These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT, because the factors affecting salinity findings in the sensitivity analysis (e.g., modeling assumptions, physical hydrodynamic mechanisms) are similar between the ELT and LLT (see Appendix 8H, Attachment 1 in Appendix A of the RDEIR/SDEIS). Assuming the compliance location at Emmaton instead of Threemile Slough in the CALSIM II modeling decreased exceedances at Emmaton from 28% to 15% under Alternative 4, operations scenario H3 at the LLT (see Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS for more discussion of these sensitivity analyses), which would still be greater than Existing Conditions, but is very close to the No Action Alternative (ELT). Table 2 of Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS indicates that most of these exceedances are a result of modeling artifacts, but some exceedances are due to deadpool conditions that occurred in 1977, 1981, and 1990 under Alternative 4 scenario H3 at the LLT and not under Existing Conditions. As discussed in Chapter 5, *Water Supply*, Section 5.3.1, *Methods for Analysis*, of this RDEIR/SDEIS, under extreme hydrologic and operational conditions where there is not enough water supply to meet all requirements, CALSIM II uses a series of operating rules to reach a solution that is a simplified version of the very complex decision processes that SWP and CVP operators would use in actual extreme conditions. Thus, it is unlikely that the Emmaton objective would actually be violated due to dead pool conditions. However, these results indicate that water supply could be either under greater stress or under stress earlier in the year, and EC levels at Emmaton and in the western Delta may increase as a result, leading to EC degradation and increased possibility of adverse effects to agricultural beneficial uses.

This is evidenced in the modeling results, which indicated that long-term monthly average EC levels at Emmaton would increase 1–12% for the entire period modeled (1976–1991) and 4–33% during the drought period modeled (1987–1991), relative to the No Action Alternative (ELT) (Table EC-16 in Appendix B of this RDEIR/SDEIS). The largest increases in EC would occur during the summer months of the drought period, and more generally in dry and critical water year types. During these periods, additional flow in the Sacramento River at Emmaton would reduce or eliminate increases in EC. It is expected that for May–September of dry and critical water years, less pumping from the north Delta intakes and greater reliance on south Delta intakes would allow for enough flow in the Sacramento River at Emmaton to reduce water quality degradation to levels closer to the No Action Alternative that would be considered not adverse.

San Joaquin River at San Andreas Landing

Alternative 2D is not expected to have adverse effects on EC in the San Joaquin River at San Andreas Landing, relative to Existing Conditions and the No Action Alternative (ELT). Modeling results estimated that the percent of days the San Andreas Landing EC objective would be exceeded would increase by <1% relative to Existing Conditions, and the percent of days out of compliance would increase from 1% under Existing Conditions to 2% (Table EC-9 in Appendix B of this RDEIR/SDEIS). San Andreas Landing average EC would decrease 6% for the entire period modeled, but would increase 2% during the drought period modeled, relative to Existing Conditions (Table EC-16 in Appendix B of this RDEIR/SDEIS). Results relative to the No Action Alternative (ELT) were similar (Table EC-16 in Appendix B of this RDEIR/SDEIS). However, sensitivity analyses performed for Alternative 4 scenario H3 at the LLT indicate that many of these exceedances are likely modeling artifacts, and the small number of remaining exceedances would be small in magnitude, lasting only a few days, and could be addressed with real time operations of the SWP and CVP (see Chapter 8, Section 8.3.1.1, *Models Used and Their Linkages*, of this RDEIR/SDEIS for a description of real time operations of the SWP and CVP). These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT, because the factors affecting salinity findings in the sensitivity analysis (e.g., modeling assumptions, physical hydrodynamic mechanisms) are similar between the ELT and LLT (see Appendix 8H Attachment 1, in Appendix A of the RDEIR/SDEIS).

San Joaquin River at Prisoners Point

Modeling results indicated that the EC objective that applies between the San Joaquin River at Jersey Point and Prisoners Point would be exceeded at Prisoners Point more often under Alternative 2D than under Existing Conditions and the No Action Alternative (ELT). However, modeling results without restoration areas would be expected to show a lesser effect, and remaining exceedances are expected to be able to be addressed via real-time operations, including real time management of the north Delta and south Delta intakes, as well as Head of Old River Barrier management. Further discussion is provided below.

Modeling results estimated that the percent of days the Prisoners Point EC objective would be exceeded would increase from 6% under Existing Conditions, or 1% under the No Action Alternative (ELT), to 18% and the percent of days out of compliance with the EC objective would increase from 10% under Existing Conditions, or 1% under the No Action Alternative (ELT), to 20% (Table EC-9 in Appendix B of this RDEIR/SDEIS). The magnitude of the exceedances is estimated to be very small—the objective is 440 µmhos/cm, and the EC during times of exceedance was generally between 440 and 550 µmhos/cm. The exceedances generally occurred in drier water years, when flows are lower. During these times, the EC in the San Joaquin River at Vernalis is greater than in the Sacramento River entering the Delta, and is high enough on its own to cause an exceedance.

There are two main drivers of the increase in exceedances under the alternative: an increase in San Joaquin River flow at Prisoners Point during April and May under the alternative, relative to Existing Conditions and the No Action Alternative (ELT), and a reduction in the amount of Sacramento River water moving past Prisoners Point under the alternative. The result is increased San Joaquin River water at Prisoners Point, and a reduction in the dilution that the Sacramento River provides the higher EC San Joaquin River. The increase in San Joaquin River flow at Prisoners Point is due to a reduction in pumping from the south Delta under the alternative, as well as due to the presence of the Head of Old River Barrier, which increases flow in the San Joaquin River downstream of Old River by preventing flow from entering Old River. The reduction in Sacramento River water influence is due to less pumping at the south Delta pumping plants (i.e., greater pumping draws more Sacramento River water through the Delta).

Sensitivity analyses conducted for Alternative 4 scenario H3 at the LLT indicated that removing all tidal restoration areas (such as is largely the case in Alternative 2D at the ELT) would reduce the number of exceedances by about 9 percentage points, but there would still be more exceedances than under Existing Conditions or the No Action Alternative. Sensitivity analyses also indicated that if the Head of Old River Barrier was open in April and May, exceedances would be reduced by about 5 percentage points. Both of these analyses also showed lower EC during April and May, including during times when modeling showed the objective to be exceeded. These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT. Results of the sensitivity analyses indicate that the exceedances are partially a function of the restoration that was assumed in the Alternative 2D modeling, but partly due also to operations of the alternative itself, perhaps due to Head of Old River Barrier assumptions and south Delta export differences (see Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS for more discussion of these sensitivity analyses). Appendix 8H, Attachment 2, in Appendix A of the RDEIR/SDEIS contains a more detailed assessment of the likelihood of these exceedances estimated via modeling for Alternatives 1–9 impacting aquatic life beneficial uses. Specifically, Appendix 8H, Attachment 2, in Appendix A of the RDEIR/SDEIS discusses whether these exceedances might have indirect effects on striped bass spawning in the Delta, and concludes that the high level of uncertainty precludes making a definitive determination for those alternatives. However, based on the sensitivity analyses conducted, modeling of Alternative 2D that did not contain restoration areas would likely show a lesser level of effects than presented herein (using the Alternative 2 ELT modeling), both in terms of frequency and magnitude of exceedance. Additionally, by adaptively managing the Head of Old River Barrier and the fraction of south Delta versus north Delta diversions, EC levels at Prisoners Point would likely be decreased to a level that would not adversely affect aquatic life beneficial uses.

Suisun Marsh

For Suisun Marsh October–May is the period when Bay-Delta WQCP EC objectives for protection of fish and wildlife apply. Modeling results indicate that average EC for the entire period modeled would increase in the Sacramento River at Collinsville during the months of March through May relative to Existing Conditions, by 0.1–0.2 mS/cm (Table EC-11 in Appendix B of this RDEIR/SDEIS). In Montezuma Slough at National Steel, average EC levels would increase in January through March by 0.2–0.4 mS/cm (Table EC-12 in Appendix B of this RDEIR/SDEIS). The most substantial EC increase would occur in Montezuma Slough near Beldon Landing, with long-term average EC levels increasing by 1.5–5.3 mS/cm, depending on the month, at least doubling during some months the long-term average EC relative to Existing Conditions (Table EC-13 in Appendix B of this RDEIR/SDEIS). Sunrise Duck Club and Volanti Slough also would have long-term average EC increases during October–May ranging 1.3–3.1 mS/cm (Tables EC-14 and EC-15 in Appendix B of this RDEIR/SDEIS). Modeled long-term average EC increases in Suisun Marsh under Alternative 2D relative to the No Action Alternative (ELT) are similar to the increases relative to Existing Conditions.

However, modeling used for the assessment of Alternative 2D assumed no operation of the Montezuma Slough Salinity Control Gates, but the project description assumes continued operation of the Salinity Control Gates, consistent with assumptions included in the No Action Alternative. A sensitivity analysis modeling run conducted for Alternative 4 scenario H3 at the LLT with the gates operational consistent with the No Action Alternative resulted in substantially lower EC levels than indicated in the original Alternative 4 modeling results discussed above, but EC levels were still somewhat higher than EC levels under Existing Conditions and the No Action Alternative for several locations and months. Another modeling run with the gates operational and restoration areas removed resulted in EC levels nearly equivalent to Existing Conditions and the No Action Alternative (see Appendix 8H, Attachment 1, of the Draft EIR/EIS for more information on these sensitivity analyses). Since Alternative 2D at the ELT includes operation of the gates, and includes very little tidal restoration areas, it is anticipated that EC increases in Suisun Marsh predicted via the modeling would not occur, and that EC in Suisun Marsh under Alternative 2D would be very similar to Existing Conditions and No Action Alternative (ELT). Depending on where tidal restoration areas assumed to be included in the No Action Alternative are located, EC under Alternative 2D could be less than under the No Action Alternative (ELT). For these reasons, any changes in EC in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

SWP/CVP Export Service Areas

Under Alternative 2D, at the Banks and Jones pumping plants, there would be no exceedance of the Bay-Delta WQCP s 1,000 µmhos/cm EC objective for the entire period modeled (Table EC-10 in Appendix B of this RDEIR/SDEIS), which is the same as under Alternative 4. Relative to Existing Conditions, average EC levels under Alternative 2D would decrease 26–27% for the entire period modeled and 22–23% during the drought period modeled. Relative to the No Action Alternative (ELT), average EC levels would similarly decrease, by 23% for the entire period modeled and 19–20% during the drought period modeled (Table EC-16 in Appendix B of this RDEIR/SDEIS). Based on the decreases in long-term average EC levels that would occur at the Banks and Jones pumping plants, Alternative 2D would not cause degradation of water quality with respect to EC in the SWP/CVP Export Service Areas rather, Alternative 2D would improve long-term average EC conditions in the SWP/CVP Export Service Areas.

Commensurate with the EC decrease in exported waters, an improvement in lower San Joaquin River average EC levels would be expected since EC in the lower San Joaquin River is, in part, related to irrigation water deliveries from the Delta. While the magnitude of this expected lower San Joaquin River improvement in EC is difficult to predict, the relative decrease in overall loading of EC-elevating constituents to the Export Service Areas would likely alleviate or lessen any expected increase in EC at Vernalis related to decreased annual average San Joaquin River flows.

The export area of the Delta is listed on the state's CWA Section 303(d) list as impaired due to elevated EC Alternative 2D would result in lower average EC levels relative to Existing Conditions and the No Action Alternative (ELT) and, thus, would not contribute to additional beneficial use impairment related to elevated EC in the SWP/CVP Export Service Areas waters.

NEPA Effects: In summary, based on the results of the modeling and sensitivity analyses conducted, it is unlikely that there would be increased frequency of exceedance of agricultural EC objectives in the western, interior, or southern Delta. However, modeling results indicate that there could be increased long-term and drought period average EC levels during the summer months that would occur in the western Delta (i.e., in the Sacramento River at Emmaton) under Alternative 2D relative to the No Action Alternative (ELT), that could contribute to adverse effects on the agricultural beneficial uses. In addition, the increased frequency of exceedance of the San Joaquin River at Prisoners Point EC objective could contribute to adverse effects on fish and wildlife beneficial uses (specifically, indirect adverse effects on striped bass spawning), though there is a high degree of uncertainty associated with this impact. Suisun Marsh is CWA Section 303(d) listed as impaired due to elevated EC, but EC levels are not expected to change substantially under Alternative 2D, relative to the No Action Alternative (ELT), and thus it is not expected that they would contribute to additional beneficial use impairment. The increases in EC in the Sacramento River at Emmaton, particularly during summer months of dry and critical water years, and the additional exceedances of water quality objectives in the San Joaquin River at Prisoners Point constitute an adverse effect on water quality. Mitigation Measure WQ-11 would be available to reduce these effects.

CEQA Conclusion: River flow rate and reservoir storage reductions that would occur under Alternative 2D, relative to Existing Conditions, would not be expected to result in a substantial adverse change in EC levels in the reservoirs and rivers upstream of the Delta, given that: changes in the quality of watershed runoff and reservoir inflows would not be expected to occur in the future; the state's regulation of point-source discharge effects on Delta salinity-elevating parameters and the expected further regulation as salt management plans are developed; the salt-related TMDLs adopted and being developed for the San Joaquin River; and the expected improvement in lower San Joaquin River average EC levels commensurate with the lower EC of the irrigation water deliveries from the Delta.

Relative to Existing Conditions, Alternative 2D would not result in any substantial increases in long-term average EC levels in the SWP/CVP Export Service Areas, and there would be no exceedance of the Bay-Delta WQCP EC objective for this area of the Delta. Average EC levels for the entire period modeled would decrease at both the Banks and Jones pumping plants and, thus, this alternative would not contribute to additional beneficial use impairment related to elevated EC in the SWP/CVP Export Service Areas waters. Rather, this alternative would improve long-term EC levels in the SWP/CVP Export Service Areas, relative to Existing Conditions.

Further, relative to Existing Conditions, Alternative 2D would not result in substantial increases in long-term average EC in Suisun Marsh. Thus, EC levels in Suisun Marsh are not expected to further degrade existing EC levels and thus would not contribute additionally to adverse effects on the fish and wildlife beneficial uses. Because EC is not bioaccumulative, any changes in long-term average EC levels would not directly cause bioaccumulative problems in fish and wildlife. Suisun Marsh is CWA Section 303(d) listed as impaired due to elevated EC, but EC levels are not expected to change substantially under Alternative 2D, relative to Existing Conditions, and thus it is not expected that they would contribute to additional beneficial use impairment.

In the Plan Area, Alternative 2D is not expected to result in an increase in the frequency with which Bay-Delta WQCP EC objectives are exceeded, except for at the San Joaquin River at Prisoners Point (fish and wildlife objective; 12% increase). The increased frequency of exceedance of the fish and wildlife objective at Prisoners Point could contribute to adverse effects on aquatic life (specifically, indirect adverse effects on striped bass spawning), though there is a high degree of uncertainty associated with this impact. However, modeling of Alternative 2D that did not contain restoration areas would likely show a lesser level of effects than presented herein (using the Alternative 2 ELT modeling), both in terms of frequency and magnitude of exceedance. Additionally, by adaptively managing the Head of Old River Barrier and the fraction of south Delta versus north Delta diversions, EC levels at Prisoners Point would likely be decreased to a level that would not adversely affect aquatic life beneficial uses.

Average EC levels at Emmaton would increase by 4% during the drought period modeled. The largest monthly average increases in EC would occur during the summer months of the drought period, and more generally in dry and critical water year types. The increases in drought period average EC levels could cause substantial water quality degradation that would potentially contribute to adverse effects on the agricultural beneficial uses in the western Delta. The comparison to Existing Conditions reflects changes in EC due to both Alternative 2D operations and climate change/sea level rise. The adverse effects expected to occur at Emmaton would be due in part to the effects of climate change/sea level rise, and in part due to Alternative 2D operations. This is evidenced by the significant effects expected in the No Action Alternative (ELT) at Emmaton relative to Existing Conditions, as well as the fact that a lesser level of adverse effects is expected at Emmaton under Alternative 2D relative to the No Action Alternative (ELT). During summer of dry and critical water years, additional flow in the Sacramento River at Emmaton would reduce or eliminate increases in EC. It is expected that for May–September of dry and critical water years, less pumping from the north Delta intakes and greater reliance on south Delta intakes would allow for enough flow in the Sacramento River at Emmaton to reduce water quality degradation to levels closer to the No Action Alternative that would not be expected to adversely affect beneficial uses. Because EC is not bioaccumulative, the increases in long-term average EC levels would not directly cause bioaccumulative problems in aquatic life or humans. The western Delta is CWA Section 303(d) listed for elevated EC and the increased EC degradation that could occur in the western Delta could make beneficial use impairment measurably worse. Based on these findings, this impact in the Plan Area is considered to be significant. Implementation of Mitigation Measure WQ-11 would be expected to reduce these effects to a less than significant level.

Mitigation Measure WQ-11: Avoid, Minimize, or Offset, as Feasible, Reduced Water Quality Conditions

Please see Mitigation Measure WQ-11 in Section 4.3.4, of the RDEIR/SDEIS.

Impact WQ-12: Effects on Electrical Conductivity Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15 and 16

***NEPA Effects*:** The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would present no new direct sources of EC to the affected environment, including areas upstream of the Delta, within the Delta region, and in the SWP/CVP Export Service Areas. As they pertain to EC, implementation of these environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment. Moreover, some habitat restoration activities would occur on lands within the Delta currently used for irrigated agriculture. Such replacement or substitution of land use activity is not expected to result in new or increased sources of EC to the Delta and, in fact, could decrease EC through elimination of high EC agricultural runoff.

Environmental Commitment 4 would result in some tidal habitat restoration, however, the areal extent would be small relative to the existing and No Action Alternative tidal area and, thus not expected to appreciably affect the magnitude of daily tidal water exchange at the restoration areas or alter other hydrodynamic conditions in adjacent Delta channels that would result in measurable EC changes.

In summary, implementation of the environmental commitments would not be expected to adversely affect EC levels in the affected environment and thus would not adversely affect beneficial uses or substantially degrade water quality with regard to EC within the affected environment. Therefore, the effects on EC from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 2D would not present new or substantially changed sources of EC to the affected environment. Thus, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would have negligible, if any, adverse effects on EC levels throughout the affected environment and would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria that would result in adverse effects on any beneficial uses within affected water bodies. Further, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause significant long-term water quality degradation such that there would be greater risk of adverse effects on beneficial uses. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-13: Effects on Mercury Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of the Alternative 2D on mercury levels in surface waters upstream of the Delta relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). This is because factors which affect mercury concentrations in surface waters upstream of the Delta are similar under Alternatives 4 and 2D. The changes in flow in the Sacramento River under Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT) would not be of the magnitude of storm flows, in which substantial sediment-associated mercury is mobilized. Therefore, mercury loading should not be substantially different due to changes in flow. In addition, even though it may be flow-affected, total mercury concentrations remain well below criteria at upstream locations. Any negligible changes in mercury concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to mercury. Both waterborne methylmercury concentrations and largemouth bass fillet mercury concentrations are expected to remain above guidance levels at upstream of Delta locations, but would not change substantially because the anticipated changes in flow are not expected to substantially change mercury loading relative to Existing Conditions or the No Action Alternative (ELT).

The upstream of Delta areas in the north will benefit from the implementation of the Cache Creek, Sulfur Creek, Harley Gulch, and Clear Lake Mercury TMDLs and the American River methylmercury TMDL. These projects will target specific sources of mercury and methylation upstream of the Delta and could result in net improvement to Delta mercury loading in the future. The implementation of these projects could help to ensure that upstream of Delta environments will not be substantially degraded for water quality with respect to mercury or methylmercury.

In the LLT, the primary difference will be changes in flow regime due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 2D would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-14. See Chapter 8, Section 8.3.1.3, *Plan Area,* in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

The effects of Alternative 2D on waterborne concentrations of mercury (Table Hg-1 in Appendix B of this RDEIR/SDEIS) and methylmercury (Table Hg-2 in Appendix B of this RDEIR/SDEIS), and fish tissue mercury concentrations for largemouth bass fillet (Tables Hg-11 and Hg-12 in Appendix B of this RDEIR/SDEIS) were evaluated for nine Delta locations.

Similar to Alternative 4, increases in long-term average mercury concentrations relative to Existing Conditions and the No Action Alternative (ELT) would be very small, 0.3 ng/L or less. Also, use of assimilative capacity for mercury relative to the 25 ng/L ecological threshold under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT), would be very low, approximately 2% or less for all Delta locations (Table Hg-15 in Appendix B of this RDEIR/SDEIS). These concentration changes and small changes in assimilative capacity for mercury are not expected to result in adverse (or positive) effects to beneficial uses.

Changes in methylmercury concentrations in water also are expected to be very small. The greatest annual average methylmercury concentration under Alternative 2D would be 0.166 ng/L for the San Joaquin River at Buckley Cove, for the drought period modeled, which would be slightly higher than Existing Conditions (0.161 ng/L) and slightly lower than the No Action Alternative (ELT) (0.168 ng/L) (Table Hg-2 in Appendix B of this RDEIR/SDEIS). All methylmercury concentrations in water were estimated to exceed the TMDL guidance objective of 0.06 ng/L under Existing Conditions and, therefore, no assimilative capacity exists.

Fish tissue estimates for largemouth bass fillet show small or no increases in mercury concentrations relative to Existing Conditions and the No Action Alternative (ELT) based on long-term annual average concentrations for mercury at the Delta locations (Tables Hg-11 and Hg-12 in Appendix B of the RDEIR/SDEIS). Concentrations expected for Alternative 2D, with Equation 1, show increases of 9 percent or less, relative to Existing Conditions and the No Action Alternative (ELT), in all years (Table Hg-11 in Appendix B of this RDEIR/SDEIS). Concentrations expected with Equation 2 show increases from 10 percent to 13 percent in Mokelumne River (South Fork) at Staten Island, Old River at Rock Slough, and San Joaquin River at Antioch relative to Existing Conditions in all years and an increase of 13 percent at Staten Island relative to the No Action Alternative (ELT) in all years (Table Hg-12 in Appendix B of this RDEIR/SDEIS). Because the increases are relatively small, and it is not evident that substantive increases are expected at numerous locations throughout the Delta, these changes are expected to be within the uncertainty inherent in the modeling approach, and would likely not be measurable in the environment. See Appendix 8I, *Mercury*, of the Draft EIR/EIS for a complete discussion of the uncertainty associated with the fish tissue estimates.

Briefly, the bioaccumulation models contain multiple sources of uncertainty associated with their development. These are related to: analytical variability; temporal and/or seasonal variability in Delta source water concentrations of merthylmercury; interconversion of mercury species (i.e., the non-conservative nature of methylmercury as a modeled constituent); and limited sample size (both in number of fish and time span over which the measurements were made), among others. Although there is considerable uncertainty in the models used, the results serve as a reasonable approximations of a very complex process. Considering the uncertainty, small (i.e., <20–25%) increases or decreases in modeled fish tissue mercury concentrations at a low number of Delta locations (i.e., 2–3) should be interpreted to be within the uncertainty of the overall approach, and not predictive of actual adverse effects. Larger increases, or increases evident throughout the Delta, can be interpreted as more reliable indicators of potential adverse effects.

In the LLT, the primary difference will be changes in the Delta source water fractions to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

SWP/CVP Export Service Areas

The analysis of mercury and methylmercury in the SWP/CVP Export Service Areas was based on concentrations estimated at the Banks and Jones pumping plants. Both waterborne total and methylmercury concentrations for Alternative 2D, at the Jones and Banks pumping plants would be lower than Existing Conditions and the No Action Alternative (ELT) (Tables Hg-1 and Hg-2 in Appendix B of this RDEIR/SDEIS). Therefore, there would be increased assimilative capacity for mercury at these locations (Table Hg-15 in Appendix B of this RDEIR/SDEIS).

The largest improvements in largemouth bass tissue mercury concentrations and Exceedance Quotients ([EQs]; modeled tissue divided by TMDL guidance concentration) for Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT) at any location within the Delta are expected for the Banks and Jones pumping plants export pump locations. Concentrations expected for Alternative 2D at the export pump locations with Equation 1 in all years show decreases relative to Existing Conditions (10% to 12%) and relative to the No Action Alternative (ELT) (11% to 13%) (Table Hg-11 in Appendix B of this RDEIR/SDEIS).

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on mercury are expected to be similar to those described above.

NEPA Effects: Based on the above discussion, Alternative 2D would not cause concentrations of mercury and methylmercury in water and fish tissue in the affected environment to be substantially different from the No Action Alternative (ELT and LLT) and, thus, would not cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Because any increases in mercury or methylmercury concentrations are not likely to be measurable, changes in mercury concentrations or fish tissue mercury concentrations would not make any existing mercury-related impairment measurably worse. In comparison to the No Action Alternative (ELT and LLT), Alternative 2D would not be expected to increase levels of mercury by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of mercury in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Based on these findings, the effects of Alternative 2D on mercury in the affected environment are considered to be not adverse.

CEQA Conclusion: Under Alternative 2D, greater water demands and climate change would alter the magnitude and timing of reservoir releases and river flows upstream of the Delta in the Sacramento River watershed and east-side tributaries, relative to Existing Conditions. Concentrations of mercury and methylmercury upstream of the Delta would not be substantially different relative to Existing Conditions due to the lack of important relationships between mercury/methylmercury concentrations and flow for the major rivers.

Methylmercury concentrations exceed criteria at all locations in the Delta and no assimilative capacity exists. However, monthly average waterborne concentrations of total and methylmercury, over the period of record, under Alternative 2D would be very similar to Existing Conditions. Similarly, estimates of fish tissue mercury concentrations show small differences would occur among sites for Alternative 2D as compared to Existing Conditions for Delta sites.

Assessment of effects of mercury in the SWP/CVP Export Service Areas were based on effects on mercury concentrations and fish tissue mercury concentrations at the Banks and Jones pumping plants. The Banks and Jones pumping plants are expected to show increased assimilative capacity for waterborne mercury and decreased fish tissue concentrations of mercury for Alternative 2D, all scenarios, as compared to Existing Conditions.

As such, Alternative 2D is expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Because any increases in mercury or methylmercury concentrations are not likely to be measurable, changes in mercury concentrations or fish tissue mercury concentrations would not make any existing mercury-related impairment measurably worse. In comparison to Existing Conditions, Alternative 2D would not increase levels of mercury by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of mercury in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-14: Effects on Mercury Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** The potential types of effects on mercury resulting from implementation of the environmental commitments under Alternative 2D would be generally similar to those described under Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). However, the magnitude of effects on mercury and methylmercury at locations upstream of the Delta, in the Delta, and the SWP/CVP Export Service Areas related to habitat restoration would be considerably lower than described for Alternative 4. This is because the amount of habitat restoration to be implemented under Alternative 2D would be very low compared to the total proposed restoration area that would be implemented under Alternative 4. The small amount of habitat restoration to be implemented under Alternative 2D may occur on lands in the Delta formerly used for irrigated agriculture. Habitat restoration proposed under Alternative 2D has the potential to increase water residence times and increase accumulation of organic sediments that are known to enhance methylmercury bioaccumulation in biota in the vicinity of the restored habitat areas. Design of restoration sites would be guided by Environmental Commitment 12, which requires development of site-specific mercury management plans as restoration actions are implemented. The effectiveness of minimization and mitigation actions implemented according to the mercury management plans is not known at this time, although the potential to reduce methylmercury concentrations exists based on current research. Although Environmental Commitment 12 would be implemented with the goal to reduce this potential effect, there remain uncertainties related to site-specific restoration conditions and the potential for increases in methylmercury concentrations in the Delta in the vicinity of the restored areas. Therefore, the effect of Environmental Commitments 3, 4, 6–12, 15, and 16 on mercury and methylmercury is considered to be adverse.

***CEQA Conclusion*:** There would be no substantial, long-term increase in mercury or methylmercury concentrations or loads in the rivers and reservoirs upstream of the Delta or the waters exported to the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 relative to Existing Conditions. However, in the Delta, due to the small amount of tidal restoration areas proposed, relative to Existing Conditions, uptake of mercury from water and/or methylation of inorganic mercury may increase in localized areas as part of the creation of new, marshy, shallow, or organic-rich restoration areas. Although not quantifiable, on a local level, increases in methylmercury concentrations may be measurable. Methylmercury is CWA Section 303(d)-listed within the affected environment, and therefore any potential measurable increase in methylmercury concentrations would make existing mercury-related impairment measurably worse. Because mercury is bioaccumulative, increases in water-borne mercury or methylmercury that could occur in some areas could bioaccumulate to somewhat greater levels in aquatic organisms and would, in turn, pose health risks to fish, wildlife, or humans. Design of restoration sites would be guided by Environmental Commitment 12, which requires development of site-specific mercury management plans as restoration actions are implemented. The effectiveness of minimization and mitigation actions implemented according to the mercury management plans is not known at this time, although the potential to reduce methylmercury concentrations exists based on current research. Although Environmental Commitment 12 would be implemented with the goal to reduce this potential effect, the uncertainties related to site specific restoration conditions and the potential for increases in methylmercury concentrations in the Delta result in this potential impact being considered significant. No mitigation measures would be available until specific restoration actions are proposed. Therefore, this impact is considered significant and unavoidable.

Impact WQ-15: Effects on Nitrate Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), nitrate levels in the major rivers (Sacramento, Feather, American) are low, generally due to ample dilution available in the reservoirs and rivers relative to the magnitude of the point and non-point source discharges, and there is no correlation between historical water year average nitrate concentrations and water year average flow in the Sacramento River at Freeport. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 2D, relative to Existing Conditions or the No Action Alternative (ELT), are expected to have negligible, if any, effects on average reservoir and river nitrate-N concentrations in the Sacramento River watershed upstream of the Delta.

In the San Joaquin River watershed, nitrate concentrations are higher than in the Sacramento River watershed, owing to use of nitrate based fertilizers throughout the lower watershed. The correlation between historical water year average nitrate concentrations and water year average flow in the San Joaquin River at Vernalis is a weak inverse relationship—that is, generally higher flows result in lower nitrate concentrations, while low flows result in higher nitrate concentrations (linear regression r^2=0.49; Figure 2 in Appendix 8J, *Nitrate*, of the Draft EIR/EIS). Under Alternative 2D, long-term average flows at Vernalis would decrease an estimated 1% relative to Existing Conditions and would remain virtually the same relative to the No Action Alternative (ELT). Given the relatively small decreases in flows and the weak correlation between nitrate and flows in the San Joaquin River, it is expected that nitrate concentrations in the San Joaquin River would be minimally affected, if at all, by anticipated changes in flow rates under the No Action Alternative (ELT).

In the LLT, the primary difference will be changes in flow regime due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on nitrate are expected to be similar to those described above.

Any negligible changes in nitrate concentrations that may occur under Alternative 2D in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies, with regard to nitrate.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-16. See section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Mass balance calculations indicate that under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT), nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives (Table N-8 in Appendix B of this RDEIR/SDEIS). Although changes at specific Delta locations and for specific months may be substantial on a relative basis (Table N-9 in Appendix B of this RDEIR/SDEIS), the absolute concentration of nitrate in Delta waters would remain low (<1.4 mg/L-N) in relation to the drinking water MCL of 10 mg/L-N, as well as all other thresholds (see *Nitrate* within Chapter 8, Section 8.3.17, *Constituent-Specific Considerations Used in the Assessment*, in Appendix A of the RDEIR/SDEIS). Long-term average nitrate concentrations are anticipated to remain below about 0.6 mg/L-N at all 11 Delta assessment locations except the San Joaquin River at Buckley Cove, where long-term average concentrations would be somewhat above 1 mg/L-N. Nevertheless, at this location, long-term average nitrate concentrations would be similar under Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT). Overall, the difference in long-term average nitrate concentrations at various locations throughout the Delta under Alternative 2D compared to Alternative 4 would be negligible (i.e., <0.1 mg/L). As was similarly concluded for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), no additional exceedances of the MCL are anticipated at any location under Alternative 2D (Table N-8 in Appendix B of this RDEIR/SDEIS).

Use of assimilative capacity relative to the drinking water MCL of 10 mg/L-N under Alternative 2D would be low or negligible (i.e., <2%) in comparison to both Existing Conditions and the No Action Alternative (ELT), for all locations and months, for all modeled years (1976–1991), and for the drought period (1987–1991) (Table N-11 in Appendix B of this RDEIR/SDEIS). One exception is for Old River at Rock Slough in October/November, where use of assimilative capacity relative to Existing Conditions would be up to about 4%. Changes in use of assimilative capacity relative to Existing Conditions and No Action Alternative (ELT) under Alternative 2D would be approximately the same as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of this RDEIR/SDEIS).

As described for Alternative 4 (see in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), actual nitrate concentrations would likely be higher than the modeling results indicate in certain locations under Alternative 2D. This is the mass balance modeling does not account for contributions from the SRWTP, which would be implementing nitrification/partial denitrification, or Delta wastewater treatment plant dischargers that practice nitrification, but not denitrification. However, for the reasons described for Alternative 4, any increases in nitrate concentrations that may occur at certain locations within the Delta under Alternative 2D would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the water quality at these locations, with regard to nitrate.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on nitrate are expected to be similar to those described above.

SWP/CVP Export Service Areas

Assessment of effects of Alternative 2D on nitrate in the SWP/CVP Export Service Areas is based on effects on nitrate at the Banks and Jones pumping plants.

Results of the mass balance calculations indicate that relative to Existing Conditions and the No Action Alternative (ELT), nitrate concentrations at Banks and Jones pumping plants under Alternative 2D are anticipated to decrease on a long-term average annual basis (Table N-8 in Appendix B of this RDEIR/SDEIS). During the late summer, particularly in the drought period assessed, concentrations are expected to increase substantially on a relative basis (i.e., up to 67%), but the absolute value of these changes (i.e., in mg/L-N) would be small. Additionally, given the many factors that contribute to potential algal blooms in the SWP and CVP canals within the Export Service Areas, and the lack of studies that have shown a direct relationship between nutrient concentrations in the canals and reservoirs and problematic algal blooms in these water bodies, there is no basis to conclude that these small (i.e., generally <0.4 mg/L-N), seasonal increases in nitrate concentrations would increase the potential for problem algal blooms in the SWP/CVP Export Service Areas. Overall, the difference in long-term average nitrate concentrations at Banks and Jones pumping plants under Alternative 2D compared to Alternative 4 would be negligible (i.e., <0.1 mg/L) (Table N-9 in Appendix B of this RDEIR/SDEIS). As was similarly concluded for Alternative 4, no additional exceedances of the MCL are anticipated under Alternative 2D (Table N-8 in Appendix B of this RDEIR/SDEIS). On a monthly average basis and on a long-term annual average basis, for all modeled years and for the drought period only, use of assimilative capacity available under Existing Conditions and the No Action Alternative (ELT), relative to the 10 mg/L-N MCL, would be negligible (<2.2%) for both Banks and Jones pumping plants (Table N-11 in Appendix B of this RDEIR/SDEIS). Use of assimilative capacity relative to Existing Conditions and the No Action Alternative (ELT) for Alternative 2D would be slightly less than expected to occur under Alternative 4.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on nitrate are expected to be similar to those described above.

Any increases in nitrate concentrations that may occur in water exported via Banks and Jones pumping plants are not expected to result in adverse effects to beneficial uses or substantially degrade the quality of exported water, with regard to nitrate.

***NEPA Effects*:** Modified reservoir operations and subsequent changes in river flows under Alternative 2D, relative to the No Action Alternative (ELT and LLT), are expected to have negligible, if any, effects on reservoir and river nitrate concentrations upstream of Freeport in the Sacramento River watershed and upstream of the Delta in the San Joaquin River watershed. In the Delta, nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives. No additional exceedances of the 10 mg/L-N MCL are anticipated at any Delta location, and use of assimilative capacity available under the No Action Alternative, relative to the drinking water MCL of 10 mg/L-N, would be low. Long-term average nitrate concentrations at Banks and Jones pumping plants are anticipated to differ negligibly relative to the No Action Alternative (ELT and LLT) and no additional exceedances of the 10 mg/L-N MCL are anticipated. Therefore, the effects on nitrate from implementing water conveyance facilities are considered to be not adverse.

CEQA Conclusion: Nitrate concentrations are generally low in the reservoirs and rivers of the watersheds, owing to substantial dilution available for point sources and the lack of substantial nonpoint sources of nitrate upstream of the SRWTP in the Sacramento River watershed, and in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers). Although higher in the San Joaquin River watershed, nitrate concentrations are not well-correlated with flow rates. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 2D, relative to Existing Conditions, are expected to have negligible, if any, effects on reservoir and river nitrate concentrations upstream of Freeport in the Sacramento River watershed and upstream of the Delta in the San Joaquin River watershed.

In the Delta, results of the mass balance calculations indicate that under Alternative 2D, relative to Existing Conditions, nitrate concentrations throughout the Delta are anticipated to remain low (<1.4 mg/L-N) relative to adopted objectives. No additional exceedances of the 10 mg/L-N MCL are anticipated at any location, and use of assimilative capacity available under Existing Conditions, relative to the drinking water MCL of 10 mg/L-N, would be low or negligible (i.e., <2%) for virtually all locations and months.

Assessment of effects of nitrate in the SWP/CVP Export Service Areas is based on effects on nitrate concentrations at the Banks and Jones pumping plants. Results of the mass balance calculations indicate that under Alternative 2D, relative to Existing Conditions, long-term average nitrate concentrations at Banks and Jones pumping plants are anticipated to change negligibly. No additional exceedances of the 10 mg/L-N MCL are anticipated, and use of assimilative capacity available under Existing Conditions, relative to the MCL would be negligible (i.e., <2.2%) for both Banks and Jones pumping plants for all months.

Based on the above, there would be no substantial, long-term increase in nitrate concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the SWP/CVP Export Service Areas under Alternative 2D relative to Existing Conditions. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because nitrate concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Nitrate is not CWA Section 303(d) listed within the affected environment and thus any increases that may occur in some areas and months would not make any existing nitrate-related impairment measurably worse because no such impairments currently exist. Because nitrate is not bioaccumulative, increases that may occur in some areas and months would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-16: Effects on Nitrate Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Some habitat restoration activities included in Environmental Commitments 3, 4, and 6–11 would occur on lands within the Delta formerly used for agriculture. As discussed for Impact WQ-2, increased biota that may result in those areas may increase ammonia, which in turn may be converted to nitrate by established microbial communities. However, the areal extent of the new habitat implemented for the Environmental Commitments would be less than the existing and No Action Alternative habitat areas, and similar habitat exists currently in the Delta and is not identified as contributing to adverse nitrate conditions. Thus, these land use changes would not be expected to substantially increase nitrate concentrations in the Delta. Implementation of Environmental Commitments 12, 15, and 16 do not include actions that would affect nitrate sources or loading. Based on these findings, the effects on nitrate from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

***CEQA Conclusion*:** Land use changes that would occur from the environmental commitments are not expected to substantially increase nitrate concentrations, because the amount of area to be converted would be small relative to existing habitat, and existing habitats are not known for contributing to adverse nitrate conditions. Thus, it is expected that implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because nitrate concentrations are not expected to increase substantially due to these environmental commitments, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Nitrate is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing nitrate-related impairment measurably worse because no such impairments currently exist. Because nitrate is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-17: Effects on Dissolved Organic Carbon Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 2D on DOC concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 because factors affecting DOC concentrations in these water bodies would be similar. Moreover, long-term average flow and DOC levels in the Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated. Thus changes in system operations and resulting reservoir storage levels and river flows under Alternative 2D would not be expected to cause substantial long-term changes in DOC concentrations in the water bodies upstream of the Delta. Any changes in DOC levels in water bodies upstream of the Delta under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not be of sufficient frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies.

Delta

Effects of water conveyance facilities on long-term average DOC concentrations under Alternative 2D in the Delta would be similar to the effects discussed for Alternative 4. To the extent that habitat restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. However, there would be less potential for increased DOC concentrations at western Delta locations associated with habitat restoration under Alternative 2D because very little would occur relative to Alternative 4. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-

18. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Under Alternative 2D, the geographic extent of effects pertaining to long-term average DOC concentrations in the Delta would be less extensive, and the magnitude of predicted long-term change and relative frequency of concentration threshold exceedances would be similar to, or lower than, the changes described for Alternative 4. The effects of Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT) are discussed together because the direction and magnitude of predicted change are similar. Relative to the Existing Conditions and No Action Alternative (ELT), Alternative 2D would result in small increases in long-term average DOC concentrations for both the modeled 16-year period (1976–1991) and drought period (1987–1991) at several interior Delta locations (increases up to 0.3 mg/L at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, and Contra Costa Pumping Plant #1) (Table DOC-2 in Appendix B of this RDEIR/SDEIS). The increases in average DOC concentrations would correspond to more frequent concentration threshold exceedances, with the greatest change occurring at the Contra Costa Pumping Plant #1 associated with the 3 mg/L threshold (i.e., increase from 52% under Existing Conditions to 69% under Alternative 2D for the modeled 16-year period). The change in frequency of threshold concentration exceedances at other assessment locations would be similar or lower.

While Alternative 2D would lead to slightly higher long-term average DOC concentrations at some municipal water intakes and Delta interior locations, the predicted change would not be expected to adversely affect MUN beneficial uses, or any other beneficial use. As discussed for Alternative 4, substantial changes in ambient DOC concentrations would need to occur before significant changes in drinking water treatment plant design or operations are triggered. The increases in long-term average DOC concentrations estimated to occur at various Delta locations under Alternative 2D are of sufficiently small magnitude that they would not require existing drinking water treatment plants to substantially upgrade treatment for DOC removal above levels currently employed.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on DOC are expected to be similar to those described above.

Relative to Existing Conditions and the No Action Alternative (ELT and LLT), Alternative 2D would lead to predicted improvements in long-term average DOC concentrations at Barker Slough, as well as Banks and Jones pumping plants (discussed below).

SWP/CVP Export Service Areas

Under the Alternative 2D, long-term average DOC concentrations would decrease at Barker Slough (as much as 0.2 mg/L) and at both the Banks and Jones pumping plants (as much as 0.5 mg/L) relative to Existing Conditions, and the reductions would be similar compared to No Action Alternative (ELT) (Table DOC-2 in Appendix B of this RDEIR/SDEIS). Decreases in long-term average DOC would result in generally lower exceedance frequencies for concentration thresholds, although the frequency of exceedances of the 3 mg/L threshold during the modeled drought period would increase at the Banks and Jones pumping plants (i.e., increase at Banks pumping plant from 57% under Existing Conditions to 77% under Alternative 2D). Comparisons to the No Action Alternative (ELT) yield similar trends, but with slightly smaller magnitude drought period changes.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on DOC are expected to be similar to those described above.

Maintenance of SWP and CVP facilities under Alternative 2D would not be expected to create new sources of DOC or contribute towards a substantial change in existing sources of DOC in the affected area.

NEPA Effects: In summary, the operations and maintenance activities under Alternative 2D, relative to the No Action Alternative (ELT and LLT), would not cause a substantial long-term change in DOC concentrations in the water bodies upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas. The long-term average DOC concentrations at the Barker Slough and Banks and Jones pumping plants are predicted to decrease (by up to 0.5 mg/L), while long-term average DOC concentrations for some Delta interior locations are predicted to increase by as much as 0.3 mg/L. However, the increase in long-term average DOC concentration that could occur within the Delta interior would not be of sufficient magnitude to adversely affect the MUN beneficial use, or any other beneficial uses, of Delta waters. Based on these findings, the effect of operations and maintenance activities on DOC under Alternative 2D is determined to be not adverse.

CEQA Conclusion: For the same reasons described for Alternative 4, the operations and maintenance activities under Alternative 2D, relative to the Existing Conditions, would not cause a substantial long-term change in DOC concentrations in the water bodies upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas. Any modified reservoir operations and subsequent changes in river flows under Alternative 2D, relative to Existing Conditions, would not be expected to result in a substantial adverse change in DOC levels upstream of the Delta. Moreover, long-term average flow and DOC at Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated; therefore, changes in river flows would not be expected to cause a substantial long-term change in DOC concentrations upstream of the Delta.

Relative to Existing Conditions, the Alternative 2D would result in relatively small increases (i.e., ≤0.3 mg/L) in long-term average DOC concentrations at some interior Delta locations. The predicted increases under the operational scenarios modeled would not substantially increase the frequency with which long-term average DOC concentrations exceeds 2, 3, or 4 mg/L. While the operational scenarios would lead to slightly higher long-term average DOC concentrations at the interior Delta locations and some municipal water intakes, the predicted changes would not be expected to adversely affect MUN beneficial uses, or any other beneficial use.

Relative to Existing Conditions, Alternative 2D would result in reduced long-term average DOC concentrations at the Banks and Jones pumping plants and Barker Slough. However, Alternative 2D would result in slightly greater frequency of exceedance of the 3 mg/L DOC concentration threshold during the modeled drought period. Nevertheless, an overall improvement in DOC-related water quality would be predicted in the SWP/CVP Export Service Areas.

Based on the above, the operations and maintenance activities of Alternative 2D would not result in any substantial change in long-term average DOC concentration. The increases in long-term average DOC concentration that could occur within the Delta would not be of sufficient magnitude to adversely affect the MUN beneficial use, or any other beneficial uses, of Delta waters or waters of the SWP/CVP Service Area. Because DOC is not bioaccumulative, the increases in long-term average DOC concentrations would not directly cause bioaccumulative problems in aquatic life or humans.

Finally, DOC is not causing beneficial use impairments and thus is not CWA Section 303(d) listed for any water body within the affected environment. Because long-term average DOC concentrations are not expected to increase substantially, no long-term water quality degradation with respect to DOC is expected to occur and, thus, no adverse effects on beneficial uses would occur. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-18: Effects on Dissolved Organic Carbon Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Relative to existing habitat and that to be developed under the No Action Alternative (ELT and LLT), the area of new habitat restoration implemented for the Environmental Commitments would be very small. Implementation of non-habitat restoration environmental commitments would not be expected to have substantial, if even measurable, effect on DOC concentrations upstream of the Delta, within the Delta, and in the SWP/CVP Export Service Areas, because they would present no major sources of DOC to the affected environment. Consequently, any increases in average DOC levels in the affected environment are not expected to be of sufficient frequency, magnitude and geographic extent that would adversely affect the MUN beneficial use, or any other beneficial uses, of the affected environment, nor would potential increases substantially degrade water quality with regard to DOC. Based on these findings, the effect of the environmental commitments on DOC is determined to be not adverse.

CEQA Conclusion: Implementation of habitat restoration (i.e., Environmental Commitments 4, 6, 7, and 10), relative to the Existing Conditions, is not expected to cause a substantial long-term change in DOC concentrations in the water bodies upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas, because the land area proposed for restoration would be relatively small compared to existing land area and sources of DOC. Implementation of other environmental commitments also would not be expected to have substantial, if even measurable, effect on DOC concentrations upstream of the Delta, within the Delta, and in the SWP/CVP Export Service Areas, because they would present no major sources of DOC to the affected environment. Consequently, increases in average DOC levels in the affected environment are not expected to be of sufficient frequency, magnitude and geographic extent that would adversely affect the MUN beneficial use, or any other beneficial uses, of the affected environment, nor would potential increases substantially degrade water quality with regard to DOC. Furthermore, DOC is not bioaccumulative, therefore changes in DOC concentrations would not cause bioaccumulative problems in aquatic life or humans. Finally, DOC is not causing beneficial use impairments and thus is not CWA Section 303(d) listed for any water body within the affected environment. Because long-term average DOC concentrations are not expected to increase substantially, no long-term water quality degradation with respect to DOC is expected to occur and, thus, no adverse effects on beneficial uses would occur. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-19: Effects on Pathogens Resulting from Facilities Operations and Maintenance

The effects of operation of the water conveyance facilities under Alternative 2D on pathogen levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). As described for Alternative 4, pathogen concentrations in the Sacramento and San Joaquin Rivers have a minimal relationship to flow rate in these rivers. Further, urban runoff contributions during the dry season would be expected to be a relatively small fraction of the rivers' total flow rates. During wet weather events, when urban runoff contributions would be higher, the flows in the rivers also would be higher. Given the small magnitude of urban runoff contributions relative to the magnitude of river flows and that pathogen concentrations in the rivers have a minimal relationship to river flow rate, river flow rate and reservoir storage reductions that would occur under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not be expected to result in a substantial adverse change in pathogen concentrations in the reservoirs and rivers upstream of the Delta.

The effects of Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be changes in the relative percentage of water throughout the Delta being comprised of various source waters (i.e., water from the Sacramento River, San Joaquin River, Bay water, eastside tributaries, and agricultural return flow), due to potential changes in inflows particularly from the Sacramento River watershed. However, as described for Alternative 4, it is expected there would be no substantial change in Delta pathogen concentrations in response to a shift in the Delta source water percentages under this alternative or substantial degradation of these water bodies, with regard to pathogens, because it is expected that pathogen sources in close proximity to Delta sites would have a greater influence on pathogen levels at the site, rather than the primary source(s) of water to the site. In-Delta potential pathogen sources, including water-based recreation, tidal habitat, wildlife, and livestock-related uses, would continue under this alternative. As such, there is not expected to be substantial, if even measurable, changes in pathogen concentrations in the SWP/CVP Export Service Area waters.

As such, Alternative 2D would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or U.S. EPA-recommended pathogen criteria would be exceeded in water bodies of the affected environment located upstream of the Delta or substantially degrade the quality of these water bodies, with regard to pathogens.

NEPA Effects: Because pathogen levels are expected to be minimally affected relative to the No Action Alternative (ELT and LLT), the effects on pathogens from implementing Alternative 2D are determined to be not adverse.

CEQA Conclusion: The effects of Alternative 2D on pathogen levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because the factors that would affect pathogen levels in the surface waters of these areas would be similar. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pathogen concentrations are not expected to increase substantially, no long-term water quality degradation for pathogens is expected to occur and, thus, no adverse effects on beneficial uses would occur. The San Joaquin River in the Stockton Deep Water Ship Channel is CWA Section 303(d) listed for pathogens. Because no measurable increase in Deep Water Ship Channel pathogen concentrations are expected to occur on a long-term basis, further degradation and impairment of this area is not expected to occur. Finally, pathogens are not bioaccumulative constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-20: Effects on Pathogens Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Environmental Commitments 3, 4, and 6–11 would involve habitat restoration actions. This could result in localized increases in wildlife-related coliforms relative to the No Action Alternative (ELT and LLT). The Delta currently supports similar habitat types and, with the exception of the CWA Section 303(d) listing for the Stockton Deep Water Ship Channel, is not recognized as exhibiting pathogen concentrations that rise to the level of adversely affecting beneficial uses. As such, the potential increase in wildlife-related coliform concentrations due to tidal habitat creation is not expected to adversely affect beneficial uses. The remaining environmental commitments would not be expected to affect pathogen levels, because they are actions that do not affect the presence of pathogen sources. Based on these findings, the effects on pathogens from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, and 6–11 could result in localized increases in wildlife-related coliforms relative to Existing Conditions. The Delta currently supports similar habitat types and, with the exception of the CWA Section 303(d) listing for the Stockton Deep Water Ship Channel, is not recognized as exhibiting pathogen concentrations that rise to the level of adversely affecting beneficial uses. As such, the potential increase in wildlife-related coliform concentrations due to tidal habitat creation is not expected to adversely affect beneficial uses. Therefore, the environmental commitments are not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pathogen concentrations are not expected to increase substantially, no long-term water quality degradation for pathogens is expected to occur and, thus, no adverse effects on beneficial uses would occur. The San Joaquin River in the Stockton Deep Water Ship Channel is CWA Section 303(d) listed for pathogens. Because no measurable increase in Deep Water Ship Channel pathogen concentrations are expected to occur on a long-term basis, further degradation and impairment of this area is not expected to occur. Finally, pathogens are not bioaccumulative constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-21: Effects on Pesticide Concentrations Resulting from Facilities Operations and Maintenance

The effects of Alternative 2D on pesticide levels in surface waters upstream of the Delta, relative to Existing Conditions and the No Action Alternative (ELT), would be similar to those expected to occur under Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because under Alternative 2D, the primary factor that would influence pesticide concentrations in surface waters upstream of the Delta—the effect of timing and magnitude of reservoir releases on dilution capacity—is expected to change by a similar degree. As shown in Tables P-1 through P-4 in Appendix B of this RDEIR/SDEIS, changes in average winter and summer flow rates, relative to Existing Conditions and the No Action Alternative (ELT), are expected to be similar to or less than changes in flow rates expected under Alternative 4 in the Sacramento River at Freeport, American River at Nimbus, Feather River at Thermalito and the San Joaquin River at Vernalis (shown in Tables 1–4 in Appendix 8L, *Pesticides*, of the Draft EIR/EIS). Similarly, the primary factor that would influence pesticide concentrations in surface waters of the Delta and in the SWP/CVP Export Service Areas (i.e., changes in San Joaquin River, Sacramento River and Delta Agriculture source water fractions at various Delta locations, including Banks and Jones pumping plants) is expected to change by a similar degree. As shown for Alternative 2D (Figures B.4-67 through B.4-88 in Appendix B of this RDEIR/SDEIS), the percent change in monthly average source water fractions would be similar to changes expected under Alternative 4 (Figures 133–175 in Appendix 8D, *Source Water Fingerprinting Results*, of the Draft EIR/EIS).

It was concluded for Alternative 4, and thus for Alternative 2D based on similar flow changes, that the potential average summer flow reductions would not be of sufficient magnitude to substantially increase in-river pesticide concentrations or alter the long-term risk of pesticide-related effects on aquatic life beneficial uses upstream of the Delta. Greater long-term average flow reductions, and corresponding reductions in dilution/assimilative capacity, would be necessary before long-term risk of pesticide related effects on aquatic life beneficial uses would be adversely altered. Similarly, the modeled changes in the source water fractions of Sacramento River, San Joaquin River, and Delta agriculture water under Alternative 2D would not be of sufficient magnitude to substantially alter the long-term risk of pesticide-related toxicity to aquatic life, nor adversely affect other beneficial uses of the Delta. Based on the general observation that San Joaquin River, in comparison to the Sacramento River, is a greater contributor of organophosphate insecticides in terms of greater frequency of incidence and presence at concentrations exceeding water quality benchmarks, modeled increases in Sacramento River fraction at Banks and Jones would generally represent an improvement in export water quality respective to pesticides.

The flow changes in the LLT would be expected in the ranges of that described above for Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT), and that described for Alternative 4 relative to the No Action Alternative (LLT) in Chapter 8, Section 8.3.3.9, in Appendix A of this RDEIR/SDEIS. Thus, similar to above and Alternative 4, the flow changes that would occur in the LLT under Alternative 2D, relative to Existing Conditions and the No Action Alternative (LLT), would not be expected to result in changes in dilution of pesticides of sufficient magnitude to substantially alter the long-term risk of pesticide-related toxicity to aquatic life, nor adversely affect other beneficial uses upstream of the Delta, in the Delta, or the SWP/CVP Export Service Areas.

NEPA Effects: In summary, the changes in long-term average flows on the Sacramento, Feather, American, and San Joaquin Rivers under Alternative 2D relative to the No Action Alternative (ELT and LLT) would be of insufficient magnitude to substantially increase the long-term risk of pesticide-related water quality degradation and related toxicity to aquatic life in these water bodies upstream of the Delta. Similarly, changes in source water fractions to the Delta would be of insufficient magnitude to substantially alter the long-term risk of pesticide-related water quality degradation and related toxicity to aquatic life in the Delta or CVP/SWP Export Service Areas. Therefore, the effects on pesticides from the water conveyance facilities are determined not to be adverse.

***CEQA Conclusion*:** Based on the discussion above, the effects of Alternative 2D on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to or slightly less than those described for the Alternative 4. The considered operational scenarios of Alternative 2D would not result in any substantial change in long-term average pesticide concentration or result in substantial increase in the anticipated frequency with which long-term average pesticide concentrations would exceed aquatic life toxicity thresholds or other beneficial use effect thresholds upstream of the Delta, at the 11 assessment locations analyzed for the Delta, or the SWP/CVP service area. Numerous pesticides are currently used throughout the affected environment, and while some of these pesticides may be bioaccumulative, those present-use pesticides for which there is sufficient evidence for their presence in waters affected by SWP and CVP operations (i.e., diazinon, chlorpyrifos, diuron, and pyrethroids) are not considered bioaccumulative, and thus changes in their concentrations would not directly cause bioaccumulative problems in aquatic life or humans. Furthermore, while there are numerous CWA Section 303(d) listings throughout the affected environment that name pesticides as the cause for beneficial use impairment, the modeled changes in upstream river flows and Delta source water fractions under Scenarios H3–H4 would not be expected to make any of these beneficial use impairments measurably worse. Because long-term average pesticide concentrations are not expected to increase substantially, no long-term water quality degradation with respect to pesticides is expected to occur and, thus, no adverse effects on beneficial uses would occur. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-22: Effects on Pesticide Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of pesticides, and the potential short-term loading from former agricultural lands would be expected to degrade and dissipate rapidly. Therefore, relative to the No Action Alternative (ELT), the effects on pesticides from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to be not adverse.

***CEQA Conclusion*:** Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of pesticides, and the potential short-term loading from former agricultural lands would be expected to degrade and dissipate rapidly, such that pesticide levels would differ little from Existing Conditions. Therefore, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause substantial long-term increase in pesticide concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the SWP/CVP Export Service Areas. As such, these environmental commitments are not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because pesticide concentrations are not expected to increase substantially, no long-term water quality degradation for pesticides is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term pesticide concentrations that may occur throughout the affected environment would not be expected to make any existing beneficial use impairments measurably worse. Environmental Commitments 3, 4, 6–12, 15, 16 do not include the use of pesticides known to be bioaccumulative in animals or humans, nor do the environmental commitments propose the use of any pesticide currently named in a CWA Section 303(d) listing of the affected environment. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-23: Effects on Phosphorus Concentrations Resulting from Facilities Operations and Maintenance

The effects of Alternative 2D on phosphorus concentrations in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because factors which affect phosphorus concentrations in surface waters of these areas are the same under Alternative 4 and Alternative 2D. As described for Alternative 4, phosphorus loading to waters upstream of the Delta is not anticipated to change, and because changes in flows do not necessarily result in changes in concentrations or loading of phosphorus to these water bodies, substantial changes in phosphorus concentration are not anticipated under Alternative 2D, relative to Existing Conditions or the No Action Alternative (ELT and LLT), upstream of the Delta. Phosphorus concentrations may increase during January through March at locations in the Delta where the source fraction of San Joaquin River water increases, due to the higher concentration of phosphorus in the San Joaquin River during these months compared to Sacramento River water or San Francisco Bay water. However, based on the DSM2 fingerprinting results (Figures B.4-1 through B.4-66 in Appendix B of this RDEIR/SDEIS), together with source water concentrations (in Figure 8-56 in Appendix A of the RDEIR/SDEIS), the magnitude of increases during these months is expected to be negligible to low (i.e., <0.02 mg/L) at all Delta locations relative to Existing Conditions and the No Action Alternative (ELT and LLT). Thus, phosphorus concentrations in the Delta and waters exported from Banks and Jones pumping plants to the SWP/CVP Export Service Areas are expected to be similar to Existing Conditions and the No Action Alternative (ELT and LLT).

NEPA Effects: In summary, operation of the water conveyance facilities would have little to no effect on phosphorus concentrations in water bodies upstream of the Delta, in the Plan Area, and the waters exported to the SWP/CVP Export Service Areas, relative to the No Action Alternative (ELT and LLT). Thus, effects of the water conveyance facilities on phosphorus are considered to be not adverse.

CEQA Conclusion**:** The effects of Alternative 2D on phosphorus levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for the Alternative 4. There would be no substantial, long-term increase in phosphorus concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the CVP and SWP service areas under Alternative 2D relative to Existing Conditions. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because phosphorus concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Phosphorus is not CWA Section 303(d) listed within the affected environment and thus any minor increases that may occur in some areas would not make any existing phosphorus-related impairment measurably worse because no such impairments currently exist. Because phosphorus is not bioaccumulative, minor increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-24: Effects on Phosphorus Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects**:** Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of phosphorus. Therefore, relative to the No Action Alternative (ELT and LLT), the effects on phosphorus from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion: Environmental Commitments 3, 4, 6–12, 15, and 16 do not involve actions that would contribute long-term additional loading of phosphorus. Therefore, there would be no substantial, long-term increase in phosphorus concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the waters exported to the SWP/CVP Export Service Areas due to implementation of these environmental commitments relative to Existing Conditions. Because phosphorus concentrations are not expected to increase substantially due to these environmental commitments, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. Phosphorus is not CWA Section 303(d) listed within the affected environment and, thus, the environmental commitments would not make any existing phosphorus-related impairment measurably worse because no such impairments currently exist. Because phosphorus is not bioaccumulative, any increases that may occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-25: Effects on Selenium Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 2D on selenium concentrations in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), because factors affecting selenium concentrations in these water bodies would be similar. Substantial point sources of selenium do not exist upstream in the Sacramento River watershed, in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), or upstream of the Delta in the San Joaquin River watershed. Nonpoint sources of selenium within the watersheds of the Sacramento River and the eastern tributaries also are relatively low, resulting in generally low selenium concentrations in the reservoirs and rivers of those watersheds. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 2D, relative to Existing Conditions or the No Action Alternative (ELT and LLT), are expected to have negligible, if any, effects on reservoir and river selenium concentrations upstream of Freeport in the Sacramento River watershed or in the eastern tributaries upstream of the Delta. Similarly, it is expected that selenium concentrations in the San Joaquin River would be minimally affected, if at all, by anticipated changes in flow rates under Alternative 2D, given the relatively small decreases in flows and the considerable variability in the relationship between selenium concentrations and flows in the San Joaquin River. Any negligible changes in selenium concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to selenium.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 2D would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-26. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Alternative 2D would result in small changes in average selenium concentrations in water relative to Existing Conditions and No Action Alternative (ELT) at all modeled Delta assessment locations

(Table Se-1 in Appendix B of this RDEIR/SDEIS). Long-term average concentrations at some interior and western Delta locations would increase by 0.01–0.04 µg/L for the entire period modeled (1976–1991). These small increases in selenium concentrations in water would result in small reductions (4% or less) in available assimilative capacity for selenium, relative to USEPA's draft water quality criterion of 1.3 µg/L (Table Se-8c in Appendix B of this RDEIR/SDEIS). The long-term average selenium concentrations in water under Alternative 2D (range 0.09–0.40 µg/L) would be similar to Existing Conditions (range 0.09–0.41 µg/L) and the No Action Alternative (ELT) (range 0.09–0.39 µg/L), and would be below the draft water quality criterion of 1.3 µg/L (Table Se-1 in Appendix B of this RDEIR/SDEIS). These changes would be nearly identical to those under Alternative 4.

Relative to Existing Conditions and the No Action Alternative (ELT), Alternative 2D would result in small changes (about 1% or less) in estimated selenium concentrations in most biota (whole-body fish, bird eggs [invertebrate diet or fish diet], and fish fillets) throughout the Delta, with little difference among locations (Tables Se-2c and Se-4c in Appendix B of this RDEIR/SDEIS). Level of Concern Exceedance Quotients (i.e., modeled tissue divided by Level of Concern benchmarks) for selenium concentrations in those biota for all years and for drought years are less than 1.0, indicating low probability of adverse effects. Similarly, Advisory Tissue Level Exceedance Quotients for selenium concentrations in fish fillets for all years and drought years are less than 1.0. Estimated selenium concentrations in sturgeon for the San Joaquin River at Antioch are predicted to increase by about 19 percent relative to Existing Conditions and to the No Action Alternative (ELT) in all years (from about 4.7 to about 5.6 mg/kg dry weight [dw]), and those for sturgeon in the Sacramento River at Mallard Island are predicted to increase by about 13 percent in all years (from about 4.4 to 5.0 mg/kg dw) (Tables Se-5 and Se-6 in Appendix B of this RDEIR/SDEIS). Selenium concentrations in sturgeon during drought years are expected to increase by about 4 to 7 percent at those locations (from about 6.9 to 7.3 mg/kg dw) (Tables Se-5 and Se-6 in Appendix B of this RDEIR/SDEIS). Detection of small changes in whole-body sturgeon such as those estimated for the western Delta would require very large sample sizes because of the inherent variability in fish tissue selenium concentrations. Low Toxicity Threshold Exceedance Quotients for selenium concentrations in sturgeon in the western Delta would exceed 1.0 for drought years at both locations (as they do for Existing Conditions and the No Action Alternative (ELT)) and for all years in the San Joaquin River at Antioch (where quotient increases from 0.94 to 1.1) (Table Se-7 in Appendix B of this RDEIR/SDEIS). The High Toxicity Threshold Quotient would be less than 1.0 at both locations for all years and drought years (Table Se-7 in Appendix B of this RDEIR/SDEIS).

The disparity between larger estimated changes for sturgeon and smaller changes for other biota is attributable largely to differences in modeling approaches, as described in Appendix 8M, *Selenium*, in Appendix A of this RDEIR/SDEIS. The model for most biota was calibrated to encompass the varying concentration-dependent uptake from waterborne selenium concentrations (expressed as the K_d, which is the ratio of selenium concentrations in particulates [as the lowest level of the food chain] relative to the waterborne concentration) that was exhibited in data for largemouth bass in 2000, 2005, and 2007 at various locations across the Delta. In contrast, the modeling for sturgeon could not be similarly calibrated at the two western Delta locations and used literature-derived uptake factors and trophic transfer factors for the estuary from Presser and Luoma (2013). As noted in Appendix 8M, there was a significant negative log-log relationship of K_d to waterborne selenium concentration that reflected the greater bioaccumulation rates for bass at low waterborne selenium than at higher concentrations. There was no difference in bass selenium concentrations in the Sacramento River at Rio Vista in comparison to the San Joaquin River at Vernalis in 2000, 2005, and 2007 [Foe 2010], despite a nearly 10-fold difference in waterborne selenium. Thus, there is more confidence in the site-specific modeling based on the Delta-wide model that was calibrated for bass data than in the estimates for sturgeon based on “fixed” K_ds for all years and for drought years without regard to waterborne selenium concentration at the two locations in different time periods.

Residence time of water in the Delta is expected to increase relative to Existing Conditions primarily as a result of habitat restoration (8,000 acres of tidal habitat restoration and enhancements to the Yolo Bypass) that is assumed to occur under the No Action Alternative (ELT) separate from Alternative 2D. Although estimates of the residence time increases are not available for Alternative 2D, estimates for Alternative 2 at the Late Long Term (presented in Table 8-60a in Section 8.3.1.7 of Appendix A in the *Microcystis* subsection) which contained 65,000 acres of tidal restoration are available, and is expected that residence time increases under Alternative 2D would be substantially less than identified for Alternative 2 in the table.

If increases in fish tissue or bird egg selenium were to occur as a result of increased residence time, the increases would likely be of concern only where fish tissues or bird eggs are already elevated in selenium to near or above thresholds of concern. That is, where biota concentrations are currently low and not approaching thresholds of concern (which, as discussed above, is the case throughout the Delta, except for sturgeon in the western Delta), changes in residence time alone would not be expected to cause them to then approach or exceed thresholds of concern. Thus, the most likely area in which biota tissues would be at levels high enough that additional bioaccumulation due to increased residence time from restoration areas would be a concern is the western Delta and Suisun Bay for sturgeon. Based on the expected minor increases in residence time in the western Delta and Suisun Bay, any increases are not expected to be of sufficient magnitude to substantially affect selenium bioaccumulation.

Relative to Existing Conditions and the No Action Alternative (ELT), Alternative 2D would result in essentially no change in selenium concentrations throughout the Delta for most biota (about 1% or less), although larger increases in selenium concentrations are predicted for sturgeon in the western Delta. Concentrations of selenium in sturgeon would exceed only the lower benchmark, indicating a low potential for effects. The modeling of bioaccumulation for sturgeon is less calibrated to site-specific conditions than that for other biota, which was calibrated on a robust dataset for modeling of bioaccumulation in largemouth bass as a representative species for the Delta. Overall, Alternative 2D would not be expected to substantially increase the frequency with which applicable water quality criterion, or toxicity and level of concern benchmarks would be exceeded in the Delta (there being only a small increase for sturgeon relative to the low benchmark and no exceedance of the high benchmark) or substantially degrade the quality of water in the Delta, with regard to selenium. These changes would be similar to those described for Alternative 4.

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on selenium are expected to be similar to those described above.

SWP/CVP Export Service Areas

Alternative 2D would result in small (0.06–0.09 µg/L) decreases in long-term average selenium concentrations in water at the Banks and Jones pumping plants, relative to Existing Conditions and the No Action Alternative (ELT), for the entire period modeled (Table Se-1 in Appendix B of this RDEIR/SDEIS). These decreases in long-term average selenium concentrations in water would result in increases in available assimilative capacity for selenium at these pumping plants, relative to the USEPA's draft water quality criterion of 1.3 μg/L (Table Se-8c in Appendix B of this RDEIR/SDEIS). The long-term average selenium concentrations in water for Alternative 2D (range 0.15–0.19 μg/L) would be well below the draft water quality criterion of 1.3 μg/L (Table Se-1 in Appendix B of this RDEIR/SDEIS).

Relative to Existing Conditions and the No Action Alternative (ELT), Alternative 2D would result in small changes (about 1% or less) in estimated selenium concentrations in biota (whole-body fish, bird eggs [invertebrate diet], bird eggs [fish diet], and fish fillets) (Table Se-4c in Appendix B of this RDEIR/SDEIS). Concentrations in biota would not exceed any selenium toxicity or level of concern benchmarks for Alternative 2D (Table Se-4c in Appendix B of this RDEIR/SDEIS).

In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on selenium are expected to be similar to those described above.

***NEPA Effects*:** Relative to the No Action Alternative (ELT and LLT), Alternative 2D would result in essentially negligible changes in selenium concentrations in water upstream of the Delta. Similarly, there would be negligible changes in selenium water and most biota concentrations in the Delta, with no exceedances of benchmarks for biological effects. For sturgeon in the Delta, there would be only a small increase of threshold exceedance relative to the low benchmark for sturgeon and no exceedance of the high benchmark. At the Banks and Jones pumping plants, Alternative 2D would cause no increases in the frequency with which applicable benchmarks would be exceeded and would slightly improve the quality of water in selenium concentrations. Therefore, the effects on selenium (both as waterborne and as bioaccumulated in biota) from Alternative 2D are considered to be not adverse.

***CEQA Conclusion*:** There are no substantial point sources of selenium in watersheds upstream of the Delta, and no substantial nonpoint sources of selenium in the watersheds of the Sacramento River and the eastern tributaries. Nonpoint sources in the San Joaquin Valley that contribute selenium to the Delta will be controlled through a TMDL developed by the Central Valley Water Board (2001) for the lower San Joaquin River, established limits for the Grassland Bypass Project, and Basin Plan objectives (Central Valley Water Board [2010 d] and State Water Board [2010b, 2010c]) that are expected to result in decreasing discharges of selenium from the San Joaquin River to the Delta. Consequently, any modified reservoir operations and subsequent changes in river flows under Alternative 2, relative to Existing Conditions, are expected to cause negligible changes in selenium concentrations in water. Any negligible changes in selenium concentrations that may occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies as related to selenium.

Relative to Existing Conditions, modeling estimates indicate Alternative 2D would result in essentially no change in selenium concentrations in water or most biota throughout the Delta, with no exceedances of benchmarks for biological effects. The Low Toxicity Threshold Exceedance Quotient for selenium concentrations in sturgeon for all years in the San Joaquin River at Antioch would increase slightly, from 0.94 for Existing Conditions to 1.1 for Alternative 2D. Concentrations of selenium in sturgeon would exceed only the lower benchmark, indicating a low potential for effects. Overall, Alternative 2D would not be expected to substantially increase the frequency with which applicable benchmarks would be exceeded in the Delta (there being only a small increase for sturgeon exceedance relative to the low benchmark for sturgeon and no exceedance of the high benchmark) or substantially degrade the quality of water in the Delta, with regard to selenium.

Assessment of effects of selenium in the SWP/CVP Export Service Areas is based on effects on selenium concentrations at the Banks and Jones pumping plants. Relative to Existing Conditions, Alternative 2D would cause no increases in the frequency with which applicable benchmarks would be exceeded, and would slightly improve the quality of water in selenium concentrations at the Banks and Jones pumping plants.

Based on the above, selenium concentrations that would occur in water under Alternative 2D would not cause additional exceedances of applicable state or federal numeric or narrative water quality objectives/criteria, or other relevant water quality effects thresholds identified for this assessment, by frequency, magnitude, and geographic extent that would result in adverse effects to one or more beneficial uses within affected water bodies. In comparison to Existing Conditions, water quality conditions under Alternative 2D would not increase levels of selenium by frequency, magnitude, and geographic extent such that the affected environment would be expected to have measurably higher body burdens of selenium in aquatic organisms, thereby substantially increasing the health risks to wildlife (including fish) or humans consuming those organisms. Water quality conditions under this alternative with respect to selenium would not cause long-term degradation of water quality in the affected environment, and therefore would not result in use of available assimilative capacity such that exceedances of water quality objectives/criteria would be likely and would result in substantially increased risk for adverse effects to one or more beneficial uses. This alternative would not further degrade water quality by measurable levels, on a long-term basis, for selenium and, thus, cause the CWA Section 303(d)-listed impairment of beneficial use to be made discernibly worse. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-26: Effects on Selenium Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Environmental Commitments 3, 4, 6–12, 15, and 16 would not increase selenium loading, and the amount of restoration that would occur would be minimal relative to the area of the Delta and implemented such that any localized changes in residence time are unlikely to measurably change selenium concentrations in water or biota relative to the No Action Alternative (ELT and LLT), under which more restoration would occur. Therefore, the effects on selenium from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to be not adverse.

***CEQA Conclusion*:** Environmental Commitments 3, 4, 6–12, 15, and 16 would not increase selenium loading, and the amount of restoration that would occur would be minimal relative to the area of the Delta and implemented such that any localized changes in residence time are unlikely to measurably change selenium concentrations in water or biota relative to Existing Conditions. Therefore, it is expected that with implementation of these environmental commitments there would be no substantial, long-term increase in selenium concentrations in water in the rivers and reservoirs upstream of the Delta, water in the Delta, or the waters exported to the SWP/CVP Export Service Areas, relative to Existing Conditions. As such, these environmental commitments would not contribute to additional exceedances of applicable water quality objectives/criteria. Given the factors discussed in the assessment above and for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), any increases in bioaccumulation rates from waterborne selenium that could occur in some areas as a result of increased water residence times would not be of sufficient magnitude and geographic extent that any portion of the Delta would be expected to have measurably higher body burdens of selenium in aquatic organisms, and therefore would not substantially increase risk for adverse effects to beneficial uses. Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause long-term degradation of water quality resulting in sufficient use of available assimilative capacity such that occasionally exceeding water quality objectives/criteria would be likely. Also, these environmental commitments would not result in substantially increased risk for adverse effects to any beneficial uses. Furthermore, although the Delta is a CWA Section 303(d)-listed water body for selenium, given the discussion in the assessment above, it is unlikely that restoration areas would result in measurable increases in selenium in fish tissues or bird eggs such that the beneficial use impairment would be made discernibly worse.

Because it is unlikely that substantial increases in selenium in fish tissues or bird eggs would occur such that effects on aquatic life beneficial uses would be anticipated, and because of the avoidance and minimization measures that are designed to further minimize and evaluate the risk of such increases (see Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP for more detail on AMM27) as well as the Selenium Management environmental commitment (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS this impact is considered less than significant. No mitigation is required.

Impact WQ-27: Effects on Trace Metal Concentrations Resulting from Facilities Operations and Maintenance

The effects of operation of the water conveyance facilities under Alternative 2D on trace metal concentrations in surface waters upstream of the Delta, relative to Existing Conditions and the No Action Alternative (ELT and LLT) would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS).

Given the poor association of dissolved trace metal concentrations with flow, river flow rate and reservoir storage reductions that would occur under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not be expected to result in a substantial adverse change in trace metal concentrations in the reservoirs and rivers upstream of the Delta.

In the Delta, for metals of primarily aquatic life concern (copper, cadmium, chromium, lead, nickel, silver, and zinc), average and 95th percentile trace metal concentrations of the primary source waters to the Delta are very similar, and very large changes in source water fraction would be necessary to effect a relatively small change in trace metal concentration at a particular Delta location. Moreover, average and 95th percentile trace metal concentrations for these primary source waters are all below their respective water quality criteria, including those that are hardness-based (see Tables 8-51 and 8-52 in Appendix A of this RDEIR/SDEIS). No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and given that the average and 95th percentile source water concentrations for copper, cadmium, chromium, led, nickel, silver, and zinc do not exceed their respective criteria, more frequent exceedances of criteria in the Delta would not occur. For metals of primarily human health and drinking water concern (arsenic, iron, manganese), average and 95th percentile concentrations are also very similar (see Tables 8–10 in Appendix 8N,*Trace Metals*, of the Draft EIR/EIS) and average concentrations are below human health criteria. No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and given that the average water concentrations for arsenic, iron, and manganese do not exceed water quality criteria, more frequent exceedances of drinking water criteria in the Delta would not be expected to occur.

Because Alternative 2D would not result in substantial increases in trace metal concentrations in the water exported from the Delta or diverted from the Sacramento River through the proposed conveyance facilities, there is not expected to be substantial changes in trace metal concentrations in the SWP/CVP Export Service Areas, relative to Existing Conditions or the No Action Alternative (ELT and LLT).

As such, Alternative 2D would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or CTR criteria would be exceeded in the water bodies of the affected environment or substantially degrade the quality of these water bodies, with regard to trace metals.

NEPA Effects: Alternative 2D would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or CTR criteria would be exceeded in the water bodies of the affected environment or substantially degrade the quality of these water bodies, with regard to trace metals, relative to the No Action Alternative (ELT and LLT)., Therefore, the effects on trace metals from implementing Alternative 2D are determined to not be adverse.

CEQA Conclusion: While Alternative 2D would alter the magnitude and timing of reservoir releases north, south and east of the Delta, this would have no substantial effect on the various watershed sources of trace metals. Moreover, long-term average flow and trace metals at Sacramento River at Hood and San Joaquin River at Vernalis are poorly correlated; therefore, changes in river flows would not be expected to cause a substantial long-term change in trace metal concentrations upstream of the Delta.

Average and 95th percentile trace metal concentrations are very similar across the primary source waters to the Delta. Given this similarity, very large changes in source water fraction would be necessary to effect a relatively small change in trace metal concentration at a particular Delta location. Moreover, average and 95th percentile trace metal concentrations for these primary source waters are all below their respective water quality criteria. No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and given that trace metals do not already exceed water quality criteria, more frequent exceedances of criteria in the Delta would not be expected to occur under Alternative 2D.

Because Alternative 2D is not expected to result in substantial changes in trace metal concentrations in Delta waters, which includes Banks and Jones pumping plants, effects on trace metal concentrations in the SWP/CVP Export Service Area are expected to be negligible.

As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because trace metal concentrations are not expected to increase substantially, no long-term water quality degradation for trace metals is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term trace metal concentrations that may occur in water bodies of the affected environment would not be expected to make any existing beneficial use impairments measurably worse. The trace metals discussed in this assessment are not considered bioaccumulative, and thus would not directly cause bioaccumulative problems in aquatic life or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-28: Effects on Trace Metal Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Because Environmental Commitments 3, 4, 6–12, 15, and 16 present no new sources of trace metals to the affected environment, the effects on trace metal concentrations from implementing these environmental commitments are determined to be not adverse.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause substantial long-term increase in trace metal concentrations in the rivers and reservoirs upstream of the Delta, in the Delta Region, or the SWP/CVP Export Service Areas, because they present no new sources of trace metals to the affected environment. As such, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because trace metal concentrations are not expected to increase substantially, no long-term water quality degradation for trace metals is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term trace metal concentrations that may occur throughout the affected environment would not be expected to make any existing beneficial use impairments measurably worse. The trace metals discussed in this assessment are not considered bioaccumulative, and thus would not directly cause bioaccumulative problems in aquatic life or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-29: Effects on TSS and Turbidity Resulting from Facilities Operations and Maintenance

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS), the operation of the water conveyance facilities under Alternative 2D is expected to have a minimal effect on TSS and turbidity levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions and the No Action Alternative (ELT and LLT). This is because the factors that would affect TSS and turbidity levels in the surface waters of these areas would be the same. TSS concentrations and turbidity levels in rivers upstream of the Delta are affected primarily by: 1) TSS concentrations and turbidity levels of the water released from the upstream reservoirs, 2) erosion occurring within the river channel beds, which is affected by river flow velocity and bank protection, 3) TSS concentrations and turbidity levels of tributary inflows, point-source inputs, and nonpoint runoff as influenced by surrounding land uses; and 4) phytoplankton, zooplankton and other biological material in the water. Within the Delta, TSS concentrations and turbidity levels in Delta waters are affected by TSS concentrations and turbidity levels of inflows (and associated sediment load), as well as fluctuation in flows within the channels due to the tides, with sediments depositing as flow velocities and turbulence are low at periods of slack tide, and sediments becoming suspended when flow velocities and turbulence increase when tides are near the maximum. TSS and turbidity variations can also be attributed to phytoplankton, zooplankton and other biological material in the water. These factors would be similar under Alternative 2D and Alternative 4, are expected to be minimally different from Existing Conditions and the No Action Alternative (ELT and LLT). Because Alternative 2D is expected to have minimal effect on TSS concentrations and turbidity levels in Delta waters, including water exported at the south Delta pumps, relative to Existing Conditions or the No Action Alternative (ELT and LLT), Alternative 2D also is expected to have minimal effect on TSS concentrations and turbidity levels in the SWP/CVP Export Service Areas waters.

NEPA Effects: Because TSS concentrations and turbidity levels are expected to be minimally affected relative to the No Action Alternative (ELT and LLT), the effects on TSS and turbidity from implementing Alternative 2D are determined to not be adverse.

CEQA Conclusion: As described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS) changes in river flow rate and reservoir storage that would occur under Alternative 2D, relative to Existing Conditions, would not be expected to result in a substantial adverse change in TSS concentrations and turbidity levels in the reservoirs and rivers upstream of the Delta, given that suspended sediment concentrations are more affected by season than flow. Within the Delta, geomorphic changes associated with sediment transport and deposition are usually gradual, occurring over years, and high storm event inflows would not be substantially affected. Thus, it is expected that the TSS concentrations and turbidity levels in the affected channels would not be substantially different from the levels under Existing Conditions. There is not expected to be substantial, if even measurable, changes in TSS concentrations and turbidity levels in the SWP/CVP Export Service Areas waters under Alternative 2D, relative to Existing Conditions, because this alternative is not expected to result in substantial changes in TSS concentrations and turbidity levels at the south Delta export pumps, relative to Existing Conditions. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives where such objectives are not exceeded under Existing Conditions. Because TSS concentrations and turbidity levels are not expected to be substantially different, long-term water quality degradation is not expected, and, thus, beneficial uses are not expected to be adversely affected. Finally, TSS and turbidity are neither bioaccumulative nor CWA Section 303(d) listed constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-30: Effects on TSS and Turbidity Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Localized, temporary changes in TSS and turbidity could occur associated with the restoration actions of Environmental Commitments 3, 4, 6–12, 15, and 16. However, these changes would be gradual and not expected to substantially differ from No Action Alternative (ELT and LLT) conditions. Therefore, the effects on TSS and turbidity from implementing these environmental commitments are determined to be not adverse.

***CEQA Conclusion*:** It is expected that the TSS concentrations and turbidity levels Upstream of the Delta, in the Plan Area, and the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not be substantially different relative to Existing Conditions, except within localized areas of the Delta modified through creation of habitat and open water. Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives where such objectives are not exceeded under Existing Conditions. Because TSS concentrations and turbidity levels Upstream of the Delta, in the greater Plan Area, and in the SWP/CVP Export Service Areas are not expected to be substantially different, long-term water quality degradation is not expected relative to TSS and turbidity, and, thus, beneficial uses are not expected to be adversely affected. Finally, TSS and turbidity are neither bioaccumulative nor CWA Section 303(d) listed constituents. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-31: Water Quality Effects Resulting from Construction-Related Activities for the Water Conveyance Facilities and Environmental Commitments

The potential construction-related water quality effects that would occur under Alternative 2D would be similar to the effects described for Alternative 4A (see Section 4.3.4 of the RDEIR/SDEIS). This is because the type, size and number of construction activities for water conveyance facilities and environmental commitments that would occur under Alternative 2D would be similar to Alternative 4A. The construction-related activities for the water conveyance facilities under Alternative 2D would be similar to those described for Alternative 4A. However, there would be more construction activity associated with two additional intakes and the area of in-water habitat restoration activities implemented under Alternative 2D would be greater.

NEPA Effects: The types and magnitude of potential construction-related water quality effects associated with implementation of Alternative 2D would be very similar to the effects discussed for Alternative 4A. Nevertheless, the construction of water conveyance facilities and environmental commitments, with the implementation of the BMPs specified in Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS and other agency permitted construction requirements, would result in the potential water quality effects being largely avoided and minimized. The specific environmental commitments that would be implemented under Alternative 2D would be similar to those described for Alternative 4A. Consequently, relative to the No Action Alternative (ELT), Alternative 2D would not be expected to cause exceedance of applicable water quality objectives/criteria or substantial water quality degradation with respect to constituents of concern, and thus would not adversely affect any beneficial uses upstream of the Delta, in the Delta, or in the SWP/CVP Export Service Areas. Therefore, with implementation of environmental commitments presented in Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS, the potential construction-related water quality effects are considered to be not adverse.

CEQA Conclusion: Because environmental commitments would be implemented under Alternative 2D for construction-related activities along with agency-issued permits that also contain construction requirements to protect water quality, the construction-related effects, relative to Existing Conditions, would not be expected to cause or contribute to substantial alteration of existing drainage patterns which would result in substantial erosion or siltation on- or off-site, substantial increased frequency of exceedances of water quality objectives/criteria, or substantially degrade water quality with respect to the constituents of concern on a long-term average basis, and thus would not adversely affect any beneficial uses in water bodies upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas. Moreover, because the construction-related activities would be temporary and intermittent in nature, the construction would involve negligible discharges, if any, of bioaccumulative or CWA Section 303(d) listed constituents to water bodies of the affected environment. As such, construction activities would not contribute measurably to bioaccumulation of contaminants in organisms or humans or cause CWA Section 303(d) impairments to be discernibly worse. Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-32: Effects on *Microcystis* Bloom Formation Resulting from Facilities Operations and Maintenance

Upstream of the Delta

Adverse effects from *Microcystis* upstream of the Delta have only been documented in lakes such as Clear Lake, where eutrophic levels of nutrients give cyanobacteria a competitive advantage over other phytoplankton during the bloom season. Large reservoirs upstream of the Delta are typically characterized by low nutrient concentrations, where other phytoplankton outcompete cyanobacteria, including *Microcystis*. In the rivers and streams of the Sacramento River watershed, watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), and the San Joaquin River upstream of the Delta under Existing Conditions, bloom development is limited by high water velocity and low residence times. These conditions are not expected to change under Alternative 2D or the No Action Alternative (ELT and LLT). Consequently, any modified reservoir operations under Alternative 2D are not expected to promote *Microcystis* production upstream of the Delta, relative to Existing Conditions and the No Action Alternative (ELT and LLT).

Delta

Modeling that adequately accounted for the effects of water conveyance facilities operations and maintenance and the hydrodynamic impacts of the environmental commitments on long-term average residence times in the six Delta sub-areas was not available for Alternative 2D, so the hydrodynamic effects of this alternative on *Microcystis* were determined qualitatively. For the assessment of Alternative 4, modeling scenarios included assumptions regarding how certain habitat restoration activities of the project alternative would affect Delta hydrodynamics, so the impacts due solely to operations and maintenance of the water conveyance facilities under Alternative 4 could not be determined. Because the assessment for Alternative 2D is qualitative, the effects discussed for the Delta under water conveyance facilities are related solely to operations and maintenance, not the hydrodynamic effects of restoration actions, which are discussed in Impact WQ-33.

The effects of Alternative 2D on *Microcystis* levels, and thus microcystin concentrations in the Delta, relative to Existing Conditions, would be less than those described for Alternative 4 in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS for the reasons discussed below.

Under Alternative 2D, a portion of the Sacramento River water which would be conveyed through the Delta to the south Delta intakes under Existing Conditions would be replaced at various locations throughout the Delta by other source water due to diversion of Sacramento River water at the north Delta intake under Alternative 2D. The change in flow paths of water through the Delta that would occur under Alternative 2D could result in localized increases in residence time in various Delta sub-regions, and decreases in residence time in other areas. In general, there is substantial uncertainty regarding the extent that operations and maintenance of Alternative 2D would result in a net increase in water residence times at various locations throughout the Delta relative to Existing Conditions. In contrast to Alternative 2D, the combination of the habitat restoration and operations and maintenance assumptions included in the hydrodynamic modeling of Alternative 4 resulted in a substantial increase in water residence times, and thus a potential increase in *Microcystis* abundance, at numerous locations throughout the Delta at the LLT relative to Existing Conditions.

Besides the effects of operations and maintenance described above, substantial increases in water residence times due to factors unrelated to the project alternative, including habitat restoration (8,000 acres of tidal habitat and enhancements to the Yolo Bypass), sea level rise and climate change, are expected to occur in the Delta, relative to Existing Conditions. Although there is uncertainty regarding the degree to which operations and maintenance of the project alternative would affect water residence times in the Delta, it is likely that such effects would be small in comparison to the combined effects of restoration activities, sea level rise and climate change. Slight increases in ambient water temperatures (1.3–2.5°F), due to climate change in the ELT, are expected to occur in the Delta under Alternative 2D, relative to Existing Conditions. However, due to the combination of the effects of restoration activities unrelated to the project alternative, climate change, and sea level rise on increased residence times, as well as the effects of climate change on increased ambient water temperatures, it is possible that increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta would occur, relative to Existing Conditions. The magnitude by which water temperatures and residence times would increase due to these factors would be less under Alternative 2D than under Alternative 4.

The effects of Alternative 2D on *Microcystis* levels, and thus microcystin concentrations in the Delta relative to the No Action Alternative (ELT and LLT) would be less than those described for Alternative 4 in Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS for the reasons discussed below.

As described relative to Existing Conditions, operations and maintenance of Alternative 2D could alter source water flow paths through the Delta, which could result in localized increases in residence time in various Delta sub-regions, and decreases in residence time in other areas. In general, there is substantial uncertainty regarding the extent that operations and maintenance of Alternative 2D would result in a net increase in water residence times at various locations throughout the Delta relative to the No Action Alternative (ELT). The previously discussed influence of factors unrelated to implementation of the project alternative, including habitat restoration (8,000 acres of tidal habitat restoration and enhancements to the Yolo Bypass), climate change and sea level rise, on increased water residence times, as well as the influence of climate change on increased ambient water temperatures in the Delta, would occur under both Alternative 2D and No Action Alternative (ELT). In summary, operations and maintenance of Alternative 2D is not expected to increase water residence times or ambient water temperatures throughout the Delta, and thus result in adverse effects on *Microcystis*, relative to No Action Alternative (ELT and LLT).

SWP/CVP Export Service Area

The effects of Alternative 2D on *Microcystis* levels, and thus microcystin concentrations, in the SWP/CVP Export Service Areas relative to Existing Conditions would be less than those described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). As described above for the Delta, source waters to the south Delta intakes could be adversely affected relative to Existing Conditions by *Microcystis* both from an increase in Delta water temperatures associated with climate change and from an increase in water residence times. The impacts from increased Delta water residence times would be primarily related to habitat restoration (8,000 acres of tidal habitat restoration and enhancements to the Yolo Bypass) that is assumed to occur separate from Alternative 2D. The combined effect of these factors on *Microcystis* in source waters to the south Delta intakes would likely be much greater than the influence of operations and maintenance of Alternative 2D, the effects of which are uncertain. In contrast to Alternative 2D, the combination of the habitat restoration and operations and maintenance assumptions included in the hydrodynamic modeling of Alternative 4 resulted in a substantial increase in water residence times, and thus a potential increase in *Microcystis* abundance, at numerous locations throughout the Delta relative to Existing Conditions. Increases in ambient air temperatures due to climate change relative to Existing Conditions are expected under this alternative. Increases in ambient air temperatures are expected to result in warmer ambient water temperatures, and thus conditions more suitable to *Microcystis* growth, in the water bodies of the SWP/CVP Export Service Areas. The incremental increase in long-term average air temperatures would be less at the ELT (2.0°F), compared to the LLT (4.0°F).

The effects of Alternative 2D on *Microcystis* levels, and thus microcystin concentrations, in the SWP/CVP Export Service Areas, relative to the No Action Alternative (ELT and LLT), are expected to be less than effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9, in Appendix A of the RDEIR/SDEIS). This is because effects of *Microcystis* on water exports from Banks and Jones pumping plants would be different between Alternative 2D and Alternative 4. Specifically, under Alternative 2D, the fraction of water flowing through the Delta that would reach the existing south Delta intakes is not expected to be adversely affected by *Microcystis* blooms, relative to the No Action Alternative (ELT and LLT), as discussed in the *Delta* section above; while under Alternative 4 this fraction of water is expected to be adversely affected by *Microcystis* blooms, relative to the No Action Alternative (LLT). Additionally, conditions in the SWP/CVP Export Service Areas under Alternative 2D are not expected to become more conducive to *Microcystis* bloom formation, relative to the No Action Alternative (ELT and LLT), because neither water residence time nor water temperatures are projected to increase in the SWP/CVP Export Service Areas.

NEPA Effects: For the reasons discussed above, the effects on *Microcystis* in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas from implementing water conveyance facilities are determined to be not adverse.

CEQA Conclusion: For the reasons described above, the effects of operations and maintenance of water conveyance facilities under Alternative 2D on *Microcystis* in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas, relative to Existing Conditions, would be less than those described for the Alternative 4. As such, this alternative would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. *Microcystis* and microcystins are not CWA Section 303(d) listed within the affected environment and thus any increases that could occur in some areas would not make any existing *Microcystis* impairment measurably worse because no such impairments currently exist. Because *Microcystis* and microcystins are not bioaccumulative, increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. However, it is possible that increases in the frequency, magnitude, and geographic extent of *Microcystis* blooms in the Delta would occur under Alternative 2D for reasons unassociated with operations and maintenance of the project alternative, including tidal habitat restoration activities, climate change and sea level rise. While long-term water quality degradation may occur and, thus, impacts on beneficial uses could occur, these impacts are not related to implementation of Alternative 2D. Although there is considerable uncertainty regarding this impact, the effects on *Microcystis* from implementing water conveyance facilities are determined to be less than significant. No mitigation is required.

Impact WQ-33: Effects on *Microcystis* Bloom Formation Resulting from Environmental Commitments

Effects on *Microcystis* from implementation of environmental commitments under Alternative 2D would be the same as those described for Alternative 4A.

NEPA Effects: Based on the discussion for Impact WQ-33 in Section 4.3.4 of this RDEIR/SDEIS, the effects on *Microcystis* from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to be not adverse.

CEQA Conclusions: Based on the discussion for Impact WQ-33 in Section 4.3.4 of this RDEIR/SDEIS, Environmental Commitments 3, 4, 6–12, 15, and 16 would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. *Microcystis* and microcystins are not CWA Section 303(d) listed within the affected environment and thus any increases that could occur in some areas would not make any existing *Microcystis* impairment measurably worse because no such impairments currently exist. Because *Microcystis* and microcystins are not bioaccumulative, increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Because *Microcystis* levels are not expected to increase substantially, no long-term water quality degradation from *Microcystis* or microcystins is expected to occur and, thus, no adverse effects to beneficial uses would occur. Furthermore, any negligible changes in long-term *Microcystis* levels that may occur throughout the affected environment would not be expected to make any existing beneficial use impairments measurably worse. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-34: Effects on San Francisco Bay Water Quality Resulting from Facilities Operations and Maintenance and Environmental Commitments

The effects analysis presented in the preceding impacts (Impact WQ-1 through WQ-33) concluded that Alternative 2D would have a less-than-significant impact/no adverse effect on the following constituents in the Delta:

- Boron
- Bromide
- Chloride
- Dissolved organic carbon (DOC)
- Dissolved oxygen
- Pathogens
- Pesticides
- Trace metals
- Turbidity and TSS
- *Microcystis*

Elevated concentrations of boron are of concern in drinking and agricultural water supplies. Chloride, DOC, and bromide concentrations also are of concern in drinking water supplies. However, waters in the San Francisco Bay are not designated to support municipal water supply (MUN) and agricultural supply (AGR) beneficial uses. Changes in Delta dissolved oxygen, pathogens, pesticides, trace metals, and turbidity and TSS are not anticipated to be of a frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of the Delta. Changes in *Microcystis* would be primarily due to factors unassociated with the project alternative. Thus, changes in boron, bromide, chloride, DOC, dissolved oxygen, pathogens, pesticides, trace metals, turbidity and TSS, and *Microcystis* in Delta outflow associated with implementation of Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT) are not anticipated to be of a frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of the of San Francisco Bay, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of this RDEIR/SDEIS).

Elevated EC is of concern for its effects on the agricultural beneficial use (AGR) and fish and wildlife beneficial uses. San Francisco Bay does not have an AGR beneficial use designation. As described for Alternative 4, salinity throughout San Francisco Bay is largely a function of the tides, as well as to some extent the freshwater inflow from upstream. However, the changes in Delta outflow due to Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would be minor compared to tidal flows, and thus no substantial adverse effects on salinity, or fish and wildlife beneficial uses, downstream of the Delta are expected.

Also, as described for Alternative 4, changes in nutrient loading would not be expected to contribute to adverse effects to beneficial uses. Changes in nitrogen (ammonia and nitrate) loading to Suisun and San Pablo Bays under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT), would not adversely impact primary productivity in these embayments because light limitation and grazing current limit algal production in these embayments. Nutrient levels and ratios are not considered a direct driver of *Microcystis* and cyanobacteria levels in the North Bay. The only postulated effect of changes in phosphorus loads to Suisun and San Pablo Bays is related to the influence of nutrient stoichiometry on primary productivity. However, there is uncertainty regarding the impact of nutrient ratios on phytoplankton community composition and abundance. As described for Alternative 4, any effect on phytoplankton community composition would likely be small compared to the effects of grazing from introduced clams and zooplankton in the estuary. Therefore, changes in total nitrogen and phosphorus loading that would occur in Delta outflow to San Francisco Bay, relative to Existing Conditions and the No Action Alternative (ELT and LLT), are not expected to result in degradation of water quality with regard to nutrients that would result in adverse effects to beneficial uses.

Similar to Alternative 4, loads of mercury, methylmercury, and selenium from the Delta to San Francisco Bay are estimated to change relatively little due to changes in source water fractions and net Delta outflow that would occur under Alternative 2D, relative to Existing Conditions and the No Action Alternative (ELT and LLT), because changes in Delta outflow would be similar.

NEPA Effects: Based on the discussion above, Alternative 2D, relative to the No Action Alternative (ELT and LLT), would not cause further degradation to water quality with respect to boron, bromide, chloride, dissolved oxygen, DOC, EC, mercury, pathogens, pesticides, selenium, nutrients (ammonia, nitrate, phosphorus), trace metals, turbidity and TSS, or *Microcystis* in the San Francisco Bay. Further, changes in these constituent concentrations in Delta outflow would not be expected to cause changes in Bay concentrations of frequency, magnitude, and geographic extent that would adversely affect any beneficial uses. In summary, effects on the San Francisco Bay from implementation of water conveyance facilities and Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

CEQA Conclusion: As with Alternative 4, Alternative 2D would not be expected to cause long-term degradation of water quality in San Francisco Bay resulting in sufficient use of available assimilative capacity such that occasionally exceeding water quality objectives/criteria would be likely and would result in substantially increased risk for adverse effects to one or more beneficial uses. Further, this alternative would not be expected to cause additional exceedance of applicable water quality objectives/criteria in the San Francisco Bay by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Any changes in boron, bromide, chloride, and DOC in the San Francisco Bay would not adversely affect beneficial uses, because the uses most affected by changes in these parameters, MUN and AGR, are not beneficial uses of the Bay. Further, no substantial changes in dissolved oxygen, pathogens, pesticides, trace metals, turbidity or TSS, and *Microcystis* are anticipated in the Delta due to the implementation of Alternative 2D, relative to Existing Conditions, therefore, no substantial changes to these constituents levels in the Bay are anticipated. Changes in Delta salinity would not contribute to measurable changes in Bay salinity, as the change in Delta outflow would be two to three orders of magnitude lower than (and thus minimal compared to) the Bay's tidal flow and thus, have minimal influence on salinity changes. Changes in nutrient load, relative to Existing Conditions, are expected to have minimal effect on water quality degradation, primary productivity, or phytoplankton community composition. As with Alternative 4, the change in mercury and methylmercury load (which is based on source water and Delta outflow), relative to Existing Conditions, would be within the level of uncertainty in the mass load estimate and not expected to contribute to water quality degradation, make the CWA Section 303(d) mercury impairment measurably worse or cause mercury/methylmercury to bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Similarly, based on Alternative 4 estimates, the increase in selenium load would be minimal, and total and dissolved selenium concentrations would be expected to be the same as Existing Conditions, and less than the target associated with white sturgeon whole-body fish tissue levels for the North Bay. Thus, the change in selenium load is not expected to contribute to water quality degradation, or make the CWA Section 303(d) selenium impairment measurably worse or cause selenium to bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

4.4.5 Geology and Seismicity

Impact GEO-1: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Strong Seismic Shaking of Water Conveyance Features during Construction

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These intakes would be located where the intakes are sited for Alternative 1A. These differences would present a slightly higher hazard of seismic shaking but would not substantially change the hazard of loss of property, personal injury, or death during construction. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the discussion of Impact GEO-1 under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion**:** Seismically induced ground shaking that is estimated to occur and the resultant ground motion anticipated at Alternative 2D construction sites, including the intake locations, the tunnels, the pipelines and the forebays, could cause collapse or other failure of project facilities while under construction. DWR would conform to Cal-OSHA and other state code requirements, such as shoring, bracing, lighting, excavation depth restrictions, required slope angles, and other measures, to protect worker safety as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS. Conformance with these standards and codes is an environmental commitment of the project (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Conformance with these health and safety requirements and the application of accepted, proven construction engineering practices would reduce this risk and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 2D. This impact would be less than significant. No mitigation is required.

Impact GEO-2: Loss of Property, Personal Injury, or Death from Settlement or Collapse Caused by Dewatering during Construction of Water Conveyance Features

Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. Soil excavation in areas with shallow or perched groundwater levels would require the pumping of groundwater from excavations to allow for construction of facilities. This can be anticipated at all intake locations (Sites 1–5), where 70% of the dewatering for Alternative 2D would take place. All of the intake locations for Alternative 2D are located on alluvial floodbasin deposits, alluvial floodplain deposits and natural levee deposits. Similar dewatering may be necessary where intake and forebay pipelines cross waterways and major irrigation canals east of the Sacramento River and north of the proposed intermediate forebay.

NEPA Effects: This potential effect could be substantial because settlement or collapse during dewatering could cause injury of workers at the construction sites as a result of collapse of excavations. The hazard of settlement and subsequent collapse of excavations would be evaluated by assessing site-specific geotechnical and hydrological conditions at intake locations, as well as where intake and forebay pipelines cross waterways and major irrigation canals. The additional intakes would present a slightly higher hazard of settlement or collapse but would not substantially change the hazard of loss of property, personal injury, or death during construction. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Impact GEO-2, Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion: Settlement or failure of excavations during construction could result in loss of property or personal injury. However, DWR would conform to Cal-OSHA and other state code requirements, such as using seepage cutoff walls, shoring, and other measures, to protect worker safety as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS. DWR has made an environmental commitment to use the appropriate code and standard requirements to minimize potential risks (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 2D. The impact would be less than significant. No mitigation is required.

Impact GEO-3: Loss of Property, Personal Injury, or Death from Ground Settlement during Construction of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These differences would present a slightly higher hazard of ground settlement of tunnels but would not change the hazard of loss of property, personal injury, or death during construction. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4, but somewhat greater due to the two additional structures. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion: Ground settlement as a result of geotechnical investigation and the tunneling operation could result in loss of property or personal injury during construction. However, DWR would conform to Cal-OSHA, USACE and other design requirements to protect worker safety as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS. DWR has made conformance to geotechnical design recommendations and monitoring an environmental commitment and an avoidance and minimization measure (Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Hazards to workers and project structures would be controlled at safe levels and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 2D. The impact would be less than significant. No mitigation is required.

Impact GEO-4: Loss of Property, Personal Injury, or Death from Slope Failure during Construction of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional intakes would have a slightly higher hazard of slope failure at borrow and storage sites and would not change the hazard of loss of property, personal injury, or death during construction. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion: Settlement/failure of cutslopes of borrow sites and failure of soil/RTM fill slopes could result in loss of property or personal injury during construction. However, because DWR would conform to Cal-OSHA and other state code requirements and conform to applicable geotechnical design guidelines and standards, such as USACE design measures, as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS, the hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 2D. The impact would be less than significant. No mitigation is required.

Impact GEO-5: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Construction-Related Ground Motions during Construction of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional structures would have a slightly higher hazard of structural failure from construction-related ground motions and would create only a slightly greater hazard of loss of property, personal injury, or death during operation of the water conveyance features due to a greater number of structures. The effects of Alternative 2D would, therefore, be similar to 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion**:** Construction-related ground motions could initiate liquefaction, which could cause failure of structures during construction. However, because DWR would conform with Cal-OSHA and other state code requirements and conform to applicable design guidelines and standards, such as USACE design measures, as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS, the hazard would be controlled to a level that would protect worker safety (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 2D. The impact would be less than significant. No mitigation is required.

Impact GEO-6: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Rupture of a Known Earthquake Fault during Operation of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional intakes would have a slightly higher hazard of fault rupture would have a slight increase on the hazard of loss of property, personal injury, or death during operation of the water conveyance features due to the additional structures. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion**:** There are no active faults capable of surface rupture that extend into the Alternative 2D alignment. Facilities lying directly on or near active blind faults, such as the concrete batch plants and fuel stations near Twin Cities Road and Interstate 5 and at the expanded Clifton Court Forebay, as well as the expanded Forebay itself for Alternative 2D, may have an increased likelihood of loss of property or personal injury at these sites in the event of seismically-induced ground shaking. However, DWR would conform to Cal-OSHA and other state code requirements, such as shoring, bracing, lighting, excavation depth restrictions, required slope angles, and other measures, to protect worker safety as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS. Conformance with these standards and codes is an environmental commitment of the project (see Appendix 3B, *Environmental Commitments,* in Appendix A of this RDEIR/SDEIS). Conformance with these health and safety requirements and the application of accepted, proven construction engineering practices would reduce this risk and there would be no increased likelihood of loss of property, personal injury or death due to construction of Alternative 2D. This impact would be less than significant. No mitigation is required.

Impact GEO-7: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Strong Seismic Shaking during Operation of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional intakes would have a slightly higher hazard of structural failure from seismic shaking and would marginally increase the hazard of loss of property, personal injury, or death during operation of the water conveyance features due to the greater number of structures. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

***CEQA Conclusion*:** Seismically induced strong ground shaking could damage pipelines, tunnels, intake facilities, pumping plant, and other facilities. The damage could disrupt the water supply through the conveyance system. In an extreme event, an uncontrolled release of water from the damaged conveyance system could cause flooding and inundation of structures. (Please refer to Chapter 6, *Surface Water*, of the Draft EIR/EIS for a detailed discussion of potential flood impacts.) However, through the final design process, which would be supported by geotechnical investigations required by DWR's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS), measures to address this hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these codes and standards is an environmental commitment by DWR to ensure that ground shaking risks are minimized as the water conveyance features are operated (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 2D. The impact would be less than significant. No mitigation is required.

Impact GEO-8: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Seismic-Related Ground Failure (Including Liquefaction during Operation of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional intakes would have a slightly higher hazard of structural failure from ground failure and would result in a marginal increase in the hazard of loss of property, personal injury, or death during operation of the water conveyance features due to the greater number of structures. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

***CEQA Conclusion*:** Seismically induced ground shaking could cause liquefaction. Liquefaction could damage pipelines, tunnels, intake facilities, pumping plant, and other facilities, and thereby disrupt the water supply through the conveyance system. In an extreme event, flooding and inundation of structures could result from an uncontrolled release of water from the damaged conveyance system. (Please refer to Chapter 6, *Surface Water* of the Draft EIR/EIS for a detailed discussion of potential flood impacts.) However, through the final design process, measures to address the liquefaction hazard would be required to conform to applicable design codes, guidelines, and standards as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS. Conformance with these design standards is an environmental commitment by DWR to ensure that liquefaction risks are minimized as the water conveyance features are operated (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The hazard would be controlled to a safe level and there would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 2D. The impact would be less than significant. No mitigation is required.

Impact GEO-9: Loss of Property, Personal Injury, or Death from Landslides and Other Slope Instability during Operation of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional structures create a slightly higher hazard of landslides and other slope instability and would only marginally increase the hazard of loss of property, personal injury, or death during operation of the water conveyance features. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion**:** Unstable levee slopes and natural stream banks may fail, either from high pore-water pressure caused by high rainfall and weak soil, or from seismic shaking. Structures constructed on these slopes could be damaged or fail entirely as a result of slope instability. However, through the final design process, measures to address this hazard would be required to conform to applicable design codes, guidelines, and standards. As described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, a geotechnical engineer would develop slope stability design criteria (such as minimum slope safety factors and allowable slope deformation and settlement) for the various anticipated loading conditions during facility operations. DWR would also ensure that measures to address this hazard would be required to conform to applicable design codes, guidelines, and standards. Conformance with these codes and standards is an environmental commitment by DWR to ensure cut and fill slopes and embankments will be stable as the water conveyance features are operated and there would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 2D (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The impact would be less than significant. No mitigation is required.

Impact GEO-10: Loss of Property, Personal Injury, or Death from Seiche or Tsunami during Operation of Water Conveyance Features

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, but would entail two additional intakes. These additional intakes would create a slightly higher hazard of seiche or tsunami and would only marginally change the hazard of loss of property, personal injury, or death during operation of the water conveyance features due to the additional structures. The effects of Alternative 2D would, therefore, be similar to those of Alternative 4. See the description and findings under Alternative 4 in Appendix A of this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion**:** Based on recorded tsunami wave heights at the Golden Gate (Contra Costa Transportation Agency 2009) and in the interior of the San Francisco Bay and on tsunami inundation maps prepared by the California Department of Conservation (2009), the height of a tsunami wave reaching the Suisun Marsh and the Delta would be small because of the distance from the ocean and attenuating effect of the San Francisco Bay. Similarly, the potential for a significant seiche to occur in most parts of the project area is considered low because the seismic hazard and the geometry of the water bodies (i.e., wide and shallow) near conveyance facilities are not favorable for a seiche to occur. However, assuming the West Tracy fault is potentially active, a potential exists for a seiche to occur in the expanded Clifton Court Forebay. The impact would not be significant because the expanded Clifton Court Forebay embankment would be designed and constructed according to applicable design codes, guidelines, and standards as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS to contain and withstand the anticipated maximum seiche wave height, as required by DWR's environmental commitments (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). There would be no increased likelihood of loss of property, personal injury or death due to operation of Alternative 2D from seiche or tsunami. The impact would be less than significant. No additional mitigation is required.

Impact GEO-11: Ground Failure Caused by Increased Groundwater Surface Elevations from Unlined Canal Seepage as a Result of Operating the Water Conveyance Facilities

NEPA Effects: Alternative 2D would not involve construction of unlined canals; therefore, there would be no increase in groundwater surface elevations and consequently no effect caused by canal seepage. There would be no adverse effect.

***CEQA Conclusion*:** Alternative 2D would not involve construction of unlined canals; therefore, there would be no increase in groundwater surface elevations and consequently no impact caused by canal seepage. The impact would be less than significant. No mitigation is required.

Impact GEO-12: Loss of Property, Personal Injury, or Death Resulting from Structural Failure Caused by Rupture of a Known Earthquake Fault at Restoration Opportunity Areas

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar under Alternative 2D to those under Alternative 4A, but would involve a slightly greater acreage of restoration, as described in Section 4.1.3.3 of this RDEIR/SDEIS. The effect would be similar to that of Alternative 4A. See Impact GEO-12 under Alternative 4A in this RDEIR/SDEIS. There would be no adverse effect.

***CEQA Conclusion*:** According to the available AP Earthquake Fault Zone Maps, only the Suisun Marsh ROA could be affected by rupture of an earthquake fault. The active Green Valley fault crosses the southwestern corner of the ROA. The active Cordelia fault extends approximately 1 mile into the northwestern corner of the ROA. Rupture of the Cordelia and Green Valley faults could occur at the Suisun Marsh ROA and damage ROA facilities, such as levees and berms. Damage to these features could result in their failure, causing flooding of otherwise protected areas. However, Alternative 2D would not include Environmental Commitments in the Suisun Marsh area.

Additionally, the final design process for habitat restoration and enhancement activities in the ROAs would include measures to address the fault rupture hazard, as required to conform to applicable design codes, guidelines, and standards. As described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, such design codes, guidelines, and standards include the Division of Safety of Dams *Guidelines for Use of the Consequence Hazard Matrix and Selection of Ground Motion Parameters*, DWR's Division of Flood Management *FloodSAFE Urban Levee Design Criteria*, and USACE's *Engineering and Design—Earthquake Design and Evaluation for Civil Works Projects*. Conformance with these design standards is an environmental commitment by the project proponents to ensure that fault rupture risks are minimized as the Environmental Commitments are implemented (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Therefore, any hazard would be controlled to a safe level and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. The impact would be less than significant. No mitigation is required.

Impact GEO-13: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Strong Seismic Shaking at Restoration Opportunity Areas

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar under Alternative 2D to those under Alternative 4A but would involve a slightly greater acreage of restoration, as described in Section 4.1.3.3 of this RDEIR/SDEIS. See Impact GEO-13 under Alternative 4A in this RDEIR/SDEIS. There would be no adverse effect.

***CEQA Conclusion*:** Ground shaking could damage levees, berms, and other structures. Among all the ROAs, the Suisun Marsh ROA would be the most subject to ground shaking because of its proximity to active faults. However, Alternative 2D would not include Environmental Commitments in the Suisun Marsh area. Additionally, conformance with design standards is an environmental commitment by the project proponents to ensure that any remaining strong seismic shaking risks are minimized as the conservation activities are operated and there would be no increased likelihood of loss of property, personal injury or death in the ROAs (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The impact would be less than significant. No mitigation is required.

Impact GEO-14: Loss of Property, Personal Injury, or Death from Structural Failure Resulting from Seismic-Related Ground Failure (Including Liquefaction beneath Restoration Opportunity Areas

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar under Alternative 2D to those under Alternative 4A but would involve a slightly greater acreage of restoration, as described in Section 4.1.3.3. See Impact GEO-14 under Alternative 4A in this RDEIR/SDEIS. There would be no adverse effect.

***CEQA Conclusion*:** Earthquake-induced ground shaking could cause liquefaction, resulting in damage to or failure of levees, berms, and other features constructed at the restoration areas. Failure of levees and other structures could result in flooding of otherwise protected areas. However, through the final design process, measures to address the liquefaction hazard would be required to conform to applicable design codes, guidelines, and standards as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS. As described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, such design codes, guidelines, and standards include USACE's *Engineering and Design—Stability Analysis of Concrete Structures* and *Soil Liquefaction during Earthquakes,* by the Earthquake Engineering Research Institute. Conformance with these design standards is an environmental commitment by the project proponents to ensure that liquefaction risks are minimized as the water conservation features are implemented (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). The hazard would be controlled to a safe level and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. The impact would be less than significant. No mitigation is required.

Impact GEO-15: Loss of Property, Personal Injury, or Death from Landslides and Other Slope Instability at Restoration Opportunity Areas

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar under Alternative 2D to those under 4A but would involve a slightly greater acreage of restoration, as described in Section 4.1.3.3. See Impact GEO-15 under Alternative 4A in this RDEIR/SDEIS. There would be no adverse effect.

CEQA Conclusion: Unstable new and existing levee and embankment slopes could fail as a result of seismic shaking and as a result of high soil-water content during heavy rainfall and cause flooding of otherwise protected areas. However, because project proponents would conform to applicable design guidelines and standards, such as USACE design measures, as laid out in Chapter 9, *Geology and Seismicity*, of the Draft EIR/EIS, the hazard would be controlled to a safe level and would not create an increased likelihood of loss of property, personal injury or death of individuals in the ROAs. The impact would be less than significant. No mitigation is required.

Impact GEO-16: Loss of Property, Personal Injury, or Death from Seiche or Tsunami at Restoration Opportunity Areas as a Result of Implementing the Conservation Actions

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar under Alternative 2D to those under 4A but would involve a slightly greater acreage of restoration, as described in Section 4.1.3.3. The distance from the ocean and attenuating effect of the San Francisco Bay would likely allow only a low tsunami wave height to reach the Suisun Marsh and the Delta. Conditions for a seiche to occur at the ROAs are not favorable. Therefore, the effect would not be adverse.

CEQA Conclusion: Based on recorded tsunami heights at the Golden Gate Bridge, the height of a tsunami wave reaching the ROAs would be small because of the distance from the ocean and attenuating effect of the San Francisco Bay. Similarly, the potential for a significant seiche to occur in the project area that would cause loss of property, personal injury, or death at the ROAs is considered low because conditions for a seiche to occur at the ROAs are not favorable. The impact would be less than significant. No mitigation is required.

4.4.6 Soils

Impact SOILS-1: Accelerated Erosion Caused by Vegetation Removal and Other Soil Disturbances as a Result of Constructing the Proposed Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4 but would include two additional intakes. These intakes would be identical to where the intakes are sited for Alternative 1A. These differences would present a slightly higher hazard of accelerated soil erosion because the primary work areas that would involve extensive soil disturbance (i.e., staging areas, borrow areas, and intakes) within the Alternative 2D footprint are underlain by soils with a moderate or high susceptibility to wind erosion (Natural Resources Conservation Service 2010a) (Figure 10-6). However, the addition of two additional intakes would not substantially change the project effects on water soil erosion. The effects of Alternative 2D would, therefore, be similar to those under Alternative 4. See the discussion of Impact SOILS-1 under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: Construction of the proposed water conveyance facility under Alternative 2D could cause substantial accelerated erosion. DWR would be required to obtain coverage under the General Permit for Construction and Land Disturbance Activities, necessitating the preparation of a SWPPP and an erosion control plan (described in detail under Alternative 4 in Chapter 10, *Soils*, in Appendix A of this RDEIR/SDEIS). Proper implementation of the requisite SWPPP and compliance with the General Permit (as discussed in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS) would ensure that there would not be substantial soil erosion resulting in daily site runoff turbidity in excess of 250 NTUs as a result of construction of the proposed water conveyance facility. Additionally, implementation of the environmental commitment Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material would help reduce wind blowing of excavated soils, particularly peat soils, during transport and placement at spoils storage, disposal, and reuse areas. Therefore, there would not be an adverse effect.

***CEQA Conclusion*:** Vegetation removal and other soil disturbances associated with construction of water conveyance facilities could cause accelerated water and wind erosion of soil. However, DWR would seek coverage under the state General Permit for Construction and Land Disturbance Activities, necessitating the preparation of a SWPPP and an erosion control plan. As a result of implementation of the requisite SWPPP, and compliance with the General Permit, there would not be substantial soil erosion resulting in daily site runoff turbidity in excess of 250 NTUs the effect would be less than significant. No mitigation is required.

Impact SOILS-2: Loss of Topsoil from Excavation, Overcovering and Inundation as a Result of Constructing the Proposed Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4 but would include two additional intakes. Construction operations would be the same as under Alternative 4 but occur over a larger area, and therefore the effects on topsoil under Alternative 2D would be slightly greater than those under Alternative 4, but would otherwise be similar. See the discussion of Impact SOILS-2 under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: Topsoil effectively would be lost as a resource as a result of its excavation (e.g., forebays, borrow areas, tunnel shafts, levee foundations, intake facilities, pumping plants):

overcovering (e.g., levees and embankments, spoil storage, pumping plants); and water inundation (e.g., forebays, sedimentation basins, and solids lagoons). DWR has made an environmental commitment for Disposal Site Preparation which would require that a portion of the temporary sites selected for storage of spoils, RTM and dredged material will be set aside for topsoil storage and the topsoil would be saved for reapplication to disturbed areas, thereby lessening the effect. However, this effect would be adverse because it would result in a substantial loss of topsoil. Mitigation Measures SOILS-2a and SOILS-2b would reduce the severity of this effect.

***CEQA Conclusion*:** Construction of the water conveyance facilities would involve excavation, overcovering, and inundation of topsoil over extensive areas, thereby resulting in a substantial loss of topsoil despite a commitment for Disposal Site Preparation. The impact on soils in the project area would be significant. Mitigation Measures SOILS-2a and SOILS-2b would minimize and compensate for these impacts, but not to a less-than-significant level because topsoil would be permanently lost over extensive areas. Therefore, this impact is considered significant and unavoidable.

Mitigation Measure SOILS-2a: Minimize Extent of Excavation and Soil Disturbance

Please see Mitigation Measure SOILS-2a under Impact SOILS-2 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure SOILS-2b: Salvage, Stockpile, and Replace Topsoil and Prepare a Topsoil Storage and Handling Plan

Please see Mitigation Measure SOILS-2b under Impact SOILS-2 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Impact SOILS-3: Property Loss, Personal Injury, or Death from Instability, Failure, and Damage from Construction on or in Soils Subject to Subsidence as a Result of Constructing the Proposed Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes. The locations of these intakes would be identical to the intake sites proposed under Alternative 1A and would be constructed in areas in which the near-surface soils have approximately 2–4% organic matter content. Compared to organic soils, these mineral soils would not be subject to appreciable subsidence caused by organic matter decomposition because there is relatively little organic matter available to decompose. However, without adequate engineering, certain structures (such as the forebay levees and interior) could be subject to appreciable subsidence resulting in potentially adverse effects. Damage to or collapse of the project facilities could occur if they are constructed in soils and sediments that are subject to subsidence or differential settlement. Therefore the effects from potential soil subsidence under Alternative 2D would be similar to those under Alternative 4, but greater due to two additional structures. See the discussion of Impact SOILS-3 under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: This potential effect could be substantial because the facilities could be located on unstable soils that are subject to subsidence. Geotechnical studies (as described in the Geotechnical Exploration Plan—Phase 2 [California Department of Water Resources 2014]) would be conducted at all facilities to identify the types of soil avoidance or soil stabilization measures that should be implemented to ensure that the facilities are constructed to withstand subsidence and settlement and to conform to applicable state and federal standards (Appendix 3B, *Environmental*

Commitments, in Appendix A of this RDEIR/SDEIS). These investigations would build upon the geotechnical data reports (California Department of Water Resources 2010a, 2010b, 2011) and the CERs (California Department of Water Resources 2010a, 2010b, 2015), as well as the results of the investigations that will be conducted under the Geotechnical Exploration Plan—Phase 2 (California Department of Water Resources 2014). Conforming to state and federal design standards (described in detail under Alternative 4 in Chapter 10, *Soils*, in Appendix A of this RDEIR/SDEIS), including conduct of site-specific geotechnical evaluations, would ensure that appropriate design measures are incorporated into the project and any subsidence that takes place under the project facilities would not jeopardize their integrity. Therefore, there would not be an adverse effect.

CEQA Conclusion**:** Some of the conveyance facilities would be constructed on soils that are subject to subsidence. Subsidence occurring after the facility is constructed could result in damage to or failure of the facility. However, as stated in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, DWR would be required to design and construct the facilities according to state and federal design standards and guidelines (e.g., California Building Code, American Society of Civil Engineers Minimum Design Loads for Buildings and Other Structures, ASCE-7-10, 2010). Conforming to these codes would reduce the potential hazard of subsidence or settlement to acceptable levels by avoiding construction directly on or otherwise stabilizing the soil material that is prone to subsidence. Because these measures would reduce the potential hazard of subsidence or settlement to meet design standards, the impact would be less than significant. No mitigation is required.

Impact SOILS-4: Risk to Life and Property as a Result of Constructing the Proposed Water Conveyance Facilities in Areas of Expansive, Corrosive, and Compressible Soils

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes. These intakes would be located where the intakes were sited for Alternative 1A. Some of the intakes would be built on soils with high shrink-swell potential (note areas of high linear extensibility in Figure 10-4 in the Draft EIR/EIS). The remainder of the alignment would have similar properties of expansiveness, corrosivity, and compressibility as discussed under Alternative 4. Therefore, the effects under Alternative 2D would therefore be similar to those under Alternative 4, but slightly greater. See discussion of Impact SOILS-4 under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: The integrity of the water conveyance facilities, including tunnels, pipelines, intake facilities, pumping plants, access roads and utilities, and other features could be adversely affected because they would be located on expansive, corrosive, and compressible soils. However, all facility design and construction would be executed in conformance with the CBC (described in detail under Alternative 4 in Chapter 10, *Soils*, in Appendix A of this RDEIR/SDEIS), which specifies measures to mitigate effects of expansive soils, corrosive soils, and soils subject to compression and subsidence. By conforming to the CBC and other applicable design standards, potential effects associated with expansive and corrosive soils and soils subject to compression and subsidence would be offset. There would be no adverse effect.

CEQA Conclusion**:** Some of the project facilities would be constructed on soils that are subject to expansion, corrosion to concrete and uncoated steel, and compression under load. Expansive soils could cause foundations, underground utilities, and pavements to crack and fail. Corrosive soils could damage in-ground facilities or shorten their service life. Compression/settlement of soils after a facility is constructed could result in damage to or failure of the facility. However, because DWR would be required to design and construct the facilities in conformance with state and federal design standards, guidelines, and building codes (e.g., CBC and USACE design standards). Conforming to these codes and standards is an environmental commitment by DWR to ensure that potential adverse effects associated with expansive and corrosive soils and soils subject to compression and subsidence would be offset (see Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Therefore, this impact would be less than significant. No mitigation is required.

Impact SOILS-5: Accelerated Bank Erosion from Increased Channel Flow Rates as a Result of Operations

Alternative 2D has identical operations to Alternative 2A but would have the same potential effect on accelerated bank erosion as under Alternative 4. See the discussion of Impact SOILS-5 under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: River channel bank erosion/scour is a natural process. The rate of natural erosion can increase during high flows and as a result of wave effect on banks during high wind conditions.

In general, changes in river flow rates associated with project operations would remain within the range that presently occurs. However, the operational components would cause changes in the tidal flows in some Delta channels, specifically those that lead into the major habitat restoration areas (Suisun Marsh, Cache Slough, Yolo Bypass, and South Delta ROAs). In major channels leading to the restoration areas, tidal flow velocities may increase; this may cause some localized accelerated erosion/scour.

However, the increased flows would be offset by implementation of Environmental Commitment 4 which could involve dredging of these major channels, which would create a larger channel cross-section (see description of restoration actions in Chapter 3, *Description of Alternatives*, Section 3.6.2, in Appendix A of this RDEIR/SDEIS). The larger cross-section would allow river flow rates to be similar to that of other high tidal flows in the region. Moreover, as presently occurs and as is typical with most naturally-functioning river channels, local erosion and deposition within the tidal habitats is expected as part of the restoration.

For most of the existing channels that would not be subject to tidal flow restoration, there would be no adverse effect to tidal flow volumes and velocities. The tidal prism would increase by 5–10%, but the intertidal (i.e., MHHW to MLLW) cross-sectional area also would be increased such that tidal flow velocities would be reduced by 10–20% compared to Existing Conditions. Consequently, no appreciable increase in scour is anticipated.

The effect would not be adverse because there would be no net increase in river flow rates and, accordingly, no net increase in channel bank scour.

***CEQA Conclusion*:** Changes in operational flow regimes could cause increases in flow rates in channels and sloughs, potentially leading to increases in channel bank scour. However, where such changes are expected to occur (i.e., at the mouths of tidal marsh channels), the project would also entail expansion of the channel cross-section to increase the tidal prism at these locations described in Chapter 3, *Description of Alternatives*, Section 3.6.2, in Appendix A of this RDEIR/SDEIS. The net effect would be to reduce the channel flow rates by 10–20% compared to Existing Conditions. Consequently, no appreciable increase in scour is anticipated. The impact would be less than significant. No mitigation is required.

Impact SOILS-6: Accelerated Erosion Caused by Clearing, Grubbing, Grading, and Other Disturbances Associated with Implementation of Proposed Environmental Commitments 3, 4, 6-11

Effects on accelerated erosion from implementation of Environmental Commitments under Alternative 2D, as described in Section 4.1.3.3 of this RDEIR/SDEIS, would be similar in mechanism and magnitude to those described for Alternative 4A. Any differences would be due to differing acreages or locations, but would be slight. See the discussion in Section 4.3.6 of Impact SOILS-6 under Alternative 4A of this RDEIR/SDEIS.

NEPA Effects: Implementation of some of the Environmental Commitments under Alternative 2D would involve ground disturbance and construction activities that could lead to accelerated soil erosion rates and consequent loss of topsoil. However, as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, the project proponents would be required to obtain coverage under the General Permit for Construction and Land Disturbance Activities, necessitating the preparation of a SWPPP and an erosion control plan. Proper implementation of the requisite SWPPP, site-specific BMPs, and compliance with the General Permit would ensure that accelerated water and wind erosion as a result of implementing Environmental Commitments would not be an adverse effect.

***CEQA Conclusion*:** Vegetation removal and other soil disturbances associated with construction of restoration areas could cause accelerated water and wind erosion of soil. However, the project proponents would seek coverage under the state General Permit for Construction and Land Disturbance Activities. Permit conditions would include erosion and sediment control BMPs and compliance with water quality standards. As a result of implementation of permit conditions, the impact would be less than significant. No mitigation is required.

Impact SOILS-7: Loss of Topsoil from Excavation, Overcovering and Inundation Associated with Restoration Activities as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–11

Effects from implementation of Environmental Commitments under Alternative 2D on loss of topsoil would be similar in mechanism to those described for Alternative 4A. Differences in Environmental Commitments, as described in Section 4.1.3 of this RDEIR/SDEIS, would be slight. See the discussion in Section 4.3.6 of Impact SOILS-7 under Alternative 4A of this RDEIR/SDEIS.

NEPA Effects: Topsoil effectively would be lost as a resource as a result of its excavation (e.g., levee foundations, water control structures); overcovering (e.g., levees, embankments, application of fill material in subsided areas); and water inundation (e.g., aquatic habitat areas) over areas of the Plan Area. Based on ICF's calculations using a geographic information system, implementation of habitat restoration activities at the ROAs would result in excavation, overcovering, or inundation of a minimum of over a thousand acres of topsoil. This effect would be adverse because it would result in a substantial loss of topsoil. Mitigation Measures SOILS-2a and SOILS-2b would reduce the severity of this effect.

***CEQA Conclusion*:** Significant impacts could occur if there is loss of topsoil from excavation, overcovering, and inundation associated with restoration activities as a result of implementing the proposed Environmental Commitments. Implementation of the Environmental Commitments would involve excavation, overcovering, and inundation (to create aquatic habitat areas) of topsoil over extensive areas, thereby resulting in a substantial loss of topsoil. The impact would be significant.

Mitigation Measures SOILS-2a and SOILS-2b would minimize and compensate for these impacts to a degree, but not to a less-than-significant level. Therefore, this impact is considered significant and unavoidable.

Mitigation Measure SOILS-2a: Minimize Extent of Excavation and Soil Disturbance

Please see Mitigation Measure SOILS-2a under Impact SOILS-2 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure SOILS-2b: Salvage, Stockpile, and Replace Topsoil and Prepare a Topsoil Storage and Handling Plan

Please see Mitigation Measure SOILS-2b under Impact SOILS-2 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Impact SOILS-8: Property Loss, Personal Injury, or Death from Instability, Failure, and Damage from Construction on Soils Subject to Subsidence as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–11

Effects from implementation of Environmental Commitments under Alternative 2D (as described in Section 4.1.3 of this RDEIR/SDEIS) related to subsidence would be similar in mechanism to those described for Alternative 4A. See the discussion of Impact SOILS-8 under Alternative 4A in Appendix A of this RDEIR/SDEIS.

NEPA Effects: This potential effect could be substantial because the facilities could be located on unstable soils that are subject to subsidence. However, as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, geotechnical studies would be conducted at all the ROAs to identify the types of soil stabilization that should be implemented to ensure that levees, berms, and other features are constructed to withstand subsidence and settlement and to conform to applicable state and federal standards.

With construction of all levees, berms, and other conservation features designed and constructed to withstand subsidence and settlement and through conformance with applicable state and federal design standards, this effect would not be adverse.

***CEQA Conclusion*:** Some of the restoration area facilities would be constructed on soils that are subject to subsidence. Subsidence occurring after the facility is constructed could result in damage to or failure of the facility. However, as outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, because the project proponents would be required to design and construct the facilities according to state and federal design standards and guidelines (which may involve, for example, replacement of the organic soil), the impact would be less than significant. No mitigation is required.

Impact SOILS-9: Risk to Life and Property from Construction in Areas of Expansive, Corrosive, and Compressible Soils as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–11

Effects from implementation of Environmental Commitments under Alternative 2D, as described in Section 4.1.3 of this RDEIR/SDEIS, resulting from construction of conservation actions in areas of expansive, corrosive, or compressible soils would be similar in mechanism to those described for Alternative 4A. See the discussion of Impact SOILS-9 under Alternative 4A of this RDEIR/SDEIS.

NEPA Effects: ROA specific geotechnical studies and testing would be completed prior to construction of the Environmental Commitments within the ROAs. The site-specific studies and tests would identify specific areas where engineering soil properties, including soil compressibility, may require special consideration during construction of specific features within ROAs. Conformity with USACE, CBC and other design standards for construction on expansive, corrosive and/or compressible soils described in detail in Chapter 10, *Soils*, in the Draft EIR/EIS, would prevent adverse effects of such soils.

***CEQA Conclusion*:** Some of the Environmental Commitments facilities could be constructed on soils that are subject to expansion, corrosive to concrete and uncoated steel, and compress under load. Expansive soils could cause foundations, underground utilities, and pavements to crack and fail. Corrosive soils could damage in-ground facilities or shorten their service life. Compression or settlement of soils after a facility is constructed could result in damage to or failure of the facility. However, as outlined in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, because the project proponents would be required to design and construct the facilities according to state and federal design standards, guidelines, and building codes (which may involve, for example, soil lime stabilization, cathodic protection of steel, and soil replacement), this impact would be considered less than significant. No mitigation is required.

4.4.7 Fish and Aquatic Resources

The principal features of Alternative 2D are described in section 4.1.3. This alternative is similar to Alternative 4A in terms of water conveyance facilities but includes five north Delta intakes as opposed to three under Alternative 4A, as well as Operational Scenario B (as opposed to Operational Scenario H3+ for Alternative 4A). The analysis below includes a comparison between Alternative 2D in the early long term (a scenario termed A2D_ELT when discussing results based on water operations modeling) and the No Action Alternative in the early long term (a scenario termed NAA_ELT, which is the baseline for NEPA purposes), as well as a comparison between A2D_ELT and Existing Conditions (which is the baseline for CEQA purposes, and is at the current time frame as opposed to the early long term). Additionally, the effects of Alternative 2D in the LLT are similar to the effects of the alternative in the ELT, except where noted.

Delta Smelt

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-1: Effects of Construction of Water Conveyance Facilities on Delta Smelt

The potential effects of construction of the water conveyance facilities on delta smelt or their designated critical habitat would be similar to those described for Alternative 4A (Impact AQUA-1) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to delta smelt.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-1, the effect would not be adverse for delta smelt or designated critical habitat. This is because local water quality conditions (very low electrical conductivity and typically low turbidity) in the proposed north Delta intakes reach limits habitat suitability. In addition, changes to Clifton Court Forebay occur in a marginal environment within which delta smelt are trapped once entrained, with little prospect of effective salvage. The principal in-water work activities at the Head of Old River operable barrier will be conducted during August–November, and therefore would have minimal temporal overlap with delta smelt; the location of this site generally would be expected to result in minimal spatial overlap with delta smelt. Moreover, any habitat losses will be offset by restoration of up to 65 acres of tidal habitat and the beneficial operational effects of Alternative 2D (described below) on the Delta as a whole.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-1, the impact of the construction of water conveyance facilities on delta smelt and critical habitat would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA-1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-2: Effects of Maintenance of Water Conveyance Facilities on Delta Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-2, the effect would not be adverse for delta smelt.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-2 for delta smelt, the impact of the maintenance of water conveyance facilities on delta smelt or critical habitat would be less than significant and no mitigation is required.

Water Operations of Water Conveyance Facilities

Impact AQUA-3: Effects of Water Operations on Entrainment of Delta Smelt

Water Exports from SWP/CVP South Delta Facilities

Overall, operational activities under Alternative 2D would benefit delta smelt by reducing average proportional entrainment at the south Delta facilities. Average juvenile proportional entrainment (March–June) would be 0.13 (i.e., 13% of the juvenile population) under Alternative 2D, which would be reduced 0.007 (a 5% relative decrease) compared to baseline (0.13 for the No Action Alternative in the early long-term [NAA_ELT]) (Table 11-2D-1). As described under Alternative 1A and Alternative 2A (Impact AQUA-3), the greatest relative reductions in larval/juvenile proportional entrainment would be in wetter years (28% to 33% relative decrease compared to NAA_ELT). Average adult proportional entrainment (December–March) for all water year types would be reduced under Alternative 2D by 0.02 (a 28% relative decrease) under Alternative 2D compared to NAA_ELT (Table 11-2D-1).

Table 11-2D-1. Differences in Proportional Entrainment of Delta Smelt at SWP/CVP South Delta Facilities

	Proportional Entrainment[a] Difference in Proportions (Relative Change in Proportions)	
Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Total Population		
Wet	-0.047 (-43%)	-0.028 (-13%)
Above Normal	-0.045 (-28%)	-0.055 (-48%)
Below Normal	-0.004 (-2%)	-0.054 (-32%)
Dry	0.016 (6%)	-0.016 (-7%)
Critical	0.001 (0%)	0.0 (0%)
All Years	-0.019 (-9%)	0.002 (1%)
Larval/Juvenile Delta Smelt (March–June)		
Wet	-0.007 (-18%)	-0.015 (-33%)
Above Normal	-0.016 (-19%)	-0.025 (-28%)
Below Normal	0.011 (8%)	-0.002 (-1%)
Dry	0.023 (13%)	0.008 (4%)
Critical	0.004 (2%)	0.004 (2%)
All Years	0.003 (3%)	-0.007 (-5%)
Adult Delta Smelt[b] (December–March)		
Wet	-0.040 (-58%)	-0.040 (-57%)
Above Normal	-0.029 (-36%)	-0.029 (-36%)
Below Normal	-0.016 (-19%)	-0.015 (-18%)
Dry	-0.008 (-9%)	-0.008 (-10%)
Critical	-0.004 (-5%)	-0.001 (-2%)
All Years	-0.022 (-28%)	-0.021 (-28%)
	Shading indicates >5% or more increased entrainment.	

Note: Negative values indicate lower entrainment loss under Alternative 2D than under EXISTING CONDITIONS or NAA_ELT.

[a] Proportional entrainment index (U.S. Fish and Wildlife Service 2008a).

[b] Adult proportional entrainment adjusted according to Kimmerer (2011).

Water Exports from SWP/CVP North Delta Intake Facilities

As described for Alternative 1A and for Alternative 2A (Impact AQUA-3 for delta smelt), delta smelt would face potential entrainment and impingement at the proposed north Delta diversion facilities. The exposure to potential entrainment would be low, however, because only a very small proportion of the population occurs at this location. The intakes would be screened to exclude fish larger than 22-mm SL, which would include juvenile delta smelt. There would be potential negative effects from entrainment of smaller life stages (eggs and larvae) and potential impingement and screen contact by juveniles and adults (Appendix B, *Entrainment*, Section B.6.2.3).

Predation Associated with Entrainment

As described in Impact AQUA-3 for Alternative 2A, pre-screen losses of delta smelt at the SWP/CVP facilities are believed to be high. Under Alternative 2D, pre-screen losses at the south Delta facilities would decrease commensurate with entrainment reductions described above. Structures associated with the proposed north Delta intakes could attract piscivorous fish, potentially increasing localized predation risk. However few delta smelt would be expected to occur in the vicinity of the north Delta intakes, thus limiting their exposure to the predation risk.

NEPA Effects: Under Alternative 2D, overall potential entrainment of delta smelt would be reduced at the south Delta SWP/CVP facilities. Entrainment and impingement could potentially occur at the proposed north Delta intakes, but the risk would be low due to the location, design and operation of intakes, and offset by reduced entrainment at the south Delta facilities. Furthermore, any potential effects would be reduced by monitoring and adaptive management through real-time operations. Overall, Alternative 2D would not have an adverse effect and may be beneficial to delta smelt due to a small reduction in entrainment and associated predation losses at the south Delta facilities, and minimal entrainment at the north Delta facilities.

CEQA Conclusion: As described above, operations under Alternative 2D would reduce average adult proportional entrainment by 0.022 (a 28% relative decrease) compared to Existing Conditions. Larval/juvenile entrainment would be similar or slightly greater (3% relative increase) on average, and increase by 0.023 (13% relative increase) in dry years compared to Existing Conditions (Table 11-2D-1). However, this would affect a small proportion of the population (0.3% on average, 2.3% in below normal years).

This CEQA interpretation of the biological modeling differs from the NEPA analysis, which is likely attributable to different modeling assumptions (as described fully in Section 11.3.3 and Alternative 1A Impact AQUA-3). Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. Note that the analysis for larvae and juveniles includes both OMR flows and X2 as predictors of proportional entrainment; primarily because of sea level rise assumptions, X2 would be further upstream in the ELT even with similar water operations, so that the comparison of the action alternative in the ELT to Existing Conditions is confounded.

Therefore, the impact analysis is better informed by the results from the NEPA analysis presented above, which accounts for sea level rise by considering the NAA in the ELT. When climate change is factored in, larval-juvenile delta smelt proportional entrainment is reduced 0.007 (5% relative decrease) on average compared to conditions without BDCP, and is similar or only slightly greater in below normal years (Table 11-2D-1).

The risk of entrainment and impingement at the proposed north Delta intakes is low due to the low abundance of delta smelt in the vicinity, and would be further minimized by fish screens.

Overall, Alternative 2D would not significantly increase entrainment and associated predation losses at the south Delta facilities, and would minimize entrainment at the north Delta facilities. Furthermore, any potential impacts would be reduced by monitoring and adaptive management by real-time operations. The impact is considered to be less than significant, and no mitigation would be required.

Impact AQUA-4: Effects of Water Operations on Spawning and Egg Incubation Habitat for Delta Smelt

NEPA Effects: The effects of operations under Alternative 2D on abiotic spawning habitat would be similar to those described for Alternative 2A (Impact AQUA-4). Flow reductions below the north Delta intakes would not reduce available spawning habitat. In-Delta water temperatures, which can affect spawning timing, would not change across Alternatives, because they would be in thermal equilibrium with atmospheric conditions and not strongly influenced by the flow changes. The effect of Alternative 2D operations on spawning would not be adverse, because there would be little change in abiotic spawning conditions for delta smelt.

CEQA Conclusion: As described above, operations under Alternative 2D would not reduce abiotic spawning habitat availability or change spawning temperatures for delta smelt. Consequently, the impact would be less than significant, and no mitigation is required.

Impact AQUA-5: Effects of Water Operations on Rearing Habitat for Delta Smelt

As described for Alternative 4A (Impact AQUA-5 for delta smelt), rearing habitat conditions for juvenile delta smelt were evaluated using the fall abiotic habitat index (Feyrer et al. 2011); further details and limitations of this method are discussed under Alternative 4A. Alternative 2D includes the BiOp Fall X2 requirements, and as such the abiotic habitat index under Alternative 2D would be similar to NAA_ELT (Table 11-2D-3).

NEPA Effects: Inclusion of the BiOp Fall X2 requirements results in there being little difference in abiotic habitat between Alternative 2D and NAA_ELT, when applying the fall abiotic habitat index method. As such, this effect would not be adverse.

Table 11-2D-3. Differences in Delta Smelt Fall Abiotic Index (hectares) between Alternative 2D (A2D_ELT) and Existing Conditions/NAA_ELT Scenarios, Averaged by Prior Water Year Type

Water Year	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
All	1,133 (28%)	82 (2%)
Wet	2,476 (53%)	36 (1%)
Above Normal	2,007 (52%)	62 (1%)
Below Normal	199 (5%)	161 (4%)
Dry	138 (4%)	149 (4%)
Critical	8 (0%)	8 (0%)

Note: Negative values indicate lower habitat indices under preliminary proposal scenarios. Water year 1922 was omitted because water year classification for prior year was not available.

CEQA Conclusion: Alternative 2D would not result in less rearing habitat area (based on the Feyrer et al. 2011 abiotic habitat index) compared to Existing Conditions. Averaged across all water year types, Alternative 2D would result in an overall increase in the abiotic habitat index by 28% (Table 11-2D-3). This increase is a function of Alternative 2D including the BiOp Fall X2 requirements in wet and above normal years (Existing Conditions does not include Fall X2). The NEPA analysis is a better approach for isolating the effect of the Alternative from the effects of sea level rise, climate change, future water demands, and implementation of required actions under the BiOps such as the Fall X2 requirement. When compared to the NAA_ELT and informed by the NEPA analysis, the average delta smelt abiotic habitat index under Alternative 2D would be similar to NAA_ELT (Table 11-2D-3).

The impact of Alternative 2D would be less than significant. No mitigation is required.

Impact AQUA-6: Effects of Water Operations on Migration Conditions for Delta Smelt

More detailed discussion of water temperature and turbidity as migration cues for delta smelt is provided under Alternative 4A. As described above in Impact AQUA-4, in-Delta water temperatures would not change in response to Alternative 2D flows. Although Alternative 2D would result in sediment being removed at the north Delta intakes, Alternative 2D is not expected to affect suspended sediment concentration during the first flush of precipitation that cues delta smelt migration. With regard to suspended sediment concentrations at other times of the year, any effect will be minimized through the reintroduction of sediment collected at the north Delta intakes into tidal natural communities restoration projects (Environmental Commitment 4), consistent with the Environmental Commitment addressing Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material.

NEPA Effects: Alternative 2D may decrease sediment supply to the estuary, with the potential for decreased habitat suitability for delta smelt in some locations, but there would not be an adverse effect during the migration period and water temperature would not be affected by Alternative 2D water operations. Operations of Alternative 2D would not affect turbidity or temperatures during the migration period, and therefore the impact on migration conditions for delta smelt would not be adverse relative to NAA_ELT.

CEQA Conclusion: As described above, operations under Alternative 2D would not substantially alter the turbidity cues associated with winter flush events that may initiate the adult delta smelt migration. Additionally there would be no appreciable changes in water temperatures under Alternative 2D. Consequently, the impact on adult delta smelt migration conditions would be less than significant, and no mitigation is required.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-7: Effects of Construction of Restoration Measures on Delta Smelt

Impact AQUA-8: Effects of Contaminants Associated with Restoration Measures on Delta Smelt

Impact AQUA-9: Effects of Restored Habitat Conditions on Delta Smelt

Impact AQUA-10: Effects of Methylmercury Management on Delta Smelt (Environmental Commitment 12)

Impact AQUA-13: Effects of Localized Reduction of Predatory Fish on Delta Smelt (Environmental Commitment 15)

Impact AQUA-14: Effects of Nonphysical Fish Barriers on Delta Smelt (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on delta smelt for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Longfin Smelt

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-19: Effects of Construction of Water Conveyance Facilities on Longfin Smelt

The potential effects of construction of the water conveyance facilities on longfin smelt would be similar to those described for Alternative 4A (Impact AQUA-19) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to longfin smelt.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-19, the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-19, the impact of the construction of water conveyance facilities on longfin smelt would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-20: Effects of Maintenance of Water Conveyance Facilities on Longfin Smelt

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-20, the effect would not be adverse for longfin smelt.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-20, the impact of the maintenance of water conveyance facilities on longfin smelt would be less than significant and no mitigation is required.

Water Operations of Water Conveyance Facilities

Impact AQUA-21: Effects of Water Operations on Entrainment of Longfin Smelt

Water Exports from SWP/CVP South Delta Facilities

For larval longfin smelt, particle tracking model simulations indicate that overall the magnitude of entrainment risk is low under all hydrologic conditions and starting geographic distributions (wetter and drier). Average entrainment loss under Alternative 2D with the wetter starting distribution was 1.0% compared to 1.7% under NAA_ELT, a 41% relative decrease (Table 11-2D-4). Average entrainment loss with the drier starting distribution was 1.3% for Alternative 2D compared to 2.2% under NAA_ELT, a 42% decline in relative terms. The risk of entrainment would be greater during years when outflows during late winter and spring are low (generally in dry years, as modeled by the drier distribution), with reduced entrainment under Alternative 2D compared to baseline conditions. Overall, larval entrainment would be reduced under Alternative 2D relative to NAA_ELT.

Table 11-2D-4. Percentage of Particles (and Difference) Representing Longfin Smelt Larvae Entrained by the South Delta Facilities under Alternative 2D and Baseline Scenarios

	Percent Particles Entrained			Difference (and Relative Difference)	
Starting Distribution	EXISTING CONDITIONS	NAA_ELT	A2D_ELT	A2D_ELT vs. EXISTING CONDITIONS	A2D_ELT vs. NAA_ELT
Wetter	1.9	1.7	1.0	-0.88 (-47%)	-0.70 (-41%)
Drier	2.5	2.2	1.3	-1.21 (-48%)	-0.94 (-42%)

Note: 60-day runs of PTM. Negative difference values indicate lower entrainment under the alternative compared to the baseline scenario.

As with the other alternatives, juvenile and adult longfin smelt entrainment at the south Delta facilities was estimated with the salvage-density method, normalized to fall midwater trawl index values. Entrainment under Alternative 2D would be reduced compared to NAA_ELT. Entrainment averaged across all water year types would be reduced for juvenile longfin smelt by 52% compared to NAA_ELT; entrainment would decrease for adults by 67% compared to NAA_ELT (Table 11-2D-5). As discussed for Alternative 2A (Impact AQUA-21 for longfin smelt), entrainment would be highest in critical years. Under Alternative 2D, entrainment in critical years would be reduced 32% for juveniles and 17% for adults, compared to NAA_ELT. This reflects substantial reductions in south Delta exports under Alternative 2D for December to June.

Table 11-2D-5. Longfin Smelt Entrainment Index (March–June) at the SWP and CVP Salvage Facilities and Differences (Absolute and Percentage) between Model Scenarios

		Absolute Difference (Percent Difference)	
Life Stage	Water Year Types	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Juvenile (March–June)	Wet	-52,583 (-82%)	-56,464 (-83%)
	Above Normal	-2,093 (-46%)	-2,370 (-49%)
	Below Normal	-524 (-17%)	-522 (-17%)
	Dry	-13,883 (-3%)	-61,071 (-11%)
	Critical	-197,270 (-35%)	-172,763 (-32%)
	All Years	-129,613 (-48%)	-152,345 (-52%)
Adult (December–March)	Wet	-100 (-78%)	-106 (-79%)
	Above Normal	-438 (-67%)	-489 (-70%)
	Below Normal	-938 (-48%)	-1,030 (-51%)
	Dry	-384 (-32%)	-400 (-33%)
	Critical	-5,968 (-24%)	-3,847 (-17%)
	All Years	-2,382 (-66%)	-2,452 (-67%)
	Shading indicates >5% increase in entrainment index.		

Water Exports from SWP/CVP North Delta Intake Facilities

The proposed new north Delta intakes would increase entrainment potential in this area, but entrainment of longfin smelt and potential exposure to predators at the diversion structures would be extremely low because this species is rarely encountered in surveys this far upstream (California Department of Fish and Game 2012a; 2012b; 2013b).

In summary, under Alternative 2D potential entrainment of longfin smelt would be reduced at the SWP/CVP south Delta facilities. Entrainment loss of longfin smelt at the proposed north Delta intakes would be rare because longfin smelt are not expected to occur in that area of the Sacramento River, and the intakes would be screened.

Predation Associated with Entrainment

Pre-screen loss of longfin smelt at the south Delta facilities is typically attributed to predation (as described for Impact AQUA-3 for Alternative 1). Under Alternative 2D, pre-screen loss is expected to decrease commensurate with entrainment reductions. Predation loss at the proposed north Delta intakes would be limited because longfin smelt rarely occur that far upstream.

NEPA Effects: In conclusion, the effect on entrainment and entrainment-related predation loss under Alternative 2D would be beneficial because of the substantial reduction in entrainment and predation loss at the south Delta facilities.

CEQA Conclusion: As described above, entrainment loss of longfin smelt would be reduced under Alternative 2D. Entrainment and associated predation loss at the south Delta facilities under Alternative 2D would decrease 48% for juveniles and 66% for adults compared to Existing Conditions. Based on particle tracking simulations, entrainment of larval longfin smelt to the south delta facilities would be expected to be less than baseline under most scenarios. Predation loss at the proposed north Delta intakes would be limited because longfin smelt rarely occur that far upstream.

The impact under Alternative 2D would be beneficial to the species because of the reduction in entrainment and predation loss for both juveniles and adults.

Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt

As noted for Alternative 4A, background on the general distribution of longfin smelt and the evidence for relationships between longfin smelt abundance with freshwater outflow is provided in detail in the discussion for Alternative 4. The X2–longfin smelt abundance relationship provided by Kimmerer et al. (2009) was used to evaluate the effects of the alternatives on longfin smelt, following the historical observation that lower X2 (farther downstream) correlates with increased recruitment (represented by abundance indices in trawl surveys), although it is not understood if or how this would affect spawning, egg incubation, and/or rearing longfin smelt. Relationships between X2 and longfin smelt abundance developed by Kimmerer et al. (2009) were used to determine how the changes in winter-spring X2 position described above might influence longfin smelt abundance the following fall.

NEPA Effects: Modeling results based on Kimmerer et al. (2009) predict longfin smelt Fall Midwater and Bay Otter Trawl indices would decrease for most water year types, relative to NAA_ELT, based on changes in winter-spring flow alone (Table 11-2D-7). Alternative 2D operations would be expected to result in 8–9% lower longfin smelt abundance compared to NAA_ELT, for all years combined.

Table 11-2D-7. Estimated Differences between Scenarios for Longfin Smelt Relative Abundance in the Fall Midwater Trawl or Bay Otter Trawl

	Fall Midwater Trawl Relative Abundance		Bay Otter Trawl Relative Abundance	
Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
All	-1,627 (-18%)	-601 (-8%)	-6,382 (-21%)	-2,243 (-9%)
Wet	-3,490 (-18%)	-1204 (-7%)	-14,526 (-21%)	-4663 (-8%)
Above Normal	-1,842 (-18%)	-843 (-9%)	-6,885 (-21%)	-3,159 (-11%)
Below Normal	-896 (-20%)	-372 (-9%)	-2,862 (-23%)	-1,224 (-12%)
Dry	-410 (-18%)	-148 (-7%)	-1,179 (-21%)	-431 (-9%)
Critical	-54 (-5%)	4 (0%)	-141 (-7%)	6 (0%)
	Shading indicates greater than 10% decrease in relative abundance.			

During the period of longfin smelt rearing from January–June, Delta outflows would be similar (<10% difference) to NAA_ELT in all months except April and May, when flows averaged all years would be reduced 12%. The adverse effect of reduced Delta outflow on longfin smelt would be minimized with Mitigation Measures AQUA-22a-c (see below) but would remain adverse.

CEQA Conclusion: Average Delta outflow under Alternative 2D would be similar (less than 5% difference, averaged over all years) to Existing Conditions in winter (January, February, March) and decreased in spring (13% in April, 17% in May, 14% in June). Relative longfin smelt abundance based on Kimmerer et al. 2009 decreased 18–21% on average compared to Existing Conditions (Table 11-2D-7), with greatest reductions in below normal water years (20–23% lower under Alternative 2D).

Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2 could be significant because the alternative could substantially reduce relative abundance based on Kimmerer et al. 2009. However, and as noted for Alternative 4A, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed above (Section 11.3.3), because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA) models anticipated future conditions that would occur at 2025, including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the NEPA analysis, which compares results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, longfin smelt relative abundance, based on Kimmerer et al. (2009), decreased 8% to 9% on average relative to conditions without BDCP (Table 11-2D-7). These modeling results represent the increment of change attributable to the alternative and address the limitations of the comparison the CEQA baseline (Existing Conditions). The Adaptive Management and Monitoring Program included in Alternative 2D would allow for an evaluation of the necessary volume and timing of spring outflow. However, based on the Kimmerer et al. (2009) approach applied for this analysis, Alternative 2D would result in a significant impact on longfin smelt due to a decrease in abundance of 8% to 9% for a species experiencing a sustained poor population status (the 2014 fall midwater trawl index was the second lowest on record). Because of the potential for this alternative to reduce longfin smelt abundance, this impact is considered significant. To mitigate this effect, Mitigation Measures AQUA-22a, AQUA-22b, and AQUA 22c would be implemented. However, no feasible mitigation exists and as such, based on the Kimmerer et al. (2009) regression, this impact is considered significant and unavoidable.

Mitigation Measure AQUA-22a: Following Initial Operations of Water Conveyance Facilities, Conduct Additional Evaluation and Modeling of Impacts to Longfin Smelt to Determine Feasibility of Mitigation to Reduce Impacts to Spawning and Rearing Habitat

Please refer to Mitigation Measure AQUA-22a under Alternative 1A, Impact AQUA-22.

Mitigation Measure AQUA-22b: Conduct Additional Evaluation and Modeling of Impacts on Longfin Smelt Rearing Habitat Following Initial Operations of Water Conveyance Facilities

Please refer to Mitigation Measure AQUA-22b under Alternative 1A, Impact AQUA-22.

Mitigation Measure AQUA-22c: Consult with USFWS and CDFW to Identify and Implement Feasible Means to Minimize Effects on Longfin Smelt Rearing Habitat Consistent with Water Conveyance Facilities

Please refer to Mitigation Measure AQUA-22c under Alternative 1A, Impact AQUA-22.

Impact AQUA-23: Effects of Water Operations on Rearing Habitat for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on rearing habitat for longfin smelt is included in *Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.*

Impact AQUA-24: Effects of Water Operations on Migration Conditions for Longfin Smelt

The analysis, NEPA Effects and CEQA Conclusion for effects of water operations on migration conditions for longfin smelt is included in *Impact AQUA-22: Effects of Water Operations on Spawning, Egg Incubation, and Rearing Habitat for Longfin Smelt.*

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-25: Effects of Construction of Restoration Measures on Longfin Smelt

Impact AQUA-26: Effects of Contaminants Associated with Restoration Measures on Longfin Smelt

Impact AQUA-27: Effects of Restored Habitat Conditions on Longfin Smelt

Impact AQUA-28: Effects of Methylmercury Management on Longfin Smelt (Environmental Commitment 12)

Impact AQUA-31: Effects of Localized Reduction of Predatory Fish on Longfin Smelt (Environmental Commitment 15)

Impact AQUA-32: Effects of Nonphysical Fish Barriers on Longfin Smelt (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on longfin smelt for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Winter-Run Chinook Salmon

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-37: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

The potential effects of construction of the water conveyance facilities on winter-run Chinook salmon or their designated critical habitat would be similar to those described for Alternative 4A (Impact AQUA-37) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to winter-run Chinook salmon.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-37, the effect would not be adverse for winter-run Chinook salmon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-37, the impact of the construction of water conveyance facilities on winter-run Chinook salmon and critical habitat would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-38: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Winter-Run ESU)

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-38, the effect would not be adverse for winter-run Chinook salmon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-38 for winter-run Chinook salmon, the impact of the maintenance of water conveyance facilities on winter-run Chinook salmon or critical habitat would be less than significant and no mitigation is required.

Water Operations of Water Conveyance Facilities

Impact AQUA-39: Effects of Water Operations on Entrainment of Chinook Salmon (Winter-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Entrainment losses would be reduced under Alternative 2D (A2D_ELT) at the south Delta facilities. Losses for all years combined would decrease by approximately 4,700 fish (67–68%) compared to NAA_ELT (Table 11-2D-8). Entrainment would be reduced in all water year types, ranging from moderate reductions in critical water years (15% fewer fish compared to NAA_ELT) to significant reductions in wet years (90% fewer fish entrained) (Table 11-2D-8). Pre-screen losses, typically attributed to predation, would be expected to decrease commensurate with decreased entrainment at the south Delta facilities.

The proportion of the annual winter-run Chinook population (assumed to be 500,000 juveniles approaching the Delta) lost at the south Delta facilities across all years is very small, averaging 1.4% under NAA_ELT and decreasing to 0.45% under Alternative 2D.

Table 11-2D-8. Juvenile Winter-Run Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2D

	Absolute Difference (Percent Difference)[a]	
Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-10,212 (-90%)	-10,935 (-90%)
Above Normal	-5,424 (-82%)	-5,574 (-82%)
Below Normal	-3,890 (-54%)	-4,076 (-55%)
Dry	-853 (-22%)	-717 (-20%)
Critical	-262 (-21%)	-171 (-15%)
All Years	-4,553 (-67%)	-4,701 (-68%)

Shading indicates10% or greater increased entrainment.

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The effect of Alternative 2D on entrainment and impingement at the North Delta facilities would be the same as described for Alternative 2A (Impact AQUA-39) because both alternatives would have state-of-the-art screens installed to prevent entrainment and be designed to minimize impingement.

Predation Associated with Entrainment

Pre-screen loss of juvenile Chinook salmon at the south Delta facilities is typically attributed to predation, and is expected to decrease under Alternative 2D, commensurate with entrainment reductions. Predation at the north Delta would increase due to the installation of the proposed North Delta diversions on the Sacramento River. Application of bioenergetics modeling for ELT water temperature with a median predator density for the five intakes proposed under Alternative 2D predicts increased predation loss of about 7,450 juveniles, or 0.29% of the winter-run Chinook salmon juvenile index of abundance under Alternative 2D (Table 11-2D-1; note that this estimate does not provide context to the level of predation in this reach that would occur without implementation of Alternative 4A; See additional discussion under Impact AQUA-42).

Table 11-2D-1. Winter-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes (Five Intakes for Alternative 2D)

Striped Bass at NDD (Five Intakes)			Winter-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Juvenile Production Entering the Delta[1]
Low	18	154	1,127	0.04%
Median	119	1,017	7,449	0.29%
High	219	1,872	13,708	0.53%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (*BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference).

[1] Estimated as 2.6 million juveniles. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

NEPA Effects: Due to reduced entrainment and associated predation loss at the south Delta facilities, together with state-of-the-art screening at the north Delta intakes, the effect of Alternative 2D water operations on winter-run Chinook entrainment would be not be adverse and would be beneficial.

CEQA Conclusion: As described above, entrainment losses of juvenile Chinook salmon at the south Delta facilities would decrease under Alternative 2D (A2D_ELT) compared to Existing Conditions (Table 11-2D-8). At the north Delta facilities, the screened intakes as designed would exclude this species, although there is some potential for impingement or contact by smaller fish with the screen, as well as predation near the screens. Overall impacts of Alternative 2D water operations on entrainment of Chinook salmon (winter-run ESU) would be less than significant and would be beneficial due to a reduction in entrainment and no mitigation would be required.

Impact AQUA-40: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 2D would reduce the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon relative to NAA_ELT.

Mean flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam were examined during the May through September winter-run spawning and egg incubation period (Appendix B, *Supplemental Modeling for New Alternatives*). Lower flows can reduce the instream area available for spawning and egg incubation. Flows under A2D_ELT during May, through August would generally be similar to or greater than flows under NAA_ELT. Flows under A2D_ELT during September would generally be lower than flows under NAA_ELT by up to 18%. These modeling results indicate that there would generally be no flow-related effects of Alternative 2D on spawning and egg incubation habitat except during September, in which there would be intermittent negligible-to-small flow reductions.

Shasta Reservoir storage volume at the end of May influences flow rates below the dam during the May through September winter-run spawning and egg incubation period. May Shasta storage volume under A2D_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-2D-9).

Table 11-2D-9. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-19 (0%)	-7 (0%)
Above Normal	-89 (-2%)	-63 (-1%)
Below Normal	-102 (-2%)	-6 (0%)
Dry	-230 (-6%)	-27 (-1%)
Critical	-218 (-9%)	79 (4%)

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no substantial differences (<5%) in mean monthly water temperature between NAA_ELT and A2D in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-12. There would be 3 (4%) more years with a "red" level of concern under A2D_ELT than under NAA_ELT. This difference would not be biologically meaningful to winter-run Chinook salmon spawners and eggs, as the 3 years constitute a small proportion of the 82 year period used for analysis, as long as the years were not consecutive, which they were not in this case.

Table 11-2D-10. Maximum Water Temperature Thresholds for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Location	Period	Maximum Water Temperature °F)	Purpose
Upper Sacramento River			
Bend Bridge	May–Sep	56	Winter- and spring-run spawning and egg incubation
		63	Green sturgeon spawning and egg incubation
Red Bluff	Oct–Apr	56	Spring-, fall-, and late fall–run spawning and egg incubation
Hamilton City	Mar–Jun	61 (optimal), 68 (lethal)	White sturgeon spawning and egg incubation
Feather River			
Robinson Riffle (RM 61.6)	Sep–Apr	56	Spring-run (Sep-Jan) and steelhead (Jan-Apr) spawning and incubation
	May–Aug	63	Spring-run and steelhead rearing
Gridley Bridge	Oct–Apr	56	Fall- and late fall–run spawning and steelhead rearing
	May–Sep	64	Green sturgeon spawning, incubation, and rearing
American River			
Watt Avenue Bridge	May–Oct	65	Juvenile steelhead rearing

Table 11-2D-11. Number of Days per Month Required to Trigger Each Level of Concern for Water Temperature Exceedances in the Sacramento River for Covered Salmonids and Sturgeon Provided by NMFS and Used in the BDCP Effects Analysis

Exceedance above Water Temperature Threshold (°F)	Level of Concern			
	None	Yellow	Orange	Red
1	0-9 days	10-14 days	15-19 days	≥20 days
2	0-4 days	5-9 days	10-14 days	≥15 days
3	0 days	1-4 days	5-9 days	≥10 days

Table 11-2D-12. Differences between Baseline and Alternative 2D Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern[a]	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Red	29 (59%)	3 (4%)
Orange	-10 (-71%)	-2 (-50%)
Yellow	-16 (-100%)	-1 (NA)
None	-3 (-100%)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] For definitions of levels of concern, see Table 11-2D-11.

Total degree-days exceeding 56°F at Bend Bridge were summed for all years by month and water year type during May through September (Table 11-2D-13). Total degree-days (all water year types combined) under A2D would be up to 12% lower than under NAA_ELT during May and June and up to 10% higher during July through September.

Table 11-2D-13. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
May	Wet	458 (121%)	-41 (-4.7%)
	Above Normal	107 (50%)	-128 (-29%)
	Below Normal	253 (116%)	-35 (-7%)
	Dry	196 (105%)	-89 (-19%)
	Critical	175 (79%)	-43 (-10%)
	All	1,189 (98%)	-336 (-12%)
June	Wet	280 (73%)	-85 (-11%)
	Above Normal	56 (38%)	-58 (-22%)
	Below Normal	122 (88%)	-18 (-6%)
	Dry	144 (77%)	-65 (-16%)
	Critical	183 (46%)	-61 (-9%)
	All	786 (62%)	-286 (-12%)
July	Wet	261 (50%)	39 (5%)
	Above Normal	119 (147%)	43 (27%)
	Below Normal	172 (117%)	-12 (-4%)
	Dry	332 (118%)	75 (14%)
	Critical	775 (94%)	-9 (-1%)
	All	1,659 (90%)	136 (4%)
August	Wet	971 (139%)	35 (2%)
	Above Normal	339 (83%)	53 (8%)
	Below Normal	500 (189%)	8 (1%)
	Dry	1,134 (169%)	326 (22%)
	Critical	1,236 (83%)	-40 (-1%)
	All	4,181 (119%)	383 (5%)
September	Wet	116 (16%)	107 (14%)
	Above Normal	197 (28%)	317 (53%)
	Below Normal	771 (103%)	318 (27%)
	Dry	1,381 (108%)	132 (5%)
	Critical	1,000 (48%)	-30 (-1%)
	All	3,466 (62%)	844 (10%)

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be lower or similar to mortality under NAA_ELT except in below normal water years (25% higher). The increase in the percent of winter-run population subject to mortality in below normal years would be 0.3%. Therefore, the increase in mortality from NAA_ELT to A2D_ELT during a below normal year, although large on a relative scale (i.e., 25%

difference), would be negligible at an absolute scale to the winter-run population (i.e., 0.3%; Table 11-2D-14).

Table 11-2D-14. Difference and Percent Difference in Percent Mortality of Winter-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0.3 (85%)	-0.01 (-2%)
Above Normal	0.4 (90%)	-0.04 (-4%)
Below Normal	1 (72%)	0.3 (25%)
Dry	2 (106%)	0.02 (1%)
Critical	20 (75%)	-3 (-5%)
All	4 (78%)	-0.3 (-4%)

SacEFT predicts that there would be a 24% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2D_ELT relative to NAA_ELT (Table 11-2D-15). On an absolute scale, this reduction would be smaller (i.e., 11%). SacEFT predicts that the percentage of years with good (lower) redd scour risk under A2D_ELT would be similar to the percentage of years under NAA_ELT. SacEFT predicts that the percentage of years with good egg incubation conditions under A2D_ELT would be similar to that under NAA_ELT. SacEFT predicts that there would be a 17% decrease (5% on an absolute scale) in the percentage of years with good (lower) redd dewatering risk under A2D_ELT relative to NAA_ELT. These results indicate that there would be small to moderate negative effects of Alternative 2D on spawning habitat.

The biological significance of a reduction in available suitable spawning habitat varies at the population level in response to a number of factors, including adult escapement. For those years when adult escapement is less than the carrying capacity of the spawning habitat, a reduction in area would have little or no population level effect. In years when escapement exceeds carrying capacity of the reduced habitat, competition among spawners for space (e.g., increased redd superimposition) would increase, resulting in reduced reproductive success. The reduction in the frequency of years in which spawning habitat availability is considered to be good by SacEFT could result in reduced reproductive success and abundance of winter-run Chinook salmon if the number of spawners is limited by spawning habitat quantity. However, it is unlikely that spawning habitat is limiting to winter-run Chinook salmon due to their small spawning adult population sizes in recent years relative to historical numbers.

Table 11-2D-15. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Winter-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Spawning WUA	-23 (-40%)	-11 (-24%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-9 (-9%)	0 (0%)
Redd Dewatering Risk	-1 (-4%)	-5 (-17%)
Juvenile Rearing WUA	-5 (-10%)	8 (22%)
Juvenile Stranding Risk	-5 (-25%)	-17 (-53%)

WUA = Weighted Usable Area.

NEPA Effects: Considering the range of results presented here for winter-run Chinook salmon spawning and egg incubation, this effect would be adverse because it has the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. There would be small to moderate reductions in flow during September that would degrade spawning and egg incubation conditions for winter-run Chinook salmon. Total degree-days would be up to 10% higher under Alternative 2D during a substantial portion (3 of 5 months) of the spawning and egg incubation period. Further, SacEFT predicts that the number of years with good winter-run spawning habitat would be reduced by 24% under Alternative 2D and the number of years with good (lower) redd dewatering risk would be 5% lower (Table 11-2D-15). This effect is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this effect to a level that is not adverse would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this would be an unavoidable adverse effect because there is no feasible mitigation available. Even so, proposed mitigation (Mitigation Measure AQUA-40a through AQUA-40c) has the potential to reduce the severity of impact, although not necessarily to a not adverse level.

CEQA Conclusion: In general, Alternative 2D would degrade the quantity and quality of spawning and egg incubation habitat for winter-run Chinook salmon relative to the Existing Conditions.

CALSIM mean flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the May through September winter-run spawning and egg incubation period (Appendix B, *Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be similar to flows under Existing Conditions during May through August with few exceptions (up to 14% lower) and would generally be up to 24% lower during September.

Shasta Reservoir storage volume at the end of May under A2D_ELT would be similar to Existing Conditions in wet, above normal, and below normal water years, but lower by 6% and 9% in dry and critical water years, respectively (Table 11-2D-9). This indicates that there would be a small to moderate effect of Alternative 2D on flows during the spawning and egg incubation period.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the May through September winter-run spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and

Alternative 2D throughout the period except in critical years during August and September at Keswick (6% and 5% higher, respectively) and in critical years during August at Bend Bridge (6% higher).

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. The number of years classified as "red" would increase by 59% under A2D relative to Existing Conditions (Table 11-2D-12). This would cause a negative effect to winter-run Chinook salmon spawning and egg incubation.

Total degree-days exceeding 56°F at Bend Bridge were summed for all years by month and water year type during May through September (Table 11-2D-13). Total degree-days (all water year types combined) under A2D would be 62% to 119% higher than that under Existing Conditions depending on month throughout the period. This would cause a negative effect to winter-run Chinook salmons spawning and egg incubation.

The Reclamation egg mortality model predicts that winter-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be 72 to 106% greater on a relative scale and up to 20% greater on an absolute scale than mortality under Existing Conditions depending on water year type (Table 11-2D-14). These increases would only affect the winter-run population during critical years, in which the absolute percent increase of the winter-run population would be 20%. These results indicate that Alternative 2D would cause increased winter-run Chinook salmon egg mortality in the Sacramento River.

SacEFT predicts that there would be a 40% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-15). SacEFT predicts that the percentage of years with good (lower) redd scour risk under A2D_ELT would be similar to the percentage of years under Existing Conditions. SacEFT predicts that the percentage of years with good egg incubation conditions under A2D_ELT would be 9% lower than under Existing Conditions. SacEFT predicts that the percentage of years with good (lower) redd dewatering risk under A2D_ELT would be 4% lower than the percentage of years under Existing Conditions. These results indicate that Alternative 2D would cause large reductions in spawning WUA. However, due to the highly suppressed population size of winter-run Chinook salmon relative to historical population sizes, it is unlikely that spawning habitat is currently limiting.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would be significant because it has the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Reservoir storage would be lower under Alternative 2D, particularly in critical years (9% lower). The number of years with a red level of concern regarding water temperatures and exceedances of NMFS temperature thresholds would be substantially greater under Alternative 2D. Egg mortality in drier years, during which winter-run Chinook salmon would already be stressed due to reduced flows and increased temperatures, would be up to 75% greater due to Alternative 2D compared to the Existing Conditions (Table 11-2D-14). Further, the number of years with "good" spawning habitat would be 40% lower due to Alternative 2D compared to the Existing Conditions (Table 11-2D-15), which represents a substantial reduction in spawning habitat and, therefore, in adult spawner and redd carrying capacity. This impact is a result of the specific reservoir operations and resulting flows associated with this alternative. Applying mitigation (e.g., changing reservoir operations in order to alter the flows) to the extent necessary to reduce this impact to a less-than-significant level would fundamentally change the alternative, thereby making it a different alternative than that which has been modeled and analyzed. As a result, this impact is significant and unavoidable because there is no feasible mitigation available. Even so, proposed below is mitigation that has the potential to reduce the severity of impact though not to a less-than-significant level.

Mitigation Measure AQUA-40a: Following Initial Operations of Water Conveyance Facilities, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Spawning Habitat

Although analysis conducted as part of the EIR/EIS determined that Alternative 2D would have significant and unavoidable adverse effects on spawning habitat, this conclusion was based on the best available scientific information at the time and may prove to have been overstated. Upon the commencement of operations of water conveyance facilities and continuing through the life of the permit, the project proponents will monitor effects on spawning habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2D.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2D operations only. Development of mitigation actions for the incremental impact on spawning habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2D.

Mitigation Measure AQUA-40b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Spawning Habitat Following Initial Operations of Water Conveyance Facilities

Following commencement of initial operations of water conveyance facilities and continuing through the life of the permit, the project proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to spawning habitat under Alternative 2D. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program.

Mitigation Measure AQUA-40c: Consult with NMFS, USFWS, and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Spawning Habitat Consistent with Water Conveyance Facilities

In order to determine the feasibility of reducing the effects of water conveyance facilities operations on winter-run Chinook salmon habitat, the project proponents will consult with NMFS, USFWS and CDFW to identify and implement any feasible operational means to minimize effects on spawning habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-40d.

If feasible means are identified to reduce impacts on spawning habitat consistent with the overall operational framework of Alternative 2D without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on winter-run Chinook salmon habitat is not feasible under Alternative 2D operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on winter-run Chinook salmon would remain significant and unavoidable.

Impact AQUA-41: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Winter-Run ESU)

In general, Alternative 2D would not reduce the quantity and quality of rearing habitat for fry and juvenile winter-run Chinook salmon relative to NAA_ELT.

Sacramento River mean flows between Keswick and upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix *B, Supplemental Modeling for New Alternatives*). Lower flows can lead to reduced extent and quality of fry and juvenile rearing habitat. Flows under A2D_ELT would generally be lower than flows under NAA_ELT by up to 24% during September and November, and similar to flows under NAA_ELT during August, October and December. The biological implications of the flow reductions is analyzed below in the SALMOD and SacEFT analyses.

Mean water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be negligible differences (<5%) in mean monthly water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under A2D_ELT would be 22% higher on a relative scale (8% on an absolute scale) than the percentage of years under NAA_ELT (Table 11-2D-14). However, the percentage of years with good (low) juvenile stranding risk under A2D_ELT is predicted to be 53% lower on a relative scale (17% on an absolute scale)) than under NAA_ELT. These results indicate that the quantity of juvenile rearing habitat in the Sacramento River would be slightly higher under A2D_ELT relative to NAA_ELT, but the quality of this habitat, with respect to stranding risk, would be reduced.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under A2D_ELT would be 5% lower than the habitat-related mortality with NAA_ELT. These results are inconsistent with SacEFT results, which indicate that juvenile stranding risk would increase under A2D_ELT (Table 11-2D-14).

Both SacEFT and SALMOD are considered to be reliable models for winter-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP and SacEFT has been peer-reviewed. Therefore, results of both models were used to draw conclusions about winter-run Chinook salmon rearing conditions. The SALMOD model incorporates effects to all early life stages, including eggs, fry, and juveniles. Therefore, although SacEFT predicts that juvenile stranding risk may increase under Alternative 2D, when combined with all early life stage effects in SALMOD, the effects of Alternative 2D would be marginally beneficial to winter-run Chinook salmon survival. Further, these results indicate that the August through November flow reductions in the Sacramento River identified above would not have a biological effect on winter-run Chinook salmon rearing.

NEPA Effects: Collectively, these modeling results indicate that the effect of Alternative 2D is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat and substantially interfere with winter-run Chinook salmon rearing. There would be no substantial effects of Alternative 2D on flows or water temperatures. SALMOD and SacEFT predicted contradicting results regarding habitat-related mortality. SacEFT found that juvenile stranding risk is expected to increase. However, the SALMOD model found that Alternative 2D would provide a minor beneficial effect (5% reduction in habitat-related mortality) to early life stages of winter-run Chinook salmon. The SALMOD results include the effects to all early life stages combined and, therefore, are more representative of the overall effects to winter-run Chinook salmon in the upper Sacramento River.

CEQA Conclusion: In general, Alternative 2D would not reduce the quantity and quality of fry and juvenile rearing habitat for winter-run Chinook salmon relative to the Existing Conditions.

Sacramento River mean flows between Keswick and upstream of Red Bluff were examined for the juvenile winter-run Chinook salmon rearing period (August through December) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be similar to flows under Existing Conditions during December, but up to 24% lower than Existing Conditions during August, September, October, and November, except for September of wet and above normal years (to 29% greater).

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the August through December winter-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D throughout the period except in critical years during August and September at Keswick (6% and 5% higher, respectively) and in critical years during August at Bend Bridge (6% higher).

SacEFT predicts that the percentage of years with good juvenile rearing habitat availability, measured as weighted usable area, under A2D_ELT would be 10% lower on a relative scale (5% lower on an absolute scale) than under Existing Conditions (Table 11-2D-14). In addition, the percentage of years with good (low) juvenile stranding risk under A2D_ELT is predicted to be 25% lower on a relative scale (5% lower on an absolute scale) than under Existing Conditions. This indicates that the quantity and quality, with respect to stranding, of juvenile rearing habitat in the Sacramento River would be marginally lower under A2D_ELT relative to Existing Conditions.

SALMOD predicts that winter-run smolt equivalent habitat-related mortality under A2D_ELT would not be different (<5%) from that under Existing Conditions. These results are somewhat inconsistent with SacEFT results, which indicate that the number of years with good juvenile rearing WUA and with good (low) stranding risk would both decrease under A2D_ELT (Table 11-2D-14). Both SacEFT and SALMOD are considered to be reliable models for winter-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP. Therefore, results of both models were used to draw conclusions about winter-run Chinook salmon rearing conditions. The SALMOD model incorporates effects to all early life stages, including eggs, fry, and juveniles. Therefore, although SacEFT predicts that juvenile stranding risk may increase under A2D_ELT, when combined with all early life stage effects in SALMOD, A2D_ELT is predicted to have minor effects on winter-run Chinook salmon rearing.

Summary of CEQA Conclusion

These modeling results indicate that the impact could be significant because it has the potential to substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Differences in flows are moderately large during the majority of months and water year types. Water temperatures would be higher than those under NAA_ELT in the Sacramento River during critical water years, when winter-run Chinook salmon would already be stressed due to reduced flows and increased temperatures, in a portion of the winter-run rearing period. SALMOD and SacEFT predicted contradicting results regarding habitat-related mortality, although, because SALMOD incorporates more of the life cycle of winter-run Chinook salmon, its results are more representative of overall effects to winter-run Chinook salmon in the upper Sacramento River.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in the Sacramento River would generally be similar between NAA_ELT and Alternative 2D. SacEFT predicts that juvenile stranding risk may increase under Alternative 2D, but when combined with all early life stage effects in SALMOD, the effects of the alternative would be marginally beneficial to winter-run Chinook salmon. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-42: Effects of Water Operations on Migration Conditions for Chinook Salmon (Winter-Run ESU)

In general, the effects of Alternative 2D on winter-run Chinook salmon migration conditions relative to the NAA_ELT are adverse because although the operations of the NDD would take into account triggers developed by DFW and NMFS that would allow for adjustments in NDD operations to minimize and avoid effects on Chinook salmon and steelhead, the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes poses an unacceptable risk to winter-run Chinook salmon.

Upstream of the Delta

Mean flows in the Sacramento River upstream of Red Bluff were examined for the July through November juvenile emigration period. A substantial reduction in flow may reduce the ability of juvenile winter-run Chinook salmon to migrate effectively down the Sacramento River due to a reduction in olfactory cues, although there is little empirical evidence supporting this. Mean flows under A2D_ELT would generally be similar to flows under NAA_ELT, except during September and November, in which flows would be up to 18% lower under A2D_ELT. The largest flow reductions would occur in above normal, and below normal water year types. The flow reductions would not be large enough to have biologically meaningful effects on juvenile emigration conditions.

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run Chinook salmon juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D in any month or water year type throughout the period at either location.

Mean flows in the Sacramento River upstream of Red Bluff were examined during the adult winter-run Chinook salmon upstream migration period (December through August). A reduction in flows may reduce the olfactory cues needed by adults to return to natal spawning grounds in the upper Sacramento River. Flows under A2D_ELT would generally be similar to or greater than those under NAA_ELT except for dry water years during August, in which flow would be up to 11% lower under A2D_ELT. This reduction would not be large or frequent enough to cause biologically meaningful effects on adult migration conditions.

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D in any month or water year type throughout the period at either location.

Overall, Sacramento River migration flows and water temperatures during the winter-run Chinook salmon juvenile and adult migration periods would not differ substantially between Alternative 2D and NAA_ELT.

Through-Delta

The effects of Alternative 2D on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Juveniles

During the juvenile winter-run Chinook salmon emigration period (November to early May), mean monthly flows downstream of the north Delta diversion facility under Alternative 2D would be reduced up to 33% compared to NAA_ELT, depending on the month and water-year type.

The north Delta export facilities would replace aquatic habitat and likely attract piscivorous fish around the intake structures. The predation effects of Alternative 2D would be similar to those described for Alternatives 1A and 2A (see details in Impact AQUA-42), because there are five intakes for these alternatives. The five NDD intakes would remove or modify habitat along that portion of the migration corridor (13 acres aquatic habitat and 2.3 linear miles of shoreline). As described above under Impact AQUA-39, potential predation losses at the north Delta intakes, as estimated by the bioenergetics model with median density of predators (119 striped bass per 1,000 feet of intake), would be less than 0.3% compared to the annual production estimated for the Sacramento Valley that enters the Delta (Table 11-2D-1). As discussed for Alternative 4A, a conservative assumption of 5% loss per intake (based on GCID losses; Vogel 2008) would yield a cumulative loss of 18.5% of juvenile winter-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate which does not take into account baseline levels of predation.

Through-Delta survival to Chipps Island by emigrating juvenile winter-run Chinook salmon was modeled by the DPM. Average survival under Alternative 2D would be 33% across all years, 25% in drier years, and 45% in wetter years (Table 11-2D-16). Compared to NAA_ELT, juvenile survival would decrease 1.6% across all years (a 5% relative decrease) and decrease 2.0% (7% relative decrease) in drier years. As described for Alternative 4A, the modeling of NAA_ELT does not account for actions that are assumed to be included under NAA that would be pursued as part of other projects and programs, notably Yolo Bypass improvements and tidal habitat restoration under the NMFS and USFWS BiOps. As shown for Alternative 4A, the difference in through-Delta survival between Alternative 2D and NAA_ELT would be somewhat greater if the improvements to Yolo Bypass (particularly Fremont Weir modifications) were included in the modeling for NAA_ELT.

Table 11-2D-16. Through-Delta Survival (%) of Emigrating Juvenile Winter-Run Chinook Salmon under Alternative 2D

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA_ELT	A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wetter Years	46.3	46.3	45.2	-1.2 (-3%)	-1.1 (-2%)
Drier Years	28.0	27.2	25.3	-2.7 (-9%)	-2.0 (-7%)
All Years	34.9	34.4	32.7	-2.1 (-7%)	-1.6 (-5%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, declined under Alternative 2D by no more than 10% during the December through June migration period for winter-run adults (Table 11-2D-17). The reductions in percentage are small in comparison with the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect winter-run adult migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. For further discussion of the topic see the analysis for Alternative 1A.

Table 11-2D-17. Percentage (%) of Water at Collinsville that Originated in the Sacramento River and San Joaquin River during the Adult Salmonid Migration Period for Alternative 2D

Month	Percentage of Water			Difference	
	EXISTING CONDITIONS	NAA_ELT	A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Sacramento River					
September	60	65	60	0	-5
October	60	64	64	4	0
November	60	64	63	2	-2
December	67	67	65	-2	-2
January	76	75	73	-3	-2
February	75	74	69	-7	-5
March	78	77	68	-10	-9
April	77	76	67	-10	-10
May	69	67	60	-9	-7
June	64	61	56	-8	-5
San Joaquin River					
September	0.3	0.2	1.9	1.6	1.7
October	0.2	0.2	4.7	4.5	4.5
November	0.4	0.8	6.0	5.6	5.2
December	0.9	1.0	3.1	2.2	2.1
January	1.6	1.7	3.1	1.5	1.5
February	1.4	1.5	4.0	2.6	2.5
March	2.6	2.6	6.3	3.7	3.7
April	6.3	6.2	10.7	4.4	4.5

Shading indicates a difference of 10% or greater in flow proportion.

NEPA Effects: Overall, the results indicate that the effect of Alternative 2D is adverse due to the cumulative effects associated with five north Delta intake facilities, including juvenile mortality related to near-field effects (e.g., impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, Alternative 2D would not affect migration conditions for winter-run Chinook salmon, as migration flows and water temperatures would not differ substantially between Alternative 2D and NAA_ELT.

Adult attraction flows under Alternative 2D would be lower than those under NAA_ELT, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2D on winter-run Chinook salmon related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating winter-run Chinook salmon, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to very significant effects (~ 19% mortality above current baseline levels). As noted for Alternative 4A, Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction studies to better understand how to minimize losses associated with the new intake structures will be implemented as part of the final NDD screen design effort. As with Alternative 4A, Alternative 2D also includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for winter-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

As described for Alternative 4A, the DPM is a flow-based model incorporating flow-survival and junction routing relationships with flow modeling of water operations to estimate relative differences between scenarios in smolt migration survival throughout the entire Delta. The DPM predicted that smolt migration survival under Alternative 2D would be lower than survival estimated for NAA_ELT, based on operations assuming no adjustments made in real-time in response to actual presence of fish. Although refinements to the DPM are likely to occur based on new data available from future studies and the current analysis has some uncertainty, the DPM analysis of Alternative 2D on juvenile winter-run Chinook salmon migration suggests a potential adverse effect of small magnitude. This adverse effect would be reduced through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 2D of specific important environmental commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of winter-run Chinook salmon juveniles into the low-survival interior Delta.

Overall, primarily as a result of unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on winter-run Chinook salmon, this effect is adverse. While implementation of the environmental commitments noted above and mitigation measures listed below would address these impacts, these are not anticipated to reduce the impacts to a level considered not adverse.

CEQA Conclusion: In general, Alternative 2D would degrade migration conditions for winter-run Chinook salmon relative to the Existing Conditions.

Upstream of the Delta

Mean flows in the Sacramento River upstream of Red Bluff were examined during the July through November juvenile emigration period. Flows under A2D_ELT for juvenile migrants would generally be similar to flows under Existing Conditions during July, and would be up to 22% lower during August through November, except for September of wet and above normal year types, in which the flows would be 20% and 27% higher, respectively (Appendix *B, Supplemental Modeling for New Alternatives)*. The flow reductions would not be large or frequent enough to cause biologically meaningful effects on juvenile emigration conditions.

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the July through November winter-run juvenile emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D throughout the period except in critical years during August and September at Keswick (6% and 5% higher, respectively) and in critical years during August at Bend Bridge (6% higher).

Mean flows under A2D_ELT in the Sacramento River upstream of Red Bluff during December through August would generally be similar to flows under Existing Conditions, except during August, in which flows would be up to 12% lower. These reductions in flow would not be large or frequent enough to cause biologically meaningful effects on adult migration conditions.

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the December through August winter-run upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D throughout the period except in critical years during August at both locations (6% higher at both locations).

Through-Delta

As described above, predation losses of migrating juvenile winter-run Chinook would increase at the five north Delta intakes, hypothetically ranging from less than 1% up to nearly 19% that reach the north Delta. Through-Delta survival of emigrating juvenile winter-run Chinook salmon averaged across all years would decrease slightly compared to Existing Conditions (2.1% lower, a 7% relative decrease for all years) (Table 11-2D-16).

For migrating adults, olfactory cues, based on the proportion of Sacramento River flows, would be similar (10% or less difference) to Existing Conditions during the winter-run Chinook salmon migration period (Table 11-2D-17). For further discussion of this topic see the analysis for Alternative 1A.

Summary of CEQA Conclusion

Overall, Alternative 2D would significantly affect the migration conditions for winter-run Chinook salmon, relative to the Existing Conditions. Through-Delta survival of emigrating juveniles has the potential to be appreciably reduced, compared to Existing Conditions. There would be little effect of Alternative 2D on adult olfactory cues in the Delta. Water temperatures under Alternative 2D in the Sacramento River upstream of the Delta would generally be similar to those under Existing Conditions during both the juvenile and adult winter-run Chinook salmon migration periods. Flows in the Sacramento River upstream of the Delta would be similar during the adult migration period, although reduced during the juvenile migration period.

Implementation of *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers* (all of which are summarized further in Section 4.1.3.3) would address the through-Delta impacts, but are not anticipated to reduce them to a level considered less than significant because of the presence of five intakes. As a result of these changes in migration conditions, this impact is significant and unavoidable.

Mitigation Measure AQUA-42a: Following Initial Operations of Water Conveyance Facilities, Conduct Additional Evaluation and Modeling of Impacts to Winter-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Although analysis conducted as part of this recirculated EIR/EIS determined that Alternative 2D would have significant and unavoidable adverse effects on migration habitat, this conclusion was based on the best available scientific information at the time and may prove to have been over- or understated. Upon the commencement of operations of the proposed water conveyance facilities and continuing through the life of the permit, the project proponents will monitor effects on migration habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2D.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2D operations only. Development of mitigation actions for the incremental impact on migration habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2D.

Mitigation Measure AQUA-42b: Conduct Additional Evaluation and Modeling of Impacts on Winter-Run Chinook Salmon Migration Conditions Following Initial Operations of Water Conveyance Facilities

Following commencement of initial operations of the proposed water conveyance facilities and continuing through the life of the permit, the project proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to migration habitat under Alternative 2D. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program.

Mitigation Measure AQUA-42c: Consult with NMFS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Winter-Run Chinook Salmon Migration Conditions Consistent with Water Conveyance Facility Operations

In order to determine the feasibility of reducing the effects of water conveyance facility operations on winter-run Chinook salmon habitat, the project proponents will consult with NMFS and the Department of Fish and Wildlife to identify and implement any feasible operational means to minimize effects on migration habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-42a.

If feasible means are identified to reduce impacts on migration habitat consistent with the overall operational framework of Alternative 2D without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on winter-run Chinook salmon habitat is not feasible under Alternative 2D operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on winter-run Chinook salmon would remain significant and unavoidable.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-43: Effects of Construction of Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-44: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Winter-Run ESU)

Impact AQUA-45: Effects of Restored Habitat Conditions on Chinook Salmon (Winter-Run ESU)

Impact AQUA-46: Effects of Methylmercury Management on Chinook Salmon (Winter-Run ESU) (Environmental Commitment 12)

Impact AQUA-49: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Winter-Run ESU) (Environmental Commitment 15)

Impact AQUA-50: Effects of Nonphysical Fish Barriers on Chinook Salmon (Winter-Run ESU) (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on winter-run Chinook salmon for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Spring-Run Chinook Salmon

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-55: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

The potential effects of construction of the water conveyance facilities on spring-run Chinook salmon or their designated critical habitat would be similar to those described for Alternative 4A (Impact AQUA-55) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to spring-run Chinook salmon.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-55, the effect would not be adverse for spring-run Chinook salmon or designated critical habitat.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-55, the impact of the construction of water conveyance facilities on spring-run Chinook salmon and critical habitat would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-56: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Spring-Run ESU)

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-56, the effect would not be adverse for spring-run Chinook salmon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-56 for spring-run Chinook salmon, the impact of the maintenance of water conveyance facilities on spring-run Chinook salmon or critical habitat would be less than significant and no mitigation is required.

Water Operations of Water Conveyance Facilities

Impact AQUA-57: Effects of Water Operations on Entrainment of Chinook Salmon (Spring-Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Based on the salvage-density method, entrainment losses under Alternative 2D would decrease by approximately 53% compared to NAA_ELT averaged across all years (Table 11-2D-18). Entrainment reductions under Alternative 2D would be greater in wetter years, ranging from slightly greater (9%) in dry years up to 86% decrease in wet years compared to Existing Conditions (Table 11-2D-18). Pre-screen losses, typically attributed to predation, would also decrease commensurate with entrainment reductions.

The proportion of the annual spring-run Chinook population (assumed to be 750,000 juveniles approaching the Delta) lost at the south Delta facilities across all years averaged 5.2% under NAA_ELT, and would decrease to 2.4% under Alternative 2D.

Table 11-2D-18. Juvenile Spring-Run Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2D

	Absolute Difference (Percent Difference)[a]	
Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-76,409 (-86%)	-80,570 (-87%)
Above Normal	-15,223 (-57%)	-16,341 (-59%)
Below Normal	-1,692 (-27%)	-2,003 (-30%)
Dry	1,413 (9%)	-211 (-1%)
Critical	-2,582 (-22%)	-1,876 (-17%)
All Years	-19,431 (-51%)	-20,901 (-53%)

Shading indicates 10% or greater increased entrainment.

[a] Estimated annual number of fish lost, based on normalized data.

Water Exports from SWP/CVP North Delta Intake Facilities

The impacts from the proposed SWP/CVP north Delta intakes on spring-run Chinook salmon would be the same as described for Impact AQUA-57 for spring-run Chinook Salmon under Alternative 2A. State-of-the-art fish screens operated with an adaptive management plan would be expected to eliminate entrainment risk for juvenile spring-run Chinook salmon to these intakes.

Predation Associated with Entrainment

Entrainment-related predation loss of spring-run Chinook salmon at the south Delta facilities would be lower than baseline due to a reduction in entrainment loss (see analysis above). Predation at the north Delta would be increased at the proposed North Delta intake facilities on the Sacramento River, as discussed below in Impact AQUA-60.

NEPA Effects: Under Alternative 2D, entrainment of juvenile spring-run Chinook salmon at the south Delta facilities was estimated to be lower than NAA_ELT across all water years (considering the all-year salvage density results). It is concluded that this reduction, in addition to associated reduction in predation losses, would offset any losses associated with predation at the north Delta intakes. Therefore, the effect would not be adverse.

CEQA Conclusion: As described above, operational activities associated with water exports from SWP/CVP south Delta facilities would result in an overall decrease in entrainment and associated predation losses for juvenile spring-run Chinook salmon, albeit with substantial variation among water year types (Table 11-2D-18). Consequently, the impact of water operations on entrainment of juvenile Chinook salmon (spring-run ESU) is considered less than significant, and no mitigation would be required.

Impact AQUA-58: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Spring-Run ESU)

In general, the effects of Alternative 2D on spawning and egg incubation habitat for spring-run Chinook salmon relative to NAA_ELT are not adverse.

Sacramento River

There has been a small, inconsistent spawning population (<400 individuals) in the mainstem Sacramento River primarily upstream of Red Bluff Diversion Dam over the past decade (Azat 2012).

Flows in the Sacramento River between Keswick and upstream of Red Bluff during the spring-run Chinook salmon spawning and incubation period (September through January) under A2D_ELT would generally be similar to or greater than flows under NAA_ELT except in September and November, in which flows would be up to 24% lower than those under NAA_ELT, depending on location and water year type (Appendix *B, Supplemental Modeling for New Alternatives*).

Shasta Reservoir storage volume at the end of September influences flows downstream of the dam during the spring-run spawning and egg incubation period (September through January). Storage under A2D_ELT would be similar to storage under NAA_ELT in all water year types (Table 11-2D-19).

Table 11-2D-19. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Shasta Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-286 (-9%)	11 (0%)
Above Normal	-346 (-11%)	17 (1%)
Below Normal	-229 (-8%)	-62 (-2%)
Dry	-172 (-7%)	30 (1%)
Critical	-137 (-12%)	60 (6%)

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period at either location.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-12 for Bend Bridge and in Table 11-2D-20 for Red Bluff. At Bend Bridge, there would be 3 (4%) more years with a "red" level of concern and 2 (50%) fewer years with an "orange" level of concern for Alternative 2Drelative to NAA_ELT. At Red Bluff, there would be 2 (18%) fewer years with an "orange" level of concern, under Alternative 2D and 2 (7%) more years with a "yellow" level of concern.

Table 11-2D-20. Differences between Baseline and Alternative 2D Scenarios in the Number of Years in Which Water Temperature Exceedances above 56°F Are within Each Level of Concern, Sacramento River at Red Bluff, October through April

Level of Concern[a]	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Red	9 (75%)	0 (0%)
Orange	5 (83%)	-2 (-18%)
Yellow	15 (115%)	2 (7%)
None	-29 (-57%)	0 (0%)

[a] For definitions of levels of concern, see Table 11-2D-11.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days (all water year types combined) under Alternative 2D would be 12% lower than those under NAA_ELT during May and June and up to 10% higher during July through September (Table 11-2D-13). At Red Bluff, total degree-days under Alternative 2D would be similar to or lower than those under NAA_ELT except during November and March (3% and 18% 8higher, respectively), (Table 11-2D-21).

Table 11-2D-21. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Sacramento River at Red Bluff, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
October	Wet	437 (170%)	15 (2%)
	Above Normal	206 (79%)	9 (2%)
	Below Normal	246 (118%)	-12 (-3%)
	Dry	411 (84%)	37 (4%)
	Critical	353 (59%)	-62 (-6%)
	All	1653 (91%)	-13 (0%)
November	Wet	11 (1,100%)	3 (33%)
	Above Normal	4 (NA)	1 (33%)
	Below Normal	2 (NA)	0 (0%)
	Dry	38 (475%)	-4 (-8%)
	Critical	21 (525%)	3 (14%)
	All	76 (585%)	3 (3%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	1 (NA)	0 (0%)
	Above Normal	1 (NA)	1 (NA)
	Below Normal	10 (111%)	9 (90%)
	Dry	20 (143%)	0 (0%)
	Critical	11 (1,100%)	0 (0%)
	All	43 (179%)	10 (18%)
April	Wet	101 (88%)	4 (2%)
	Above Normal	77 (55%)	5 (2%)
	Below Normal	86 (109%)	-8 (-5%)
	Dry	108 (58%)	1 (0%)
	Critical	39 (325%)	-3 (-6%)
	All	411 (77%)	-1 (0%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be similar to mortality under NAA_ELT in wet, dry and critical years, but greater in above normal (30% greater) and below normal (36% greater) water years (Table 11-2D-22). Absolute scale increases of 5% and 8% of the spring-run population under above normal and below normal water years would have a negligible to small effect on the population. Combining all water year types, there would be no effect of Alternative 2D on egg mortality (3% absolute change).

Table 11-2D-22. Difference and Percent Difference in Percent Mortality of Spring-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	4 (41%)	0.3 (2%)
Above Normal	8 (58%)	5 (30%)
Below Normal	17 (142%)	8 (36%)
Dry	23 (116%)	2 (4%)
Critical	19 (25%)	1 (1%)
All	13 (59%)	3 (8%)

SacEFT predicts that there would be a minimal (<5%) difference in the percentage of years with good spawning availability, measured as weighted useable area, between A2D_ELT and NAA_ELT (Table 11-2D-23). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under A2D_ELT relative to NAA_ELT (Table 11-2D-23). SacEFT predicts that there would be an 11% decrease (7% decrease on absolute scale) in the percentage of years with good (lower) egg incubation conditions under A2D_ELT relative to NAA_ELT. SacEFT predicts that there would be a minimal (<5%) difference in the percentage of years with good (lower) redd dewatering risk under A2D_ELT relative to NAA_ELT. It is unlikely that spawning habitat availability is currently limiting to spring-run Chinook salmon due to deeply suppressed escapement values over the past decade. Given this, these SacEFT outputs may be less important to spring-run Chinook salmon spawning.

Table 11-2D-23. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Spring-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Spawning WUA	-12 (-17%)	1 (2%)
Redd Scour Risk	0 (0%)	0 (0%)
Egg Incubation	-28 (-33%)	-7 (-11%)
Redd Dewatering Risk	-9 (-18%)	-1 (-2%)
Juvenile Rearing WUA	7 (32%)	4 (16%)
Juvenile Stranding Risk	3 (16%)	2 (10%)
WUA = Weighted Usable Area.		

The results of the SacEFT model and Reclamation egg mortality model are inconsistent with regard to predicted conditions for spring-run salmon eggs. SacEFT predicts that egg incubation habitat would decrease (7% absolute scale decrease) and the Reclamation egg mortality model predicts that overall egg mortality would not change (<5% absolute scale) under the A2D_ELT relative to NAA_ELT. The SacEFT uses mid-August through early March as the egg incubation period, based on Vogel and Marine (1991), and the reach between ACID Dam and Battle Creek for redd locations. The Reclamation egg mortality model uses the number of days after Julian week 33 (mid-August) that it takes to accumulate 750 temperature units to hatching and another 750 temperature units to emergence. Temperatures units are calculated by subtracting 32°F from daily river temperature and are computed on a daily basis. As a result, egg incubation duration is generally mid-August through January, but is dependent on river temperature. The Reclamation model uses the reach between ACID Dam and Jelly's Ferry (approximately 5 river miles downstream of Battle Creek), which includes 95% of Sacramento River spawning locations based on 2001–2004 redd survey data (Reclamation 2008). The SacEFT model has been peer-reviewed, and the Reclamation egg mortality model has been extensively reviewed and used in prior biological assessments and BiOps. Therefore, both results are considered valid and were considered in drawing conclusions about spring-run egg mortality in the Sacramento River.

Clear Creek

Flows in Clear Creek were examined during the spring-run Chinook salmon spawning and egg incubation period (September through January). Mean flows under A2D_ELT would be similar to flows under NAA_ELT throughout the period for all water year types, except September of critical water years (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. The greatest reduction in flows under A2D_ELT would be the same as that under NAA_ELT in all water year types, except for 33% greater (worse) maximum reduction in dry years (Table 11-2D-24).

Water temperatures were not modeled in Clear Creek.

Table 11-2D-24. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (NA)	0 (NA)
Above Normal	-41 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-100 (NA)	-33 (-50%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) where spring-run Chinook primarily spawn during September through January (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would not differ from NAA_ELT because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006).

Oroville Reservoir storage volume at the end of September influence flows downstream of the dam during the spring-run spawning and egg incubation period. Mean storage volume at the end of September under A2D_ELT would be similar to or up to 17% greater than storage under NAA_ELT, depending on water year type (Table 11-2D-25).

Table 11-2D-25. Difference and Percent Difference in September Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-656 (-23%)	66 (3%)
Above Normal	-670 (-28%)	-113 (-6%)
Below Normal	-374 (-19%)	-49 (-3%)
Dry	-46 (-3%)	192 (17%)
Critical	48 (5%)	131 (14%)

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the egg incubation period to the flow in September when spawning is assumed to occur. Flows in the low-flow channel during September through January were identical between A2D_ELT and NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives*). Therefore, there would be no effect of Alternative 2D on redd dewatering in the Feather River low-flow channel.

Mean water temperatures were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) during September through January (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during September through January (Table 11-2D-26). The percent of months exceeding the threshold under Alternative 2D would generally be lower (up to 16% lower on an absolute scale) than the percent under NAA_ELT during September, October and November and similar during other months.

Table 11-2D-26. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, September through January

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
September	0 (0%)	-1 (-1%)	4 (4%)	0 (0%)	-1 (-3%)
October	11 (50%)	10 (133%)	7 (120%)	5 (200%)	0 (0%)
November	9 (350%)	5 (400%)	2 (200%)	0 (NA)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
NAA_ELT vs. A2D_ELT					
September	0 (0%)	-1 (-1%)	-2 (-3%)	-5 (-6%)	-6 (-14%)
October	-16 (-33%)	-6 (-26%)	-4 (-21%)	-4 (-33%)	-6 (-71%)
November	1 (13%)	-2 (-29%)	-1 (-25%)	-2 (-100%)	-1 (-100%)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

The effects of A2D_ELT on water temperature-related spawning and egg incubation conditions for spring-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months for months that exceed the 56°F NMFS threshold during the September through January spring-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-2D-27). Combining all water year types, there would be a reduction of 19 degree-months in the number of degree-months exceeding the NMFS threshold under A2D_ELT relative to NAA_ELT for October and an increase of 8 degree-months for September. There would be negligible differences in degree months between NAA_ELT and A2D_ELT in the other months. Results are highly variable when separating out by water year type, ranging from 9 more degree-months (absolute scale) under A2D_ELT in below normal water years during September to 7 fewer degree-months under A2D_ELT in critical water years during September. The absolute scale is used to compare results for these analyses because large relative differences (percent differences) between NAA_ELT and A2D_ELT in most cases are mathematical artifacts due to the small values of degree-months for NAA_ELT (i.e., dividing by a small number amplifies the relative difference), which would not translate into biologically meaningful effects on spring-run Chinook salmon.

Table 11-2D-27. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, September through January

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
September	Wet	-7 (-6%)	2 (2%)
	Above Normal	0 (0%)	3 (8%)
	Below Normal	14 (23%)	9 (14%)
	Dry	30 (43%)	1 (1%)
	Critical	4 (6%)	-7 (-9%)
	All	41 (12%)	8 (2%)
October	Wet	9 (180%)	-1 (-7%)
	Above Normal	5 (50%)	-3 (-17%)
	Below Normal	11 (157%)	-3 (-14%)
	Dry	16 (229%)	-5 (-18%)
	Critical	7 (88%)	-6 (-29%)
	All	47 (127%)	-19 (-18%)
November	Wet	2 (NA)	1 (100%)
	Above Normal	3 (100%)	0 (0%)
	Below Normal	2 (200%)	-2 (-40%)
	Dry	9 (NA)	2 (29%)
	Critical	1 (NA)	-2 (-67%)
	All	17 (425%)	-1 (-5%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

NEPA Effects: Collectively, these modeling results indicate that the effect of Alternative 2D on spring-run Chinook salmon spawning and egg incubation conditions would not be adverse because the alternative does not substantially reduce the amount of suitable spawning and egg incubation habitat or substantially interfere with spring-run Chinook salmon spawning and egg incubation. There are no substantial changes to flows, cold water pool storage, or water temperatures that would cause a biologically meaningful negative effect to spring-run Chinook salmon spawners or eggs. The Reclamation Egg Mortality Model also indicates that there would be no biologically meaningful effects. However, one model, SacEFT, shows adverse effects for egg incubation. After extensive investigation of these modeling results, they appear to be a function of high model sensitivity to relatively small changes in estimated upstream conditions, which may or may not accurately predict adverse effects. Overall, based on the results of all models except the SacEFT, this impact would not be adverse.

CEQA Conclusion: Collectively, the results of the Impact AQUA-58 CEQA analysis show that the difference between the CEQA baseline and Alternative 2D could be significant because, when compared to the CEQA baseline, the alternative, including climate change, would substantially reduce the quantity and quality of spawning and egg incubation habitat for spring-run Chinook salmon relative to Existing Conditions, However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 2D would not affect the quantity and quality of spawning and egg incubation habitat for spring-run Chinook salmon relative to the CEQA conclusion.

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff were examined during the spring-run Chinook salmon spawning and incubation period (September through January). Mean flows under A2D_ELT during January and December would generally be similar to flows under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT during October and November would be up to 18% lower (both months at Keswick). Mean flows under A2D_ELT during September would be up to 24% lower (dry water years at Keswick) and up to 29% higher (above normal water years at Keswick) than flows under Existing Conditions.

Shasta Reservoir mean storage volume at the end of September would be 7% to 12% lower under A2D_ELT relative to Existing Conditions depending on water year type (Table 11-2D-19).

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the September through January spring-run Chinook salmon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At Keswick, mean water temperatures under A2D_ELT during September of critical water years would be 5% greater than those under Existing Conditions, but would not be different in other water year types or months during the period. At Bend Bridge, mean temperatures under A2D_ELT would be similar (<5% difference) to those under Existing Conditions in all months and water year types during the period.

The number of days on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September at Bend Bridge and October through April at Red Bluff) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern” as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-12 for Bend Bridge and in Table 11-2D-20 for Red Bluff. At Bend Bridge, there would be a 59% increase in the number of years with a “red” level of concern under Alternative 2D relative to Existing Conditions. At Red Bluff, there would be 75%, 83%, and 115% increases in the number of years with “red”, “orange”, and “yellow” levels of concern, respectively, under Alternative 2D relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Bend Bridge during May through September and at Red Bluff during October through April. At Bend Bridge, total degree-days (all water years combined) under Alternative 2D would be 62% to 119% higher than those under Existing Conditions depending on the month (Table 11-2D-13). At Red Bluff, total degree-days under Alternative 2D would be 77% to 585% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-2D-21).

The Reclamation egg mortality model predicts that spring-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be 4% to 23% greater (absolute value) than mortality under Existing Conditions depending on water year type, with a 13% increase in the mortality rate for all water year types combined (Table 11-2D-22).

SacEFT predicts that there would be a 17% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-23). SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd scour risk under A2D_ELT relative to Existing Conditions. SacEFT predicts that there would be a 33% decrease in the percentage of years with good (lower) egg incubation conditions under A2D_ELT relative to Existing Conditions, respectively. SacEFT predicts that there would be an 18% decrease in the percentage of years with good (lower) redd dewatering risk under A2D_ELT relative to Existing Conditions. These results indicate that spawning and egg incubation conditions for spring-run Chinook salmon would be poor relative to Existing Conditions. However, it is not known whether spawning habitat is limiting to the spring-run Chinook salmon population in the Sacramento River, especially given the recent sharp decline in annual escapement estimates.

Clear Creek

Flows in Clear Creek during the spring-run Chinook salmon spawning and egg incubation period (September through January) under A2D_ELT would generally be similar to or greater than flows under Existing Conditions except during September of critical water years (18% reduction) (Appendix *B, Supplemental Modeling for New Alternatives*).

The potential risk of spring-run Chinook salmon redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. The greatest reduction in flows under A2D_ELT would be 33% to 100% greater (worse) than Existing Conditions in above normal, dry, and critical years, and would be similar to and 53% lower (better) than that under Existing Conditions in wet and below normal water years, respectively (Table 11-2D-24).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River low-flow channel under A2D_ELT are not different from Existing Conditions during the spring-run spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Flows in October through January (800 cfs) would be equal to or greater than the spawning flows in September (773 cfs) for all model scenarios.

Oroville Reservoir storage volume at the end of September would be 5% higher to 28% lower under A2D_ELT relative to Existing Conditions depending on water year type (Table 11-2D-25).

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. Mean flows in the low-flow channel during September and during October through January were identical between A2D_ELT and Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*). Therefore, there would be no effect of Alternative 2D on redd dewatering in the Feather River low-flow channel.

Water temperatures were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) during September through January (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean temperatures under A2D_ELT would be similar to (<5% difference) those under Existing Conditions in all months and water year types during the period.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during September through January (Table 11-2D-26). The percent of months exceeding the threshold under Alternative 2D would be similar to or up to 11% higher (absolute scale) than under Existing Conditions during September through November. There would be no difference in the percent of months exceeding the threshold between Existing Conditions and Alternative 2D during December and January.

Total degree-months exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during September through January (Table 11-2D-27). Total degree-months (all water years combined) exceeding the threshold under A2D_ELT would be 12% to 425% greater than those under Existing Conditions during September through November. There would be no difference in total degree-months between Existing Conditions and A2D_ELT during December and January.

Summary of CEQA Conclusion

Under Alternative 2D (including climate change effects), there are flow and storage reductions, as well as temperature increases in the Sacramento River that would lead to biologically meaningful increases in egg mortality and overall reduced habitat conditions for spawning spring-run and egg incubation, as compared to Existing Conditions. Flows in the Feather River low-flow channel do not differ between Alternative 2D and Existing Conditions. However, water temperature analyses in the Feather River low-flow channel using thresholds developed in coordination with NMFS indicate that there would be moderate to large negative effects on temperature conditions during spring-run Chinook salmon spawning and egg incubation.

Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of spring-run as a result of egg mortality.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS

BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows, reservoir storage, and water temperatures in the Sacramento River would be similar between NAA_ELT and Alternative 2D. There would be no effects of Alternative 2D on spawning and egg incubation conditions in Clear Creek, and small beneficial or no effects on flows, reservoir storage, and water temperatures in the Feather River. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-59: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Spring-Run ESU)

In general, Alternative 2D would not affect the quantity and quality of rearing habitat for fry and juvenile spring-run Chinook salmon relative to NAA_ELT.

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix *B, Supplemental Modeling for New Alternatives*). Flows between December and March under A2D_ELT would generally be similar to or greater than those under NAA_ELT. Flows during November would be up to 24% lower under A2D_ELT than under NAA_ELT.

As reported in Impact AQUA-40, May Shasta storage volume under A2D_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-2D-9).

As reported in Impact AQUA-58, September Shasta storage volume would be similar to storage under NAA_ELT in all water year types (Table 11-2D-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the November through March spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile rearing WUA conditions under A2D_ELT would be 16% higher than that under NAA_ELT, although this would be a 4% difference on an absolute scale (Table 11-2D-23). SacEFT predicts that, the percentage of years with good (lower) juvenile stranding risk conditions under A2D_ELT would be 10% higher than under NAA_ELT, although this would be a 2% difference on an absolute scale.

SALMOD predicts that spring-run smolt equivalent habitat-related mortality would be 5% lower under A2D_ELT than NAA_ELT.

Clear Creek

Flows in Clear Creek below Whiskeytown during the November through March spring-run rearing period under A2D_ELT would generally be similar to flows under NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during November through June were reviewed to determine flow-related effects on larval and juvenile spring-run rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Relatively constant flows in the low flow channel throughout this period under A2D_ELT would not differ from those under NAA_ELT. In the high flow channel, flows under A2D_ELT would be similar to or up to 121% greater than flows under NAA_ELT during November through June, with few exceptions during which flows would be up to 17% lower under A2D_ELT.

May Oroville storage under A2D_ELT would be similar to storage under NAA_ELT (Table 11-2D-28).

As reported in Impact AQUA-58, September Oroville storage volume would be similar to or up to 17% higher than under NAA_ELT depending on water year type (Table 11-2D-25).

Table 11-2D-28. Difference and Percent Difference in May Water Storage Volume (thousand acre-feet) in Oroville Reservoir for Model Scenarios

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-22 (-1%)	-3 (0%)
Above Normal	-118 (-3%)	-59 (-2%)
Below Normal	-155 (-5%)	11 (0%)
Dry	-346 (-13%)	4 (0%)
Critical	-133 (-7%)	6 (0%)

Water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during November through June (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period at either location.

The percent of months exceeding the 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during May and June (Table 11-2D-29). Although spring-run typically rear in the Feather River from November through June, NMFS requested that these months be evaluated to be consistent with water temperature targets set during the Oroville Dam FERC relicensing process, and evaluated in the NMFS (2009) Draft BiOp on the Oroville Dam project. As indicated in Table 11-2D-10, this criterion applies to both spring-run Chinook salmon and steelhead rearing. Therefore, the months of interest to spring-run Chinook salmon here are May and June only. The steelhead analysis below includes the remaining months through August. The percent of months exceeding the threshold under Alternative 2D would generally be similar to or lower (up to 21% lower on an absolute scale) than the percent under NAA_ELT.

Table 11-2D-29. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 63°F Threshold, May through August

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
May	2 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
June	4 (7%)	6 (23%)	2 (50%)	1 (NA)	0 (NA)
July	0 (0%)	0 (0%)	0 (0%)	17 (24%)	25 (63%)
August	0 (0%)	9 (10%)	15 (26%)	17 (61%)	10 (100%)
NAA_ELT vs. A2D_ELT					
May	-1 (-33%)	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)
June	-20 (-25%)	-21 (-39%)	-21 (-74%)	-2 (-67%)	0 (NA)
July	0 (0%)	0 (0%)	-1 (-1%)	-9 (-9%)	-10 (-13%)
August	0 (0%)	-2 (-3%)	-7 (-9%)	-9 (-16%)	-10 (-33%)

Total degree-months exceeding 63°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during May and June (Table 11-2D-30). As discussed above, although this table includes results through August, only May and June results apply to spring-run Chinook salmon. The steelhead analysis below includes the remaining months. Total degree-months (all water years combined) under Alternative 2D would be similar to or lower than those under NAA_ELT, depending on the month.

Table 11-2D-30. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Feather River above Thermalito Afterbay, May through August

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
May	Wet	0 (NA)	0 (NA)
	Above Normal	1 (NA)	0 (0%)
	Below Normal	0 (NA)	0 (NA)
	Dry	2 (NA)	1 (100%)
	Critical	2 (NA)	0 (0%)
	All	4 (NA)	0 (0%)
June	Wet	10 (67%)	-7 (-22%)
	Above Normal	4 (29%)	-4 (-18%)
	Below Normal	6 (46%)	-7 (-27%)
	Dry	13 (57%)	-2 (-5%)
	Critical	9 (150%)	-1 (-6%)
	All	41 (58%)	-22 (-16%)
July	Wet	22 (18%)	-1 (-1%)
	Above Normal	10 (23%)	0 (0%)
	Below Normal	15 (25%)	0 (0%)
	Dry	21 (30%)	2 (2%)
	Critical	24 (46%)	6 (9%)
	All	91 (26%)	6 (1%)
August	Wet	17 (19%)	7 (7%)
	Above Normal	9 (36%)	2 (6%)
	Below Normal	15 (39%)	1 (2%)
	Dry	26 (65%)	2 (3%)
	Critical	15 (36%)	-5 (-8%)
	All	82 (35%)	7 (2%)

NA = could not be calculated because the denominator was 0.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because rearing habitat conditions would not be substantially reduced. There would be no substantial effects of Alternative 2D on rearing habitat for spring-run Chinook salmon in the Sacramento River. This conclusion is based on the similarity between Alternative 2D and the NEPA baseline in water temperatures during all months of the rearing period and in flows during all months except November. Results of SacEFT and SALMOD also support this conclusion. In the Feather River, habitat conditions would improve under Alternative 2D relative to the NEPA baseline. There would be no effects to spring-run Chinook salmon rearing in Clear Creek.

CEQA Conclusion: Collectively, the results of the Impact AQUA-59 CEQA analysis show that the difference between the CEQA baseline and Alternative 2D could be significant because, when compared to the CEQA baseline, the alternative, including climate change, would substantially reduce the quantity and quality of juvenile rearing habitat for spring-run Chinook salmon relative to

Existing Conditions, However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 2D would not affect the quantity and quality of juvenile rearing habitat for spring-run Chinook salmon relative to the CEQA conclusion.

Sacramento River

Flows were evaluated during the November through March larval and juvenile spring-run Chinook salmon rearing period in the Sacramento River between Keswick Dam and just upstream of Red Bluff (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would be generally similar to or greater than those under Existing Conditions, except during November, in which flows would be up to 18% lower under A2D_ELT than under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*).

As reported in Impact AQUA-40, Shasta Reservoir storage volume at the end of May under A2D_ELT would be similar to Existing Conditions in wet, above normal, and below normal water years, but lower by 6% and 9% in dry and critical water years, respectively (Table 11-2D-9). As reported in Impact AQUA-58, storage volume at the end of September under A2D_ELT would be 7% to 12% lower relative to Existing Conditions (Table 11-2D-19).

Mean monthly water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round spring-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, there would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2D, except for 6% and 5% increases at Keswick during August and September of critical water years and 6% at Bend Bridge during August of critical water years.

SacEFT predicts that under A2D_ELT both the percentage of years with good juvenile rearing WUA conditions and the percentage of years with good (lower) juvenile stranding risk conditions would be greater than those under Existing Conditions (Table 11-2D-23).

SALMOD predicts that spring-run smolt equivalent habitat-related mortality under A2D_ELT would be 11% lower than under Existing Conditions.

Clear Creek

Flows in Clear Creek during the November through March rearing period under A2D_ELT would generally be similar to or greater than flows under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures were not modeled in Clear Creek.

Feather River

Relatively constant flows in the low flow channel throughout the November through June period under A2D_ELT would not differ from those under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*). In the high flow channel (at Thermalito Afterbay), flows under A2D_ELT would be mostly lower than flows under Existing Conditions during November through

February (up to 47% lower) and would be similar to or greater than flows under Existing Conditions (up to 157%) during March through June.

May Oroville storage volume under A2D_ELT would be similar to Existing Conditions in wet, above normal and below normal water years and would be 13% and 7% lower than Existing Conditions in dry and critical water years, respectively (Table 11-2D-28).

As reported in Impact AQUA-58, September Oroville storage volume would be similar to Existing Conditions in dry and critical water years and would be 23%, 28%, and 19% lower than Existing Conditions in wet, above normal, and below normal water years, respectively (Table 11-2D-25).

Water temperatures in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were evaluated during the November through June juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperature under Alternative 2D would be similar to those under Existing Conditions during all months and water year types, throughout the period at both locations.

The percent of months exceeding the 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during May and June (Table 11-2D-29). Although spring-run typically rear in the Feather River from November through June, NMFS requested that these months be evaluated to be consistent with water temperature targets set during the Oroville Dam FERC relicensing process, and evaluated in the NMFS (2009) Draft BiOp on the Oroville Dam project. As indicated in Table 11-2D-10, this criterion applies to both spring-run Chinook salmon and steelhead rearing. Therefore, the months of interest to spring-run Chinook salmon here are May and June only. The steelhead analysis below includes the remaining months. The percent of months exceeding the threshold under A2D_ELT would be similar to those under Existing Conditions.

Total degree-months exceeding 63°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during May and June (Table 11-2D-30). As discussed above, although this table includes results through August, only May and June results apply to spring-run Chinook salmon. The steelhead analysis below includes the remaining months. Total degree-months (all water years combined) under A2D_ELT would be similar to those under Existing Conditions during May, but 58% higher during June.

Summary of CEQA Conclusion

Under Alternative 2D, there would be large flow reductions in the Feather River in several months, depending on water year type. Both SacEFT and SALMOD predict improvements to rearing habitat availability for spring-run Chinook salmon in the Sacramento River under Alternative 2D. Exceedances above NMFS temperature thresholds would be higher under Alternative 2D relative to Existing Conditions. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of spring-run Chinook salmon as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on flows, reservoir storage, and water temperatures during the months and locations analyzed would be minimal. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the effects of Alternative 2D on spring-run Chinook salmon juvenile rearing habitat conditions would be less than significant and no mitigation is necessary.

Impact AQUA-60: Effects of Water Operations on Migration Conditions for Chinook Salmon (Spring-Run ESU)

In general, Alternative 2D would degrade migration conditions for spring-run Chinook salmon relative to NAA_ELT.

Upstream of the Delta

Sacramento River

Flows in the Sacramento River upstream of Red Bluff were evaluated during the December through May juvenile Chinook salmon spring-run migration period. Mean flows under A2D_ELT during December through May would be similar to or greater than flows under NAA_ELT throughout the migration period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Flows in the Sacramento River upstream of Red Bluff were evaluated during the April through August adult spring-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or greater than flows under NAA_ELT, except for 11% lower flow during August of dry water year types.

Water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Clear Creek

Mean flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under A2D_ELT would be similar to flows under NAA_ELT throughout the period (Appendix *B, Supplemental Modeling for New Alternatives*).

Mean flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under A2D_ELT would be similar to flows under NAA_ELT, except for 14% lower flow in July of critical water years and 11% greater flow in August of critical years (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile Chinook salmon spring-run migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or greater than flows under NAA_ELT throughout the period, with minor exceptions.

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Flows in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT during April through June would be similar to or up to 88% greater than (June of below normal water years) flows under NAA_ELT. Mean flows under A2D_ELT during July and August would generally be lower than flows under NAA_ELT by up to 48% (July of critical water years).

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period, except for a 5% higher water temperature under A2D_ELT in July of critical water years.

Through-Delta

The effects of Alternative 2D on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Juveniles

Flows under Alternative 2D would decrease up to 33% depending on month and water-year type downstream of the north Delta facilities compared to baseline conditions (NAA_ELT). The intake structures would replace aquatic habitat and likely attract piscivorous fish around the intake structures. As described for Alternative 1A, the five NDD intakes would remove or modify habitat along that portion of the migration corridor (13 acres aquatic habitat and 2.3 linear miles of shoreline). Potential predation losses at the north Delta intakes, as estimated by the bioenergetics model with median density of predators (119 striped bass per 1,000 feet of intake), would be less than 0.5% compared to the annual production estimated for the Sacramento Valley (Table SR_bioenergetics). A conservative assumption of 5% loss per intake (based on data from GCID; Vogel 2008) would yield a cumulative loss of 19.2% of juvenile spring-run Chinook that reach the north Delta. This assumption is uncertain and represents an upper bound estimate. See additional discussion in Impact AQUA-42 for winter-run Chinook salmon in Alternative 4A.

Table SR_bioenergetics. Spring-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes (Five Intakes for Alternative 2D)

Striped Bass at NDD (Five Intakes)			Spring-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Production Entering the Delta[1]
Low	18	154	2,145	0.05%
Median	119	1,017	14,180	0.34%
High	219	1,872	26,096	0.62%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (*BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference).

[1] Estimated as 4.2 million juveniles. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

Through-Delta survival to Chipps Island (DPM) by emigrating juvenile spring-run Chinook salmon under Alternative 2D would average 29% across all years, 23% in drier years, and 38% in wetter years (Table 11-2D-31). Compared to NAA_ELT, juvenile survival would decrease, 1.9% lower across all years (a 6% relative decrease) and 3.1% lower (8% relative decrease) in wetter years. As described for Alternative 4A, the modeling of NAA_ELT does not account for actions that are assumed to be included under NAA that would be pursued as part of other projects and programs, notably Yolo Bypass improvements and tidal habitat restoration under the NMFS and USFWS BiOps. As shown for Alternative 4A, the difference in through-Delta survival between Alternative 2D and NAA_ELT would be somewhat greater if the improvements to Yolo Bypass (particularly Fremont Weir modifications) were included in the modeling for NAA_ELT.

Table 11-2D-31. Through-Delta Survival (%) of Emigrating Juvenile Spring-Run Chinook Salmon under Alternative 2D

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA_ELT	A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wetter Years	42.1	41.4	38.3	-3.8 (-10%)	-3.1 (-8%)
Drier Years	24.8	24.3	23.2	-1.7 (-6%)	-1.2 (-4%)
All Years	31.3	30.7	28.9	-2.5 (-7%)	-1.9 (-6%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

When climate change effects are accounted for (NAA_ELT), during the overall spring-run upstream migration from March-June the proportion of Sacramento River water would decrease 5% to 10% compared to NAA_ELT (Table 11-2D-17). Although Sacramento River attraction flows would be reduced during these months relative to Existing Conditions, the Sacramento River would still represent 56% to 68% of Delta flows. For a discussion of the topic see the analysis for Alternative 1A.

NEPA Effects: Overall, the results indicate that the effect of Alternative 2D is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g., impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, migration conditions for spring-run Chinook salmon under Alternative 2D would not be adverse because flow and temperature conditions would generally be similar to those under the NEPA baseline.

Adult attraction flows under Alternative 2D would be lower than those under NAA_ELT, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2D on spring-run Chinook salmon related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating spring-run Chinook salmon, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to very significant effects (~ 19% mortality above current baseline levels). As noted for Alternative 4A, Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction studies to better understand how to minimize losses associated with the new intake structures will be implemented as part of the final NDD screen design effort. As with Alternative 4A, Alternative 2D also includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for spring-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain. See additional discussion under Impact AQUA-42 of Alternative 4A for winter-run Chinook salmon.

As described for Alternative 4A, the DPM is a flow-based model incorporating flow-survival and junction routing relationships with flow modeling of water operations to estimate relative differences between scenarios in smolt migration survival throughout the entire Delta. The DPM predicted that smolt migration survival under Alternative 2D would be lower than survival estimated for NAA_ELT, based on operations assuming no adjustments made in real-time in response to actual presence of fish. Although refinements to the DPM are likely to occur based on new data available from future studies and the current analysis has some uncertainty, the DPM analysis of Alternative 2D on juvenile spring-run Chinook salmon migration suggests a potential adverse effect of small magnitude. This adverse effect would be reduced through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 2D of specific important environmental commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of spring-run Chinook salmon juveniles into the low-survival interior Delta.

Overall, primarily as a result of unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects on spring-run Chinook salmon associated with the presence and operation of the five intakes, this effect is adverse. While implementation of the environmental commitments noted above and mitigation measures listed below would address these impacts, these are not anticipated to reduce the impacts to a level considered not adverse.

CEQA Conclusion:

Upstream of the Delta

In general, Alternative 2D would affect migration conditions for spring-run Chinook salmon relative to the Existing Conditions.

Sacramento River

Mean flows in the Sacramento River upstream of Red Bluff during the December through May juvenile spring-run Chinook salmon migration period under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions, except during March of below normal water years (7% decrease) and May of wet years (10% decrease) (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the December through May juvenile Chinook salmon spring-run emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

Mean flows in the Sacramento River upstream of Red Bluff during the April through August adult spring-run Chinook salmon upstream migration period under A2D_ELT would generally be similar to or slightly greater than Existing Conditions, except during May of wet years (10% decrease) and August of dry (12% decrease) and critical (12% decrease) water years.

Water temperatures in the Sacramento River at Red Bluff were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period, except for a 5% higher water temperature under A2D_ELT during August of critical water years.

Clear Creek

Mean flows in Clear Creek during the November through May juvenile Chinook salmon spring-run migration period under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions, except for 40% greater flow in January of wet water years (Appendix *B, Supplemental Modeling for New Alternatives*).

Flows in Clear Creek during the April through August adult spring-run Chinook salmon upstream migration period under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures were not modeled in Clear Creek.

Feather River

Flows were examined for the Feather River at the confluence with the Sacramento River during the November through May juvenile Chinook salmon spring-run migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to flows under Existing Conditions, with some exceptions (up to 17% lower and up to 18% greater).Mean monthly water temperatures in the Feather River at the confluence with the Sacramento River were examined during the November through May juvenile spring-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period. Flows were examined for the Feather River at the confluence with the Sacramento River during the April through August adult spring-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows during April through June under A2D_ELT would generally be similar to or up to 82% greater than (June of below normal water years) flows under Existing Conditions, except for 10% lower flow in May of wet years. Flows during July and August under A2D_ELT would generally be lower by up to 53% than flows under Existing Conditions, except for 13% greater flow in August of wet years.

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the April through August adult spring-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period, except for a 6% higher water temperature under A2D_ELT in July of critical water years.

Through-Delta

Through Delta survival by emigrating juvenile spring-run Chinook salmon would decrease 2.3% (7% relative decrease) under Alternative 2D across all years compared to Existing Conditions (Table 11-2D-31). Losses due to predation at the five north Delta intakes could hypothetically range from less than 2% up to 19.2% of juvenile spring-run Chinook that reach the north Delta, as calculated for Impact AQUA-60 for Alternative 1A.

Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, declined 10% to 12% during the April and May migration period for spring-run adults under Alternative 2D compared to Existing Conditions (Table 11-2D-17). The reductions in percentage are small in comparison with the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to significantly impact adult migration. Sacramento River attraction flows would still represent 59% to 67% of Delta flows. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 in Alternative 1A.

Summary of CEQA Conclusion

Overall, Alternative 2D would significantly affect the migration conditions for spring-run Chinook salmon, relative to the Existing Conditions. Through-Delta survival of emigrating juveniles has the potential to be appreciably reduced, compared to Existing Conditions. There would be little effect of Alternative 2D on adult olfactory cues in the Delta. Upstream of the Delta, the results indicate that the effect would be less than significant because it would not substantially reduce the suitability of migration habitat or interfere with the movement of fish. Flows in the Sacramento River and Clear Creek and water temperatures in the Sacramento and Feather Rivers would generally not be affected by Alternative 2D. Flows in the Feather River would be substantially lower in 2 months of the 5-month adult migration period and substantially higher in one month of the period. There would be occasional moderately lower flow reductions in other months of the juvenile and adult migration periods.

Implementation of *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers* (all of which are summarized further in Section 4.1.3.3, in this RDEIR/SDEIS) would address the through-Delta impacts, but are not anticipated to reduce them to a level considered less than significant because of the presence of five intakes. As a result of these changes in migration conditions, this impact is significant and unavoidable.

In addition to the environmental commitments above, the mitigation measures identified below would provide an adaptive management process that would be conducted as a part of the Adaptive Management and Monitoring Program, for assessing impacts and developing appropriate minimization measures. However, this would not necessarily result in a less than significant determination, so it is concluded that the impact is significant and unavoidable.

Mitigation Measure AQUA-60a: Following Initial Operations of Water Conveyance Facilities, Conduct Additional Evaluation and Modeling of Impacts to Spring-Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-60a under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60b: Conduct Additional Evaluation and Modeling of Impacts on Spring-Run Chinook Salmon Migration Conditions Following Initial Operations of Water Conveyance Facilities

Please refer to Mitigation Measure AQUA-60b under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Mitigation Measure AQUA-60c: Consult with NMFS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Spring-Run Chinook Salmon Migration Conditions Consistent with Water Conveyance Facilities

Please refer to Mitigation Measure AQUA-60c under Alternative 1A (Impact AQUA-60) for spring-run Chinook salmon.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-61: Effects of Construction of Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-62: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Spring-Run ESU)

Impact AQUA-63: Effects of Restored Habitat Conditions on Chinook Salmon (Spring-Run ESU)

Impact AQUA-64: Effects of Methylmercury Management on Chinook Salmon (Spring-Run ESU) (Environmental Commitment 12)

Impact AQUA-67: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Spring-Run ESU) (Environmental Commitment 15)

Impact AQUA-68: Effects of Nonphysical Fish Barriers on Chinook Salmon (Spring-Run ESU) (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on spring-run Chinook salmon for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Fall-/Late Fall–Run Chinook Salmon

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-73: Effects of Construction of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

The potential effects of construction of the water conveyance facilities on fall-/late fall–run Chinook salmon would be similar to those described for Alternative 4A (Impact AQUA-73) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in

Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to fall-/late fall–run Chinook salmon.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-73, the effect would not be adverse for fall-/late fall–run Chinook salmon and critical habitat.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-73, the impact of construction of the water conveyance facilities on fall-/late fall–run Chinook salmon and critical habitat would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-74: Effects of Maintenance of Water Conveyance Facilities on Chinook Salmon (Fall-/Late Fall–Run ESU)

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-56, the effect would not be adverse for fall-/late fall–run Chinook salmon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-74 for fall-/late fall–run Chinook salmon, the impact of the maintenance of water conveyance facilities on fall-/late fall–run Chinook salmon would be less than significant and no mitigation is required.

Water Operations of Water Conveyance Facilities

Impact AQUA-75: Effects of Water Operations on Entrainment of Chinook Salmon (Fall-/Late Fall–Run ESU)

Water Exports from SWP/CVP South Delta Facilities

Alternative 2D (A2D_ELT) would decrease entrainment of fall-run Chinook salmon by approximately 56% and late fall–run Chinook salmon by approximately 41% compared to NAA_ELT (Table 11-2D-32). Entrainment reductions under Alternative 2D would be greater in wetter years, ranging from little difference in dry years up to 85% decrease compared to Existing Conditions.

Table 11-2D-32. Juvenile Chinook Salmon Annual Entrainment Index at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2D

	Absolute Difference (Percent Difference)[a]	
Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Fall-Run Chinook Salmon		
Wet	-108,653 (-85%)	-114,129 (-86%)
Above Normal	-20,655 (-63%)	-21,452 (-64%)
Below Normal	-4,906 (-36%)	-4,737 (-35%)
Dry	303 (2%)	-1,390 (-7%)
Critical	-12,950 (-32%)	-10,896 (-28%)
All Years	-30,369 (-55%)	-31,696 (-56%)
Late Fall–Run Chinook Salmon		
Wet	-4,033 (-67%)	-4,204 (-68%)
Above Normal	-315 (-55%)	-313 (-55%)
Below Normal	-27 (-49%)	-29 (-50%)
Dry	-35 (-26%)	-26 (-21%)
Critical	-33 (-20%)	-22 (-15%)
All Years	-661 (-34%)	-682 (-35%)
	Shading indicates 10% or greater increased entrainment.	

[a] Estimated annual number of fish lost, based on normalized data.

For juvenile late fall-run Chinook salmon, entrainment under Alternative 2D would decrease by 35% compared to NAA_ELT averaged across all years (Table 11-2D-32). Entrainment reductions would be substantially greater in wetter years, ranging from approximately 26% decrease in dry years to 67% decrease in wet years compared to Existing Conditions.

The proportion of the annual juvenile population (assumed to be 23 million fall-run juveniles and 1 million late fall–run juveniles) lost at the south Delta facilities is very low under baseline conditions (<0.25% for both runs), and would be reduced under Alternative 2D.

Water Exports from SWP/CVP North Delta Intake Facilities

Impacts from the proposed north Delta intake facilities for fall-/late fall–run Chinook salmon, such as impingement and predation exposure risks, would be expected to be similar to those described above for winter-run Chinook salmon. Impacts would also be the same as described for Alternative 2D. State-of-the-art fish screens would be expected to eliminate entrainment risk for juvenile fall-/late fall–run Chinook salmon to these intakes.

Predation Associated with Entrainment

Entrainment-related predation loss of fall- and late fall-run Chinook salmon at the south Delta facilities would be lower than baseline due to a reduction in entrainment loss (see analysis above). Predation at the north Delta would be increased at the proposed North Delta intake facilities on the Sacramento River, as discussed below in Impact AQUA-78.

NEPA Effects: Under Alternative 2D potential entrainment and associated predation loss of juvenile Chinook salmon of all races (winter, spring, fall and late fall–run) would be similar or reduced compared to baseline at the SWP/CVP south delta facilities. Entrainment of Chinook salmon at the proposed SWP/CVP north Delta intakes would not be expected to occur due to the state-of-the-art fish screens; there would be a potential for impingement, but this risk would be minimized due to the design and operation of the facilities. It is concluded that the improvements at the south Delta would offset losses due to predation at the north Delta. Therefore the effect on fall-/late fall–run Chinook salmon entrainment from Alternative 2D would not be adverse.

***CEQA Conclusion**:* As described above, entrainment and associated predation loss of juvenile Chinook salmon of all races (winter, spring, fall and late fall–run) would be similar or reduced compared to baseline at the SWP/CVP south delta facilities. Entrainment of Chinook salmon at the proposed SWP/CVP north delta intakes would not be expected to occur due to the state-of-the-art fish screens; there would be a potential for impingement, but this risk would be minimized due to the design and operation of the facilities. Predation at the north Delta intakes could occur. Overall, impacts of water operations on entrainment of juvenile Chinook salmon (fall-/late fall–run ESU) would be beneficial due to a general reduction in entrainment and no mitigation would be required.

Impact AQUA-76: Effects of Water Operations on Spawning and Egg Incubation Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 2D would not affect spawning and egg incubation habitat for fall-/late fall–run Chinook salmon relative to NAA_ELT.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be greater than or similar to flows under NAA_ELT in October, December, and January. During November, flows under A2D_ELT would be 6% to 18% lower than under NAA_ELT, depending on water year type. These results indicate that there would generally be no flow-related effects of Alternative 2D on spawning and egg incubation habitat except during November, in which there would be small intermittent flow reductions.

Shasta Reservoir storage at the end of September could affect flows during the fall-run spawning and egg incubation period. As reported in Impact AQUA-58 for spring-run Chinook salmon, end of September Shasta Reservoir storage would be similar to storage under NAA_ELT in all water year types (Table 11-2D-19).

Water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a “level of concern” as defined in Table 11-2D-11. Differences between baselines and A2D_ELT in the levels of concern across all months and all 82 modeled years are presented in Table 11-2D-20. There would be no difference in the number of years with a “red” level of concern under A2D_ELT, 2 (18%) fewer years with an “orange” level of concern, and 2 (7%) more years with a “yellow” level of concern.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days (all water years combined) under A2D_ELT would be 10 degree-days (18%) higher than those under NAA_ELT during March, and would be similar for the remaining 6 months (Table 11-2D-21). This total degree-day difference during March across 82 years would correspond to a negligible difference per day. Therefore, this would not result in a negative effect to fall-run Chinook salmon spawning and egg incubation.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be lower than or similar to mortality under NAA_ELT in all water year types, including below normal years for which the mortality rate would increase by 2% (absolute scale), which is not substantial (Table 11-2D-33). Therefore, these results indicate that A2D_ELT would have negligible effects on fall-run Chinook salmon egg mortality.

Table 11-2D-33. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	4 (39%)	0.1 (1%)
Above Normal	5 (46%)	1 (7%)
Below Normal	7 (62%)	2 (11%)
Dry	7 (48%)	-0.2 (-1%)
Critical	5 (18%)	-0.3 (-1%)
All	5 (39%)	0.4 (2%)

SacEFT predicts that there would be a 33% increase in the percentage of years with good spawning availability for fall-run Chinook salmon, measured as weighted usable area, under A2D_ELT relative to NAA_ELT (Table 11-2D-34). SacEFT predicts that there would be a 12% reduction in the percentage of years with good (lower) redd scour risk under A2D_ELT relative to NAA_ELT. SacEFT predicts that there would be no difference between A2D_ELT and NAA_ELT in the number of years with good egg incubation conditions. SacEFT predicts that there would be a 7% reduction in the percentage of years with good (lower) redd dewatering risk under A2D_ELT relative to NAA_ELT.

Table 11-2D-34. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Fall-Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Spawning WUA	9 (19%)	14 (33%)
Redd Scour Risk	-3 (-5%)	-8 (-12%)
Egg Incubation	-5 (-5%)	0 (0%)
Redd Dewatering Risk	0 (0%)	-2 (-7%)
Juvenile Rearing WUA	1 (3%)	-4 (-11%)
Juvenile Stranding Risk	-8 (-26%)	0 (0%)

WUA = Weighted Usable Area.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be greater than or similar to flows under NAA_ELT throughout the period.

Shasta Reservoir storage at the end of September would affect flows during the late fall–run spawning and egg incubation period. As reported in Impact AQUA-58 for spring-run Chinook salmon, end of September Shasta Reservoir storage would be similar to storage under NAA_ELT in all water year types (Table 11-2D-19).

The Reclamation egg mortality model predicts that late fall-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be similar to mortality under NAA_ELT in all water years, including above normal water years in which, although there would be a 15% relative reduction in the mortality rate, the absolute reduction would be only 1% of the late fall-run population (Table 11-2D-35).

Table 11-2D-35. Difference and Percent Difference in Percent Mortality of Late Fall–Run Chinook Salmon Eggs in the Sacramento River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	1 (72%)	-0.2 (-6%)
Above Normal	1 (49%)	-1 (-15%)
Below Normal	2 (119%)	0 (0%)
Dry	2 (67%)	-0.1 (-2%)
Critical	1 (57%)	-0.2 (-5%)
All	1 (71%)	-0.2 (-5%)

Water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-20. There would be no difference in the number of years with a "red" level of concern under A2D_ELT, 2 (18%) fewer years with an "orange" level of concern, and 2 (7%) more years with a "yellow" level of concern.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days (all water years combined) under A2D_ELT would be 10 degree-days (18%) higher than those under NAA_ELT during March, and would be similar for the remaining 6 months (Table 11-2D-21). This total degree-day difference during March across 82 years would correspond to a negligible difference per day. Therefore, this would not result in a negative effect to late fall-run Chinook salmon spawning and egg incubation.

SacEFT predicts that there would be a 6% decrease in the percentage of years with good spawning availability for late fall–run Chinook salmon, measured as weighted usable area, under A2D_ELT relative to NAA_ELT (Table 11-2D-36). SacEFT predicts that there would be a negligible (<5%) differences in the percentage of years with good (lower) egg incubation conditions and redd scour and dewatering risks between A2D_ELT and NAA_ELT.

Table 11-2D-36. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Late Fall–Run Chinook Salmon Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Spawning WUA	-7 (-13%)	-3 (-6%)
Redd Scour Risk	-3 (-4%)	-1 (-1%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-5 (-8%)	1 (2%)
Juvenile Rearing WUA	-2 (-4%)	-14 (-25%)
Juvenile Stranding Risk	-21 (-29%)	-9 (-15%)

WUA = Weighted Usable Area.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Clear Creek flows below Whiskeytown Reservoir were examined for the September through February fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to flows under NAA_ELT, except for 10% lower flow in September of critical water years.

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning is assumed to occur. The greatest monthly reduction in Clear Creek flows during September through February under A2D_ELT would be the same as the greatest reduction under NAA_ELT for all water year types, except for a 33% larger maximum reduction (50% relative increase in greatest reduction) in dry water years (Table 11-2D-37).

Table 11-2D-37. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in Clear Creek below Whiskeytown Reservoir during the September through February Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (NA)	0 (NA)
Above Normal	-41 (NA)	0 (0%)
Below Normal	53 (100%)	0 (NA)
Dry	-100 (NA)	-33 (-50%)
Critical	-33 (-50%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in September, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

Feather River

Fall-Run

Flows in the Feather River in the low flow and high flow channels were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows in the low-flow channel under A2D_ELT would be identical to those under NAA_ELT. Mean flows in the high-flow channel under A2D_ELT would generally be similar to or up to 26% greater (during December of critical water years) than those under NAA_ELT, except for a 17% reduction in flow during January of below normal water years.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. Flows in the low-flow channel during October through January were identical between A2D_ELT and NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives*). Therefore, there would be no effect of Alternative 2D on redd dewatering in the Feather River low-flow channel.

Water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period at either location.

The percent of months exceeding the 56°F temperature threshold in the Feather River at Gridley was evaluated during October through April (Table 11-2D-38). The percent of months exceeding the threshold under A2D_ELT would be similar to or less than (up to 14% less, absolute scale) the percent under NAA_ELT.

Table 11-2D-38. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 56°F Threshold, October through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
October	-4 (-4%)	5 (6%)	2 (3%)	15 (36%)	17 (93%)
November	7 (200%)	2 (200%)	0 (NA)	0 (NA)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	2 (33%)	5 (133%)	2 (200%)	1 (NA)	0 (NA)
April	6 (9%)	6 (11%)	14 (44%)	6 (36%)	4 (33%)
NAA_ELT vs. A2D_ELT					
October	-5 (-5%)	-4 (-4%)	-9 (-10%)	-11 (-17%)	-14 (-28%)
November	-5 (-31%)	-2 (-40%)	-2 (-100%)	-1 (-100%)	0 (NA)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-9 (-47%)	0 (0%)	-1 (-25%)	-1 (-50%)	-1 (-100%)
April	-2 (-3%)	-5 (-7%)	-6 (-12%)	-6 (-21%)	-1 (-8%)

NA = could not be calculated because the denominator was 0.

The effects of Alternative 2D on water temperature-related spawning and egg incubation conditions for fall-run Chinook salmon in the Feather River were also analyzed by comparing the total degree-months in the Feather River at Gridley for months that exceed the 56°F NMFS threshold during the October through April fall-run Chinook salmon spawning and egg incubation period for all 82 years (Table 11-2D-39). Total degree-months (all water year types combined) would be similar between NAA_ELT and A2D_ELT for all months of the period.

Table 11-2D-39. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River at Gridley, October through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
October	Wet	31 (42%)	-3 (-3%)
	Above Normal	10 (23%)	-4 (-7%)
	Below Normal	14 (25%)	-3 (-4%)
	Dry	21 (40%)	-1 (-1%)
	Critical	17 (41%)	-1 (-2%)
	All	92 (35%)	-13 (-4%)
November	Wet	2 (NA)	1 (100%)
	Above Normal	3 (150%)	0 (0%)
	Below Normal	3 (300%)	0 (0%)
	Dry	6 (NA)	0 (0%)
	Critical	3 (300%)	-1 (-20%)
	All	17 (425%)	0 (0%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	1 (NA)	0 (0%)
	Above Normal	-1 (-100%)	0 (NA)
	Below Normal	7 (700%)	1 (14%)
	Dry	6 (150%)	-1 (-9%)
	Critical	6 (150%)	0 (0%)
	All	19 (190%)	0 (0%)
April	Wet	15 (107%)	0 (0%)
	Above Normal	9 (39%)	1 (3%)
	Below Normal	6 (15%)	0 (0%)
	Dry	19 (39%)	3 (5%)
	Critical	14 (48%)	3 (8%)
	All	65 (42%)	9 (4%)

NA = could not be calculated because the denominator was 0.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under A2D_ELT would be similar on an absolute scale (ranging from a 2% reduction to a 1% increase, depending on water year type) to mortality under NAA_ELT despite the large relative differences (-25% to 26%). The absolute differences are used here as more reliable estimators of differences in mortality rates because they are directly related to the size of the egg population (Table 11-2D-40). An increase of 1% in the mortality rate would not cause an overall effect to fall-run Chinook salmon.

Table 11-2D-40. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the Feather River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	2 (126%)	0 (16%)
Above Normal	2 (139%)	0 (18%)
Below Normal	2 (119%)	1 (26%)
Dry	3 (117%)	-2 (-25%)
Critical	5 (94%)	-1 (-12%)
All	2 (113%)	0 (-4%)

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or up to 27% greater (critical water years) than flows under NAA_ELT during October and would be lower (up to 15% lower) than flows under NAA_ELT during November of wet, above normal and below normal water years. Mean flows during December and January would generally be similar between A2D_ELT and NAA_ELT, with minor exceptions.

Water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period, except for 5% higher water temperatures in October of wet, below normal and dry water years.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2D-41). The percent of months exceeding the threshold under A2D_ELT would similar to or up to 12% lower (absolute scale) than the percent under NAA_ELT.

Table 11-2D-41. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 56°F Threshold, November through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
November	26 (57%)	25 (91%)	21 (155%)	16 (650%)	9 (700%)
December	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	2 (20%)	2 (33%)	4 (150%)	1 (100%)	1 (NA)
April	11 (16%)	6 (10%)	10 (22%)	10 (31%)	4 (14%)
NAA_ELT vs. A2D_ELT					
November	-11 (-13%)	-9 (-14%)	-9 (-20%)	-12 (-40%)	-9 (-47%)
December	-1 (-100%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-4 (-20%)	-4 (-27%)	-4 (-38%)	0 (0%)	-1 (-50%)
April	-6 (-7%)	-6 (-8%)	-9 (-13%)	-7 (-15%)	-1 (-4%)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2D-42). Total degree-months would be similar between NAA_ELT and Alternative 2D for all months.

Table 11-2D-42. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the American River at the Watt Avenue Bridge, November through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
November	Wet	33 (132%)	-6 (-9%)
	Above Normal	14 (127%)	-3 (-11%)
	Below Normal	22 (275%)	-4 (-12%)
	Dry	23 (177%)	-3 (-8%)
	Critical	18 (113%)	0 (0%)
	All	110 (151%)	-16 (-8%)
December	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	1 (NA)	0 (0%)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	1 (NA)	0 (0%)
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	2 (100%)	0 (0%)
	Above Normal	3 (NA)	0 (0%)
	Below Normal	2 (67%)	0 (0%)
	Dry	4 (100%)	-1 (-11%)
	Critical	7 (70%)	0 (0%)
	All	18 (95%)	-1 (-3%)
April	Wet	19 (68%)	-3 (-6%)
	Above Normal	14 (64%)	0 (0%)
	Below Normal	15 (42%)	-1 (-2%)
	Dry	14 (18%)	-1 (-1%)
	Critical	14 (24%)	-2 (-3%)
	All	76 (34%)	-7 (-2%)

NA = could not be calculated because the denominator was 0.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. The greatest (maximum) monthly reductions in

American River flows during November through January under A2D_ELT would be 30% to 49% larger (absolute difference) than under NAA_ELT in wet, below normal, and critical water years and 2% to 9% smaller than NAA_ELT in above normal and dry water years (Table 11-2D-43).

Table 11-2D-43. Difference and Percent Difference in Greatest Monthly Reduction (Percent Change) in Instream Flow in the American River at Nimbus Dam during the October through January Spawning and Egg Incubation Period[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-18 (-83%)	-40 (NA)
Above Normal	15 (50%)	9 (37%)
Below Normal	-25 (-131%)	-30 (-197%)
Dry	21 (44%)	2 (6%)
Critical	-13 (-25%)	-49 (-312%)

NA = could not be calculated because the denominator was 0.

[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in October, when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under A2D_ELT would be similar to mortality under NAA_ELT in all water years (Table 11-2D-44).

Table 11-2D-44. Difference and Percent Difference in Percent Mortality of Fall-Run Chinook Salmon Eggs in the American River (Egg Mortality Model)

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	15 (99%)	-0.2 (-1%)
Above Normal	14 (130%)	-1 (-2%)
Below Normal	12 (101%)	0 (0%)
Dry	9 (57%)	-0.1 (-1%)
Critical	4 (19%)	0 (0%)
All	11 (76%)	-0.2 (-1%)

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be largely the same as flows under NAA_ELT throughout the period.

Mean water temperatures throughout the Stanislaus River would be similar under NAA_ELT and Alternative 2D throughout the October through January period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to flows under NAA_ELT throughout the period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). There would be no difference in mean flows between A2D_ELT and NAA_ELT for all water year types throughout the period.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, it is concluded that the effect is not adverse because spawning and egg incubation habitat conditions are not substantially reduced. There are no reductions in flows under Alternative 2D or increases in temperatures that would translate into adverse biological effects on fall-/late fall-run Chinook salmon spawning and egg incubation habitat. The Reclamation egg mortality model predicts no effects of Alternative 2D on fall-/late fall-run Chinook salmon spawning and egg incubation habitat in the Sacramento, Feather, and American Rivers and SacEFT predicts generally small or beneficial impacts on spawning and egg incubation habitat in the Sacramento River.

CEQA Conclusion: In general, the results for the Alternative 2D analysis indicate that Alternative 2D could affect spawning and egg incubation habitat for fall-/late fall–run Chinook salmon relative to the Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 2D would not affect the quantity and quality of spawning and egg incubation habitat for fall-/late fall-run Chinook salmon relative to the CEQA baseline.

Sacramento River

Fall-Run

Flows were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows in the Sacramento River upstream of Red Bluff under A2D_ELT would generally be similar to Existing Conditions during December and January During October and November, flows under A2D_ELT would be generally lower (by up to 15%) than under Existing Conditions, depending on water year type. These results indicate that there would generally be no flow-related effects of Alternative 2D on spawning and egg incubation habitat, except for intermittent negligible-to-small flow reductions during October and November. Storage volume at the end of September would be 7% to 12% lower under A2D_ELT relative to Existing Conditions, depending on water year type (Table 11-2D-19).

Water temperatures in the Sacramento River at Red Bluff were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-20. There would be 75% and 83% increases in the number of years with "red" and "orange" levels of concern under A2D_ELT relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days (all water year types combined) under A2D_ELT would be 77% to 585% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-2D-21).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be 18% to 62% greater than mortality under Existing Conditions, and 4% to 7% greater on an absolute scale (Table 11-2D-33).

SacEFT predicts that there would be a 19% increase in the percentage of years with good spawning availability, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-34). SacEFT predicts that there would be a 5% reduction in the percentage of years with good (lower) redd scour risk under A2D_ELT relative to Existing Conditions. SacEFT predicts that there would be a 5% decrease in the percentage of years with good (lower) egg incubation conditions under A2D_ELT relative to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) redd dewatering risk under A2D_ELT relative to Existing Conditions.

Late Fall–Run

Flows in the Sacramento River upstream of Red Bluff were examined during the February through May late fall–run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be greater than or similar to flows under Existing Conditions, except in below normal years during March (7% lower) and wet years during May (10% lower).

Storage volume at the end of September would be 7% to 12% lower under A2D_ELT relative to Existing Conditions (Table 11-2D-19).

Water temperatures in the Sacramento River at Red Bluff were examined during the February through May late fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

The number of days at Red Bluff on which temperature exceeded 56°F by >0.5°F to >5°F in 0.5°F increments was determined for each month during October through April and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 56°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-20. There would be 75% and 83% increases in the number of years with "red" and "orange" levels of concern under A2D_ELT relative to Existing Conditions.

Total degree-days exceeding 56°F were summed by month and water year type at Red Bluff during October through April. Total degree-days under A2D_ELT would be 77% to 585% higher than those under Existing Conditions during October, November, March, and April, and similar during December through February (Table 11-2D-21).

The Reclamation egg mortality model predicts that late fall–run Chinook salmon egg mortality in the Sacramento River under A2D_ELT would be 49% to 119% greater than mortality under Existing Conditions, depending on water year type (Table 11-2D-35). However, absolute differences in the percent of the late-fall population subject to mortality would be no more than 2% for any water year type.

SacEFT predicts that there would be a 13% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-36). SacEFT predicts that there would be a 4% decrease in the percentage of years with good (lower) redd scour risk under A2D_ELT relative to Existing Conditions. SacEFT predicts that there would be no difference in the percentage of years with good (lower) egg incubation conditions under A2D_ELT relative to Existing Conditions. SacEFT predicts that there would be an 8% decrease in the percentage of years with good (lower) redd dewatering risk under A2D_ELT relative to Existing Conditions.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Mean flows in Clear Creek below Whiskeytown Reservoir under A2D_ELT during the September through February fall-run spawning and egg incubation period would generally be similar to or up to 40% greater than (January of wet years) flows under Existing Conditions, except during September of critical water years and October of below normal years (19% and 6% lower, respectively).

The potential risk of redd dewatering in Clear Creek was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in September when spawning occurred. The greatest monthly reduction in Clear Creek flows during October through February under A2D_ELT would be similar to or smaller than that under Existing Conditions in wet and below normal water years, but the reduction would be 41%, 100%, and 33% greater (absolute, not relative, differences) under A2D_ELT in above normal, dry, and critical water years, respectively (Table 11-2D-37).

Feather River

Fall-Run

Flows in the low-flow channel during October through January under A2D_ELT would be identical to those under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives* Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows in the high-flow channel under A2D_ELT would generally be lower than flows under Existing Conditions by up to 47% during November through January, and would generally be similar to or greater than flows under Existing Conditions during October. These results indicate that there would be intermittent negligible-to-moderate flow-related effects of Alternative 2D on spawning and egg incubation habitat during November, December and January.

The potential risk of redd dewatering in the Feather River low-flow channel was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. Minimum flows in the low-flow channel were identical between A2D_ELT and Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*). Therefore, there would be no effect of Alternative 2D on redd dewatering in the Feather River low-flow channel.

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the Feather River under A2D_ELT would be 94% to 139% greater than mortality under Existing Conditions, depending on water year type, and 2% to 5% greater on an absolute scale (Table 11-2D-40).

Water temperatures in the Feather River above Thermalito Afterbay (low-flow channel) and below Thermalito Afterbay (high-flow channel) were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under A2D_ELT relative to Existing Conditions would be no different (<5%) in either the low-flow or high-flow channel throughout the period

The percent of months exceeding the 56°F temperature threshold in the Feather River at Gridley was evaluated during October through April (Table 11-2D-38). The percent of months exceeding the threshold under A2D_ELT would similar to or up to 17% higher (absolute scale) than the percent under Existing Conditions during all months except December through February, during which there would be no difference in the percent of months exceeding the threshold.

Total degree-months exceeding 56°F were summed by month and water year type at Gridley during October through April (Table 11-2D-39). Total degree-months (all water year types combined) exceeding the 56°F threshold under A2D_ELT would be 35% to 425% higher than total degree-months under Existing Conditions, except during December through February, in which there would be no differences.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the October through January fall-run spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be lower by up to 23%

than flows under Existing Conditions during October, November, and January, with some exceptions. These results indicate that there would be intermittent negligible-to-moderate flow-related effects of Alternative 2D on spawning and egg incubation habitat during October, November, and January.

Water temperatures in the American River at the Watt Avenue Bridge were examined during the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean temperatures under A2D_ELT would be 5% to 7% greater than those under Existing Conditions in October, depending on water year type, and would be similar to those under Existing Conditions during the other three months of the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2D-41). The percent of months exceeding the threshold under A2D_ELT would be up to 26% greater (absolute scale) than the percent under Existing Conditions during November, March, and April and similar to the percent under Existing Conditions during December through February.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2D-42). Total degree-months (all water year types combined) under Alternative 2D would be 34% to 151% greater than total degree-months under Existing Conditions during November, March and April and similar to total degree months under Existing Conditions during December through February.

The potential risk of redd dewatering in the American River at Nimbus Dam was evaluated by comparing the magnitude of flow reduction each month during the incubation period to the flow in October when spawning is assumed to occur. The greatest monthly reduction in American River flows during November through January would be 83%, 131%, and 25% larger (absolute differences) under A2D_ELT in wet, below normal, and critical water years, respectively, than those under Existing Conditions, and would be smaller in above normal and dry years (Table 11-2D-43).

The Reclamation egg mortality model predicts that fall-run Chinook salmon egg mortality in the American River under A2D_ELT would be 19% to 130% greater (4% to 15% absolute differences) than mortality under Existing Conditions (Table 11-2D-44).

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to those under Existing Conditions, except for January of below normal and critical water years when flows would be 8% and 12% lower, respectively.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the October through January fall-run spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under A2D_ELT would not be different (<5% difference) from those under Existing Conditions for all months and water year types.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be generally similar to or slightly higher than flows under Existing Conditions.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the October through January fall-run Chinook salmon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions during October, November and January, and would be up to 28% higher (wet years) during December.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 2D, there would be small to moderate flow reductions and increases in the exceedances of NMFS temperature thresholds in the Sacramento, Feather and American rivers that would interfere with fall-/late fall-run Chinook salmon spawning and egg incubation. The Reclamation egg mortality model predicts moderate to substantial negative impacts of Alternative 2D on fall-/late fall-run Chinook salmon in the Sacramento, Feather, and American Rivers and SacEFT predicts reduced egg incubation habitat conditions for fall-run Chinook salmon and reduced spawning habitat conditions for late fall-run Chinook salmon in the Sacramento River. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fall-/late fall-run Chinook salmon as a result of egg mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be no effect of Alternative 2D on flows, reservoir storage, and water temperatures that would cause a substantial reduction in fall-/late fall-run Chinook salmon. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-77: Effects of Water Operations on Rearing Habitat for Chinook Salmon (Fall-/Late Fall–Run ESU)

In general, Alternative 2D would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall–run Chinook salmon relative to NAA_ELT.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be greater than or similar to flows under NAA_ELT throughout the period.

Shasta Reservoir storage at the end of September would affect flows during the fall-run larval and juvenile rearing period. As reported in Impact AQUA-59 for spring-run Chinook salmon, end of September Shasta Reservoir storage would be similar to storage under NAA_ELT in all water year types (Table 11-2D-19).

Water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

SacEFT predicts that there would be an 11% decrease (4% on an absolute scale) in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under A2D_ELT relative to NAA_ELT (Table 11-2D-34). SacEFT predicts that there would be no difference in the percentage of years with “good” (lower) juvenile stranding risk under A2D_ELT relative to NAA_ELT.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under A2D_ELT would be similar to mortality under NAA_ELT.

Late Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the late fall–run Chinook salmon juvenile rearing period of March through July (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT were generally similar to or greater than those under NAA_ELT throughout the rearing period.

Shasta Reservoir storage at the end of September and May would affect flows during the late fall–run larval and juvenile rearing period. As reported in Impact AQUA-156, end of September Shasta Reservoir storage would be similar to storage under NAA_ELT in all water year types (Table 11-2D-19). Similarly, as reported in Impact AQUA-59, Shasta storage at the end of May under A2D_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-2D-9).

Water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

SacEFT predicts that there would be a 25% decrease (11% on an absolute scale) in the percentage of years with good juvenile rearing availability for late fall–run Chinook salmon, measured as weighted usable area, under A2D_ELT relative to NAA_ELT (Table 11-2D-36). SacEFT predicts that there would be a 15% reduction in the percentage of years with "good" (lower) juvenile stranding risk under A2D_ELT relative to NAA_ELT. SALMOD predicts that late fall–run smolt equivalent habitat-related mortality under A2D_ELT would be similar (<1% difference) to mortality under NAA_ELT.

Both SacEFT and SALMOD are considered to be reliable models for late fall-run Chinook salmon in the Sacramento River. SALMOD has been used for decades for assessing changes in flows associated with SWP and CVP and SacEFT has been peer-reviewed. Therefore, results of both models were used to draw conclusions about late fall-run Chinook salmon rearing conditions. The SALMOD model incorporates effects to all early life stages, including eggs, fry, and juveniles. Therefore, although SacEFT predicts that juvenile rearing habitat availability may be reduced under Alternative 2D, when combined with all early life stage effects in SALMOD, there would be no effect of the alternative on late-fall-run Chinook salmon habitat-related survival of all early life stages, including juveniles. Further, results from SALMOD are consistent with results described above that indicate that there would be no differences in instream flows or reservoir storage between NAA_ELT and Alternative 2D.

Clear Creek

No water temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to flows under NAA_ELT throughout the rearing period.

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Relatively constant flows in the low flow channel throughout this period under A2D_ELT would not differ from those under NAA_ELT. In the high flow channel, mean flows under A2D_ELT would be mostly similar to or up to 121% greater (June of below normal water years) than flows under NAA_ELT, except for January and March of below normal water years whose flows would be up to 17% lower under A2D_ELT.

As reported in Impact AQUA-59 for spring-run Chinook salmon, May Oroville storage volume under A2D_ELT would be similar to storage under NAA_ELT, (Table 11-2D-28).

As reported in Impact AQUA-58 for spring-run Chinook salmon, September Oroville storage volume under A2D_ELT would be similar to, 6% lower than, or up to 17% higher than that under NAA_ELT, depending on water year type (Table 11-2D-25).

Water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period at either location.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to flows under NAA_ELT during January through May, with minor exceptions. However, during April and May of critical water years, flows would be 22% higher and 24% lower, respectively.

Water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Stanislaus River

Mean flows in the Stanislaus River at the confluence with the San Joaquin River for Alternative 2D are not different from those under NAA_ELT, for the January through May fall-run Chinook salmon juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*).

Mean water temperatures throughout the Stanislaus River would be similar between NAA_ELT and Alternative 2D throughout the January through May fall-run rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

San Joaquin River

Mean flows in the San Joaquin River at Vernalis for Alternative 2D are not different from those under NAA_ELT, for the January through May fall-run larval and juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Mean flows in the Mokelumne River at the Delta for Alternative 2D are not different from those under NAA_ELT, for the January through May fall-run larval and juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Taken together, these modeling results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat of fish. The changes in flow rates and water temperatures are generally small and infrequent under Alternative 2D relative to the NAA_ELT. SacEFT predicts that there would be a 25% decrease in the percentage of years with good juvenile rearing habitat availability for late fall-run and a 15% reduction in the number of years with good juvenile stranding risk between Alternative 2D and the NEPA baseline. However, review of these SacEFT results in combination with the results of SALMOD, which evaluates habitat-related survival of all early life stages and found no effects of Alternative 2D, it is concluded that the effect to juvenile habitat conditions predicted by SacEFT would not have a substantial effect on early life stages combined, include juveniles, as predicted by SALMOD. As such, the effect in not adverse because it does not have the potential to substantially reduce the amount of suitable habitat of fish.

CEQA Conclusion: In general, Alternative 2D would not affect the quantity and quality of larval and juvenile rearing habitat for fall-/late fall–run Chinook salmon relative to the Existing Conditions.

Sacramento River

Fall-Run

Sacramento River flows upstream of Red Bluff were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be greater than or similar to flows under Existing Conditions, except in below normal years during March (7% lower) and wet years during May (10% lower).

As reported in Impact AQUA-59, end of September Shasta Reservoir storage would be 7% to 12% lower under A2D_ELT relative to Existing Conditions, depending on water year type (Table 11-2D-19).

Water temperatures in the Sacramento River at Red Bluff were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

SacEFT predicts that there would be a 3% increase in the percentage of years with good juvenile rearing availability for fall-run Chinook salmon, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-34). SacEFT predicts that there would be a 26% reduction in the percentage of years with “good” (lower) juvenile stranding risk under A2D_ELT relative to Existing Conditions.

SALMOD predicts that fall-run smolt equivalent habitat-related mortality under A2D_ELT would be similar to mortality under Existing Conditions.

Late Fall–Run

Year-round Sacramento River flows upstream of Red Bluff were examined for the late fall–run Chinook salmon juvenile March through July rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows during March through June under A2D_ELT were generally similar to or greater than those under Existing Conditions, with minor exceptions.

As reported in Impact AQUA-59, end of September Shasta Reservoir storage would be 7% to 12% lower under A2D_ELT relative to Existing Conditions, depending on water year type (Table 11-2D-19).

As reported in Impact AQUA-41, end of May Shasta storage under A2D_ELT would be similar to Existing Conditions in wet, above normal, and below normal water years, but lower by 6% to 9% in dry and critical water years (Table 11-2D-9).

Water temperatures in the Sacramento River at Red Bluff were examined during the March through July late fall–run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

SacEFT predicts that there would be an 4% reduction in the percentage of years with good juvenile rearing availability for late fall–run Chinook salmon, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-36). SacEFT predicts that there would be a 29% reduction in the percentage of years with “good” (lower) juvenile stranding risk under A2D_ELT relative to Existing Conditions.

SALMOD predicts that late fall–run smolt equivalent habitat-related mortality under A2D_ELT would be 5% higher than mortality under Existing Conditions.

Clear Creek

No temperature modeling was conducted in Clear Creek.

Fall-Run

Flows in Clear Creek below Whiskeytown Reservoir were examined the January through May fall-run Chinook salmon rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or slightly greater than flows under Existing Conditions for the entire period, except for 40% higher flow in January of wet years (Appendix *B, Supplemental Modeling for New Alternatives*).

Feather River

Fall-Run

Flows in the Feather River both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) during December through June were reviewed to determine flow-related effects on larval and juvenile fall-run rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Relatively constant flows in the low flow channel throughout the period under A2D_ELT would not differ from those under Existing Conditions. In the high flow channel, mean flows under A2D_ELT would be mostly lower (up to 47% in January of below normal water years) during December through March and mostly similar to or up to 157% greater (June of below normal years) than flows under Existing Conditions during April through June, with minor exceptions.

As reported under in Impact AQUA-59, May Oroville storage volume under A2D_ELT would be lower than Existing Conditions by 5% to 13%, depending on water year type, except in wet and above normal years, in which storage would be similar to Existing Conditions (Table 11-2D-25).

As reported in Impact AQUA-59, September Oroville storage volume would be 19% to 28% lower under A2D_ELT relative to Existing Conditions, depending on water year type, except in dry and critical water years, in which storage would be similar to or 5% greater than that under Existing Conditions (Table 11-2D-28).

Water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the December through June fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). In both the low-flow channel and the high-flow channel, mean water temperatures under Alternative 2D would be the same (<5% difference) as those under Existing Conditions throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined for the January through May fall-run larval and juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions, except during January in below normal, dry and critical years (12% to 14% lower), February and March of critical years (7% and 11% lower, respectively), and May of all water year types (up to 16% lower in critical years).

Water temperatures in the American River at the Watt Avenue Bridge were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no difference (<5%) in mean water temperatures between Alternative 2D and Existing Conditions throughout the rearing period.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be lower than those under Existing Conditions for most water years throughout the period (up to 29% lower in February of critical years), with some exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through May fall-run Chinook salmon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under Alternative 2D be the same (<5% difference) as those under Existing Conditions in all months during the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be slightly lower (up to 12% lower) than those under Existing Conditions for most water years throughout the period, with some exceptions Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the January through May fall-run Chinook salmon juvenile rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during January through April, and would be up to 11% lower than flows under Existing Conditions during May.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 2D, including climate change effects, there would be moderate flow reductions in the Feather River, which would interfere with fall-run Chinook salmon juvenile rearing habitat conditions. Flows in the Feather River would be lower in the majority of water year types during January and February, with flows in January up to 47% lower. SacEFT predicts that, for fall-run, there would be a 26% reduction in years with low juvenile stranding risk, indicating that flows would be more variable during the rearing period. Both SacEFT and SALMOD predict reduced rearing habitat conditions under Alternative 2D relative to Existing Conditions for late fall-run Chinook salmon. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable rearing habitat and substantially reduce the number of fall-/late fall-run Chinook salmon as a result of degraded juvenile rearing conditions.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows, reservoir storage, and water temperatures in the Sacramento River would generally be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required. Therefore, the effects of Alternative 2D on fall-/late fall-run Chinook salmon juvenile rearing habitat conditions would be less than significant and no mitigation is necessary.

Impact AQUA-78: Effects of Water Operations on Migration Conditions for Chinook Salmon (Fall-/Late Fall–Run ESU)

Upstream of the Delta

In general, Alternative 2D would degrade migration conditions for fall-/late fall–run Chinook salmon relative to NAA_ELT.

Sacramento River

Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff for juvenile fall-run migrants during February through May under A2D_ELT would be similar to or greater than flows under NAA_ELT throughout the February through May juvenile fall-run migration period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Mean flows in the Sacramento River upstream of Red Bluff during the adult fall-run Chinook salmon upstream migration period (August through December) under A2D_ELT would generally be similar to those under NAA_ELT, except during September (up to 17% lower) and November (up to 18% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Late Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under A2D_ELT would generally be similar to or slightly greater than flows under NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Mean flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under A2D_ELT would be similar to or slightly greater than those under NAA_ELT throughout the migration period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento*

River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Flows in the Clear Creek below Whiskeytown Reservoir were examined for juvenile fall-run migrants during February through May. Mean flows under A2D_ELT would be similar to flows under NAA_ELT during all months and water year types of the migration period (Appendix *B, Supplemental Modeling for New Alternatives*).

Mean flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (August through December) under A2D_ELT would be similar to those under NAA_ELT except for critical water years in August, September and October, in which flows would be 11% higher, 10% lower, and 6% lower, respectively (Appendix *B, Supplemental Modeling for New Alternatives*).

Feather River

Fall-Run

Mean flows in the Feather River at the confluence with the Sacramento River during the fall-run juvenile migration period (February through May) under A2D_ELT would generally be similar to or greater than flows under NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Mean flows in the Feather River at the confluence with the Sacramento River during the August through December fall-run Chinook salmon adult migration period under A2D_ELT would be lower by up to 32% than flows under NAA_ELT in August and September, except during critical years in which flow would be up to 14% higher, and flow would be similar to or up to 21% greater than flows under NAA_ELT in the other months of the migration period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the August through December fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be generally similar to flows under NAA_ELT during February through April, except for 22% greater flow in April of critical water years. Flows during May would be similar or slightly greater than those under NAA_ELT, except for 24% lower flow in critical years.

Water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type of the period.

Flows in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be up to 27% lower than those under NAA_ELT during August, September, and November and would be similar or up to 27% higher during October and December.

Water temperatures in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under Alternative 2D would be similar to those under NAA_ELT throughout the year. Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under Alternative 2D would be similar to those under NAA_ELT throughout the year.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under Alternative 2D would be similar to those under NAA_ELT throughout the year.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

The effects of Alternative 2D on through-Delta migration were evaluated using the approach described in Alternative 1A, Impact AQUA-42.

Fall-Run

Juveniles

Juvenile fall-run Chinook salmon migrating down the Sacramento River would generally experience lower flows below the north Delta intakes compared to Existing Conditions. Estimates of potential predation losses ranged from 0.4% (bioenergetics model, Table FR_bioenergetics) up to 20.3% (conservative assumption of 5% loss per intake, based on GCID data from Vogel 2008) of fall-run annual production.

Table FR_bioenergetics. Fall-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes (Five Intakes for Alternative 2D)

Striped Bass at NDD (Five Intakes)			Fall-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Production Entering the Delta[1]
Low	18	154	39,232	0.06%
Median	119	1,017	259,368	0.42%
High	219	1,872	477,324	0.77%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (*BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference).

[1] Estimated as 61.6 million. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

Through-Delta survival by juvenile fall-run Chinook salmon under Alternative 2D averaged across years would be 24.2% from the Sacramento River and 16.5% from the Mokelumne River, which is little different from NAA_ELT (Table 11-2D-45). In wetter years, mean survival would be 2.8% lower from the Sacramento (8% relative decrease) and 1.9% greater (10% relative increase) from the Mokelumne. As described for Alternative 4A, the modeling of NAA_ELT does not account for actions that are assumed to be included under NAA that would be pursued as part of other projects and programs, notably Yolo Bypass improvements and tidal habitat restoration under the NMFS and USFWS BiOps. As shown for Alternative 4A, the difference in through-Delta survival between Alternative 2D and NAA_ELT for fall-run Chinook salmon migrating down the Sacramento River would be somewhat greater if the improvements to Yolo Bypass (particularly Fremont Weir modifications) were included in the modeling for NAA_ELT.

Overall, Alternative 2D would have a negative effect on fall-run Chinook salmon juvenile survival due to the near-field and far-field effects of the NDD intakes.

Table 11-2D-45. Through-Delta Survival (%) of Emigrating Juvenile Fall-Run Chinook Salmon under Alternative 2D

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA_ELT	A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Sacramento River					
Wetter Years	34.5	33.0	30.2	-4.3 (-12%)	-2.8 (-8%)
Drier Years	20.6	20.6	20.6	0.0 (1%)	-0.1 (0%)
All Years	25.8	25.3	24.2	-1.6 (-4%)	-1.1 (-3%)
Mokelumne River					
Wetter Years	17.2	16.3	18.2	1.0 (4%)	1.9 (10%)
Drier Years	15.6	15.7	15.5	-0.1 (0%)	-0.2 (-1%)
All Years	16.2	15.9	16.5	0.3 (1%)	0.6 (3%)
San Joaquin River					
Wetter Years	19.3	20.7	16.4	-2.9 (-6%)	-4.3 (-10%)
Drier Years	10.0	9.8	10.9	1.0 (10%)	1.1 (11%)
All Years	13.5	13.9	13.0	-0.5 (4%)	-0.9 (3%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

Attraction flow for fall-run adults, as estimated by the percentage of Sacramento River water at Collinsville, was 5% lower in September and decreased 0% to 2% in October to December under Alternative 2D compared to NAA_ELT (Table 11-2D-17). The Sacramento River would still represent a substantial proportion (60% to 65%) of Delta outflows. The reductions in percentage are small in comparison with the magnitude of change in dilution (20% or more) reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect adult Chinook salmon migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 in Alternative 1A.

Late Fall–Run

Juveniles

Juvenile salmonids migrating down the Sacramento River would generally experience lower flows below the north Delta intakes compared to Existing Conditions. Through-Delta survival by emigrating juvenile late fall–run Chinook salmon under Alternative 2D (A2D_ELT) would average

22% across all years, ranging from 19% in drier years to 26% in wet years. Juvenile survival would decrease slightly in wetter (1.3% less survival, or 4% less in relative percentage) and similar in drier years (0.6% less survival, or 2% less in relative percentage) compared to NAA_ELT (Table 11-2D-46). Estimates of potential predation losses ranged from 1% (bioenergetics model, Table LFR_bioenergetics) up to ~20% (conservative assumption of 5% loss per intake) of fall-run annual production.

Table LFR_bioenergetics. Late Fall-Run Chinook Salmon Predation Loss at the Proposed North Delta Diversion (NDD) Intakes (Five Intakes for Alternative 2D)

Striped Bass at NDD (Five Intakes)			Late Fall-Run Chinook Consumed	
Density Assumption	Bass per 1,000 Feet of Intake	Total Number of Bass	Number	Percentage of Annual Production Entering the Delta[1]
Low	18	154	6,596	0.15%
Median	119	1,017	43,610	1.01%
High	219	1,872	80,257	1.87%

Note: Based on bioenergetics modeling of Chinook salmon consumption by striped bass (*BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference).

[1] Estimated as 4.3 million for late fall-run. See Section 5.F.3.2.1 in *BDCP Effects Analysis*, Appendix 5F Biological Stressors, hereby incorporated by reference.

Table 11-2D-46. Through-Delta Survival (%) of Emigrating Juvenile Late Fall–Run Chinook Salmon under Alternative 2D

	Percentage Survival			Difference in Percentage Survival (Relative Difference)	
Year Type	EXISTING CONDITIONS	NAA_ELT	A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wetter Years	28.8	27.5	26.2	-2.6 (-7%)	-1.3 (-4%)
Drier Years	18.8	20.0	19.4	0.7 (5%)	-0.6 (-2%)
All Years	22.5	22.8	22.0	-0.5 (0%)	-0.9 (-2%)

Note: Delta Passage Model results for survival to Chipps Island.
Wetter = Wet and above normal water years (6 years).
Drier = Below normal, dry and critical water years (10 years).

Adults

The adult late fall–run migration is from November through March, peaking in January through March. The proportion of Sacramento River water in the Delta at Collinsville would be similar (10% or less difference) to NAA_ELT throughout the adult late fall–run migration (Table 11-2D-17). Alternative 2D would not have an adverse effect on late fall–run adult migration. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. This topic is discussed further in Impact AQUA-42 in Alternative 1A.

San Joaquin River

Fall-Run

Juveniles

The only changes on San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. There are no flow changes associated with the alternatives. Survival was similar between Alternative 2D and NAA_ELT when averaged across all years, but was considerably less under Alternative 2D in wetter years. As described in more detail for Alternative 4A, this reflects the assumptions of the DPM, wherein there is a positive relationship between survival and exports, based on current relationships; but there is considerable uncertainty in effects on San Joaquin River Chinook salmon survival at the very low levels of south Delta exports in wetter years under Alternative 2D because the studies upon which the DPM flow- and export-survival relationships are based did not include these very low levels of exports. As noted under Alternative 4A, SalSim, a different analysis tool, would be expected to illustrate a benefit of Alternative 2D across any modeled year for Alternative 2D, which is more in keeping with the anticipated effect of the alternative. Overall and in light of these uncertainties, Alternative 2D would not have an adverse effect on through-Delta migration for San Joaquin River fall-run Chinook salmon because the reduction in south Delta exports generally would be expected to benefit through-Delta survival.

Adults

Alternative 2D would slightly increase the proportion of San Joaquin River water in the Delta in September through December by 1.7 to 5.2% compared to NAA_ELT). As noted under Alternative 4A, although the relative change is substantial (i.e., a severalfold increase in the percentage of flow from the San Joaquin River under Alternative 2D compared to NAA_ELT), the percentage of flow attributable to San Joaquin River water under all scenarios is quite low (no more than around 5%). However, even the seemingly small increase in San Joaquin River flow could provide moderate benefits: as illustrated in *BDCP Appendix 5.C, Section 5C.5.3.13.1.5 hereby incorporated by reference*, based on the study of Marston et al. (2012), greater olfactory cues under Alternative 2D could decrease severalfold the straying rate of adult San Joaquin River Chinook salmon to the Sacramento River. This would not be an adverse effect on adult fall-run Chinook salmon migrating to the San Joaquin River.

NEPA Effects: Overall, the results indicate that the effect of Alternative 2D is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, flows in the American River would be up to 27% lower during the majority (three of the five) months of the fall-run Chinook salmon adult migration period. These reductions in flow may impact the ability of adult fall-run Chinook salmon to migrate upstream successfully. There would be no other adverse effects of Alternative 2D on upstream flows or water temperatures during the juvenile or adult migration periods for fall- and late fall-run Chinook salmon.

Adult attraction flows under Alternative 2D would be lower than those under NAA_ELT, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2D on fall-run/late fall-run Chinook salmon related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating fall-run/late fall-run Chinook salmon, although there is high uncertainty regarding the potential effects. Estimates within the effects analysis range from very low levels of effects (<1% mortality) to very significant effects (~ 20% mortality above current baseline levels). As noted for Alternative 4A, Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction studies to better understand how to minimize losses associated with the new intake structures will be implemented as part of the final NDD screen design effort. As with Alternative 4A, Alternative 2D also includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for fall-run/late fall-run Chinook. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain. See additional discussion under Impact AQUA-42 of Alternative 4A for winter-run Chinook salmon.

As described for Alternative 4A, the DPM is a flow-based model incorporating flow-survival and junction routing relationships with flow modeling of water operations to estimate relative differences between scenarios in smolt migration survival throughout the entire Delta. The DPM predicted that smolt migration survival under Alternative 2D would be lower than survival estimated for NAA_ELT, based on operations assuming no adjustments made in real-time in response to actual presence of fish. Although refinements to the DPM are likely to occur based on new data available from future studies and the current analysis has some uncertainty, the DPM analysis of Alternative 2D on juvenile fall-run/late fall-run Chinook salmon migration suggests a potential adverse effect of small magnitude. This adverse effect would be reduced through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 2D of specific important environmental commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of fall-run/late fall-run Chinook salmon juveniles into the low-survival interior Delta.

Overall, primarily as a result of substantially reduced upstream flows and unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on fall-run/late fall-run Chinook salmon, this effect is adverse. While implementation of the environmental commitments noted above and mitigation measures listed below would address these impacts, these are not anticipated to reduce the impacts to a level considered not adverse.

CEQA Conclusion: In general, Alternative 2D would affect migration conditions for fall-/late fall–run Chinook salmon relative to the Existing Conditions.

Upstream of the Delta

Sacramento River

Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff for juvenile fall-run migrants during February through May under A2D_ELT would generally be similar to or greater than those under

Existing Conditions, except during March of below normal water years (7% lower) and during May of wet water years (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

Mean flows in the Sacramento River upstream of Red Bluff during the adult fall-run Chinook salmon upstream migration period (August through December) under A2D_ELT would generally be similar to flows under Existing Conditions during December and lower than those under Existing Conditions in the other months of the migration period (up to 22% lower in September of dry years), except for higher flows during September of wet and above normal years (20% and 27% higher, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the August through November adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D during September or October of any water year type.

Late Fall-Run

Mean flows in the Sacramento River upstream of Red Bluff for juvenile late fall-run migrants (January through March) under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions throughout the period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the January through March juvenile late fall-run Chinook salmon emigration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

Mean flows in the Sacramento River upstream of Red Bluff during the adult late fall-run Chinook salmon upstream migration period (December through February) under A2D_ELT would generally be similar to or slightly greater than those under Existing Conditions throughout the period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Red Bluff were examined during the December through February adult late fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

Clear Creek

Water temperature modeling was not conducted in Clear Creek.

Fall-Run

Mean flows in Clear Creek below Whiskeytown Reservoir during the juvenile fall-run Chinook salmon upstream migration period (February through May) under A2D_ELT would be similar to or greater than those under Existing Conditions throughout the period (Appendix *B, Supplemental Modeling for New Alternatives*).

Mean flows in Clear Creek below Whiskeytown Reservoir during the adult fall-run Chinook salmon upstream migration period (August through December) under A2D_ELT would generally be similar to those under Existing Conditions, except during September of critical water years (19% lower)(Appendix *B, Supplemental Modeling for New Alternatives*).

Feather River

Fall-Run

Mean flows in the Feather River at the confluence with the Sacramento River during the fall-run juvenile migration period (February through May) under A2D_ELT would generally be similar to or greater than flows under Existing Conditions, except in below normal years during February and March (11% and 16% lower, respectively) and in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

Mean flows in the Feather River at the confluence with the Sacramento River during the August through December fall-run Chinook salmon adult migration period under A2D_ELT would generally be similar to or greater than flows under Existing Conditions (up to 102% greater for September of wet years), except in below normal and dry years during August and September (up to 43% lower).

Water temperatures in the Feather River at the confluence with the Sacramento River were examined during the August through December fall-run Chinook salmon adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2D during September or October of any water year type.

American River

Fall-Run

Flows in the American River at the confluence with the Sacramento River were examined during the February through May juvenile Chinook salmon fall-run migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT during February through April would generally be similar to or greater than flows under Existing Conditions, except for slightly lower flows during February of dry and critical water years, March of critical years, and April of above normal years. Flows would be lower under A2D_ELT during May of all water year types (up to 16% lower).

Water temperatures in the American River at the confluence with the Sacramento River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

Flows in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT during August, September, and November of all water year types would be lower than flows under Existing Conditions (up to 52% lower in August of dry years). Mean flows under A2D_ELT during October and December would be up to 14% lower than those under Existing Conditions in some water years and up to 16% higher in other water years.

Water temperatures in the American River at the confluence with the Sacramento River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under Alternative 2D would be similar (<5% difference) to those under Existing Conditions during September, November and December, and would be 5% higher than those under Existing Conditions during August of dry water years and 5% to 6% higher during October of all water year types except critical years.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be lower than those under Existing Conditions (up to 29% lower) for most water year types in all months of the period, although flows under A2D_ELT in February and March of wet years would be up to 17% greater.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be 9%, 7% and 6% lower than those under Existing Conditions during, respectively, August and September of wet years and October of below normal water years.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under AD2D_ELT would be 5% to 12% lower than those under Existing Conditions during February through May of below normal, dry and critical years, except for February of below normal years for which flows under AD2_ELT would be similar to those under Existing Conditions.

Flows in the San Joaquin River at Vernalis were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be up to 14% lower than those under Existing Conditions during August and September and would be similar to or greater than those under Existing Conditions during the remainder of the migration period.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the February through May juvenile fall-run Chinook salmon migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under Alternative 2D would be similar to those under Existing Conditions during February and up to 6%, 7%, and 11% lower than those under Existing Conditions during March, April and May, respectively.

Flows in the Mokelumne River at the Delta were examined during the August through December adult fall-run Chinook salmon upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be up to 32% lower than those under Existing Conditions during August and September, would be generally similar during October and November, and would be up to 28% greater during December.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Based on the proportion of Sacramento River flows, olfactory cues would be similar (10% or less difference) to Existing Conditions for nearly all months of the year. The 10% decrease in March would affect the last month of the late fall-run adult migration. Through the Delta, Sacramento River flows below the NDD would be reduced compared to baseline conditions during adult and juvenile migration periods. Modeled juvenile survival (DPM) is expected to be similar or slightly lower in all water year types (4% relative decrease across all years, 12% decrease in wetter years). Estimated predation losses of juveniles migrating past the five intakes could hypothetically range from <1% to ~20% of annual production, although the latter estimate is a conservative upper bound. The adaptive management program would provide a mechanism for making adjustments to minimize this effect to some extent. In addition, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* would be implemented to reduce potential effects. However, the benefits of these actions are uncertain. As a result of changes in predation and habitat associated with five NDD structures, this impact is significant.

Summary of CEQA Conclusion

Overall, Alternative 2D would significantly affect the migration conditions for fall-run/late fall-run Chinook salmon, relative to the Existing Conditions. Through-Delta survival of emigrating juveniles has the potential to be appreciably reduced, compared to Existing Conditions. There would be little negative effect of Alternative 2D on adult olfactory cues in the Delta. Upstream of the Delta, there would be substantial reductions in flows in multiple waterways under Alternative 2D relative to Existing Conditions that would slow or inhibit migration of juveniles and adult fall-/late fall-run Chinook salmon. In the American River, there would be increases in temperatures during the adult fall-run migration period that would increase thermal stress on migrants.

Implementation of *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers* (all of which are summarized further in Section 4.1.3.3 of this RDEIR/SDEIS) would address the through-Delta impacts, but are not anticipated to reduce them to a level considered less than significant because of the presence of five intakes. As a result of these changes in migration conditions, this impact is significant and unavoidable.

In addition to the environmental commitments above, the mitigation measures identified below would provide an adaptive management process that would be conducted as a part of the Adaptive Management and Monitoring Program, for assessing impacts and developing appropriate minimization measures. However, this would not necessarily result in a less than significant determination, so it is concluded that the impact is significant and unavoidable.

Mitigation Measure AQUA-78a: Following Initial Operations of Water Conveyance Facilities, Conduct Additional Evaluation and Modeling of Impacts to Fall-/Late Fall–Run Chinook Salmon to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Please refer to Mitigation Measure AQUA-78a under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78b: Conduct Additional Evaluation and Modeling of Impacts on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Following Initial Operations of Water Conveyance Facilities

Please refer to Mitigation Measure AQUA-78b under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Mitigation Measure AQUA-78c: Consult with NMFS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Fall-/Late Fall–Run Chinook Salmon Migration Conditions Consistent with Water Conveyance Facility Operations

Please refer to Mitigation Measure AQUA-78c under Alternative 1A (Impact AQUA-78) for fall/late fall-run Chinook salmon.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-79: Effects of Construction of Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-80: Effects of Contaminants Associated with Restoration Measures on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-81: Effects of Restored Habitat Conditions on Chinook Salmon (Fall-/Late Fall–Run ESU)

Impact AQUA-82: Effects of Methylmercury Management on Chinook Salmon (Fall-/Late Fall–Run ESU) (Environmental Commitment 12)

Impact AQUA-85: Effects of Localized Reduction of Predatory Fish on Chinook Salmon (Fall-/Late Fall–Run ESU) (Environmental Commitment 15)

Impact AQUA-86: Effects of Nonphysical Fish Barriers on Chinook Salmon (Fall-/Late Fall–Run ESU) (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on fall/late fall-run Chinook salmon for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Steelhead

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-91: Effects of Construction of Water Conveyance Facilities on Steelhead

The potential effects of construction of the water conveyance facilities on steelhead or their designated critical habitat would be similar to those described for Alternative 4A (Impact AQUA-91) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to steelhead.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-91, the effect would not be adverse for steelhead or designated critical habitat.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-91, the impact of the construction of water conveyance facilities on steelhead and critical habitat would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-92: Effects of Maintenance of Water Conveyance Facilities on Steelhead

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-92, the effect would not be adverse for steelhead.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-92 for steelhead, the impact of the maintenance of water conveyance facilities on steelhead or critical habitat would be less than significant and no mitigation is required.

Water Operations of Water Conveyance Facilities

Impact AQUA-93: Effects of Water Operations on Entrainment of Steelhead

Water Exports from SWP/CVP South Delta Facilities

Alternative 2D would reduce overall entrainment of juvenile steelhead at the south Delta export facilities by 67%, as estimated by the salvage density method (Table 11-2D-48) across all years compared to NAA_ELT. Under Alternative 2D, the greatest reductions in entrainment would be in wetter years (91% decrease in wet years; 79% decrease in above normal years). Pre-screen loss at the south Delta facilities, typically attributed to predation, would be reduced commensurate with reductions in entrainment.

Table 11-2D-48. Juvenile Steelhead Annual Entrainment at the SWP and CVP Salvage Facilities—Differences between Model Scenarios for Alternative 2D

	Absolute Difference (Percent Difference)	
Water Year Type	EXISTING CONDITIONS vs. A2D	NAA_ELT vs. A2D
Wet	-5,618 (-90%)	-5,917 (-91%)
Above Normal	-10,182 (-78%)	-10,575 (-79%)
Below Normal	-6,084 (-51%)	-6,229 (-52%)
Dry	-1,690 (-22%)	-1,457 (-20%)
Critical	-912 (-16%)	-822 (-14%)
All Years	-6,002 (-67%)	-6,193 (-67%)

Note: Estimated annual number of fish lost, based on non-normalized data.

Steelhead predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Average pre-screen predation loss for steelhead entrained at the Clifton Court Forebay is about 80% (Clark et al. 2009) while predation loss for fish entrained at the CVP is assumed to be 15%. By reducing entrainment at the south Delta facilities, Alternative 2D would reduce predation losses commensurate with reductions in entrainment.

Water Exports from SWP/CVP North Delta Intake Facilities

The potential effects of the proposed North Delta diversions would be similar to these described for winter-run Chinook salmon juveniles (see Impact AQUA-39). The north Delta intakes would be screened and would be expected to exclude fish of around 22 mm and larger, which would prevent entrainment of steelhead juveniles.

Predation Associated with Entrainment

Pre-screen loss of juvenile steelhead at the south Delta facilities is typically attributed to predation, and is expected to decrease under Alternative 2D, commensurate with entrainment reductions. Predation at the north Delta would increase due to the installation of the proposed North Delta diversions on the Sacramento River.

NEPA Effects: The effect under Alternative 2D would not be adverse, because it is concluded that the reduction in south Delta exports and associated predation mortality would offset entrainment-related negative effects of the north Delta intakes.

CEQA Conclusion: As described above, entrainment and associated pre-screen predation losses of juvenile steelhead would decrease under Alternative 2D (A2D_ELT) compared to Existing Conditions at the south Delta export facilities (Table 11-2D-48). The north Delta screened intakes, as designed, would exclude juvenile salmonids. Impacts of water operations on entrainment of steelhead would be less than significant due to an overall reduction in entrainment and no mitigation would be required.

Impact AQUA-94: Effects of Water Operations on Spawning and Egg Incubation Habitat for Steelhead

In general, the effect of Alternative 2D on steelhead spawning habitat would be negligible relative to NAA_ELT.

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam, where the majority of steelhead spawning in the mainstem Sacramento River occurs, were examined during the primary steelhead spawning and egg incubation period of January through April (Appendix *B, Supplemental Modeling for New Alternatives*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds, leading to mortality. Mean flows under A2D_ELT throughout the period would generally be similar to or greater than those under NAA_ELT, with minor exceptions.

Water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period at either location.

SacEFT predicts that there would be a 4% decrease in the percentage of years with good spawning availability, measured as weighted usable area, under A2D_ELT relative to NAA_ELT (Table 11-2D-49). SacEFT predicts that there would be negligible (<5%) differences between NAA_ELT and A2D_ELT in the percentage of years with good (lower) redd scour risk, good (lower) egg incubation conditions, or good (lower) redd dewatering risk. These results indicate Alternative 2D would result in a small reduction in spawning habitat quantity, but no difference in redd scour or dewatering risk or temperature-related egg incubation conditions.

Table 11-2D-49. Difference and Percent Difference in Percentage of Years with "Good" Conditions for Steelhead Habitat Metrics in the Upper Sacramento River (from SacEFT)

Metric	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Spawning WUA	-2 (-4%)	-2 (-4%)
Redd Scour Risk	-3 (-4%)	0 (0%)
Egg Incubation	0 (0%)	0 (0%)
Redd Dewatering Risk	-2 (-4%)	-1 (-2%)
Juvenile Rearing WUA	1 (2%)	-3 (-7%)
Juvenile Stranding Risk	-6 (-18%)	-1 (-3%)

WUA = Weighted Usable Area.

Overall, these results indicate that the effects of Alternative 2D on steelhead spawning and egg incubation habitat in the Sacramento River would be negligible.

Clear Creek

Flows in Clear Creek were examined during the steelhead spawning and egg incubation period (January through April). Mean flows under A2D_ELT would be similar to flows under NAA_ELT throughout the period (Appendix *B, Supplemental Modeling for New Alternatives*).

Results of the flow analyses for the risk of redd dewatering for Clear Creek indicate that the greatest monthly flow reduction would be identical between NAA_ELT and A2D_ELT for all water year types (Table 11-2D-50).

Table 11-2D-50. Comparisons of Greatest Monthly Reduction (Percent Change) in Instream Flow under Alternative 2D Model Scenarios in Clear Creek during the January–April Steelhead Spawning and Egg Incubation Period[a]

Water Year Type	A2D_ELT vs. EXISTING CONDITIONS	A2D_ELT vs. NAA_ELT
Wet	-25 (-38%)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.
[a] Redd dewatering risk not applicable for months when flows during the egg incubation period were at or greater than flows in the month when spawning is assumed to occur. A negative value indicates that the greatest monthly reduction would be of greater magnitude (worse) under the alternative than under the baseline.

No water temperature modeling was conducted in Clear Creek.

Overall, these results indicate that the effects of Alternative 2D on steelhead spawning and egg incubation habitat in Clear Creek would be negligible.

Feather River

Steelhead spawning and egg incubation on the Feather River occurs primarily in Hatchery Ditch and the low-flow channel in the general vicinity of the Feather River Hatchery. Effects of A2D_ELT on flow during the spawning and egg incubation period (January through April) in the Feather River were evaluated using the results of CALSIM analyses of instream flows within the reach where the majority of steelhead spawning occurs (low-flow channel) based on estimated flows above Thermalito Afterbay (Appendix *B, Supplemental Modeling for New Alternatives*). Although recent surveys have found that very few steelhead (0 to 28%) spawn in the high-flow channel, (J. Kindopp pers. comm.), flows were also evaluated in the high-flow channel based on information in the Feather River at Thermalito Afterbay (Appendix *B, Supplemental Modeling for New Alternatives*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds leading to mortality.

Flows in the low-flow channel under A2D_ELT would not differ from NAA_ELT because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006). Mean flows under A2D_ELT at Thermalito Afterbay would generally be similar to or greater than (up to 35% greater in February of above normal water years) flows under NAA_ELT, except in wet years during January (17% lower) and in below normal years during March (13% lower).

Oroville Reservoir storage volume at the end of September and end of May influences flows downstream of the dam during the steelhead spawning and egg incubation period. Mean storage volume at the end of September under A2D_ELT would be similar to or up to 6% lower (above normal years) and 17% higher (dry years) than storage under NAA_ELT, depending on water year type (Table 11-2D-25). May Oroville storage under A2D_ELT would be similar to storage under NAA_ELT in all water years types (Table 11-2D-28).

Water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period at either location.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during January through April (Table 11-2D-51). The percent of months exceeding the threshold under A2D_ELT would generally be similar to or lower (up to 5% lower on an absolute scale) than the percent under NAA_ELT, depending on month and degrees above the threshold.

Table 11-2D-51. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River above Thermalito Afterbay Exceed the 56°F Threshold, January through April

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	0 (0%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
April	6 (71%)	1 (25%)	1 (NA)	0 (NA)	0 (NA)
NAA_ELT vs. A2D_ELT					
January	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
February	0 (NA)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
March	-1 (-50%)	0 (NA)	0 (NA)	0 (NA)	0 (NA)
April	-5 (-25%)	-5 (-44%)	-2 (-67%)	-1 (-100%)	0 (NA)

NA = could not be calculated because the denominator was 0.

Total degree-months exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during January through April (Table 11-2D-52). Total degree-months would be similar between NAA_ELT and A2D_ELT in all months.

Table 11-2D-52. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 56°F in the Feather River above Thermalito Afterbay, January through April

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
January	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
February	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (0%)	-1 (-50%)
	All	0 (0%)	-1 (-50%)
April	Wet	0 (NA)	0 (NA)
	Above Normal	2 (100%)	1 (33%)
	Below Normal	3 (75%)	0 (0%)
	Dry	6 (120%)	-1 (-8%)
	Critical	7 (NA)	0 (0%)
	All	18 (164%)	0 (0%)

NA = could not be calculated because the denominator was 0.

Overall, these modeling results indicate that the effects of Alternative 2D on steelhead spawning and egg incubation habitat in the Feather River would be negligible.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the January through April steelhead spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or greater than (up to 22% greater for April of critical water years) flows under NAA_ELT during the period, except in below normal and dry years during January (11% and 6% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives)*.

Water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period ((Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2D-41). Steelhead spawn and eggs incubate in the American River between January and April. During this period, the percent of months exceeding the threshold under A2D_ELT would be similar to or up to 9% lower (absolute scale) than the percent under NAA_ELT.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2D-42). During the January through April steelhead spawning and egg incubation period, total degree-months would be similar between NAA_ELT and A2D_ELT.

Overall, these results indicate that the effects of Alternative 2D on steelhead spawning and egg incubation habitat in the American River would be negligible.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT throughout this period would be nearly identical to flows under NAA_ELT.

Mean water temperatures throughout the Stanislaus River would be similar under NAA_ELT and Alternative 2D throughout the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*).

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT throughout this period would be nearly identical to flows under NAA_ELT.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. There would be negligible effects of Alternative 2D on upstream flows, water temperatures, and reservoir stage that would affect steelhead spawning and egg incubation in any of the rivers analyzed. Further, SacEFT predicts no effects of Alternative 2D on steelhead spawning and egg incubation habitat in the Sacramento River.

CEQA Conclusion: In general, these modeling results indicate that Alternative 2D could reduce the quantity and quality of steelhead spawning habitat relative to the Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 2D would not affect the quantity and quality of spawning and egg incubation habitat for steelhead relative to the CEQA conclusion.

Sacramento River

Flows in the Sacramento River between Keswick and upstream of Red Bluff Diversion Dam, where the majority of steelhead spawning occurs, were examined during the primary steelhead spawning and egg incubation period of January through April. (Appendix *B, Supplemental Modeling for New Alternatives*). Lower flows can reduce the instream area available for spawning and egg incubation, and rapid reductions in flow can expose redds, leading to mortality. At Keswick, mean flows under A2D_ELT during the steelhead spawning and egg incubation period would generally be similar to or greater than flows under Existing Conditions, except for flows up to 13% lower in February of dry years, March of below normal and dry years, and April of above normal and below normal years. Upstream of Red Bluff Diversion Dam, mean flows under A2D_ELT would generally be similar to or slightly greater than those under Existing Conditions.

Water temperatures in the Sacramento River at Keswick and Red Bluff were examined during the January through April primary steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period at either location.

SacEFT predicts negligible changes (<5%) in spawning habitat, redd scour risk, and redd dewatering risk between Existing Conditions and Alternative 2D, and no difference in egg incubation conditions (Table 11-2D-15).

Overall in the Sacramento River, Alternative 2D would have small reductions in mean monthly flow that would not affect steelhead spawning conditions in a biological meaningful way. SacEFT indicates that steelhead egg incubation and redd survival metrics would not be substantially affected by Alternative 2D. Impacts of Alternative 2D on water temperature would be less than significant.

Clear Creek

Flows in Clear Creek were examined during the steelhead spawning and egg incubation period (January through April). Mean flows under A2D_ELT would be similar to or up to 40% greater than flows under Existing Conditions throughout the period (Appendix *B, Supplemental Modeling for New Alternatives*).

Results of the flow analyses for the risk of redd dewatering for Clear Creek indicate that the greatest monthly flow reduction would be identical between Existing Conditions and A2D_ELT for all water year types except wet, in which the greatest reduction would be 38% lower (worse) under A2D_ELT than under Existing Conditions (Table 11-2D-50).

No water temperature modeling was conducted in Clear Creek.

Based on mean flows and increased maximum flow reductions only in wet years, there would be little effect of Alternative 2D on steelhead spawning and egg incubation habitat conditions.

Feather River

Flows were examined in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) during the steelhead spawning and egg incubation period (January through April) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows in the low-flow channel under A2D_ELT would not differ from Existing Conditions because minimum Feather River flows are included in the FERC settlement agreement and would be met for all model scenarios (California Department of Water Resources 2006). Mean flows under A2D_ELT at Thermalito Afterbay would generally be lower than flows under Existing Conditions (up to 47%

lower in January of below normal water years) during January through March, and would be similar to or greater than flows under Existing Conditions in April (up to 31% greater in April of dry years).

Oroville Reservoir storage volume at the end of September and end of May influences flows downstream of the dam during the steelhead spawning and egg incubation period. Oroville Reservoir mean storage volume at the end of September would be similar to or up to 28% lower under A2D_ELT relative to Existing Conditions depending on water year type (Table 11-2D-25). Mean May Oroville storage volume under A2D_ELT would be similar to storage under Existing Conditions in wet and above normal water years and up to 13% lower in below normal, dry and critical years (Table 11-2D-28).

Water temperatures in the Feather River low-flow channel (upstream of Thermalito Afterbay) and high-flow channel (at Thermalito Afterbay) were examined during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period at either location.

The percent of months exceeding the 56°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) was evaluated during January through April (Table 11-2D-51). The percent of months exceeding the threshold under A2D_ELT would generally be similar to the percent under Existing Conditions during January, February and March, and would be similar to or up to 6% greater (absolute scale) than the percent under Existing Conditions during April, depending on month and the degrees above the threshold.

Total degree-months exceeding 56°F were summed by month and water year type above Thermalito Afterbay (low-flow channel) during January through April (Table 11-2D-52). Total degree-months (all water years combined) would be similar between Existing Conditions and A2D_ELT during January, February and March, and 164% higher under A2D_ELT compared to Existing Conditions during April.

Overall, the effects of Alternative 2D on flows in the Feather River below Thermalito Afterbay would include substantial decreases in mean flow during some months and water year types. There would be minor increases in the exceedance of water temperature thresholds in the low-flow channel during April, coupled with reductions in coldwater pool availability in the Oroville Reservoir, especially in September.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the January through April steelhead spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be lower than flows under Existing Conditions during January, similar to or greater than flows under Existing Conditions during February through April, with some exceptions.

Water temperatures in the American River at the Watt Avenue Bridge were evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

The percent of months exceeding the 56°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during November through April (Table 11-2D-41). Steelhead spawn and eggs incubate in the American River between January and April. During January and February, there would be no differences in the percent of months exceeding the threshold between Existing Conditions and A2D_ELT. During March and April, the percent of months exceeding the threshold under A2D_ELT would be up to 11% greater (absolute scale) than the percent under Existing Conditions.

Total degree-months exceeding 56°F were summed by month and water year type at the Watt Avenue Bridge during November through April (Table 11-2D-42). During the January and February, there would be no differences in total degree-months (all water years combined) above the threshold between Existing Conditions and A2D_ELT. During March and April, total degree-months under A2D_ELT would be 95% and 34% greater than those under Existing Conditions, respectively.

Overall, these results indicate that the effects of Alternative 2D on flows would be small and inconsistent. Mean flows would be greater in some months and water years types than flows under Existing Conditions and would be lower in other months and water years types. Water temperatures would not differ significantly from Existing Conditions. However, Alternative 2D would increase exposure of spawning steelhead and their eggs to critical water temperatures.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined during the January through April steelhead spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT throughout this period would be lower than flows under Existing Conditions (up to 29% lower for February of critical water years) in all months, with minor exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River was evaluated during the January through April steelhead spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no difference (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

San Joaquin River

The mainstem San Joaquin River does not provide habitat for steelhead spawning or egg incubation.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined during the January through April steelhead spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or up to 15% higher than flows under Existing Conditions during January through March and up to 7% lower during April.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 2D, there are flow and cold water pool availability reductions in the Feather and Stanislaus Rivers, as well as temperature increases in the Feather River that would lead to biologically meaningful increases in egg mortality and overall reduced habitat conditions for spawning steelhead and egg incubation, as compared to Existing Conditions. Alternative 2D would not have significant effects on steelhead spawning conditions in the Sacramento River, Clear Creek, or the Mokelumne River. The effects of Alternative 2D on American River flows and water temperatures would be variable and would likely have a negligible net effect on steelhead spawning conditions. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of steelhead as a result of egg mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on mean monthly flows, water temperatures, and reservoir storage. Further, the SacEFT model predicts that there would be no effects to spawning and egg incubation habitat in the Sacramento River. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-95: Effects of Water Operations on Rearing Habitat for Steelhead

In general, Alternative 2D would not reduce the quantity and quality of steelhead rearing habitat relative to NAA_ELT.

Sacramento River

Juvenile steelhead rear within the Sacramento River for 1 to 2 years before migrating downstream to the ocean. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry or juveniles leading to mortality. Year-round Sacramento River flows within the reach where the majority of steelhead spawning and juvenile rearing occurs (Keswick Dam to upstream of RBDD) were evaluated (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or greater than those under NAA_ELT during most of the year, with minor exceptions, but would generally be lower under A2D_ELT during September and November (up to 24% lower at Keswick and 18% lower at Red Bluff.). The flow reductions would be mostly small and transitory and, therefore, would not have biologically meaningful effects on steelhead fry and juvenile rearing habitat.

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period at either location.

SacEFT predicts that the percentage of years with good juvenile steelhead rearing WUA conditions under A2D_ELT would be 7% lower (3% on absolute scale) than that under NAA_ELT (Table 11-2D-49). This reduction would be too small to be considered substantial. The difference in percentage of years with good (lower) juvenile stranding risk conditions between A2D_ELT and NAA_ELT would be negligible (<5%). These results indicate that Alternative 2D would have little effect on rearing habitat availability in the Sacramento River.

Based on mean monthly flows, SacEFT rearing metrics, and water temperature effects, project-related effects under Alternative 2D in the Sacramento River would not have biologically meaningful negative effects on steelhead rearing conditions.

Clear Creek

Mean flows in Clear Creek below Whiskeytown during the year-round steelhead rearing period under A2D_ELT would be similar to flows under NAA_ELT, except for lower flows (up to 14% lower) in July, September and October of critical water years and higher flows (10% higher) in August of critical years (Appendix *B, Supplemental Modeling for New Alternatives*).

Evaluation of the minimum instream flows in Clear Creek indicates that A2D_ELT would have no effect (0%) on minimum instream flows in any water year type, except for a decrease (-50 cfs or -100%) for dry water years (Table 11-2D-53).

Table 11-2D-53. Difference (cfs) and Percent Difference in Minimum Monthly Mean Flow in Clear Creek during the Year-Round Juvenile Steelhead Rearing Period

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (0%)	0 (0%)
Above Normal	0 (0%)	0 (0%)
Below Normal	-70 (-100%)	0 (NA)
Dry	-50 (-100%)	-50 (-100%)
Critical	-50 (-100%)	0 (NA)

Note: Minimum flows occurred between October and March.
NA = could not be calculated because the denominator was 0.

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. We expect that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

No water temperature modeling was conducted in Clear Creek.

These results indicate that the effects of Alternative 2D on flows would not affect juvenile steelhead rearing habitat conditions in Clear Creek.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) were reviewed to determine flow-related effects on steelhead juvenile rearing habitat (Appendix *B, Supplemental Modeling for New Alternatives*). Although there is relatively little natural steelhead production in the river, most steelhead spawning and rearing appears to occur in the low-flow channel in habitats associated with well-vegetated side channels (Cavallo et al. 2003; California Department of Water Resources unpublished data). Because these habitats are relatively uncommon they could limit natural steelhead production. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand fry and juveniles leading to mortality.

There would be no change in flows for A2D_ELT relative to NAA_ELT in the low-flow channel. Flow in the low-flow channel is projected to remain between 700 and 800 cfs except during occasional flood control releases. Mean May Oroville storage under A2D_ELT would be similar to storage under NAA_ELT for all water year types (Table 11-2D-28). Mean September Oroville storage volume would be 6% lower than storage under NAA_ELT in above normal years, similar to NAA_ELT in wet and below normal years, and up to 17% higher than storage under NAA_ELT in dry years (Table 11-2D-25).

The river channel downstream of Thermalito (high-flow channel) offers few of the habitat types upon which steelhead appear to rely in the low-flow channel. Experiments and fish observations also indicate that predation risk for juvenile steelhead is higher downstream of the Thermalito outlet (California Department of Water Resources 2004). Increased predation risk is likely a function of water temperature, whereby warm water nonnative species such as striped bass, largemouth bass, and smallmouth bass are more prevalent, and in general, have greater metabolic requirements. Thus, summer temperatures that exceed 65°F and the absence of preferred steelhead habitat currently appear to limit steelhead rearing in the river downstream of the Thermalito outlet. Comparisons of CALSIM data by month and water year type (Appendix *B, Supplemental Modeling for New Alternatives*) indicate that mean flows in the high-flow channel under A2D_ELT would generally be similar to or greater than (up to 121% greater for June of below normal water years) those under NAA_ELT in all months except July through September. During July through September, flows under A2D_ELT would be up to 49% lower than those under NAA_ELT, depending on month and water-year type.

Water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).* In the high-flow channel there would be a 6% increase in mean monthly water temperature between NAA_ELT and A2D_ELT in July of critical water years, but no difference (<5%) in any other month or water year type throughout the period at either location.

An additional analysis evaluated the percent of months exceeding a 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) (May through August) and exceeding a 56°F threshold at Gridley (October through April) for each model scenario. In the low-flow channel, the percent of months exceeding the threshold under A2D_ELT would generally be similar to or lower (up to 21% lower on an absolute scale) than the percent under NAA_ELT (Table 11-2D-29). At Gridley, the percent of months exceeding the threshold under A2D_ELT would similar to or up to 14% lower (absolute scale) than the percent under NAA_ELT (Table 11-2D-38).

Total degree-months exceeding 63°F were summed by month and water year type in the Feather River above Thermalito Afterbay (low-flow channel) during May through August, and total degree-months exceeding 56°F were summed at Gridley during October through April. In the low flow channel (Table 11-2D-30) and at Gridley (Table 11-2D-39), there would be small increases and decreases in exceedances above the thresholds, but no overall biologically meaningful effects.

Overall, these results indicate that Alternative 2D would have both increases and reductions of flow in the high-flow channel of the Feather River, depending on the month and water year type, but that there would be no net effect on juvenile steelhead rearing habitat.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to flows under NAA_ELT during December through April, with some exceptions, greater than flows under NAA_ELT during June and July, and lower (up to 27% lower) than flows under NAA_ELT during August, September and November. Depending on water year type, the mean flows under A2D_ELT during May and October would be lower than or greater than flows under NAA_ELT.

Water temperatures in the American River at the confluence with the Sacramento River and the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period at the confluence location, but there would be 5% higher water temperatures during October of wet, below normal and dry years at the Watt Avenue Bridge.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-2D-54). During May, June, and July, the percent of months exceeding the threshold under A2D_ELT would be similar to or up to 25% lower (absolute scale) than the percent under NAA_ELT. During August through October, the percent of months exceeding the threshold would mostly be similar between NAA_ELT and A2D_ELT.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-2D-55). Total degree-months (all water year types combined) exceeding the threshold would be similar between NAA_ELT and A2D_ELT or up to 51 degree-months lower under A2D_ELT in all months except August and September, in which degree-months would be 24 and 25 degree-months higher under A2D_ELT.

Table 11-2D-54. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the American River at the Watt Avenue Bridge Exceed the 65°F Threshold, May through October

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
May	20 (100%)	17 (117%)	5 (44%)	6 (100%)	1 (25%)
June	19 (29%)	19 (35%)	12 (30%)	6 (20%)	5 (24%)
July	0 (0%)	0 (0%)	7 (12%)	15 (41%)	11 (64%)
August	0 (0%)	2 (3%)	17 (21%)	46 (95%)	49 (160%)
September	9 (10%)	26 (49%)	25 (77%)	23 (146%)	19 (250%)
October	12 (250%)	9 (350%)	5 (NA)	1 (NA)	1 (NA)
NAA_ELT vs. A2D_ELT					
May	-7 (-16%)	-5 (-13%)	-7 (-32%)	0 (0%)	-2 (-29%)
June	-9 (-9%)	-6 (-8%)	-10 (-16%)	-16 (-30%)	-17 (-40%)
July	0 (0%)	-1 (-1%)	-25 (-26%)	-15 (-23%)	-19 (-39%)
August	0 (0%)	0 (0%)	0 (0%)	1 (1%)	4 (5%)
September	0 (0%)	-2 (-3%)	-1 (-2%)	1 (3%)	0 (0%)
October	-6 (-26%)	-2 (-18%)	-1 (-20%)	0 (0%)	1 (NA)

NA = could not be calculated because the denominator was 0.

Table 11-2D-55. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 65°F in the American River at the Watt Avenue Bridge, May through October

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
May	Wet	9 (150%)	0 (0%)
	Above Normal	7 (NA)	-2 (-22%)
	Below Normal	7 (233%)	-2 (-17%)
	Dry	20 (91%)	-1 (-2%)
	Critical	17 (89%)	3 (9%)
	All	60 (120%)	-2 (-2%)
June	Wet	29 (171%)	-9 (-16%)
	Above Normal	12 (50%)	-8 (-18%)
	Below Normal	12 (41%)	-16 (-28%)
	Dry	9 (13%)	-18 (-19%)
	Critical	32 (64%)	0 (0%)
	All	94 (50%)	-51 (-12%)
July	Wet	33 (42%)	-15 (-12%)
	Above Normal	9 (33%)	1 (3%)
	Below Normal	12 (35%)	-4 (-8%)
	Dry	30 (48%)	2 (2%)
	Critical	22 (27%)	-4 (-4%)
	All	106 (38%)	-20 (-5%)
August	Wet	65 (82%)	3 (2%)
	Above Normal	20 (49%)	3 (5%)
	Below Normal	28 (50%)	1 (1%)
	Dry	64 (94%)	16 (14%)
	Critical	39 (49%)	1 (1%)
	All	216 (67%)	24 (5%)
September	Wet	33 (138%)	10 (21%)
	Above Normal	14 (88%)	4 (15%)
	Below Normal	28 (100%)	9 (19%)
	Dry	32 (76%)	2 (3%)
	Critical	25 (51%)	0 (0%)
	All	132 (83%)	25 (9%)
October	Wet	5 (500%)	0 (0%)
	Above Normal	5 (NA)	0 (0%)
	Below Normal	2 (NA)	0 (0%)
	Dry	10 (NA)	1 (11%)
	Critical	10 (200%)	1 (7%)
	All	31 (517%)	1 (3%)

NA = could not be calculated because the denominator was 0.

These results indicate that effects of Alternative 2D on flow and water temperatures would not reduce juvenile steelhead rearing habitat in the American River.

Stanislaus River

Mean flows in the Stanislaus River under A2D_ELT would not differ from those under NAA_ELT throughout the year (Appendix *B, Supplemental Modeling for New Alternatives*).

Mean water temperatures throughout the Stanislaus River would be similar under NAA_ELT and A2D_ELT throughout the year-round period (Appendix 11D, Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis).

San Joaquin River

Mean flows in the San Joaquin River under A2D_ELT would not differ significantly from those under NAA_ELT throughout the year (Appendix *B, Supplemental Modeling for New Alternatives)*.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Mean flows in the Mokelumne River under Alternative 2D would not differ from those under NAA_ELT throughout the year (Appendix *B, Supplemental Modeling for New Alternatives)*.

Water temperature modeling was not conducted in the Mokelumne River.

NEPA Effects: Collectively, these modeling results indicate that the effect of Alternative 2D is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of fry and juvenile mortality. Effects of Alternative 2D on flows would be small and transitory in the Sacramento River and Clear Creek, and effects in the Feather River and the American River would be more variable, but in general are not expected to affect steelhead rearing habitat. Effects of Alternative 2D on water temperatures in the Sacramento, Feather, American and Stanislaus Rivers would be small. Overall, Alternative 2D is not expected to have biologically meaningful negative effects on steelhead rearing conditions in the ELT.

The effect of Alternative 2D in the LLT on steelhead rearing conditions would be adverse. Instream flows in the Sacramento and Feather Rivers during summer and fall months would decline from ELT to LLT such that flows would be substantially reduced under Alternative 2D relative to the NEPA baseline in the LLT. This effect is described in detail under Impact AQUA-95 for Alternative 2A.

CEQA Conclusion: In general, the modeling results presented below suggest that Alternative 2D could reduce the quantity and quality of rearing habitat for steelhead relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 2D would not affect the quantity and quality of rearing habitat for steelhead relative to the CEQA conclusion.

Sacramento River

Comparisons of CALSIM outputs of year-round flow for the Sacramento River between Keswick and upstream of Red Bluff, averaged by month and water year type, were used to evaluate effects of A2D_ELT compared to Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows for A2D_ELT at Keswick would generally be similar to or up to 16% greater than those for Existing Conditions. However, during September, flows would be up to 29%

higher in wet and above normal years and up to 24% lower in below normal, dry and critical years, and during August, October and November, flows would be up to 18% lower. The results for mean flows at Red Bluff would be similar to those for flows at Keswick, except that the differences between A2D_ELT and Existing Conditions would be smaller. The most substantial effects on juvenile rearing habitats would occur from the flow reductions in dry and critical water years of August through November. Based on the overall small size of the August through November flow reductions, and the beneficial increases in mean flow for other months and water year types, the flow reductions are not expected to have biologically meaningful negative effects on juvenile steelhead rearing conditions in the Sacramento River.

Water temperatures in the Sacramento River at Keswick and Bend Bridge were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). At both locations, mean water temperatures under A2D_ELT would generally be similar to those under Existing Conditions, except at Keswick during August and September of critical water years, in which there would be 6% and 5% higher temperatures, respectively, under Alternative 2D, and at Red Bluff during August of critical years, in which there would be 5% higher temperatures.

SacEFT predicts that there would be no difference (<5%) in the percentage of years with good rearing availability, measured as weighted usable area, under A2D_ELT relative to Existing Conditions (Table 11-2D-49). SacEFT predicts that there would be an 18% reduction in the number of years with good (lower) juvenile stranding risk under A2D_ELT relative Existing Conditions.

Overall, these results indicate that Alternative 2D would not have biologically meaningful effects on juvenile rearing success in the Sacramento River. Alternative 2D would cause small reductions in mean monthly flows during four months of the year and SacEFT predicts that stranding risk would be increased by 18%. Water temperatures would be higher in 2 months during critical water years.

Clear Creek

Mean flows in Clear Creek during the year-round rearing period under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions, except for 40% greater flow in January of wet years and 19% lower flow in September of critical years (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures were not modeled in Clear Creek.

Juvenile rearing habitat is assumed to increase in Clear Creek as instream flows increase, and therefore the use of the lowest monthly instream flow as an index of habitat constraints for juvenile rearing was selected for use in this analysis. Results of the analysis of minimum monthly instream flows affecting juvenile rearing habitat are shown in Table 11-2D-53. Results indicate that Alternative 2D would have no effect on juvenile rearing habitat, based on minimum instream flows, compared to Existing Conditions in wet and above normal water years. Minimum flows would be 100% lower in below normal years (reduction from 70 cfs to 0 cfs), and 100% lower in dry and critical water years (reduction from 50 cfs to 0 cfs).

Denton (1986) developed flow recommendations for steelhead in Clear Creek using IFIM (Figure 11-1A-4). The current Clear Creek management regime uses flows slightly lower than those recommended by Denton. Results from a new IFIM study on Clear Creek are currently being analyzed. Depending on results of this study the flow regime could be adjusted in the future. We expect that the modeled flows will be suitable for the existing steelhead populations in Clear Creek. No change in effect on steelhead in Clear Creek is anticipated.

Overall in Clear Creek, Alternative 2D would result in no biologically meaningful changes in mean monthly flow that would affect juvenile rearing habitats.

Feather River

Year-round flows in the Feather River above Thermalito Afterbay (low-flow channel) under A2D_ELT would be the same as flows under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows in the Feather River below Thermalito Afterbay (high-flow channel) under A2D_ELT would generally be similar to or up to 157% greater than flows under Existing Conditions during April through June, and would generally be lower than flows under Existing Conditions (up to 50% lower) during January through March, July, November and December. Mean flows would also be lower under AD2_ELT in August and September of below normal and dry years. During September of wet, above normal, and critical water years and August of wet years, flows under A2D_ELT would be up to 196% higher than flows under Existing Conditions.

Mean May Oroville storage volume under A2D_ELT would be similar to that under Existing Conditions in wet and above normal water years, and would be 5% to 13% lower in below normal, dry, and critical water years (Table 11-2D-28).

As reported in Impact AQUA-58 for spring-run Chinook salmon, mean September Oroville storage volume would be 19% to 28% lower under A2D_ELT relative to Existing Conditions in wet, above normal and below normal water years, and would be similar relative to Existing Conditions in dry and critical years (Table 11-2D-25).

Mean water temperatures in the Feather River in both above (low-flow channel) and at Thermalito Afterbay (high-flow channel) were examined during the year-round steelhead juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis.* There would be no differences (<5%) in mean water temperatures for any month or water year type in the low-flow channel. In the high-flow channel, mean water temperatures under AD2_ELT would be similar to those under Existing Conditions except for 6% higher temperature in July of critical water years and 5% higher temperature in August of dry years.

An additional analysis evaluated the percent of months exceeding a 63°F temperature threshold in the Feather River above Thermalito Afterbay (low-flow channel) (May through August) and exceeding a 56°F threshold at Gridley (October through April). In the low-flow channel, the percent of months exceeding the threshold under A2D_ELT would generally be similar to the percent under Existing Conditions during May, and similar or up to 25% (absolute scale) higher than the percent under Existing Conditions during June through August (Table 11-2D-29). At Gridley, the percent of months exceeding the threshold under A2D_ELT would be similar to the percent under Existing Conditions during December through February, but similar to or up to 17% greater (absolute scale) than the percent under Existing Conditions in the remaining four months (Table 11-2D-38).

Total degree-months exceeding 63°F were summed by month and water year type in the Feather River above Thermalito Afterbay (low-flow channel) during May through August and total degree-months exceeding 56°F were summed at Gridley during October through April. In the low-flow channel, total degree-months (all water years types combined) under A2D_ELT would be similar to those under Existing Conditions during May and 26% to 58% higher during June through August (Table 11-2D-30). At Gridley, total degree-months under A2D_ELT would be similar to those under Existing Conditions during December through and February and 35% to 425% greater than those under Existing Conditions in the remaining four months of the period (Table 11-2D-39).

Overall, these results indicate that Alternative 2D could affect juvenile steelhead rearing conditions in the Feather River, although very few steelhead rear in this reach of the Feather River (Cavallo et al. 2003; California Department of Water Resources unpublished data). Fish rearing in the high-low channel under Alternative 2D would experience lower flows during multiple months and fish rearing in both the low- and high-flow channels would experience increased exceedances of water temperature thresholds.

American River

Flows in the American River at the confluence with the Sacramento River were examined for the year-round steelhead rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or up to 16% greater than to flows under Existing Conditions during February and March and up to 52% lower than flows under Existing Conditions during May, August through November, and January. Mean flows during March, June, July, and December would be lower (6% to 36% lower) under A2D_ELT than under Existing Conditions for some water year types and would be greater (8% to 23% greater) for other water year types.

Water temperatures in the American River at the confluence with the Sacramento River and at the Watt Avenue Bridge were examined during the year-round steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be little difference in water temperatures (<5%) at either location, except during October of wet, above normal, below normal and dry years, for which there would 5% to 7% temperature increases at the Watt Avenue Bridge and 5% to 6% increases at the confluence location. There would also be a 5% increase in mean water temperature in July of dry years at the confluence location.

The percent of months exceeding a 65°F temperature threshold in the American River at the Watt Avenue Bridge was evaluated during May through October (Table 11-2D-54). In comparison to Existing Conditions, the temperature thresholds would be exceeded in a greater percentage of months under A2D_ELT in all the threshold categories and months by up to 49% on the absolute scale, with minor exceptions during July and August.

Total degree-months exceeding 65°F were summed by month and water year type at the Watt Avenue Bridge during May through October (Table 11-2D-55). Total degree-months (all water year types combined) would be higher in all months, by 38% to 517%, under A2D_ELT compared to Existing Conditions.

Overall, these results indicate that there would be substantial effects of Alternative 2D on juvenile steelhead rearing habitat in the American River during much of the year.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River were examined for the year-round steelhead rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows would generally be lower under A2D_ELT relative to Existing Conditions during January through July (up to 29% for February of critical water years) and would generally be similar during August through December, with minor exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the year-round juvenile steelhead rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperatures between A2D_ELT and Existing Conditions throughout the year.

San Joaquin River

Flows in the San Joaquin River at Vernalis were examined for the year-round steelhead rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be 6% to 23% lower than flows under Existing Conditions during February through September and similar to or greater than flows under Existing Conditions during October through January, with minor exceptions.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta were examined for the year-round steelhead rearing period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be 5% to 34% lower than flows under Existing Conditions during April through September, up to 28% greater than flows under Existing Conditions during December, and similar to flows under Existing Conditions during October, November, and January through March, with minor exceptions.

Water temperature modeling was not conducted in the Mokelumne River.

Summary of CEQA Conclusion

Under Alternative 2D, there would be flow reductions in the Feather, American, Stanislaus, San Joaquin, and Mokelumne rivers and water temperature increases in the Sacramento, Feather and American rivers that would lead to reductions in quantity and quality of fry and juvenile steelhead rearing habitat relative to Existing Conditions. Contrary to the NEPA conclusion set forth above, these results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of steelhead as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on flows would be small and infrequent in the Sacramento, Stanislaus, San Joaquin and Mokelumne rivers and Clear Creek. Effects in the Feather and American rivers would be variable, but net effects on rearing habitat are expected to be minor. Water temperatures in the Sacramento, Feather, American, and Stanislaus rivers would not be affected by Alternative 2D. These results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the effects of Alternative 2D on steelhead juvenile rearing habitat conditions would be less than significant in the ELT and no mitigation is necessary.

Upstream flows, reservoir operations, and water temperatures in the Sacramento and Feather rivers, and their effects on for rearing juvenile steelhead, would decline from ELT to LLT to a level that is considered significant. For more information, see the evaluation of Impact AQUA-95 under Alternative 2A.

Impact AQUA-96: Effects of Water Operations on Migration Conditions for Steelhead

In general, Alternative 2D would degrade steelhead migration conditions relative to NAA_ELT.

Upstream of the Delta

Sacramento River

Juveniles

Flows in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period. Mean flows under A2D_ELT would be 6% to 18% lower than flows under NAA_ELT during November, 5% to 12% higher than flows under NAA_ELT during May, and generally similar to flows under NAA_ELT during the remaining six months of the juvenile migration period (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Adults

Flows in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be 5% to 18% lower than flows under NAA_ELT during September and November, depending on water year type, and similar to flows under NAA_ELT in the remaining five months of the period.

Water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period

Kelts

Flows in the Sacramento River upstream of Red Bluff were evaluated during the March and April steelhead kelt (post-spawning adult) downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean Flows during these two months would not differ between NAA_ELT and A2D_ELT.

Water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period

Overall in the Sacramento River, these results indicate that Alternative 2D would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration in the Sacramento River.

Clear Creek

Water temperatures were not modeled in Clear Creek.

Juveniles

Mean flows in Clear Creek during the October through May juvenile steelhead migration period under A2D_ELT would be similar to flows under NAA_ELT except in critical years during October (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

Adults

Mean flows in Clear Creek during the September through March adult steelhead migration period under A2D_ELT would be similar to flows under NAA_ELT except in critical years during September (10% lower) and October (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

Kelt

Mean flows in Clear Creek during the March through April steelhead kelt downstream migration period under A2D_ELT would be similar to flows under NAA_ELT except in below normal years in March (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

Overall in Clear Creek, these results indicate that effects of Alternative 2D on flows would not affect juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Flows in the Feather River at the confluence with the Sacramento River were examined during the October through May juvenile steelhead migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or up to 21% greater than flows under NAA_ELT in all months and water years of the migration period, with minor exceptions.

Water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Adults

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through March adult steelhead upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean Flows under A2D_ELT would be 8% to 32% lower than flows under NAA_ELT during September, 6% to 16% higher than flows under NAA_ELT during October, 21% higher than flows under NAA_ELT in December of critical water years, and generally similar to flows under NAA_ELT in the remaining water year types and months of the period.

Water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period

Kelt

Flows in the Feather River at the confluence with the Sacramento River were examined during the March and April steelhead kelt downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or up to 6% greater than those under NAA_ELT in both months of the kelt downstream migration period.

Water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and A2D_ELT in either month of the period.

Overall in the Feather River, Alternative 2D would not have biologically meaningful effects on juvenile, adult, or kelt steelhead migration.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period. Mean flows under A2D_ELT during October would be 6% to 8% lower than flows under NAA_ELT in wet, above normal and dry years and 19% and 27% higher than flows under NAA_ELT in below normal and critical years. Mean flows under A2D_ELT during November would be 10% to 15% lower than flows under NAA_ELT in wet, above normal and below normal years and would be similar to flows under NAA_ELT in dry and critical years. In the remaining six months of the period, flows would generally be similar between A2D_ELT and NAA_ELT, except that flow in April of critical years would be 22% greater under A2D_ELT and flow in May of critical years 24% lower (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Adults

Flows in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT during September and November would be 10% to 27% lower than flows under NAA_ELT depending on water year type. Mean flows under A2D_ELT during October would be 6% to 8% lower than flows under NAA_ELT in wet, above normal and dry years, and would be 19% to 27% higher than flows under NAA_ELT in below normal and critical years. Flows would generally be similar in the remaining four months of the period.

Water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Kelt

Flows in the American River at the confluence with the Sacramento River were evaluated for the March and April kelt migration period. Mean flows under A2D_ELT would generally be similar to flows under NAA_ELT except for 22% higher flow in April of critical years (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in either month of the period.

Overall in the American River, these results indicate that Alternative 2D would not have a biologically meaningful effect on juvenile, adult, or kelt steelhead migration.

Stanislaus River

Flows in the Stanislaus River at the confluence with the San Joaquin River for A2D_ELT are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of Alternative 2D on juvenile, adult, or kelt migration in the Stanislaus River.

Further, mean monthly water temperatures in the Stanislaus River at the confluence with the San Joaquin River for A2D_ELT are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of Alternative 2D on juvenile, adult, or kelt migration in the Stanislaus River.

San Joaquin River

Flows in the San Joaquin River at Vernalis for Alternative 2D are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of Alternative 2D on juvenile, adult, or kelt migration in the San Joaquin River.

Water temperature modeling was not conducted in the San Joaquin River.

Mokelumne River

Flows in the Mokelumne River at the Delta for Alternative 2D are not different from flows under NAA_ELT for any month. Therefore, there would be no effect of Alternative 2D on juvenile, adult, or kelt migration in the Mokelumne River.

Water temperature modeling was not conducted in the Mokelumne River.

Through-Delta

Sacramento River

Juveniles

Flows in the Sacramento River below the north Delta intakes during the juvenile steelhead migration period (October through May) under Alternative 2D would be appreciably lower than NAA_ELT, with all-year average flows ranging from around 15% less in December to 28% less in November. Juvenile steelhead and juvenile winter-run Chinook salmon migrate downstream during similar months and would be exposed to similar conditions. As discussed above in Impact AQUA-42, the five north Delta intakes structures of Alternative 2D would increase potential predation loss of migrating juvenile salmonids and would displace 13 acres/2.3 linear miles of aquatic habitat. However, juvenile steelhead would be less vulnerable than winter-run Chinook salmon to predation associated with the intake facilities because of their greater size and strong swimming ability.

Adults

As assessed by DSM2 fingerprinting analysis, the average percentage of Sacramento River–origin water at Collinsville was always slightly lower under Alternative 2D than for NAA_ELT during the September-March steelhead upstream migration period. Attraction flow, as estimated by the percentage of Sacramento River water at Collinsville, under Alternative 2D was not different in October and declined 2% to 9% during other months (Table 11-2D-17). The reductions in percentage are small in comparison with the magnitude of change in dilution reported to cause a significant change in migration by Fretwell (1989) and, therefore, are not expected to affect steelhead upstream migration. While the proportion of Sacramento River flows would be reduced under Alternative 2D, the Sacramento River would still represent a substantial 60% to 73% of Delta flows and olfactory cues would still be strong for upstream migrating adults. However, uncertainty remains with regard to adult salmon behavioral response to anticipated changes in lower Sacramento River flow percentages. For further discussion of the topic see the analysis for Alternative 1A.

San Joaquin River

Juveniles

San Joaquin River flows at Vernalis would not differ between Alternative 2D and NAA_ELT, as there are no flow changes associated with any of the Alternatives. Alternative 2D would have no effect on steelhead migration success through the Delta from the perspective of changing inflows into the Delta. However, juvenile steelhead migration success would be aided by the inclusion in the water conveyance facilities of an operable barrier at the head of Old River, which would keep flow and fish in the mainstem San Joaquin River.

Adults

The percentage of water at Collinsville that originated from the San Joaquin River during the fall-run migration period (September to December) is small, typically 0.2% to less than 1% under NAA_ELT (Table 11-2D-17). Alternative 2D operations conditions would incrementally increase olfactory cues associated with the San Joaquin River, which would benefit adult steelhead migrating to the San Joaquin River.

NEPA Effects: Overall, the results indicate that the effect of Alternative 2D is adverse due to the cumulative effects associated with five north Delta intake facilities, including mortality related to near-field effects (e.g. impingement and predation) and far-field effects (reduced survival due to reduced flows downstream of the intakes) associated with the five NDD intakes.

Upstream of the Delta, these modeling results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Effects of Alternative 2D in all locations analyzed would consist primarily of small and variable effects on mean monthly flow and no effects on water temperatures for the juvenile, adult, and kelt steelhead migration periods. Adult attraction flows under Alternative 2D would be lower than those under NAA_ELT, but adult attraction flows are expected to be adequate to provide olfactory cues for migrating adults.

Near-field effects of Alternative 2D on steelhead related to impingement and predation associated with five new intakes could result in substantial effects on juvenile migrating steelhead, although there is high uncertainty regarding the potential effects. As noted for Alternative 4A, Environmental Commitment 15 would be implemented with the intent of providing localized and temporary reductions in predation pressure at the NDD. Additionally, several pre-construction studies to better understand how to minimize losses associated with the new intake structures will be implemented as part of the final NDD screen design effort. As with Alternative 4A, Alternative 2D also includes biologically-based triggers to inform real-time operations of the NDD, intended to provide adequate migration conditions for juvenile steelhead. However, at this time, due to the absence of comparable facilities anywhere in the lower Sacramento River/Delta, the degree of mortality expected from near-field effects at the NDD remains highly uncertain.

The adverse effect to juvenile steelhead migrating through the Delta via the Sacramento River would be reduced through the bypass flow criteria and real-time operations outlined above, as well as inclusion within Alternative 2D of specific important environmental commitments. These include *Environmental Commitment 6 Channel Margin Enhancement* to offset loss of channel margin habitat to the NDD footprint and far-field (water level) effects, *Environmental Commitment 15 Localized Reduction of Predatory Fishes* to limit predation potential at the NDD and *Environmental Commitment 16 Nonphysical Fish Barriers* to reduce entry of steelhead juveniles into the low-survival interior Delta.

Overall, primarily as a result of unacceptable levels of uncertainty regarding the cumulative impacts of near-field and far-field effects associated with the presence and operation of the five intakes on steelhead, this effect is adverse. While implementation of the environmental commitments noted above and mitigation measures listed below would address these impacts, these are not anticipated to reduce the impacts to a level considered not adverse.

CEQA Conclusion: Under Alternative 2D water operations, there would be a significant negative effect on the quantity and quality of steelhead migration habitat relative to the CEQA baseline.

Upstream of the Delta

Sacramento River

Juveniles

Flows in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period. Mean flows under A2D_ELT would be generally similar to or slightly higher than flows under Existing Conditions, except for 5% to 15% lower flows, depending on water year type, in October and November (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in all months of the period.

Adults

Flows in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT during September would be 20% to 27% higher in wet and above normal years than flows under Existing Conditions and 6% to 22% lower in the remaining three water year types. Mean flows under A2D_ELT during October and November would be 5% to 15% lower than flows under Existing Conditions, depending on water year type. Flows would be generally similar in the remaining four months of the migration period.

Water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento*

River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT throughout the migration period.

Kelts

Flows in the Sacramento River upstream of Red Bluff were evaluated during the March and April steelhead kelt downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to those under Existing Conditions during both months of the period.

Water temperatures in the Sacramento River upstream of Red Bluff were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and A2D_ELT in either month of the period.

Overall in the Sacramento River, Alternative 2D would not affect flow or water temperature conditions for juvenile, adult, or kelt steelhead migration.

Clear Creek

Water temperatures were not modeled in Clear Creek.

Juveniles

Mean flows in Clear Creek during the October through May juvenile steelhead migration period under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions except for 40% and 13% greater flows in January and February, respectively, of wet years (Appendix *B, Supplemental Modeling for New Alternatives*).

Adults

Mean flows in Clear Creek during the September through March adult steelhead migration period under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions, except for 19% lower flow in September of critical water years and 40% and 13% greater flows in January and February, respectively, of wet years (Appendix *B, Supplemental Modeling for New Alternatives*).

Kelt

Flows in Clear Creek during the March through April steelhead kelt downstream migration period under A2D_ELT would generally be similar to or 7% greater than flows under Existing Conditions (Appendix *B, Supplemental Modeling for New Alternatives*).

Overall in Clear Creek, Alternative 2D would not affect flow conditions for juvenile, adult, or kelt steelhead migration.

Feather River

Juveniles

Flows in the Feather River at the confluence with the Sacramento River were examined during the October through May juvenile steelhead migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Differences in mean flow in the Feather River between A2D_ELT and Existing Conditions during the juvenile steelhead migration period would be highly variable, with many months expected to have both increases and decreases in flow, depending on the water year type. Mean flows would be higher under A2D_ELT by 6% to 19% in October and January through May, depending on the water year type, and would be lower by 5% to 17% in November through March and May, depending on the water year type.

Water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT throughout the migration period.

Adults

Flows in the Feather River at the confluence with the Sacramento River were examined during the September through March adult steelhead upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Differences in mean flow in the Feather River between A2D_ELT and Existing Conditions during the adult steelhead migration period would be even more variable than those for the juvenile migration period. In particular, mean flow under A2D_ELT during September would be 21% and 28% lower than flows under Existing Conditions in below normal and dry years and would be 14%, 77% and 102% higher in critical, above normal and wet years. For the other months of the migration period, mean flows would be higher under A2D_ELT by 6% to 19% in October and January through March, depending on the water year type, and would be lower by 5% to 17% in November through March, depending on the water year type.

Water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT throughout the migration period.

Kelts

Flows in the Feather River at the confluence with the Sacramento River were examined during the March and April steelhead kelt downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or slightly greater than flows under Existing Conditions, except for 16% lower flow in March of below normal water years.

Water temperatures in the Feather River at the confluence with the Sacramento River were evaluated during the March through April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and Alternative 2D in either month of the kelt migration period.

Overall, these results indicate that migration conditions for steelhead in the Feather River would not be affected by Alternative 2D. Changes in flow from Existing Conditions to Alternative 2D would be highly variable, but no net negative effect is expected. Water temperatures would be similar between Existing Conditions and Alternative 2D.

American River

Juveniles

Flows in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to or up to 16% greater than flows under Existing Conditions during February through April. Flows under A2D_ELT would generally be lower, by up to 23% lower (November of dry years), than flows under Existing Conditions during October through January and May, with some exceptions.

Water temperatures in the American River at the confluence with the Sacramento River were evaluated during the October through May juvenile steelhead migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under A2D_ELT would be 5% to 6% higher than those under Existing Conditions during October of all water year types except critical year types, and would be similar (<5% difference) in the remaining months of the migration period.

Adults

Flows in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows during September under A2D_ELT would range from 18% lower to 47% lower, depending on water year type. Flows would generally be lower, by up to 23% lower (November of dry years), than flows under Existing Conditions during October through January, with exceptions for some water year types, and flows under A2D_ELT would generally be similar to or up to 16% greater than flows under Existing Conditions during February and March.

Water temperatures in the American River at the confluence with the Sacramento River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures under A2D_ELT would be 5% to 6% higher than those under Existing Conditions during October of all water year types except critical year types, and would be similar (<5% difference) in the remaining months of the migration period.

Kelts

Flows in the American River at the confluence with the Sacramento River were evaluated for the March and April kelt migration period. Mean flows under A2D_ELT would generally be similar to or slightly greater than flows under Existing Conditions, except for 11% lower flow in March of critical years and 7% lower flow in April of above normal years (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the American River at the confluence with the Sacramento River were evaluated during the March and April kelt migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in either month of the kelt migration period.

Overall in the American River, the effect of Alternative 2D on flows would include frequent moderate reductions in flows that would affect juvenile and adult migration conditions, particularly in drier water years, but would generally not affect kelt migration.

Stanislaus River

Juveniles

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the October through May steelhead juvenile downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to flows under Existing Conditions during October through December, and would generally be lower than flows under Existing Conditions during January through May (up to 29% lower in February of critical water years), with some exceptions.

Mean water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the October through May steelhead juvenile downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT throughout the migration period.

Adults

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be similar to flows under Existing Conditions during September through December, and would generally be lower than flows under Existing Conditions during January through March (up to 29% lower in February of critical water years), with some exceptions.

Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the September through March steelhead adult upstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT throughout the migration period.

Kelts

Flows in the Stanislaus River at the confluence with the San Joaquin River were evaluated for the March and April steelhead kelt downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean monthly flows under A2D_ELT would be up to 23% and 12% lower than flows under Existing Conditions during March and April, respectively.

Mean Water temperatures in the Stanislaus River at the confluence with the San Joaquin River were evaluated during the March and April steelhead kelt downstream migration period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in either month of the kelt migration period.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Juveniles

Flows in the San Joaquin River at Vernalis were evaluated for the October through May steelhead juvenile downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or slightly greater than flows under Existing Conditions during October through January, and up to 12% lower than flows under Existing Conditions during February through May.

Adults

Flows in the San Joaquin River at Vernalis were evaluated for the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or slightly greater than flows under Existing Conditions during October through January, and up to 12% lower than flows under Existing Conditions during September, February, and March.

Kelt

Flows in the San Joaquin River at Vernalis were evaluated for the March and April steelhead kelt downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be up to 12% and 8% lower than flows under Existing Conditions during March and April, respectively.

Mokelumne River

Water temperature modeling was not conducted in the Mokelumne River.

Juveniles

Flows in the Mokelumne River at Delta were evaluated for the October through May steelhead juvenile downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or up to 28% greater than (December of above normal years) flows under Existing Conditions during October through March and would be up to 11% lower than flows under Existing Conditions during April and May.

Adults

Flows in the Mokelumne River at Delta were evaluated for the September through March steelhead adult upstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or up to 28% greater (December of above normal years) than flows under Existing Conditions during October through March and would be up to 22% lower than flows under Existing Conditions during September.

Kelt

Flows in the Mokelumne River at Delta were evaluated for the March and April steelhead kelt downstream migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to flows under Existing Conditions during March and up to 7% lower than flows under Existing Conditions during April.

Through-Delta

Sacramento River

Juveniles

Juvenile steelhead migrating down the Sacramento River (October through May) would generally experience appreciably lower flows below the north Delta intakes compared to Existing Conditions. Analyses completed for juvenile Chinook salmon (e.g., Impact AQUA-42 for winter-run Chinook salmon) indicate that at these magnitudes of flow reductions predicted for Alternative 2D would reduce survival relative to Existing Conditions. The five intake structures would attract predators and would displace about 13 acres/2.3 linear miles of aquatic habitat.

Adults

Based on the proportion of Sacramento River water at Collinsville, olfactory cues would be similar (10% or less difference) to Existing Conditions for nearly all months of the year. The proportion of Sacramento River water at Collinsville in the main steelhead upstream migration period would range from no different in September to 10% less in March (Table 11-2D-17).

San Joaquin River

Juveniles

The only changes on San Joaquin River flows at Vernalis would result from the modeled effects of climate change on inflows to the river downstream of Friant Dam and reduced tributary inflows. As noted above in the NEPA Effects conclusion, Alternative 2D would have no effect on steelhead migration success through the Delta from the perspective of changing inflows into the Delta. However, juvenile steelhead migration success would be aided by the inclusion in the water conveyance facilities of an operable barrier at the head of Old River, which would keep flow and fish in the mainstem San Joaquin River.

Adults

The percentage of water at Collinsville that originated from the San Joaquin River during the fall-run migration period (September to December) is small, typically 0.2% to less than 3% under Existing Conditions. Alternative 2D operations conditions would incrementally increase olfactory cues associated with the San Joaquin River, which has the potential to benefit adult steelhead migrating to the San Joaquin River based on analyses conducted for adult Chinook salmon from the San Joaquin River (Marston et al. 2012).

Summary of CEQA Conclusion

Overall, Alternative 2D would significantly affect the migration conditions for steelhead, relative to the Existing Conditions, primarily as a result of effects in the Delta.

In upstream areas, there would be reductions in flow in the American, Stanislaus, and San Joaquin Rivers that would lead to biologically meaningful reductions in migration conditions, thereby reducing survival relative to Existing Conditions. Alternative 2D would not affect migration conditions for steelhead in the Sacramento, Feather, and Mokelumne Rivers or Clear Creek. Reduced migration conditions would delay or eliminate successful migration necessary to complete the steelhead life cycle. In the Sacramento and Feather rivers there would also be increases in flow that would potentially offset the effects of the flow reductions. However, taking account of the flow effects of all the rivers, the net effect would be reduced flow, resulting in reduced juvenile and adult migration conditions. Water temperatures under Alternative 2D would generally be similar to those under Existing Conditions in all rivers examined, with minor exceptions.

However, this interpretation of the biological modeling for upstream areas is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible upstream effects on mean flow and water temperatures for the juvenile, adult, and kelt migration periods.

Through-Delta survival of emigrating juvenile steelhead has the potential to be appreciably reduced, compared to Existing Conditions. There would be little negative effect of Alternative 2D on adult olfactory cues in the Delta. Implementation of *Environmental Commitment 6 Channel Margin Enhancement*, *Environmental Commitment 15 Localized Reduction of Predatory Fishes*, and *Environmental Commitment 16 Nonphysical Barriers* (all of which are summarized further in Section 4.1.3.3 of this RDEIR/SDEIS) would address the through-Delta impacts, but are not anticipated to reduce them to a level considered less than significant because of the presence of five intakes. As a result of these changes in migration conditions, this impact is significant and unavoidable.

In addition to the environmental commitments above, the mitigation measures identified below would provide an adaptive management process that would be conducted as a part of the Adaptive Management and Monitoring Program, for assessing impacts and developing appropriate minimization measures. However, this would not necessarily result in a less than significant determination, so it is concluded that the impact is significant and unavoidable.

Mitigation Measure AQUA-96a: Following Initial Operations of Water Conveyance Facilities, Conduct Additional Evaluation and Modeling of Impacts to Steelhead to Determine Feasibility of Mitigation to Reduce Impacts to Migration Conditions

Although analysis conducted above as part of the EIR/EIS determined that Alternative 2D would have significant and unavoidable adverse effects on migration habitat, this conclusion was based on the best available scientific information at the time and may prove to have been over- or understated. Upon the commencement of operations of the proposed water conveyance facilities and continuing through the life of the permit, the project proponents will monitor effects on migration habitat in order to determine whether such effects would be as extensive as concluded at the time of preparation of this document and to determine any potentially feasible means of reducing the severity of such effects. This mitigation measure requires a series of actions to accomplish these purposes, consistent with the operational framework for Alternative 2D.

The development and implementation of any mitigation actions shall be focused on those incremental effects attributable to implementation of Alternative 2D operations only. Development of mitigation actions for the incremental impact on migration habitat attributable to climate change/sea level rise are not required because these changed conditions would occur with or without implementation of Alternative 2D.

Mitigation Measure AQUA-96b: Conduct Additional Evaluation and Modeling of Impacts on Steelhead Migration Conditions Following Initial Operations of Water Conveyance Facilities

Following commencement of initial operations of the proposed water conveyance facilities and continuing through the life of the permit, the project proponents will conduct additional evaluations to define the extent to which modified operations could reduce impacts to migration habitat under Alternative 2D. The analysis required under this measure may be conducted as a part of the Adaptive Management and Monitoring Program.

Mitigation Measure AQUA-96c: Consult with NMFS and CDFW to Identify and Implement Potentially Feasible Means to Minimize Effects on Steelhead Migration Conditions Consistent with Water Conveyance Facility Operations

In order to determine the feasibility of reducing the effects of Water Conveyance Facilities operations on steelhead habitat, the BDCP proponents will consult with NMFS and the Department of Fish and Wildlife to identify and implement any feasible operational means to minimize effects on migration habitat. Any such action will be developed in conjunction with the ongoing monitoring and evaluation of habitat conditions required by Mitigation Measure AQUA-96a.

If feasible means are identified to reduce impacts on migration habitat consistent with the overall operational framework of Alternative 2D without causing new significant adverse impacts on other covered species, such means shall be implemented. If sufficient operational flexibility to reduce effects on steelhead habitat is not feasible under Alternative 2D operations, achieving further impact reduction pursuant to this mitigation measure would not be feasible under this Alternative, and the impact on steelhead would remain significant and unavoidable.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-97: Effects of Construction of Restoration Measures on Steelhead

Impact AQUA-98: Effects of Contaminants Associated with Restoration Measures on Steelhead

Impact AQUA-99: Effects of Restored Habitat Conditions on Steelhead

Impact AQUA-100: Effects of Methylmercury Management on Steelhead (Environmental Commitment 12)

Impact AQUA-103: Effects of Localized Reduction of Predatory Fish on Steelhead (Environmental Commitment 15)

Impact AQUA-104: Effects of Nonphysical Fish Barriers on Steelhead (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on steelhead for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Sacramento Splittail

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-109: Effects of Construction of Water Conveyance Facilities on Sacramento Splittail

The potential effects of construction of the water conveyance facilities on Sacramento splittail would be similar to those described for Alternative 4A (Impact AQUA-109) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to Sacramento splittail.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-109, the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-109, the impact of the construction of water conveyance facilities on Sacramento splittail would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-110: Effects of Maintenance of Water Conveyance Facilities on Sacramento Splittail

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-110, the effect would not be adverse for Sacramento splittail.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-110 for Sacramento splittail, the impact of the maintenance of water conveyance facilities on Sacramento splittail would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-111: Effects of Water Operations on Entrainment of Sacramento Splittail

Water Exports from SWP/CVP South Delta Facilities

As with Alternative 4A, the analysis of juvenile splittail entrainment for Alternative 2D used the per capita method, which evaluates how changes in exports would affect entrainment potential independent of other factors (*BDCP Effects Analysis, Appendix 5B – Entrainment; Section 5.B.5.4.5 hereby incorporated by reference*). The per capita method was used because Yolo Bypass inundation is not included in the method, thus allowing an appropriate comparison between NAA_ELT (for which Yolo Bypass improvements would occur, but were not modeled) and A2D_ELT (for which Yolo Bypass improvements would also occur as part of a program separate from Alternative 2D, and which was included in the modeling). The per capita rate of juvenile splittail entrainment under A2D_ELT, which is an index of entrainment risk of an individual splittail and is directly related to the amount of water exported, averaged across all years would be reduced 51% (Table 11-2D-58) compared to NAA_ELT. The decrease in per capita entrainment of juvenile splittail is due to reductions in south Delta water exports during the main May–June entrainment period. For adult splittail, the reductions under A2D_ELT relative to NAA_ELT averaged 68% across all years (Table 11-2D-59), again because of reduced exports.

Table 11-2D-58. Juvenile Sacramento Splittail Entrainment Indexa (per Capita Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 2D

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-1,306,268 (-65%)	-1,197,705 (-63%)
Above Normal	-68,756 (-52%)	-57,301 (-47%)
Below Normal	-1,881 (-19%)	-1,294 (-14%)
Dry	-639 (-32%)	-365 (-21%)
Critical	-594 (-45%)	-439 (-37%)
All Years	-276,477 (-51%)	-221,621 (-45%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data, estimated from delta inflow.

Table 11-2D-59. Adult Sacramento Splittail Entrainment Index[a] (Salvage Density Method) at the SWP and CVP Salvage Facilities and Differences between Model Scenarios for Alternative 2D

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-3,614 (-91%)	-3,809 (-92%)
Above Normal	-4,133 (-86%)	-4,097 (-86%)
Below Normal	-1,710 (-51%)	-1,702 (-50%)
Dry	-684 (-28%)	-620 (-26%)
Critical	-578 (-17%)	-478 (-15%)
All Years	-2,357 (-68%)	-2,399 (-68%)

Shading indicates entrainment increased 10% or more.

[a] Estimated annual number of fish lost, based on normalized data. Average (December–March).

Water Exports from SWP/CVP North Delta Intake Facilities

The impact from entrainment of splittail to the proposed SWP/CVP north Delta intakes is similar to Impact AQUA-111 under Alternative 2D. Splittail larvae would be vulnerable to entrainment to these intakes, although little is known about their densities around this vicinity. Entrainment and impingement monitoring would be implemented to determine the extent to which splittail larvae are present.

Predation Associated with Entrainment

As described for Alternative 2D (Impact AQUA-111), Sacramento splittail predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Splittail entrainment at the south Delta would be reduced under Alternative 2D by 45% (juveniles) and 68% (adults) compared to NAA_ELT; predation losses would be expected to decrease at a similar proportion.

The impact from potential predation associated with the north Delta intake structures (5 intakes) would be the same as described for Alternative 2D (Impact AQUA-111 These losses would be offset by the reduction in entrainment and predation loss at the SWP/CVP south Delta intakes, habitat restoration under Environmental Commitment 6, and reduction in potential predation under Environmental Commitment 15. Further, as described for Alternative 1A and as noted for Alternative 4A, the fishery agencies concluded that predation was not a factor currently limiting splittail abundance.

NEPA Effects: In conclusion, the effect from entrainment and predation loss under Alternative 2D would not be adverse, because while predation loss of splittail would be potentially increased at the north Delta facilities, it would be offset by substantial reductions in per capita entrainment and associated predation at the south Delta facilities compared to the NAA_ELT actions, as well as other conservation measures (Environmental Commitment 6, Environmental Commitment 15, and potentially Environmental Commitment 16).

CEQA Conclusion: Operational activities associated with reduced south Delta water exports would result in an overall decrease in the proportion of splittail population entrained for all water year types. Although entrainment of smaller life stages at the north Delta intakes is likely to occur during lower flow years when floodplain inundation is less, the bulk of reproduction occurs when floodplains are inundated, which would occur more often under NAA_ELT and Alternative 2D because of Yolo Bypass improvements; splittail emerging from the Yolo Bypass at its downstream terminus in the Cache Slough subregion would not be susceptible to north Delta intake entrainment. Under Scenario A2D_ELT, estimated juvenile entrainment and hence pre-screen predation losses would be 45% lower and adult entrainment and pre-screen predation losses would be 68% lower than Existing Conditions. The impact and conclusion for predation associated with entrainment would be the same as described above.

In conclusion, the impact of Alternative 2D from entrainment and predation loss would be less than significant because of improvements in overall proportional entrainment, and no mitigation is required.

Impact AQUA-112: Effects of Water Operations on Spawning and Egg Incubation Habitat for Sacramento Splittail

In general, Alternative 2D would have little to no effect on splittail spawning habitat relative to the NAA_ELT because improvements to the Yolo Bypass would occur under the NAA_ELT and therefore would not differentiate Alternative 2D from NAA_ELT. There would be negligible effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River, and negligible effects on water temperatures in the Feather River, relative to NAA_ELT. There would be beneficial effects on spawning conditions in channel margin and side-channel habitats from increases in flow during the spawning period in both the Sacramento River and the Feather River. There would also be a beneficial effect from reductions in the occurrence of critically high water temperatures in the Feather River in wetter water year types.

Sacramento splittail spawn in floodplains and channel margins and in side-channel habitat upstream of the Delta, primarily in the Sacramento River and Feather River. Floodplain spawning overwhelmingly dominates production in wet years. During low-flow years when floodplains are not inundated, spawning in side channels and channel margins is much more critical.

Floodplain Habitat

Effects of Alternative 2D on floodplain spawning habitat were evaluated for Yolo Bypass, using the same approach detailed for Alternative 4A. There would be little to no difference in floodplain habitat availability or acreage between NAA_ELT and Alternative 2D because Yolo Bypass improvements would be present in both (Table 11-2D-60; Table 11-2D-61).

Table 11-2D-60. Differences in Frequencies of Inundation Events (for 82-Year Simulations) of Different Durations on the Yolo Bypass under Different Scenarios and Water Year Types, February through June, from 15 2-D and Daily CALSIM II Modeling Runs

Number of Days of Continuous Inundation	Change in Number of Inundation Events for Each Scenario	
	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
30–49 Days		
Wet	-5	Little to no difference[a]
Above Normal	0	Little to no difference[a]
Below Normal	4	Little to no difference[a]
Dry	1	Little to no difference[a]
Critical	1	Little to no difference[a]
50–69 Days		
Wet	-5	Little to no difference[a]
Above Normal	0	Little to no difference[a]
Below Normal	1	Little to no difference[a]
Dry	0	Little to no difference[a]
Critical	0	Little to no difference[a]
≥70 Days		
Wet	8	Little to no difference[a]
Above Normal	2	Little to no difference[a]
Below Normal	1	Little to no difference[a]
Dry	0	Little to no difference[a]
Critical	0	Little to no difference[a]

[a] The inclusion of Yolo Bypass improvements was not modeled for NAA_ELT, but would be expected to result in minimal differences in the number of inundation events between NAA_ELT and A2D_ELT.

Table 11-2D-61. Increase in Splittail Weighted Habitat Area (HUs[c] and Percent) in Yolo Bypass from Existing Biological Conditions to Alternative 2D by Water Year Type from 15 2-D and Daily CALSIM II Modeling Runs

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	1,113 (72%)	Little to no difference[b]
Above Normal	721 (63%)	Little to no difference[b]
Below Normal	340 (259%)	Little to no difference[b]
Dry	9 (NA[a])	Little to no difference[b]
Critical	5 (NA[a])	Little to no difference[b]

[a] NA = percent differences could not be computed because no splittail weighted habitat occurred in the bypass for NAA_ELT and EXISTING CONDITIONS in those years (dividing by 0).

[b] The inclusion of Yolo Bypass improvements was not modeled for NAA_ELT, but would be expected to result in minimal differences in the weighted habitat area between NAA_ELT and H3_ELT.

[c] HUs = Habitat Units. HUs were computed as the product of habitat acreage and a Habitat Suitability Index (based on water depth) that ranges from 0 to 1, where maximum suitability = 1. Therefore, HUs are always less than or equal to habitat acreage.

As noted for Alternative 4A, a potential effect of Yolo Bypass improvements is changes in inundation of the Sutter Bypass as a result of increased flow diversion at the modified Fremont Weir. Because modification of the Fremont Weir would occur under Alternative 2D and the NAA_ELT, there would be little to no difference in inundated acreage in the lower Sutter Bypass between A2D_ELT and NAA_ELT. Therefore, Alternative 2D would not affect splittail spawning and rearing habitat in the Sutter Bypass relative to NAA_ELT.

Channel Margin and Side-Channel Habitat

In addition to spawning on floodplains, splittail spawning and larval and juvenile rearing also occur in channel margin and side-channel habitat upstream of the Delta. These habitats are likely to be especially important during dry years, when flows are too low to inundate the floodplains (Sommer et al. 2007). Side-channel habitats are affected by changes in flow because greater flows cause more flooding, thereby increasing availability of such habitat, and because rapid reductions in flow dewater the habitats, potentially stranding splittail eggs and rearing larvae. Effects of Alternative 2D on flow in side-channel habitat are expected to be most important to the splittail population in years with low flows because in years of high flows, when most production comes from floodplain habitats, the upstream side-channel habitats contribute relatively little production. However, as noted by Sommer (1997), splittail have high fecundity and so can respond rapidly to improvements in environmental conditions (e.g., floodplain inundation), so that very high recruitment occurs in years with floodplain inundation.

Effects on channel margin and side-channel habitat were evaluated by comparing flow conditions for the Sacramento River at Wilkins Slough and the Feather River at the confluence with the Sacramento River for the time-frame February through June. These are the most important months for splittail spawning and larval rearing (Sommer pers. comm.), and juveniles likely emigrate from the side-channel habitats during May and June if conditions become unfavorable.

Differences between model scenarios for monthly average flows during February through June by water-year type were determined for the Sacramento River at Wilkins Slough and for the Feather River at the confluence.

Flows under A2D_ELT relative to Existing Conditions in the Sacramento River at Wilkins Slough were compared for the February through June spawning period (Appendix *B, Supplemental Modeling for New Alternatives*). Modeling results indicate that A2D_ELT would have negligible effects (<5%) on mean flows during February through April. During May and June, flows under A2D_ELT would be up to 16% greater than flows under NAA_ELT. Due to the mostly small size of the flow increases during May and June, they are not expected to have a biologically meaningful effect on splittail spawning conditions. Modeling results also show that Sacramento splittail spawning temperature tolerances would not be exceeded in the Sacramento River under Alternative 2D.

For the Feather River at the confluence, mean flows during February through April under A2D_ELT would generally be similar to or greater than flows under NAA_ELT. During May, and especially June, mean flows under A2D_ELT would be greater than flows under NAA_ELT (up to 88% in June of below normal years), which, due to the size and frequency of the increases, would benefit splittail. The flow increases would substantially increase the amount of channel margin and side channel habitat available for splittail spawning especially during the latter part of the spawning period.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively were used to investigate the potential effects of Alternative 2D on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected for evaluating the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between NAA_ELT and A2D_ELT in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F temperature range regardless of water year type (Table 11-2D-62). In the Feather River, there would be no differences between NAA_ELT and A2D_ELT in the frequency of temperatures below 45°F. There would be a 7% reduction (absolute scale) in the frequency of exceeding the 75°F threshold for above normal water years, but due to the low magnitude of this reduction in frequency, it is not expected to have a biologically meaningful effect on splittail.

These results indicate that A2D_ELT would have no negative effects on splittail spawning conditions in channel margin and side-channel habitats resulting from changes in flow and water temperatures. Effects of A2D_ELT on mean monthly flow would consist of negligible effects or increases in flow (increases up to 16% in the Sacramento River and to 88% in the Feather River) for some months and water year types in the spawning period that would have beneficial effects on spawning habitat conditions. There would be negligible or beneficial project-related effects on exceedance of critical water temperatures in the Sacramento River.

Table 11-2D-62. Difference (Percent Difference) in Percent of Days or Months[a] during February to June in Which Temperature Would Be below 45°F or above 75°F in the Sacramento River at Hamilton City and Feather River at the Confluence with the Sacramento River[b]

	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Sacramento River at Hamilton City		
Temperatures below 45°F		
Wet	-2.8 (-61%)	0 (-1%)
Above Normal	-2.8 (-60%)	0 (0%)
Below Normal	-2.7 (-52%)	-0.1 (-6%)
Dry	-1.3 (-45%)	0 (0%)
Critical	-1.1 (-51%)	0 (0%)
All	-2.2 (-55%)	0 (-2%)
Temperatures above 75°F		
Wet	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Days were used in the Sacramento River and months were used in the Feather River.

[b] Based on the modeling period of 1922 to 2003.

Stranding Potential

As indicated above, rapid reductions in flow can dewater channel margin and side-channel habitats, potentially stranding splittail eggs and rearing larvae. Yolo Bypass improvements would occur under the NAA_ELT and therefore would exist under Alternative 2D, so there would be little to no difference in stranding potential between Alternative 2D and NAA_ELT and these effects would not be adverse.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. The effects of Alternative 2D on splittail spawning and rearing habitat would consist of negligible effects and beneficial effects in some months on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough (generally <5% change in flow) and the Feather River (increases in mean monthly flow up to 119%), and negligible effects on water temperatures in the Sacramento and Feather Rivers (generally <5% change). There would be little difference in inundation potential for the Yolo Bypass because Yolo Bypass improvements (e.g., modification of Fremont Weir) would occur regardless of Alternative 2D and therefore would be part of Alternative 2D and NAA_ELT.

CEQA Conclusion: In general, Alternative 2D would have no effect on splittail spawning habitat relative to Existing Conditions. There would be negligible flow- and temperature-related effects on channel margin and side-channel habitats in the Sacramento River at Wilkins Slough and the Feather River. Yolo Bypass improvements (e.g., modification of Fremont Weir) would occur irrespective of Alternative 2D, but are not included in Existing Conditions, so there would be generally beneficial effects to splittail coinciding with the implementation of Alternative 2D (but not as a result of Alternative 2D).

Floodplain Habitat

Comparisons of the frequencies of inundation for A2D_ELT and Existing Conditions show relatively small increases in drier years under A2D_ELT (Table 11-2D-60). In wet years, there are reductions under A2D_ELT in the frequencies of the shorter inundation periods and an increase in the frequency of the longest inundation periods (70 days or more) because a number of what would be shorter inundation periods under Existing Conditions merge to produce longer inundation periods under A2D_ELT. Coincident with implementation of Alternative 2D, there would also be increased availability of suitable spawning habitat compared to Existing Conditions (Table 11-2D-61), with increases of between 5 and 1,113 Habitat Units (HUs; see footnote in Table 11-2D-61) of suitable spawning habitat depending on water year type. Increased HUs for wet, above normal, and below normal water years are predicted to be 72%, 63%, and 259%, respectively, for A2D_ELT. Comparisons for dry and critical water years indicate increases of 9 and 5 HUs of suitable spawning habitat, respectively, compared to 0 HUs for Existing Conditions. These differences would provide beneficial effects on splittail habitat through increasing spawning habitats, but are not as a result of Alternative 2D; as noted above, these improvements would occur under Alternative 2D and NAA_ELT, but not Existing Conditions.

Channel Margin and Side-Channel Habitat

Flows were compared between A2D_ELT and Existing Conditions for the Sacramento River at Wilkins Slough (Appendix *B, Supplemental Modeling for New Alternatives*) during February through June. Mean flows under A2D _ELT would generally not differ (<5%) from those under Existing Conditions during February through April, and would be up to 17% great during May and June. Due to the small size and frequency of these flow increases, they are not expected to have a biologically meaningful effect on splittail spawning conditions.

Results for the Feather River at the confluence with the Sacramento River (Appendix *B, Supplemental Modeling for New Alternatives*) show variable effects of A2D _ELT depending on month and water year type. Results for all months except April include negligible effects (<5%), small to large increases in mean monthly flow (to 82%), and small to moderate reductions (up to 16%), depending on water year type. During April, flows would generally be similar between A2D _ELT and Existing Conditions. Based on a prevalence of negligible (<5%) or beneficial effects on flow (increases to 82%), and isolated reductions that would be of small magnitude, these results indicate that effects of Alternative 2D on flow would not have biologically meaningful negative effects on splittail spawning conditions in channel margin and side-channel habitats in the Feather River.

Simulated daily and monthly water temperatures in Sacramento River at Hamilton City and Feather River at the confluence with the Sacramento River, respectively, were used to investigate the potential effects of A2D_ELT on the suitability of water temperatures for splittail spawning and egg incubation. A range of 45°F to 75°F was selected as the suitable range for splittail spawning and egg incubation.

There would be no biologically meaningful difference (>5% absolute scale) between Existing Conditions and A2D _ELT in the frequency of water temperatures in the Sacramento River being within the suitable 45°F to 75°F temperature range regardless of water year type (Table 11-2D-62). In the Feather River, there would be no differences between Existing Conditions and A2D _ELT in frequency of temperatures below 45°F, but there would be a 7% increase in the frequency of exceeding the 75°F threshold under A2D_ELT relative to Existing Conditions in dry water years. Due to the low magnitude of this increase in frequency, it is not expected to have a biologically meaningful effect on splittail.

Stranding Potential

As noted for other alternatives, and due to a lack of quantitative tools and historical data to evaluate possible stranding effects, the following provides a narrative summary of potential effects in relation to stranding potential. The Yolo Bypass is exceptionally well-drained because of grading for agriculture, which likely helps limit stranding mortality of splittail. Moreover, water stage decreases on the bypass are relatively gradual (Sommer et al. 2001). Stranding of Sacramento splittail in perennial ponds on the Yolo Bypass does not appear to be a problem under Existing Conditions (Feyrer et al. 2004). Yolo Bypass improvements would be designed, in part, to further reduce the risk of stranding by allowing water to inundate certain areas of the bypass to maximize biological benefits, while keeping water away from other areas to reduce stranding in isolated ponds. Actions to increase the frequency of Yolo Bypass inundation that are separate from Alternative 2D but that would coincide with Alternative 2D would increase the frequency of potential stranding events in relation to Existing Conditions. For splittail, an increase in inundation frequency would also increase the production of Sacramento splittail in the bypass. While total stranding losses may be greater under Alternative 2D than under Existing Conditions (although not as a result of Alternative 2D), the total number of splittail would be expected to be greater under Alternative 2D (again, not as a result of Alternative 2D, but coincident with it).

In the Yolo Bypass, Sommer et al. (2005) found these potential losses are offset by the improvement in rearing conditions. Henning et al. (2006) also noted the potential for stranding risk as wetlands desiccate and oxygen concentrations decline, but the seasonal timing of use by juveniles may decrease these risks. Sommer et al. (2005) addressed the question of stranding and concluded the potential improvements in habitat capacity outweighed the potential stranding problems that may exist in some years. Overall, these effects are less than significant.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact is not significant because it would not substantially reduce suitable spawning habitat or substantially reduce the number of fish as a result of egg mortality. There would be negligible effects of the alternative on flow and water temperatures in channel margin habitats and side channels. Floodplain inundation and stranding potential would greater than the CEQA baseline, but not as a result of Alternative 2D, and the net result would be expected to be beneficial. No mitigation is necessary.

Impact AQUA-113: Effects of Water Operations on Rearing Habitat for Sacramento Splittail

Because both Alternative 2D and NAA_ELT are assumed to include Yolo Bypass improvements including Fremont Weir modification, there would be little to no difference in the quantity and quality of rearing habitat in the Yolo Bypass. There would be no effect on rearing conditions in channel margin and side-channel habitats due to negligible changes in mean monthly flow and water temperatures during most of the rearing period in the Sacramento River and the Feather River.

Floodplains are important rearing habitats for juvenile splittail during periods of high flows when areas like the Yolo Bypass are inundated. During low flows when floodplains are not inundated, splittail rear in side-channel and channel margin habitat. Therefore, the previous impact discussion applies to rearing as well as spawning habitat for splittail for A2D_ELT. The small and infrequent changes to flow under A2D_ELT described above would also not substantially affect splittail rearing habitat conditions.

NEPA Effects: Based on the analyses above, the effect of Alternative 2D on splittail rearing habitat is not adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of mortality.

CEQA Conclusion: In general, there would be no effect of Alternative 2D on splittail rearing habitat relative to Existing Conditions.

As described above, floodplains are important rearing habitats for juvenile splittail during periods of high flows when areas like the Yolo Bypass are inundated. Alternative 2D would not result in changes in floodplain habitat, although there would be a greater extent of floodplain habitat available coincident with implementation of Alternative 2D because of Yolo Bypass improvements (e.g., Fremont Weir modification) that would occur regardless of Alternative 2D but that are not current present under Existing Conditions. During low flows when floodplains are not inundated, splittail rear in side-channel and channel margin habitat. Therefore, the previous impact discussion applies to rearing as well as spawning habitat for splittail for Alternative 2D.

Summary of CEQA Conclusion

Based on the analyses above, the impact of Alternative 2D on splittail rearing habitat is not significant because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of mortality. There would be negligible effects of the alternative on flow and water temperatures in channel margin habitats and side channels. Floodplain inundation and stranding potential would be greater than the CEQA baseline but not as a result of Alternative 2D. No mitigation is necessary.

Impact AQUA-114: Effects of Water Operations on Migration Conditions for Sacramento Splittail

Upstream of the Delta

In general, Alternative 2D would not affect migration conditions for juvenile or adult splittail in the Sacramento River or the Feather River relative to the NAA_ELT based on negligible or beneficial effects on mean monthly flow during the migration period and negligible effects on exposure to critical water temperatures in the Feather River. Adults migrate upstream primarily in December through March and juvenile migrate primarily in April through July (Moyle et al. 2004).

The effects of Alternative 2D on splittail migration conditions would be the same as described for channel margin and side-channel habitats in the Sacramento River and Feather River for Impact AQUA-112 above. One additional month (July) is included here that was not considered in Impact AQUA-112. During July, mean flows under Alternative 2D would be up to 48% lower depending on water year type. Because this reduction would occur at the end of the migration period, particularly after multiple months of beneficially higher flows relative to NAA_ELT, the reduction is not likely to affect juvenile migration conditions. Therefore, overall, there would be no effect of Alternative 2D on migration conditions in either river.

Through-Delta

Alternative 2D is expected to generally reduce OMR reverse flows during the period of juvenile splittail migration through the Delta (May-July). OMR flows are improved in June and July compared to baseline conditions across all water years. While May flows are decreased slightly in all water year types except wet, OMR flows averaged across all water years are still positive and flowing towards the San Francisco estuary, and do not average more negative than -1,400 cfs in any given water year type. For juvenile splittail migrating down the Sacramento River past the north Delta intakes, migration flows downstream of the north Delta intakes under Alternative 2D generally would be somewhat reduced relative to NAA_ELT, which could reduce splittail survival in the more riverine reaches (as seen for juvenile Chinook salmon; Perry 2010). The greatest proportion of juvenile splittail would be expected to be emigrating from the Yolo Bypass in years when it is inundated (a more frequent occurrence under NAA_ELT and Alternative 2D because of Fremont Weir modifications) and therefore these juveniles would enter the Delta in its further downstream, tidal reaches in the Cache Slough subregion, where riverine flow-related migration influences would be very small relative to tidal flow influences.

NEPA Effects: The effect of Alternative 2D is not adverse because it would not substantially reduce or degrade migration habitat or substantially reduce the number of fish as a result of mortality.

CEQA Conclusion:

Upstream of the Delta

In general, effects of Alternative 2D would have no effect on splittail migration conditions relative to Existing Conditions due to a lack of effects to flows and water temperatures in the Sacramento River and the Feather River during the splittail migration period.

Effects of Alternative 2D on splittail migration conditions are the same as described for channel margin and side-channel habitats in Impact AQUA-112.

Through-Delta

As described above, average OMR flows under Alternative 2D are expected to generally improve during the juvenile splittail migration through the Delta, especially during the summer months. In dry and below-normal water years in May, the reverse OMR flows would be increased under Alternative 2D compared to Existing Conditions; however overall monthly average OMR flows would be similar in May compared to Existing Conditions. In addition, the periods of increased reverse flows in May would remain within the NMFS and USFWS BiOp requirements. As described above in the discussion of the NEPA Effects, juvenile splittail migrating down the Sacramento River past the north Delta intakes would experience reduced migration flows downstream of the north Delta intakes under Alternative 2D, which could reduce splittail survival in the more riverine reaches (as seen for juvenile Chinook salmon; Perry 2010). However, the greatest proportion of juvenile splittail would be expected to be emigrating from the Yolo Bypass in years when it is inundated (a more frequent occurrence under NAA_ELT and Alternative 2D because of Fremont Weir modifications) and therefore these juveniles would enter the Delta in its further downstream, tidal reaches in the Cache Slough subregion, where riverine flow-related migration influences would be very small relative to tidal flow influences. Thus the changes are expected to have a less-than-significant impact.

Summary of CEQA Conclusion

The impact is less than significant because it would not substantially reduce suitable migration habitat or substantially reduce the number of fish as a result of mortality and no mitigation is necessary. There would be negligible effects of the alternative on flow and water temperatures in channel margin habitats and side channels. Floodplain inundation and stranding potential would be greater than the CEQA baseline but not as a result of Alternative 2D. No mitigation is necessary.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-115: Effects of Construction of Restoration Measures on Sacramento Splittail

Impact AQUA-116: Effects of Contaminants Associated with Restoration Measures on Sacramento Splittail

Impact AQUA-117: Effects of Restored Habitat Conditions on Sacramento Splittail

Impact AQUA-118: Effects of Methylmercury Management on Sacramento Splittail (Environmental Commitment 12)

Impact AQUA-121: Effects of Localized Reduction of Predatory Fish on Sacramento Splittail (Environmental Commitment 15)

Impact AQUA-122: Effects of Nonphysical Fish Barriers on Sacramento Splittail (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on Sacramento splittail for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Green Sturgeon

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-127: Effects of Construction of Water Conveyance Facilities on Green Sturgeon

The potential effects of construction of the water conveyance facilities on green sturgeon or their designated critical habitat would be similar to those described for Alternative 4A (Impact AQUA-127) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to green sturgeon.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-127, the effect would not be adverse for green sturgeon or designated critical habitat.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-127, the impact of the construction of water conveyance facilities on green sturgeon and critical habitat would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-128: Effects of Maintenance of Water Conveyance Facilities on Green Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-128, the effect would not be adverse for green sturgeon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-128 for green sturgeon, the impact of the maintenance of water conveyance facilities on green sturgeon or critical habitat would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-129: Effects of Water Operations on Entrainment of Green Sturgeon

Water Exports from SWP/CVP South Delta Facilities

Alternative 2D is expected to substantially reduce overall entrainment of juvenile green sturgeon at the south Delta export facilities. Average annual loss of juvenile green sturgeon, as estimated by the salvage density method, would be approximately 37 fish for the combined SWP and CVP south Delta facilities (Table 11-2D-63; A2D_ELT). Losses would be slightly greater in wetter water year types (34 fish) than in drier years (29 fish). Losses would decrease 51–55% for Alternative 2D as compared to Existing Conditions and NAA_ELT. Entrainment reductions would be greater in wetter years (69–71% decrease) compared to Existing Conditions and NAA_ELT.

Water Exports from SWP/CVP North Delta Intake Facilities

The overall potential entrainment effects of operating the new north Delta intakes under Alternative 2D would be the same as described for Impact AQUA-129 under Alternative 2A. The intakes would have screens to avoid or reduce entrainment; there would be no adverse effect.

Predation Associated with Entrainment

Juvenile green sturgeon predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Sturgeon develop bony scutes at a young age which reduces their predation vulnerability. Based on their early development of scutes and rapid growth rates, the number of juvenile green sturgeon lost to predation at the south Delta facilities would change negligibly between Alternative 2D and NAA_ELT. The impact and conclusion for predation risk associated with the north Delta intakes would be the same as described for Alternative 2A (Impact AQUA-3 for green sturgeon).

NEPA Effects: The effect on entrainment and predation losses under Alternative 2D would not be adverse, because green sturgeon grow rapidly and develop bony scutes early in their development which reduces their predation risk; therefore the main effect would be reduced entrainment under Alternative 2D because of reduced south Delta exports.

CEQA Conclusion: As described above, annual entrainment losses of juvenile green sturgeon across all years would decrease 55% under Alternative 2D (A2D_ELT) (37 fish) relative to Existing Conditions (82 fish) (Table 11-2D-63). Impacts of water operations on green sturgeon would be less than significant due to an overall reduction in entrainment and no mitigation would be required.

Table 11-2D-63. Juvenile Green Sturgeon Annual Entrainment Index[a] at the SWP and CVP Salvage Facilities for Alternative 2D

	Entrainment Index			Absolute Difference (Percent Difference)	
Water Year[b]	EXISTING CONDITIONS	NAA_ ELT	A2D_ ELT	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet and Above Normal	116	111	34	-82 (-71%)	-77 (-69%)
Below Normal, Dry, and Critical	50	46	29	-21 (-42%)	-17 (-37%)
All Years	82	76	37	-45 (-55%)	-39 (-51%)

[a] Estimated annual number of fish lost.
[b] Sacramento Valley water year-types.

The impact of predation associated with entrainment would be the same as described immediately above because the rapid growth and development of bony scutes reduces the predation risk for juvenile green sturgeon. The impact would be less than significant.

Impact AQUA-130: Effects of Water Operations on Spawning and Egg Incubation Habitat for Green Sturgeon

In general, Alternative 2D would not affect spawning and egg incubation habitat for green sturgeon relative to NAA_ELT.

Sacramento River

Flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon (Appendix *B, Supplemental Modeling for New Alternatives*). Lower flows can reduce the instream area available for spawning and egg incubation. Mean flows under A2D_ELT would generally be similar to or slightly greater than flows under NAA_ELT during March through July at both locations

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

The number of days on which temperature exceeded 63°F by >0.5°F to >5°F in 0.5°F increments was determined for each month (May through September) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above the 63°F threshold were further assigned a "level of concern" as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-64. There would be no substantial differences between NAA_ELT and Alternative 2D in the exceedances for any of the levels of concern.

Table 11-2D-64. Differences between Baseline and Alternative 2D Scenarios in the Number of Years in Which Water Temperature Exceedances above 63°F Are within Each Level of Concern, Sacramento River at Bend Bridge, May through September

Level of Concern	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Red	4 (100%)	1 (13%)
Orange	0 (0%)	0 (0%)
Yellow	1 (50%)	-1 (-33%)
None	-5 (-7%)	0 (0%)

Total degree-days exceeding 63°F at Bend Bridge were summed by month and water year type during May through September (Table 11-2D-65). Combining all water years, total degree-days would be nearly the same under Alternative 2D relative to NAA_ELT during May through July, and would be 3% to 2% lower during August and September.

Table 11-2D-65. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 63°F in the Sacramento River at Bend Bridge, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
May	Wet	17 (131%)	0 (0%)
	Above Normal	0 (NA)	-2 (-100%)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	2 (NA)	1 (100%)
	All	19 (146%)	-1 (-3%)
June	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
July	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	159 (1988%)	0 (0%)
	All	159 (1988%)	0 (0%)
August	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	29 (NA)	0 (0%)
	Critical	635 (316%)	-31 (-4%)
	All	664 (330%)	-31 (-3%)
September	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	4 (NA)	3 (300%)
	Dry	138 (445%)	8 (5%)
	Critical	506 (190%)	-35 (-4%)
	All	648 (217%)	-24 (-2%)

NA = could not be calculated because the denominator was 0.

Feather River

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June green sturgeon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would be similar to or up to 121% greater (June of below normal years) than flows under NAA_ELT, with minor exceptions. Differences at the confluence with the Sacramento River would generally be similar to but smaller than those at Thermalito. These results indicate that flows in the Feather River would increase during the green sturgeon spawning and egg incubation period under Alternative 2D independent of climate change.

Mean water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

The percent of months exceeding the 64°F temperature threshold in the Feather River at Gridley was evaluated during May through September (Table 11-2D-66). For this impact, only the months of May and June were examined because green sturgeon spawning and egg incubation does not generally extend beyond June in the Feather River. Subsequent months are examined under Impact AQUA-131. In both May and June, the percent of months exceeding the threshold under Alternative 2D would be similar to or lower (up to 33% lower on an absolute scale) than the percent under NAA_ELT.

Table 11-2D-66. Differences between Baseline and Alternative 2D Scenarios in Percent of Months during the 82-Year CALSIM Modeling Period during Which Water Temperatures in the Feather River at Gridley Exceed the 64°F Threshold, May through September

	Degrees Above Threshold				
Month	>1.0	>2.0	>3.0	>4.0	>5.0
EXISTING CONDITIONS vs. A2D_ELT					
May	11 (35%)	7 (40%)	2 (25%)	7 (200%)	2 (100%)
June	-2 (-3%)	-11 (-13%)	-14 (-17%)	-10 (-15%)	-9 (-18%)
July	0 (0%)	0 (0%)	0 (0%)	5 (5%)	15 (21%)
August	0 (0%)	0 (0%)	5 (5%)	10 (12%)	14 (22%)
September	-16 (-23%)	-14 (-25%)	-2 (-9%)	6 (83%)	2 (100%)
NAA_ELT vs. A2D_ELT					
May	-17 (-29%)	-10 (-28%)	-10 (-44%)	-1 (-10%)	-1 (-20%)
June	-6 (-6%)	-19 (-19%)	-26 (-28%)	-32 (-37%)	-33 (-46%)
July	0 (0%)	0 (0%)	0 (0%)	-5 (-5%)	-1 (-1%)
August	0 (0%)	0 (0%)	-4 (-4%)	-5 (-5%)	-6 (-8%)
September	2 (5%)	1 (3%)	-2 (-9%)	-6 (-31%)	-4 (-43%)

Total degree-months exceeding 64°F were summed by month and water year type at Gridley during May through September (Table 11-2D-67). Only May and June were examined for spawning and egg incubation habitat here. Subsequent months are examined under Impact AQUA-131. Total degree-months exceeding the threshold under Alternative 2D would be 9% to 26% lower than those under NAA_ELT during May and June.

Table 11-2D-67. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Months (°F-Months) by Month and Water Year Type for Water Temperature Exceedances above 64°F in the Feather River at Gridley, May through September

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
May	Wet	11 (183%)	0 (0%)
	Above Normal	2 (18%)	-6 (-32%)
	Below Normal	10 (125%)	-3 (-14%)
	Dry	17 (121%)	0 (0%)
	Critical	12 (71%)	-1 (-3%)
	All	51 (91%)	-11 (-9%)

	All	3 (1%)	-122 (-26%)
July	Wet	21 (12%)	16 (9%)
	Above Normal	5 (9%)	0 (0%)
	Below Normal	22 (32%)	7 (8%)
	Dry	51 (59%)	25 (22%)
	Critical	56 (71%)	30 (29%)
	All	155 (34%)	78 (15%)
August	Wet	11 (6%)	14 (8%)
	Above Normal	18 (40%)	10 (19%)
	Below Normal	27 (39%)	9 (10%)
	Dry	70 (103%)	27 (24%)
	Critical	21 (25%)	-5 (-5%)
	All	146 (33%)	54 (10%)
September	Wet	-27 (-69%)	6 (100%)
	Above Normal	-4 (-25%)	11 (1100%)
	Below Normal	9 (32%)	-4 (-10%)
	Dry	14 (50%)	3 (8%)
	Critical	17 (85%)	-1 (-3%)
	All	9 (7%)	15 (12%)

San Joaquin River

Flows in the San Joaquin River at Vernalis under Alternative 2D during March through June would not be different from flows under NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives)*.

No water temperatures modeling was conducted in the San Joaquin River.

NEPA Effects: Collectively, these modeling results indicate that there would not be adverse effects on green sturgeon spawning and egg incubation habitat because the amount of suitable habitat would not be substantially reduced. Flow and temperature conditions would generally be similar between Alternative 2D and the NEPA baseline in the Sacramento River and San Joaquin River and would be beneficial under Alternative 2D relative the NEPA baseline in the Feather River. Alternative 2D would reduce the frequency of exceedances above NMFS temperature thresholds in the Sacramento and Feather Rivers.

CEQA Conclusion: Collectively, the results of the Impact AQUA-130 CEQA analysis show that the difference between the CEQA baseline and Alternative 2D could be significant because, when compared to the CEQA baseline, the alternative would substantially reduce the quantity and quality of spawning and egg incubation habitat for green sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 2D would not affect the quantity and quality of spawning and egg incubation habitat for green sturgeon relative to the CEQA baseline.

Sacramento River

Mean flows were examined in the Sacramento River between Keswick and upstream of Red Bluff during the March to July spawning and egg incubation period for green sturgeon (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D_ELT would generally be slightly lower than those under Existing Conditions during March and April, and would generally be similar to or slightly greater than those under Existing Conditions during June and July. Mean flows under A2D_ELT during May would be up to 13% lower (wet years) and 10% higher (below normal years) than flows under Existing Conditions. These modeling results indicate that there would be no effect on flows in the Sacramento River under A2D_ELT relative to Existing Conditions.

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the March through July green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between Existing Conditions and Alternative 2D in any month or water year type throughout the period.

There would be 4 more years with a "red" NMFS level of concern in the Sacramento River at Bend Bridge under A2D_ELT than under Existing Conditions.

Total degree-days exceeding the 63°F NMFS threshold in the Sacramento River at Bend Bridge under A2D_ELT (for all water years combined) would be up to 1,988% higher (in July) than under Existing Conditions (Table 11-2D-65). Such a large increase on the relative scale is a mathematical artifact resulting from the small value of the divisor (i.e., degree-days for Existing Conditions). On an absolute scale, the largest increase would be 664 degree days (in August), which corresponds to an average daily temperature increase over the 82-year period of about 0.3 degrees per day. This is a small change.

Feather River

Flows were examined in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River during the February through June green sturgeon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). At Thermalito, mean flows under A2D_ELT would generally be lower than those under Existing Conditions during February and March (up to 40% lower in February of below normal years), with some exceptions, and would generally be similar to or greater than those under Existing Conditions during April through June (up to 157% greater in June of below normal years). At the confluence with the Sacramento River, flows under A2D_ELT would generally be similar to those under Existing Conditions in all months and water year types of the period, except June, in which flows under A2D_ELT would be up to 82% higher. These modeling results indicate that there would generally be lower flows in the Feather River under A2D_ELT relative to Existing Conditions early in the spawning and egg incubation period and greater flows later in the period.

Mean monthly water temperatures in the Feather River at Gridley were examined during the February through June green sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would generally be no differences (<5%) in mean monthly water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

Water temperature-related effects of A2D_ELT on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were evaluated by determining the percent of months during May through September exceeding the 64°F temperature threshold in the Feather River at Gridley (Table 11-2D-66). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. During the period, the percent of months exceeding the threshold under Alternative 2D relative to Existing Conditions would be similar to or higher (up to 11% on an absolute scale) during May and similar to or lower (up to 14% lower on an absolute scale) during June. These results indicate a small to moderate beneficial effect for May and a small to moderate negative effect for June.

Water temperature-related effects of Alternative 2D on green sturgeon spawning, egg incubation, and rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-2D-67). Effects on spawning and egg incubation are evaluated here for May and June; effects on rearing are evaluated under Impact AQUA-131. Combining water years, total degree-months exceeding the threshold during May and June under A2D_ELT would be 1% to 91% greater relative to Existing Conditions. Within months, total degree-months under A2D_ELT would be consistently higher relative to Existing Conditions during May and would be higher for some water year types and lower for others during June. These results indicate that there would be a moderate negative effect of Alternative 2D on green sturgeon spawning and egg incubation temperature-related conditions in the Feather River during May and no net effect during June.

San Joaquin River

Flows under A2D_ELT were examined in the San Joaquin River at Vernalis during the March through June green sturgeon spawning and egg incubation period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows under A2D _ELT would be moderately lower (up to 16% lower in June of wet years) than those under Existing Conditions for all months of the period, with minor exceptions.

Summary of CEQA Conclusion

Under Alternative 2D, flows would generally not differ in the Sacramento River. Flows in the Feather River under Alternative 2D would be lower relative to Existing Conditions early in the spawning and egg incubation period and would higher later in the period. Water temperature conditions in the Sacramento and Feather rivers under Alternative 2D would not differ significantly relative to Existing Conditions. Flows under Alternative 2D in the San Joaquin River would be consistently lower than those under Existing Conditions. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of green sturgeon in the San Joaquin River as a result of reduced flows.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flow and water temperature conditions under Alternative 2D would be similar to or better than those under NAA_ELT. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-131: Effects of Water Operations on Rearing Habitat for Green Sturgeon

In general, Alternative 2D would not affect the quantity and quality of green sturgeon larval and juvenile rearing habitat relative to NAA_ELT.

Water temperature was used to determine the potential effects of alternatives on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Sacramento River

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Feather River

Mean water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period, except for a 6% increase of temperature in July of critical water years.

Water temperature-related effects of Alternative 2D on green sturgeon rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures exceed a 64°F temperature threshold at Gridley (Table 11-2D-66). The percent of months exceeding the 64°F temperature threshold would be similar to or lower (up to 33% lower on an absolute scale) than the percent under NAA_ELT in all months.

Water temperature-related effects of Alternative 2D on green sturgeon rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-2D-67). Combining water years, total degree-months exceeding the threshold under A2D_ELT would be 9% to 26% lower relative to NAA_ELT during May and June and 10% to 15% higher during July through September. These results indicate that there would be both beneficial and negative temperature-related effects to green sturgeon rearing in the Feather River. However, the largest increase in degree-months (78 degree-months during July) would equate to an average increase of less than one degree per month. Given the highly variable nature of the Feather River outside of the low-flow channel, this change is not expected to be biologically meaningful. In fact, it is not unexpected that this amount of change would occur daily on a diel cycle.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River. However flows in all months and water year types, based on CALSIM II, were the same or very similar between NAA_ELT and A2D_ELT (Appendix *B, Supplemental Modeling for New Alternatives*) and, therefore, no temperature effects would occur as a result of Alternative 2D.

NEPA Effects: Collectively, the results indicate that the effect would not be adverse because it does not have the potential to substantially reduce the amount of suitable rearing habitat. Water temperatures in the Sacramento and Feather Rivers and exceedances of NMFS temperature thresholds in the Feather River under Alternative 2D would be similar to those under NAA_ELT.

CEQA Conclusion: In general, Alternative 2D could reduce the quantity and quality of rearing habitat for larval and juvenile green sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 2D would not affect the quantity and quality of rearing habitat for larval and juvenile green sturgeon relative to Existing Conditions.

Water temperature was used to determine the potential effects of Alternative 2D on green sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic-oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Sacramento River

Mean water temperatures in the Sacramento River at Bend Bridge were examined during the May through October green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT for any month or water year type of the period, except a 6% higher mean temperature for August of critical water years.

Feather River

Mean water temperatures in the Feather River at Gridley were examined during the April through August green sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT for any month or water year type of the period, except for 7% and 6% higher temperatures for July of critical water years and August of dry years, respectively.

Water temperature-related effects of A2D_ELT on green sturgeon rearing habitat in the Feather River were evaluated by determining the percent of months during May through September in which water temperatures would exceed a 64°F temperature threshold at Gridley (Table 11-2D-66). The percent of months exceeding the threshold under A2D_ELT would be similar to or greater by up to 15% (absolute scale) than the percent under Existing Conditions during May, July and August, and would be lower by up to 16% (absolute scale) during June and September, except of a 6% increase in September for the >4.0°F exceedance category.

Water temperature-related effects of Alternative 2D on green sturgeon rearing habitat in the Feather River were also evaluated by determining the total degree-months exceeding the 64°F temperature threshold at Gridley (Table 11-2D-67). Combining water years, total degree-months exceeding the threshold under A2D_ELT would be 1% to 91% higher in all months. The largest increase in degree-months (155 degree-months during July) would equate to an average increase of about 2 degree per month, which would be biologically meaningful. These results indicate that there would be negative temperature-related effects of Alternative 2D on green sturgeon rearing in the Feather River.

San Joaquin River

Water temperature modeling was not conducted in the San Joaquin River.

Summary of CEQA Conclusion

Under Alternative 2D, water temperatures would be slightly higher in the Sacramento and Feather rivers than those under the CEQA baseline, and the exceedances above NMFS temperature thresholds in the Feather River would be higher, which could increase stress, mortality, and susceptibility to disease for larval and juvenile green sturgeon. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce rearing habitat and substantially reduce the number of green sturgeon as a result of fry and juvenile mortality.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on water temperatures would be negligible and exceedances above thresholds would be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NEPA baseline, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-132: Effects of Water Operations on Migration Conditions for Green Sturgeon

In general, Alternative 2D would not reduce green sturgeon migration conditions relative to NAA_ELT.

Upstream of the Delta

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through June adult migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River mean flows at Keswick under A2D_ELT would generally be similar to flows under NAA_ELT in all months except September and November, in which flows would be up to 24% lower (Appendix *B, Supplemental Modeling for New Alternatives*). Sacramento River flows at Wilkins Slough under A2D_ELT would generally be up to 18% lower than flows under NAA_ELT during September and November, up to 16% greater during May and June, and similar to flows under NAA_ELT in the remaining eight months (Appendix *B, Supplemental Modeling for New Alternatives*).

These flow reductions would be infrequent (2 out of 12 months) and, therefore, would not cause substantial effects to green sturgeon migration.

Differences between A2D_ELT and NAA_ELT in Feather River mean flows at Thermalito would vary a great deal with month and water year type. In general, mean flows under A2D_ELT would be up to 49% lower (September of below normal years) than flows under NAA_ELT during July through September, although flows in critical water years during August and September would be up to 23% higher (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be up to 121% greater (June of below normal years) during May, June and October, and similar to flows under NAA_ELT in the remaining seven months, with a number of exceptions.

Feather River mean flows at the confluence with the Sacramento River under A2D_ELT would generally be up to 48% lower (July of critical water years) than flows under NAA_ELT during July through September, although flows in critical water years during August and September would be up to 14% higher (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would generally be up to 88% greater (June of below normal years) under A2D_ELT during May, June and October, and similar to flows under NAA_ELT in the remaining six months, with minor exceptions.

These changes represent a shift in the Oroville release pattern such that greater releases are made in the spring and less release is made in the summer. Given the benthic nature of green sturgeon and that flows in the Feather River would be consistent with the flow schedule provided by NMFS during the project planning process that is meant to better mimic the natural flow regime while providing adequate storage to meet downstream temperature and water quality requirements, the reductions in summer flows at both locations in the Feather River are not expected to have a substantial effect on green sturgeon.

Larval transport flows were also examined by utilizing the positive correlation between white sturgeon year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved green sturgeon larval transport that results in improved year class strength. However, there is high uncertainty about what the mechanism responsible for this relationship with white sturgeon year class strength is because many flow variable correlate throughout the Central Valley. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. In addition, this correlation was developed using data collected in the absence of north Delta intakes. Also, there are temporal and spatial differences between green and white sturgeon larval presence that make this analysis highly uncertain and potentially not applicable (Murphy et al. 2011). In particular, during April and May, green sturgeon would be spawning and larvae rearing in the upper Sacramento River and Feather River. This mismatch in timing and location limits the confidence in using this as a surrogate for green sturgeon and suggests that year-class strength correlated with flow at another location within the Sacramento River or during a different period, if at all.

Regardless, for lack of a known relationship for green sturgeon year-class strength, the results using white sturgeon as a surrogate for green sturgeon were examined here. Results for white sturgeon presented in Impact AQUA-150 below suggest that, using the positive correlation between Delta outflow and year class strength, green sturgeon year class strength would be lower under A2D_ELT than those under NAA_ELT (up to 50% lower) (Table 11-2D-73).

Through-Delta

As described for other species (e.g., Sacramento splittail in Impact AQUA-114), migration conditions in the southern Delta generally would be considerably improved relative to NAA_ELT, because of reduced frequency of reverse OMR flows. The effect on green sturgeon would not be adverse.

NEPA Effects: Sacramento River flows would generally be similar between Alternative 2D and NAA_ELT, with few exceptions that would not be substantial. In the Feather River, there would be some summer flow reductions under Alternative 2D, but given the benthic nature of green sturgeon and that the flow regime is consistent with NMFS recommendations provided to mimic a more natural flow regime to benefit of natives species, these reductions are not expected to adversely affect green sturgeon.

Due to the removal of water at the North Delta intakes, there are substantial differences in through-Delta flows between Alternative 2D and NAA_ELT. The percentage of months exceeding the USFWS (1995) Delta outflow thresholds in April and May of wet and above normal years under Alternative 2D was appreciably lower than that under NAA_ELT. Analysis of white sturgeon year-class strength (USFWS 1995), used here as a surrogate for green sturgeon, found a positive correlation between year class strength and Delta outflow during April and May. However, there are several problems with approach, as described above that make this analysis highly uncertain and potentially not applicable.

Determining whether a relationship exists between green sturgeon year class strength and river/Delta outflow and addressing the scientific uncertainty regarding which mechanisms are responsible for the positive correlation between white sturgeon year class strength and river/Delta flow will occur through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations. Given the outcome of these investigations, Delta outflow would be appropriately set for Alternative 2D operations such that the effect on green sturgeon Delta flow conditions would not be adverse. This, combined with similarities in flow conditions between Alternative 2D and NAA_ELT in the Sacramento River, the benthic nature of green sturgeon, and a lack of confidence in using white sturgeon as a surrogate for green sturgeon given the differences in timing and location of the two species, indicate that Alternative 2D would not be adverse to migration conditions for green sturgeon.

CEQA Conclusion: In general, these modeling results indicate that Alternative 2D could reduce the quantity and quality of migration habitat for green sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 2D would not affect the quantity and quality of migration habitat for green sturgeon.

Upstream of the Delta

Analyses for green sturgeon migration conditions focused on flows in the Sacramento River between Keswick and Wilkins Slough and in the Feather River between Thermalito and the confluence with the Sacramento River during the April through October larval migration period, the August through March juvenile migration period, and the November through July adult migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Because these periods encompass the entire year, flows during all months were compared. Reduced flows could slow or inhibit downstream migration of larvae and juveniles and reduce the ability to sense upstream migration cues and pass impediments by adults.

Sacramento River mean flows at Keswick under A2D_ELT would generally be up to 18% lower than flows under Existing Conditions during October through November of all water year types, and up to 24% lower in September of below normal, dry and critical years (Appendix *B, Supplemental Modeling for New Alternatives*). During September of above normal and wet years, flows under A2D_ELT were up to 29% higher. In the other months and water year types, the mean flows would generally be similar between A2D_ELT and Existing Conditions, with several exceptions. Mean flows at Wilkins Slough under A2D_ELT would generally be up to 24% lower than flows under Existing Conditions during August through November, except for September of wet and above normal water years when flows under A2D_ELT would be up to 28% higher. Mean flow in June would be up to 17% higher under A2D_ELT, and flows would be similar in other months and water year types, with minor exceptions.

Feather River mean flows at Thermalito Afterbay under A2D_ELT would generally be up to 50% lower than flows under Existing Conditions during January, February, July, and November of most water years, and up to 47% lower in March, August, and September of below normal and dry years (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would be similar to or up to 196% higher than flows under Existing Conditions during April through June, as well as September of wet, above normal and critical years. Flows under A2D_ELT would be similar to, lower than, and higher than flows under Existing Conditions during October and December, depending on water year type. Mean flow under A2D_ELT at the confluence with the Sacramento River would generally be up to 102% greater than flows under Existing Conditions during June of most water years and September of below normal and dry years, and would generally be up to 53% lower than flows under Existing Conditions during July and during September of below normal and dry water years. Given the benthic nature of green sturgeon and that flows in the Feather River would be consistent with the flow schedule provided by NMFS during the project planning process that is meant to better mimic the natural flow regime while providing adequate storage to meet downstream temperature and water quality requirements, the reductions in summer flows at both locations in the Feather River are not expected to have a substantial effect on green sturgeon.

For Delta outflow, the percent of months exceeding outflow thresholds under A2D_ELT would consistently be lower than those under Existing Conditions for each flow threshold, water year type, and month (4% to 50% lower on a relative scale) (Table 11-2D-73).

Through-Delta

As described for other species (e.g., Sacramento splittail in Impact AQUA-114), migration conditions in the southern Delta generally would be considerably improved relative to NAA_ELT, because of reduced frequency of reverse OMR flows. The effect on green sturgeon would not be adverse.

Summary of CEQA Conclusion

Under Alternative 2D, there would be frequent small to large reductions in flows in the Sacramento River upstream of the Delta that would reduce the ability of all three life stages of green sturgeon to migrate successfully. Exceedances of Delta outflow thresholds would be lower under Alternative 2D than under Existing Conditions, although there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows co-vary with another unknown factor. Also, the appropriateness of using white sturgeon as a surrogate for green sturgeon is questionable, as described for the NEPA Effects section above. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce upstream migration conditions for green sturgeon.

However, this interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on green sturgeon migration conditions in upstream areas. Within the Plan Area, the Adaptive Management Program will evaluate water operations and make adjustments as necessary to protect green sturgeon abundance and ensure the impacts of water operations on migration conditions for green sturgeon are less than significant. Therefore, this impact is found to be less than significant and no mitigation is required.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-133: Effects of Construction of Restoration Measures on Green Sturgeon

Impact AQUA-134: Effects of Contaminants Associated with Restoration Measures on Green Sturgeon

Impact AQUA-135: Effects of Restored Habitat Conditions on Green Sturgeon

Impact AQUA-136: Effects of Methylmercury Management on Green Sturgeon (Environmental Commitment 12)

Impact AQUA-139: Effects of Localized Reduction of Predatory Fish on Green Sturgeon (Environmental Commitment 15)

Impact AQUA-140: Effects of Nonphysical Fish Barriers on Green Sturgeon (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on green sturgeon for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

White Sturgeon

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-145: Effects of Construction of Water Conveyance Facilities on White Sturgeon

The potential effects of construction of the water conveyance facilities on white sturgeon would be similar to those described for Alternative 4A (Impact AQUA-145) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to white sturgeon.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-145, the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-145, the impact of the construction of water conveyance facilities on white sturgeon would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-146: Effects of Maintenance of Water Conveyance Facilities on White Sturgeon

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-146, the effect would not be adverse for white sturgeon.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-146 for white sturgeon, the impact of the maintenance of water conveyance facilities on white sturgeon would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-147: Effects of Water Operations on Entrainment of White Sturgeon

Water Exports from SWP/CVP South Delta Facilities

Alternative 2D is expected to substantially reduce overall entrainment of juvenile white sturgeon at the south Delta export facilities, estimated as the salvage density method, by about 53–59% across all years as compared to Existing Conditions and NAA_ELT (Table 11-2D-68). As discussed for Alternative 2A (Impact AQUA-3), entrainment is highest in wet and above normal water years. Under Alternative 2D, entrainment in wet and above normal water years would be reduced 68–71% for juveniles, compared to baseline conditions. Therefore, Alternative 2D would not have adverse effects on juvenile white sturgeon.

Water Exports from SWP/CVP North Delta Intake Facilities

The potential entrainment effects of operating the new north Delta intakes under Alternative 2D would be the same as described for Impact AQUA-129 under Alternative 2A. The intakes would have screens to avoid or reduce entrainment; there would be no adverse effect.

Predation Associated with Entrainment

Juvenile white sturgeon predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Sturgeon develop bony scutes at a young age which reduces their predation vulnerability. Based on their early development of scutes and rapid growth rates, the number of juvenile white sturgeon lost to predation at the south Delta facilities would change negligibly between Alternative 2D and NAA_ELT. The impact and conclusion for predation risk associated with the north Delta intakes would be the same as described for Alternative 2A.

NEPA Effects: As concluded for Alternative 2A, the effect on entrainment and predation under Alternative 2D would not be adverse, because sturgeon grow rapidly and develop bony scutes early in their development which reduces predation risk; therefore the main effect would be reduced entrainment under Alternative 2D because of reduced south Delta exports.

CEQA Conclusion: As described above, operational activities associated with water exports from SWP/CVP south Delta facilities would result in an overall decrease in entrainment of white sturgeon under Alternative 2D compared to Existing Conditions (Table 11-2D-68; Existing Conditions vs. 2D_ELT). Impacts of Alternative 2D water operations on entrainment of white sturgeon would be less than significant due to an overall reduction in entrainment and no mitigation would be required.

Table 11-2D-68. Juvenile White Sturgeon Entrainment Index[a] at the SWP and CVP Salvage Facilities for Sacramento Valley Water Year-Types and Differences (Absolute and Percentage) between Model Scenarios

	Absolute Difference (Percent Difference)	
Water Year[b]	NAA_ELT vs. A2D_ELT	EXISTING CONDITIONS vs. A2D_ELT
Wet and Above Normal	-176 (-68%)	-205 (-71%)
Below Normal, Dry, and Critical	-10 (-28%)	-15 (-37%)
All Years	-84 (-53%)	-106 (-59%)

[a] Estimated annual number of fish lost.
[b] Sacramento Valley water year-types.

The impact of predation associated with entrainment would be the same as described immediately above because the rapid growth and development of bony scutes reduces the predation risk for juvenile white sturgeon. The impact would be less than significant.

Impact AQUA-148: Effects of Water Operations on Spawning and Egg Incubation Habitat for White Sturgeon

In general, Alternative 2D would not affect spawning and egg incubation habitat for white sturgeon relative to NAA_ELT.

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon. Mean flows under A2D_ELT would generally be similar to flows under NAA_ELT during February to April at both locations, and would be greater than flows under NAA_ELT during May in most water years (up to 16% greater) (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above each threshold were further assigned a “level of concern” as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-69. For the 61°F threshold, there would be 11 fewer (44% fewer) “red” years under A2D_ELT than under NAA_ELT. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between NAA_ELT and A2D_ELT.

Table 11-2D-69. Differences between Baselines and Alternative 2D in the Number of Years in Which Water Temperature Exceedances above the 61°F and 68°F Thresholds Are within Each Level of Concern, Sacramento River at Hamilton City, March through June

Level of Concern	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
61°F threshold		
Red	17 (213%)	-11 (-44%)
Orange	10 (67%)	4 (16%)
Yellow	-11 (-35%)	3 (15%)
None	-16 (-57%)	4 (33%)
68°F threshold		
Red	0 (NA)	0 (NA)
Orange	0 (NA)	0 (NA)
Yellow	1 (NA)	-1 (-100%)
None	-1 (-1%)	1 (1%)

NA = could not be calculated because the denominator was 0.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-2D-70, Table 11-2D-71). Total degree-days (all water years combined) exceeding the 61°F threshold under Alternative 2D would be 2 degree-day (67%) greater than those under NAA_ELT during March, which would not be biologically meaningful. During April through June, total degree days above 61°F would be 3 to 480 (2% to 14%) lower under A2D_ELT than under NAA_ELT. These totals would not be biologically meaningful to white sturgeon considering that, since there are 2,542 and 2,460 total days during May and June, respectively, over the 82-year modeling period, the average daily reduction in temperature would be <0.2 degrees. Total degree-days exceeding the 68°F threshold would be similar between NAA_ELT and A2D_ELT, except during May, in which exceedances would be 12 degree-days (40%) fewer under A2D_ELT.

Table 11-2D-70. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 61°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	2 (NA)	2 (NA)
	Dry	3 (NA)	0 (0%)
	Critical	0 (NA)	0 (NA)
	All	5 (NA)	2 (67%)
April	Wet	18 (150%)	0 (0%)
	Above Normal	15 (150%)	0 (0%)
	Below Normal	15 (250%)	-5 (-19%)
	Dry	47 (92%)	4 (4%)
	Critical	2 (200%)	-2 (-40%)
	All	97 (121%)	-3 (-2%)
May	Wet	438 (132%)	-41 (-5%)
	Above Normal	103 (47%)	-133 (-29%)
	Below Normal	219 (119%)	-50 (-11%)
	Dry	221 (109%)	-93 (-18%)
	Critical	167 (83%)	-59 (-14%)
	All	1,148 (101%)	-376 (-14%)
June	Wet	369 (64%)	-121 (-11%)
	Above Normal	102 (33%)	-105 (-21%)
	Below Normal	172 (82%)	-75 (-16%)
	Dry	212 (63%)	-118 (-18%)
	Critical	175 (47%)	-61 (-10%)
	All	1,030 (57%)	-480 (-14%)

NA = could not be calculated because the denominator was 0.

Table 11-2D-71. Differences between Baseline and Alternative 2D Scenarios in Total Degree-Days (°F-Days) by Month and Water Year Type for Water Temperature Exceedances above 68°F in the Sacramento River at Hamilton City, March through June

Month	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
March	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
April	Wet	0 (NA)	0 (NA)
	Above Normal	0 (NA)	0 (NA)
	Below Normal	0 (NA)	0 (NA)
	Dry	0 (NA)	0 (NA)
	Critical	0 (NA)	0 (NA)
	All	0 (NA)	0 (NA)
May	Wet	9 (129%)	0 (0%)
	Above Normal	1 (NA)	-12 (-92%)
	Below Normal	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

Feather River

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows at Thermalito Afterbay under A2D_ELT would generally be similar to or greater by up to 35% than those under NAA_ELT, with minor exceptions. Mean flows at the confluence with the Sacramento River under A2D _ELT would be similar to or up to 14% greater than flows under NAA_ELT.

Mean water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period. Mean water temperatures would not differ (<5%) between NAA_ELT and A2D_ELT at either location throughout the period.

San Joaquin River

Flows in the San Joaquin River at Vernalis under A2D_ELT during February through May would be similar to flows under NAA_ELT (Appendix *B, Supplemental Modeling for New Alternatives)*.

Water temperature modeling was not conducted for the San Joaquin River.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable habitat. Flows under Alternative 2D would generally be higher in the Feather River relative to the NAA_ELT and generally similar to flows under the NAA_ELT in the Sacramento and San Joaquin Rivers. Alternative 2D would not affect temperatures in any river during the white sturgeon spawning and egg incubation period.

CEQA Conclusion: Collectively, the results of the Impact AQUA-148 CEQA analysis show that the difference between the CEQA baseline and Alternative 2D could be significant because, when compared to the CEQA baseline, the alternative would substantially reduce the quantity and quality of spawning and egg incubation habitat for white sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, the comparison to the NAA_ELT is a better approach because it isolates the effects of the alternative from those of sea level rise, climate change, and future water demand. Based on this identification of the actual increment of change attributable to the alternative, Alternative 2D would not affect the quantity and quality of spawning and egg incubation habitat for white sturgeon relative to the Existing Conditions.

Sacramento River

Flows in the Sacramento River at Wilkins Slough and Verona were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix *B, Supplemental Modeling for New Alternatives*). At Wilkins Slough, mean flows under A2D_ELT would generally be similar to those under Existing Conditions. At Verona, mean flow under A2D_ELT for most of the months and water year types would be slightly lower (less than 10% lower) than flows under Existing Conditions, with a maximum flow reduction of 15% in March of below normal years.

Mean water temperatures in the Sacramento River at Hamilton City were examined during the February through May white sturgeon spawning period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

The number of days on which temperature exceeded a 61°F optimal and 68°F lethal threshold by >0.5°F to >5°F in 0.5°F increments were determined for each month (March through June) and year of the 82-year modeling period (Table 11-2D-10). The combination of number of days and degrees above each threshold were further assigned a “level of concern” as defined in Table 11-2D-11. Differences between baselines and Alternative 2D in the highest level of concern across all months and all 82 modeled years are presented in Table 11-2D-69. For the 61°F threshold, there would be 17 more (213% increase) “red” years under A2D_ELT than under Existing Conditions. For the 68°F threshold, there would be negligible differences in the number of years under each level of concern between Existing Conditions and A2D_ELT.

Total degree-days exceeding 61°F and 68°F were summed by month and water year type at Hamilton City during March through June (Table 11-2D-70, Table 11-2D-71). Total degree-days (all water year types combined) exceeding the 61°F threshold under A2D_ELT would be 5 degree-days (percent change unable to be calculated due to division by 0) to 1,148 degree-days (101%) higher depending on month. Total degree-days exceeding the 68°F threshold would differ little between Existing Conditions and Alternative 2D during March, April and June. During May, total degree-days would be 11 (157%) degree-days higher under A2D_ELT, although this small absolute difference would not cause a biologically meaningful effect on white sturgeon.

Feather River

Flows in the Feather River between Thermalito Afterbay and the confluence with the Sacramento River were examined during the February to May spawning and egg incubation period for white sturgeon (Appendix *B, Supplemental Modeling for New Alternatives*). Differences in mean flows between A2D_ELT and Existing Conditions at Thermalito Afterbay would vary greatly during the period. Mean flows during February and March of below normal and dry years would be up to 40% lower under A2D _ELT, and flows would be similar or moderately higher in other water year types. During April and May, flows would be up to 36% higher depending on water year type. Mean flows at the confluence with the Sacramento River under A2D _ELT would generally be similar to or greater than flows under Existing Conditions, except in below normal years during February and March (11% and 16% lower, respectively). These results indicate that there would be some reductions in flows in the Feather River under A2D _ELT relative to Existing Conditions.

Mean water temperatures in the Feather River below Thermalito Afterbay and at the confluence with the Sacramento River were examined during the February through May white sturgeon spawning and egg incubation period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean water temperatures would not differ between Existing Conditions and H4_ELT at either location throughout the period.

San Joaquin River

Flows under A2D_ELT were examined in the San Joaquin River at Vernalis during February through May. Mean flows under A2D _ELT during March and April would be up to 12% lower than those under Existing Conditions, whereas flows under A2D _ELT during February and May would be similar to or greater than those under Existing Conditions, with minor exceptions (Appendix *B, Supplemental Modeling for New Alternatives*).

Water temperature modeling was not conducted for the San Joaquin River.

Summary of CEQA Conclusion

Under Alternative 2D, there would be small to moderate reductions in flows in the Sacramento, Feather, and San Joaquin Rivers that would cause biologically meaningful effects to white sturgeon spawning and egg incubation habitat. Further, there would be increases in exceedances of NMFS temperature thresholds in the Sacramento River that would cause a biologically meaningful effect to white sturgeon spawning and egg incubation.

Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce the quantity and quality of suitable spawning and egg incubation habitat.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the

CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows under Alternative 2D would generally be higher in the Feather River and generally similar in the Sacramento and San Joaquin Rivers. Alternative 2D would not affect temperatures in any river during the white sturgeon spawning and egg incubation period. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows, reservoir storage, and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Impact AQUA-149: Effects of Water Operations on Rearing Habitat for White Sturgeon

In general, Alternative 2D would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to NAA_ELT.

Water temperature was used to determine the potential effects of Alternative 2D on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Mean water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean monthly water temperature between NAA_ELT and A2D_ELT in any month or water year type throughout the period.

Mean water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between NAA_ELT and Alternative 2D in any month or water year type throughout the period, except for 6% higher mean temperature in July of critical water years.

Water temperatures were not modeled in the San Joaquin River.

NEPA Effects: These modeling results indicate that the effect is not adverse because it does not have the potential to substantially reduce the amount of suitable rearing habitat. There would be no differences in water temperatures between the NEPA baseline and Alternative 2D in the Sacramento River and little difference in the Feather River throughout the white sturgeon rearing period.

CEQA Conclusion: In general, Alternative 2D would not affect the quantity and quality of white sturgeon larval and juvenile rearing habitat relative to the Existing Conditions.

Water temperature was used to determine the potential effects of Alternative 2D on white sturgeon larval and juvenile rearing habitat because larvae and juveniles are benthic oriented and, therefore, their habitat is more likely to be limited by changes in water temperature than flow rates.

Mean water temperatures in the Sacramento River at Hamilton City were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). There would be no differences (<5%) in mean water temperature between Existing Conditions and A2D_ELT in any month or water year type throughout the period.

Mean monthly water temperatures in the Feather River at Honcut Creek were examined during the year-round white sturgeon juvenile rearing period (Appendix 11D, *Sacramento River Water Quality Model and Reclamation Temperature Model Results utilized in the Fish Analysis*). Mean monthly water temperatures would be similar between Existing Conditions during all months and water year types except July of critical water years and August of dry years, in which the means would be 7% and 6% higher, respectively, under A2D_ELT. These increases would not be large or frequent enough to affect white sturgeon.

Water temperatures were not modeled in the San Joaquin River.

Summary of CEQA Conclusion

These modeling results indicate that the effect is less than significant because it does not have the potential to substantially reduce the amount of suitable habitat and no mitigation is required. There would be few differences in water temperatures between Alternative 2D and the CEQA baseline that, when combined, would not amount to a substantial effect to the white sturgeon population.

Impact AQUA-150: Effects of Water Operations on Migration Conditions for White Sturgeon

In general, the effects of Alternative 2D on white sturgeon migration conditions relative to NAA_ELT are not adverse.

Upstream of the Delta

Analyses for white sturgeon focused on the Sacramento River (North Delta to RM 143 — i.e., Wilkins Slough and Verona CALSIM nodes). Larval transport flows were represented by the average number of months per year that exceeded thresholds of 17,700 cfs (Wilkins Slough) and 31,000 cfs (Verona) (Table 11-2D-72). Exceedances of the 17,700 cfs threshold for Wilkins Slough under A2D_ELT were similar to those under NAA_ELT. The number of months per year above 31,000 cfs at Verona would range from a reduction of 1.5 months (64% lower in wet years) to an increase of 0.8 months (350% higher in dry years) relative to NAA_ELT, depending on water year type. Overall, there is no consistent difference between Alternative 2D and NAA_ELT.

Table 11-2D-72. Difference and Percent Difference in Number of Months between February and May in Which Flow Rates Exceed 17,700 and 5,300 cfs in the Sacramento River at Wilkins Slough and 31,000 cfs at Verona

	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wilkins Slough, 17,700 cfs[a]

[a] Months analyzed: February through May.
[b] Months analyzed: November through May.

The effects of changes in flow for white sturgeon under Alternative 2D was also examined by utilizing the positive correlation between year class strength and Delta outflow during April and May (USFWS 1995) under the assumption that the mechanism responsible for the relationship is that Delta outflow provides improved transport (e.g., for white sturgeon larvae or other early life stages) that results in improved year class strength. An examination of monthly average Delta outflow exceedances above 15,000 cfs, 20,000 cfs, and 25,000 cfs during April and May of wet and above-normal years was used to provide context for differences in through-Delta migration conditions, per recommendations by the Anadromous Fish Restoration Program (USFWS 1995). The percentage of months exceeding flow thresholds under A2D_ELT would consistently be lower than those under NAA_ELT (up to 50% lower) (Table 11-2D-73). These results indicate that, using the positive correlation between Delta outflow and year class strength, year class strength could be consistently lower under A2D_ELT than NAA_ELT.

Table 11-2D-73. Difference and Percent Difference in Percentage of Months in Which Average Delta Outflow is Predicted to Exceed 15,000, 20,000, and 25,000 Cubic Feet per Second in April and May of Wet and Above-Normal Water Years

Flow	Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
April			
15,000 cfs	Wet	-4 (-4%)	-4 (-4%)
	Above Normal	-17 (-18%)	-17 (-18%)
20,000 cfs	Wet	-8 (-9%)	-8 (-9%)
	Above Normal	-33 (-44%)	-33 (-44%)
25,000 cfs	Wet	-19 (-24%)	-19 (-24%)

20,000 cfs	Wet	-35 (-41%)	-23 (-32%)
	Above Normal	-17 (-40%)	-8 (-25%)
25,000 cfs	Wet	-19 (-28%)	-12 (-19%)
	Above Normal	-17 (-50%)	-17 (-50%)
April/May Average			
15,000 cfs	Wet	-8 (-8%)	-4 (-4%)
	Above Normal	-25 (-25%)	-25 (-25%)
20,000 cfs	Wet	-19 (-22%)	-19 (-22%)
	Above Normal	-17 (-25%)	-8 (-14%)
25,000 cfs	Wet	-19 (-24%)	-12 (-16%)
	Above Normal	-25 (-50%)	-25 (-50%)

For juveniles, flows in the Sacramento River at Verona were examined during the year-round migration period (Appendix *B, Supplemental Modeling for New Alternatives*). Mean flows at Verona under A2D_ELT would be lower by up to 31% relative to NAA_ELT during January through April, July, August, October, and November, as well as in September of below normal, dry and critical water years. The flows would be up to 45% greater during June and in September of wet and above normal water years, and would generally be similar in May and December (Appendix *B, Supplemental Modeling for New Alternatives*).

For adults, the average number of months per year during the November through May adult migration period in which flows in the Sacramento River at Wilkins Slough exceed 5,300 cfs was determined (Table 11-2D-72). The average number of months exceeding 5,300 cfs under A2D_ELT would be similar to the number of months under NAA_ELT.

Through-Delta

As described for other species (e.g., Sacramento splittail in Impact AQUA-114), migration conditions in the southern Delta generally would be considerably improved relative to NAA_ELT, because of reduced frequency of reverse OMR flows.

NEPA Effects: Upstream flows (above north Delta intakes) would generally be similar between Alternative 2D and NAA_ELT. The percentage of months exceeding the USFWS (1995) Delta outflow thresholds in April and May of wet and above normal years under Alternative 2D was appreciably lower than that under NAA_ELT. The exact mechanism for the correlation between white sturgeon year-class strength and Delta outflow is not known at this time and was found in the absence of north Delta intakes. One hypothesis suggests that the correlation is caused by high flows in the upper river resulting in improved migration, spawning, and rearing conditions in the upper river. In this case, there would be no causal link between Delta outflow and white sturgeon year-class strength. Another hypothesis suggests that the positive correlation is a result of higher flows through the Delta triggering more adult sturgeon to move up into the river to spawn. It is also possible that some combination of these factors are working together to produce the positive correlation between high flows and sturgeon year-class strength.

The scientific uncertainty regarding which mechanisms are responsible for the positive correlation between year class strength and river/Delta flow will be addressed through targeted research and monitoring to be conducted in the years leading up to the initiation of north Delta facilities operations as described in the adaptive management and monitoring program in Section 4.1 to inform decisions regarding Delta outflow such that the effect on white sturgeon Delta flow conditions would not be adverse. This uncertainty and the associated adaptive management and monitoring program, combined with similarities in upstream flow conditions between Alternative 2D and NAA_ELT, indicate that Alternative 2D would not be adverse to migration conditions for white sturgeon

***CEQA Conclusion:* In general, Alternative 2D could reduce the quantity and quality of migration habitat for white sturgeon relative to Existing Conditions. However, as further described below in the Summary of CEQA Conclusion, reviewing the alternative's impacts in relation to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demand. Informed by the NAA_ELT comparison, Alternative 2D would not affect the quantity and quality of migration habitat for white sturgeon.**

Upstream of the Delta

The number of months per year with exceedances above the 17,700 cfs threshold for Wilkins Slough under A2D_ELT would be similar to those under Existing Conditions on the relative scale (%), except in below normal years (25% lower) (Table 11-2D-72). The number of months per year above 31,000 cfs at Verona under A2D_ELT would range from a reduction of 1.7 months (67% reduction) in wet years to an increase of 0.7 months (260% higher) in dry years relative to Existing Conditions, depending on water year type. These changes would be small to moderate on the absolute scale (up to 1.7 fewer months per year).

For Delta outflow, the percent of months exceeding outflow thresholds under A2D_ELT would be consistently lower than those under Existing Conditions for each flow threshold, water year type, and month (4% to 50% lower on a relative scale) (Table 11-2D-73).

For juveniles, flows in the Sacramento River at Verona were examined during the year-round migration period. In general, mean flows under A2D_ELT would be lower relative to Existing Conditions during January through April and July through November, depending on water year type and with some exceptions, and would be similar in May and December. The largest reductions in flow (up to 31% lower) would occur during July through September. Flows under A2D_ELT would be higher (up to 45%) during June of above normal, below normal, and dry water years and

September of wet and above normal water years (Appendix *B, Supplemental Modeling for New Alternatives*).

For adult migration, the average number of months exceeding 5,300 cfs under A2D_ELT would be similar to the number of months under Existing Conditions, except in critical water years (5% higher) (Table 11-2D-72).

Through-Delta

Given the improved OMR flows and the range of Delta outflows under Alternative 2D that could be refined to avoid negative impacts to green sturgeon (see NEPA Effects discussion above), the potential impact of Alternative 2D on in-Delta conditions for white sturgeon is considered less than significant, and no mitigation would be required.

Summary of CEQA Conclusion

Under Alternative 2D, exceedances of the 31,000 cfs flow threshold in the Sacramento River would be lower than under Existing Conditions in wet and above normal water years, but would be higher in below normal, dry and critical years. Differences for the 17,700 cfs threshold would be smaller and less tied to water year type. Exceedance of Delta outflow thresholds would be lower under Alternative 2D, but there is high uncertainty that year class strength is due to Delta outflow or if both year class strength and Delta outflows are co-varying with another unknown factor. Juvenile migration flows in the Sacramento River at Verona would be up to 31% lower in nine of 12 months relative to Existing Conditions. These reduced flows could have a substantial effect on the ability to migrate downstream, delaying or slowing rates of successful migration downstream and increasing the risk of mortality. Contrary to the NEPA conclusion set forth above, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce migration conditions for white sturgeon.

However, this interpretation of the biological modeling is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp, including those to mitigate upstream effects of climate change and ongoing operations. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison in results between the alternative and NAA_ELT, is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, there would be negligible effects on upstream flows. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under

Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-151: Effects of Construction of Restoration Measures on White Sturgeon

Impact AQUA-152: Effects of Contaminants Associated with Restoration Measures on White Sturgeon

Impact AQUA-153: Effects of Restored Habitat Conditions on White Sturgeon

Impact AQUA-154: Effects of Methylmercury Management on White Sturgeon (Environmental Commitment 12)

Impact AQUA-157: Effects of Localized Reduction of Predatory Fish on White Sturgeon (Environmental Commitment 15)

Impact AQUA-158: Effects of Nonphysical Fish Barriers on White Sturgeon (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on white sturgeon for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Pacific Lamprey

Construction and Maintenance of Water Maintenance Facilities

Impact AQUA-163: Effects of Construction of Water Conveyance Facilities on Pacific Lamprey

The potential effects of construction of the water conveyance facilities on Pacific lamprey would be similar to those described for Alternative 4A (Impact AQUA-163) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to Pacific lamprey.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-163, the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-163, the impact of the construction of water conveyance facilities on Pacific lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-164: Effects of Maintenance of Water Conveyance Facilities on Pacific Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-164, the effect would not be adverse for Pacific lamprey.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-164 for Pacific lamprey, the impact of the maintenance of water conveyance facilities on Pacific lamprey would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-165: Effects of Water Operations on Entrainment of Pacific Lamprey

Water Exports

Alternative 2D is expected to substantially reduce average annual entrainment of Pacific lamprey, estimated by salvage density, by about 59% (Table 11-2D-74) averaged across all years compared to NAA_ELT.

The potential entrainment impacts of Alternative 2D on Pacific lamprey would be similar to Alternative 2A (Impact AQUA-165). These actions would avoid or reduce potential entrainment and the effect is not adverse.

The analysis of Pacific lamprey and river lamprey entrainment at the SWP/CVP south Delta facilities is combined because the salvage facilities do not distinguish between the two lamprey species. Similar to Alternative 2A (Impact AQUA-165), Alternative 2D is not expected to have an adverse effect on lamprey.

Predation Associated with Entrainment

Lamprey predation loss at the south Delta facilities is assumed to be proportional to entrainment loss. Lamprey entrainment to the south Delta would be reduced by 59% compared to NAA_ELT and predation losses would be expected to be reduced at a similar proportion.

NEPA Effects: Predation at the north Delta would be increased due to the construction of the proposed water export facilities on the Sacramento River. The effect on lamprey from predation loss at the north Delta is unknown because of the lack of knowledge about their distribution and population abundances in the Delta. As described for Alternative 2A, the overall effect on entrainment and predation of lamprey is considered not adverse.

CEQA Conclusion: Annual entrainment losses of lamprey would be decreased under Alternative 2D by approximately 60% compared to Existing Conditions (Table 11-2D-74). At the north Delta facilities, the screened intakes as designed would exclude this species. Impacts of Alternative 2D water operations on entrainment on Pacific lamprey are anticipated to be less than significant and may be beneficial, due to reductions in entrainment at the Delta export facilities. No mitigation would be required.

Table 11-2D-74. Lamprey Annual Entrainment Index at the SWP and CVP Salvage Facilities for Alternative 2D[a]

	Absolute Difference (Percent Difference)	
Water Year	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
All Years	-2,019 (-60%)	-1,996 (-59%)

[a] Number of fish lost, based on non-normalized data, for all months.

The impact of predation associated with entrainment would be the same as described immediately above because the additional predation losses associated with the proposed north Delta intakes would be offset by the reduction in predation loss at the south Delta. The relative impact of predation loss on the lamprey population is unknown since there is little available knowledge on their distribution and abundance in the Delta. The impact is considered to be less than significant. No mitigation is required.

Impact AQUA-166: Effects of Water Operations on Spawning and Egg Incubation Habitat for Pacific Lamprey

In general, effects of Alternative 2D would not affect the quantity and quality of Pacific lamprey spawning habitat relative to NAA_ELT.

Flow-related impacts on Pacific lamprey spawning habitat were evaluated by estimating effects of flow alterations on egg exposure, called redd dewatering risk, and effects on water temperature. A redd is a gravel-covered nest of eggs; Pacific lamprey eggs take between 18 and 49 days to incubate and must remain covered by sufficient water for that time. Rapid reductions in flow can dewater redds leading to mortality. Locations for each river used in the dewatering risk analysis were based on available literature, personal conversations with agency experts, and spatial limitations of the CALSIM II model, and include the Sacramento River at Keswick, Sacramento River at Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and American River at Nimbus Dam and at the confluence with the Sacramento River. Pacific lamprey spawn in these rivers between January and August so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage). Water temperature results from the SRWQM and the Reclamation Temperature Model were used to assess the exceedances of water temperatures under all model scenarios in the upper Sacramento, Trinity, Feather, American, and Stanislaus rivers.

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, substrate) of Pacific lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, the change in month-over-month flows is used as a surrogate for a more formal analysis, and a month-over-month flow reduction of 50% was chosen as a best professional estimate of flow conditions in which redd dewatering is expected to occur, but does not estimate empirically derived redd dewatering events. As such, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, January to August.

Flows in all rivers evaluated indicate an increase in redd cohorts exposed to month-over-month flow reductions between January and August for Alternative 2Dcompared to NAA_ELT would only occur in the Feather River (12 cohorts or 11% greater) and Sacramento River at Red Bluff (6 cohorts or 9% greater) (Table 11-2D-75). However, because the total number of cohorts would be 648 in the Feather River and 19,928 in the Sacramento River, these effects would be negligible (<2%) to the Pacific lamprey populations in these rivers. Therefore, these results indicate that there would be no effect of Alternative 2D on the number of Pacific lamprey redd cohorts predicted to experience a month-over-month change in flow of greater than 50% in all rivers.

Table 11-2D-75. Differences between Model Scenarios in Dewatering Risk of Pacific Lamprey Redd Cohorts[a]

Location	Comparison[b]	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Sacramento River at Keswick	Difference	13	1
	Percent Difference	24%	1%
Sacramento River at Red Bluff	Difference	16	6
	Percent Difference	30%	9%
Trinity River down-stream of Lewiston	Difference	-1	1
	Percent Difference	-1%	1%
Feather River at Thermalito Afterbay	Difference	-25	12
	Percent Difference	-17%	11%
American River at Nimbus Dam	Difference	28	6
	Percent Difference	33%	6%
American River at Sacramento River confluence	Difference	30	7
	Percent Difference	32%	6%

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%.
[b] Positive values indicate a higher value in A2D_ELTthan in the baseline.

Significant reduction in survival of eggs and embryos of Pacific lamprey were observed at 22°C (71.6°F; Meeuwig et al. 2005). Therefore, in the Sacramento River, this analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) using daily data from SRWQM. For other rivers, the analysis predicted the number of consecutive 2 month periods during which at least one month exceeds 22°C (71.6°F) using monthly averaged data from the Reclamation temperature model. Each individual day or month starts a new "egg cohort" such that there are 19,928 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from January 1 through August 31, and 648 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Exact spawning locations of Pacific lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

In most locations, egg cohort exposure would not differ between NAA_ELT and Alternative 2D (Table 11-2D-76). However, the number of cohorts exposed to 22°C (71.6°F) under Alternative 2D would be 6% higher in the Sacramento River at Hamilton City, 100% higher in the Trinity River at North Fork and 140% higher in the Feather River at Thermalito Afterbay. The increase in the Sacramento River is negligible considering that it represents a difference of <0.1% of the total number of egg cohorts evaluated (19,928 cohorts). Additionally, the increase in the Trinity River is negligible considering that it represents a difference of <0.3% of the total number of egg cohorts evaluated (648 cohorts).

Table 11-2D-76. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Egg Cohort Temperature Exposure[a]

Location	EXISTING CONDITIONS vs. 2D_ELT	NAA_ELT vs. 2D_ELT
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	510 (NA)	27 (6%)
Trinity River at Lewiston	2 (NA)	0 (0%)
Trinity River at North Fork	-2 (NA)	2 (100%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	72 (300%)	56 (140%)
American River at Nimbus	41 (373%)	1 (2%)
American River at Sacramento River Confluence	89 (159%)	-5 (-3%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	23 (1,150%)	0 (0%)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey egg cohorts experiencing water temperatures above 71.6°F during January to August on at least one day during a 49-Day incubation period in the Sacramento River or for at least one month during a 2-month incubation period for each model scenario in other rivers. Positive values indicate a higher value in the proposed project than in EXISTING CONDITIONS or NAA_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because Alternative 2D does not have the potential to substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Flows reductions that increase redd dewatering risk would be of similar or lower frequency under Alternative 2D relative to the NEPA baseline in all locations. There would be increased exposure risk of eggs to elevated temperatures in the Feather River, but this isolated result is not expected to cause a biologically meaningful effect to the Pacific lamprey population.

CEQA Conclusion: In general, Alternative 2D would not affect the quantity and quality of Pacific lamprey spawning habitat relative to the Existing Conditions.

Rapid reductions in flow can dewater redds leading to mortality. In the Sacramento American Rivers, Alternative 2D would increase in the number of redd cohorts predicted to experience a month-over-month change in flow of greater than 50% relative to Existing Conditions (Table 11-2D-75). The small values (13 and 16 cohorts) in the Sacramento River would not translate into biologically meaningful effects considering the total number of redd cohorts evaluated (up to 16 of 656 cohorts, or <3%). Changes would be most substantial for the American River (increased risk of dewatering exposure to 28 cohorts or 33% at Nimbus Dam, and 30 cohorts or 32% at the confluence). For the Feather River, there are 25 fewer redd cohorts (-17%) predicted to experience a month-over-month change in flow of greater than 50% for Alternative 2D relative to Existing Conditions. Minimal effects are predicted for the Trinity River (-1%).These results indicate that Alternative 2D would not have biologically meaningful effects on Pacific lamprey redd dewatering risk in the Sacramento, Feather, and Trinity Rivers; but would affect dewatering risk in the American River (maximum increases of 28 cohorts or 33% at Nimbus Dam and 30 cohorts or 32% at the Sacramento River confluence).

The number of egg cohorts exposed to 22°C (71.6°F) under Alternative 2D would be greater than that under Existing Conditions in all rivers, except the Trinity River (Table 11-2D-76).

Summary of CEQA Conclusion

Contrary to the NEPA conclusion set forth above, the results of the Impact AQUA-166 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2D could be significant because, under the CEQA baseline, the alternative could substantially reduce suitable spawning habitat and substantially reduce the number of fish as a result of egg mortality. Redd dewatering risk under Alternative 2D would be higher relative to Existing Conditions in the American River, which would increase the risk of desiccation of eggs in this river. There would be increases in egg cohorts exposed to water temperatures above 71.6°F under Alternative 2D relative to Existing Conditions in at least one location in all rivers evaluated except the Trinity River. Increased exposure to elevated temperatures would reduce egg survival in these rivers.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on flows, reservoir storage, and water temperatures during the months and locations analyzed would be minimal. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the effects of Alternative 2D on Pacific lamprey spawning and egg incubation habitat conditions would be less than significant and no mitigation is necessary.

Impact AQUA-167: Effects of Water Operations on Rearing Habitat for Pacific Lamprey

In general, Alternative 2D would have negligible effects on Pacific lamprey rearing habitat conditions relative to NAA_ELT.

Flow-related impacts to Pacific lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete exposure, called ammocoete stranding risk. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Comparisons of effects were made for ammocoete cohorts in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. An ammocoete is the filter-feeding larval stage of the lamprey that remains relatively immobile in the sediment in the same location for 5 to 7 years, after which it migrates downstream. During the upstream rearing period there is potential for ammocoete stranding from rapid reductions in flow.

The analysis of ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (January through August) and spend 7 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period.

Effects of Alternative 2D on Pacific lamprey ammocoete stranding were analyzed by calculating month-over-month flow reductions for the Sacramento River at Keswick for January through August (Table 11-2D-77). Results indicate either no effect (0%) or negligible effects (<5%) in the occurrence of flow reductions attributable solely to the project.

Table 11-2D-77. Percent Difference between Model Scenarios in the Number of Pacific Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

	Percent Difference[a]

-60%	1	0
-65%	1	1
-70%	8	2
-75%	22	4
-80%	192	4
-85%	221	32
-90%	104	0

[a] Negative values indicate reduced cohort exposure, a benefit of Alternative 2D.

These results indicate that Alternative 2D would primarily have no effect (0%), negligible effects (<5%), or decreases in stranding risk that would be beneficial to on rearing success. Isolated occurrences of small increases in dewatering for some flow reduction categories would not have biologically meaningful effects. There would also be small to moderate beneficial effects in the Feather River (decreased occurrence of flow reductions to -64%) due to project-related effects of Alternative 2D.

To evaluate water temperature-related effects of Alternative 2D on Pacific lamprey ammocoetes, we examined the predicted number of ammocoete "cohorts" that experience water temperatures greater than 71.6°F for at least one day in the Sacramento River (because daily water temperature data are available) or for at least one month in the Feather, American, Stanislaus, and Trinity rivers over a 7 year period, the maximum likely duration of the ammocoete life stage (Moyle 2002). Each individual day or month starts a new "cohort" such that there are 18,244 cohorts for the Sacramento River, corresponding to 82 years of ammocoetes being "born" every day each year from January 1 through August 31, and 593 cohorts for the other rivers using monthly data over the same period.

In general, there would be no differences in the number of ammocoete cohorts exposed to temperatures greater than 71.6°F in each river (Table 11-2D-83).There would be no difference in exposure between NAA_ELT and Alternative 2D in the Trinity River at Lewiston, but there would be 56 more cohorts (100% increase) exposed at North Fork. In addition, there would be 94 more cohorts (20% increase) exposed under Alternative 2D in the Feather River below Thermalito Afterbay, but there would be no change in cohorts exposed at Fish Barrier Dam. There would be 21 fewer cohorts (-4%) exposed under Alternative 2D in the American River at Nimbus Dam and 9 more cohorts (2%) exposed at the Sacramento River Confluence. Overall, the range of increases and decreases will balance out within rivers such that there would be no overall effect on Pacific lamprey ammocoetes.

Table 11-2D-83. Differences (Percent Differences) between Model Scenarios in Pacific Lamprey Ammocoete Cohorts Exposed to Temperatures in the Feather River Greater than 71.6°F in at Least One Day or Month

Location	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Sacramento River at Keswick[b]	0 (NA)	0 (NA)
Sacramento River at Hamilton City[b]	5,299 (NA)	-1,946 (-27%)
Trinity River at Lewiston	56 (NA)	0 (0%)
Trinity River at North Fork	112 (NA)	56 (100%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	188 (49%)	94 (20%)
American River at Nimbus	258 (133%)	-21 (-4%)
American River at Sacramento River Confluence	151 (35%)	9 (2%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	282 (504%)	-1 (0%)

NA = could not be calculated because the denominator was 0.
[a] Positive values indicate a higher value in Alternative 2D than in EXISTING CONDITIONS or NAA_ELT.
[b] Based on daily data; all other locations use monthly data; 1922–2003.

NEPA Effects: These modeling results indicate that the effect would not be adverse because it would not substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. There would be negligible effects on ammocoete cohort survival under Alternative 2D relative to the NEPA baseline for all locations. There would be increase and decreases in exposure risk of ammocoetes to elevated temperatures within each river evaluated that would balance out such that there would be no net effect on Pacific lamprey ammocoetes.

CEQA Conclusion: In general, under Alternative 2D water operations, the quantity and quality of Pacific lamprey rearing habitat would not be affected relative to the CEQA baseline.

Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Comparisons of Alternative 2D to Existing Conditions for the Sacramento River at Keswick indicate negligible changes (<5%) in occurrence of flow reductions for all flow reduction categories (Table 11-2D-77). Comparisons for the Sacramento River at Red Bluff indicate no effect (0%) or negligible effects (<5%) for all flow reduction categories except for 75% and 80% flow reductions (increases of 10% and 23% [from 10 to 23], respectively) (Table 11-2D-78). Increases of 21-34% are predicted for flow reduction categories from 75% to 90% for the Trinity River (Table 11-2D-79) based on increases from approximately 83 to 116 ammocoete cohorts exposed to stranding risk. In the Feather River, all comparisons resulted in no difference (0%), moderate reductions (19% to 64%) in the occurrence of flow reductions between 85-90% (Table 11-2D-80). In the American River, there would be large increases in the occurrence of flows reductions in the 70% to 90% range, except the 90% flow reduction category at Nimbus Dam (100% reduction) (Table 11-2D-81, Table 11-2D-82).

The number of Pacific lamprey ammocoete cohorts exposed to 71.6°F temperatures under Alternative 2D would be substantially higher than those under Existing Conditions in at least one location in all rivers evaluated (Table 11-2D-83).

Summary of CEQA Conclusion

Contrary to the NEPA conclusion set forth above, the results of the Impact AQUA-167 CEQA analysis indicate that that the difference between the CEQA baseline and Alternative 2D could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality,. Increased water temperatures would increase stress and reduce survival of lamprey ammocoetes. In the Trinity and American Rivers, there would be increases in the number of cohorts exposed to stranding risk due to increased flow reductions. Increased stranding risk in these rivers would increase the risk of desiccation and reduce survival of ammocoete cohorts. Exposure of ammocoetes to elevated temperatures under Alternative 2D would be substantially higher than those under Existing Conditions in most locations evaluated.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on flows, reservoir storage, and water temperatures during the months and locations analyzed would be minimal. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the effects of Alternative 2D on Pacific lamprey rearing habitat conditions would be less than significant and no mitigation is necessary.

Impact AQUA-168: Effects of Water Operations on Migration Conditions for Pacific Lamprey

In general, effects of Alternative 2D would be negligible relative to NAA_ELT based on a prevalence of negligible effects or beneficial increases in mean monthly flow for most of the locations analyzed, which would have a beneficial effect on migration conditions.

After 5–7 years, Pacific lamprey ammocoetes migrate downstream and become macropthalmia (juveniles) once they reach the Delta. Migration generally is associated with large flow pulses in winter months (December through March) (USFWS unpubl. data) meaning alterations in flow have the potential to affect downstream migration conditions. The effects of Alternative 2D on seasonal migration flows for Pacific lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the migration pathways of Pacific lamprey during the likely migration period (December through May) were examined for the Sacramento River at Rio Vista and Red Bluff, the Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

CALSIM flow data form the basis for the summary of changes in adult lamprey migration flows.

Sacramento River

Macropthalmia

The difference in mean monthly flow rate for the Sacramento River at Rio Vista for December to May for Alternative 2D compared to NAA_ELT indicates reductions in flow for most months/water year types in the migration period with persistent flow reductions of up to -30% depending on the specific month and water year (Appendix *B, Supplemental Modeling for New Alternatives)*. The project-related decreases in flow in the Sacramento River at Rio Vista could adversely affect outmigrating macropthalmia during these months if macropthalmia depend on flow to immigrate, but there is no scientific evidence of this.

For the Sacramento River at Red Bluff, the difference in mean monthly flow rate for Alternative 2D compared to NAA_ELT indicate negligible effects on flow attributable to the project for December through April and increases in flow attributable to the project during May of up to 12% (Appendix *B, Supplemental Modeling for New Alternatives)*. The project-related increases in flow in the Sacramento River at Red Bluff would have a beneficial effect on migration conditions.

These results indicate that project-related effects of Alternative 2D on flow consist of negligible effects (<5%), or small increases in flow that would have a beneficial effect on migration in the Sacramento River at Red Bluff, but that effects for Sacramento River at Rio Vista would consist primarily of reductions in flow, including during drier water years, for much of the macropthalmia migration period, although it is unknown whether these reductions would adversely affect outmigrating macropthalmia.

Adults

For the Sacramento River at Red Bluff for the time-frame January to June (Appendix *B, Supplemental Modeling for New Alternatives*), effects of Alternative 2D on mean monthly flow indicate effects would be negligible (<5%), except for one water year in January (6.2%), with small increases in flow (to 12%) during May and June for some water years. Increases in flow would have a beneficial effect on migration conditions.

Feather River

Macropthalmia

Comparisons for the Feather River at the confluence with the Sacramento River (Appendix *B, Supplemental Modeling for New Alternatives*) indicate negligible (<5%) project-related effects or small to moderate increases in flow (to 22%) for December through May,. Increases in mean monthly flow may be beneficial for migration conditions although there is no scientific evidence that this is true. The project would not have adverse effects on macropthalmia in the Feather River at the confluence.

Adults

For the Feather River at the confluence with the Sacramento River, January to June (Appendix *B, Supplemental Modeling for New Alternatives*), mean monthly flows under Alternative 2D are variable, with primarily negligible changes (<5%) for most months and water year types, with the exception of fairly substantial increases for most water year types for May (8–13%) and June (21–88%) that would have beneficial effects on migration conditions.

American River

Macropthalmia

Comparisons for the American River at the confluence with the Sacramento River (Appendix *B, Supplemental Modeling for New Alternatives*) indicate negligible effects (<5%) or small to moderate increases in flows in most months, with the exception of a moderate decrease during May in a critical (-24%) year and small decreases during January in below normal (-11.5%) and dry (-5.6%) years that would not have biologically meaningful effects on migration conditions.

Adults

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River for January to June (Appendix *B, Supplemental Modeling for New Alternatives*) indicate predominantly negligible effects (<5%) attributable to the project with the exception of increased flows in May (6–11%) and June (6–36%) which would enhance migration especially during drier water year types, and small decreases in flow (to -11.5%) during January in below normal and dry years and during May in a critical (-23.9%) year. that would not have biologically meaningful effects on migration conditions.

NEPA Effects: Collectively, these modeling results indicate that the effect is not adverse because it would not substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Flows in the Sacramento River at Rio Vista under Alternative 2D would be reduced relative to NAA_ELT, with persistent flow reductions to -30% throughout the migration period that could affect conditions for outmigrating macropthalmia at that location. The degree to which this reduction would affect lamprey is unknown, but given the predominance of negligible effects in other locations, it is not likely that reduced flows at this location would affect the Pacific lamprey population. Effects of Alternative 2D in the other locations analyzed would consist primarily of negligible effects (<5%), infrequent, small decreases in flow (to -7%) that would not have biologically meaningful effects, and small to substantial (to 73%) increases in flow that would have beneficial effects on migration conditions.

CEQA Conclusion: In general, the effect of Alternative 2D on Pacific lamprey migration conditions would be negligible relative to the Existing Conditions.

Sacramento River

Macropthalmia

Comparisons of mean monthly flow rates in the Sacramento River at Rio Vista (Appendix *B, Supplemental Modeling for New Alternatives*) for December to May for Alternative 2D relative to Existing Conditions indicate reductions in flow ranging from -5% to -38% in most water years for each of these months. These results indicate that effects of Alternative 2D on flow could have negative effects on outmigrating macropthalmia in the Sacramento River. Comparisons for the Sacramento River at Red Bluff (Appendix *B, Supplemental Modeling for New Alternatives*) indicate negligible (<5%) effects or small increases or decreases in flow (± 10%) that would not have biologically meaningful effects on migration conditions. Therefore, Alternative 2D would not have biologically meaningful negative effects on outmigrating macropthalmia at this location.

Adults

Comparisons of mean monthly flow for the Sacramento River at Red Bluff (Appendix *B, Supplemental Modeling for New Alternatives*) during the Pacific lamprey adult migration period from January through June indicate that for most months and water year types, flows under Alternative 2D would be similar to (<5% difference) flows under Existing Conditions, with infrequent occurrences of small-scale (to 10%) increases or decreases in flow that would not have biologically meaningful effects on migration conditions. Therefore, effects of Alternative 2D consist of negligible effects or increases in flow that would have beneficial effects, and small reductions in flow that would not have biologically meaningful effects.

Feather River

Macropthalmia

Comparisons for the Feather River at the confluence (Appendix *B, Supplemental Modeling for New Alternatives*) for December to May indicate variable effects by month and water year type, with increases in flow during December in above normal and below normal years (to 18%) and decreases in wet and critical years (to -12%), generally increases in flow during January through March in wetter years (to 11%) and decreases during some drier water year types (to -17%), and negligible effects or increases in flow (to 9%) during April and May except for a decrease (-10%) during May in wet years. Increases in flow would have beneficial effects on migration conditions, and decreases in wetter water years would not have significant effects on migration. Based on this limited occurrence of flow decreases at times that would be most critical for migration, and the prevalence of negligible effects or flow increases for most of the migration period, effects of Alternative 2D on flows would not have biologically meaningful effects on macropthalmia migration in the Feather River.

Adults

Comparisons of mean monthly flow for the Feather River at the confluence with the Sacramento River (Appendix *B, Supplemental Modeling for New Alternatives*) for January to June indicate variable effects of Alternative 2D depending on the month and water year type, with primarily negligible effects (<5%) and small increases or decreases in flow (to about 13%) that would not have biologically meaningful effects on migration conditions, with the exception of more substantial increases in flow during June in above normal (51%), below normal (58%), and critical (19%) years. These flow increases would have a beneficial effect on migration conditions. There would be more substantial decreases in flow during January in below normal years (-17%) and March in below normal years (-16%). These flow reductions are isolated occurrences of relatively small magnitude and would therefore not have biologically meaningful effects on migration conditions. Therefore, effects of Alternative 2D on flow would not affect migration conditions in the Feather River.

American River

Macropthalmia

Comparisons for the American River at the confluence with the Sacramento River (Appendix *B, Supplemental Modeling for New Alternatives*) for December to May indicate negligible effects (<5%) or decreases in flow during December and April, increases in flow during January through March for some wetter water year types (to 16%) and decreases for some drier water year types (to -13%), and decreases to -16% during May in all water year types.

Adults

Comparisons of mean monthly flow for the American River at the confluence with the Sacramento River (Appendix *B, Supplemental Modeling for New Alternatives*) for January to June indicate variable effects of Alternative 2D depending on the month and water year type, with meaningful changes in flow (±>5%) consisting of increases up to 16% (February, above normal years) that would have beneficial effects on migration conditions, and decreases to -7% in drier years. There would be primarily negligible effects (<5%) or small decreases (to -7%) and an increase of 9% (critical years) during April. There would be increases (to 8%) in all but critical years (decrease of -11%) during May, and decreases during June in wet (-21%) and critical (-36%) years with increases (to 23%) in the remaining water years.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact is not significant because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish, and no mitigation is necessary. Effects of Alternative 2D compared to Existing Conditions during the January to June adult Pacific lamprey migration period consist predominantly of negligible effects (<5%), increases in flow, or small, isolated occurrences of decreases in flow for some water year types that would not have biologically meaningful effects on migration conditions. Flows at Rio Vista would decrease for much of the period. However, the degree to which this reduction would affect lamprey is unknown, but given the predominance of negligible effects in other locations, it is not likely that reduced flows at this location would affect the Pacific lamprey population.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-169: Effects of Construction of Restoration Measures on Pacific Lamprey

Impact AQUA-170: Effects of Contaminants Associated with Restoration Measures on Pacific Lamprey

Impact AQUA-171: Effects of Restored Habitat Conditions on Pacific Lamprey

Impact AQUA-172: Effects of Methylmercury Management on Pacific Lamprey (Environmental Commitment 12)

Impact AQUA-175: Effects of Localized Reduction of Predatory Fish on Pacific Lamprey (Environmental Commitment 15)

Impact AQUA-176: Effects of Nonphysical Fish Barriers on Pacific Lamprey (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on Pacific lamprey for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

River Lamprey

Construction and Maintenance of Water Conveyance Facilities

Impact AQUA-181: Effects of Construction of Water Conveyance Facilities on River Lamprey

The potential effects of construction of the water conveyance facilities on river lamprey would be similar to those described for Alternative 4A (Impact AQUA-181) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to river lamprey.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-181, the effect would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-181, the impact of the construction of water conveyance facilities on river lamprey would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-182: Effects of Maintenance of Water Conveyance Facilities on River Lamprey

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-182, the effect would not be adverse for river lamprey.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-182 for river lamprey, the impact of the maintenance of water conveyance facilities on river lamprey would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

Impact AQUA-183: Effects of Water Operations on Entrainment of River Lamprey

The potential entrainment impacts of Alternative 2D on river lamprey would be the same as described above for Pacific lamprey (Impact AQUA-163).

NEPA Effects: The analysis of river lamprey entrainment at the SWP/CVP south Delta facilities is combined with the analysis of Pacific lamprey because the salvage facilities do not distinguish between the two lamprey species. Alternative 2D is expected to substantially reduce average annual entrainment of lamprey, estimated by salvage density, by about 59% (Table 11-2D-74) averaged across all years compared to NAA_ELT. Overall, Alternative 2D would not have adverse effects on lamprey.

CEQA Conclusion: Annual entrainment losses of juvenile green sturgeon would be decreased under Alternative 2D by approximately 60% compared to Existing Conditions (Table 11-2D-74). The screened north Delta intakes would exclude this species. Impacts of water operations on entrainment of river lamprey are considered less than significant and may be beneficial; no mitigation is required.

Impact AQUA-184: Effects of Water Operations on Spawning and Egg Incubation Habitat for River Lamprey

In general, Alternative 2D would not affect the quantity and quality of river lamprey spawning habitat relative to NAA_ELT.

Flow-related impacts to river lamprey spawning habitat were evaluated by estimating effects of flow alterations on redd dewatering risk as described for Pacific lamprey with appropriate time-frames for river lamprey incorporated into the analysis. Lower flows can reduce the instream area available for spawning and rapid reductions in flow can dewater redds leading to mortality. The same locations were analyzed as for Pacific lamprey: the Sacramento River at Keswick and Red Bluff, Trinity River downstream of Lewiston, Feather River at Thermalito Afterbay, and American River at Nimbus Dam and at the confluence with the Sacramento River. River lamprey spawn in these rivers between February and June so flow reductions during those months have the potential to dewater redds, which could result in incomplete development of the eggs to ammocoetes (the larval stage).

Dewatering risk to redd cohorts was characterized by the number of cohorts experiencing a month-over-month reduction in flows (using CALSIM II outputs) of greater than 50%. Small-scale spawning location suitability characteristics (e.g., depth, velocity, substrate) of river lamprey are not adequately described to employ a more formal analysis such as a weighted usable area analysis. Therefore, as described for Pacific lamprey, there is uncertainty that these values represent actual redd dewatering events, and results should be treated as rough estimates of flow fluctuations under each model scenario. Results were expressed as the number of cohorts exposed to dewatering risk and as a percentage of the total number of cohorts anticipated in the river based on the applicable time-frame, February to June.

Flows in all rivers evaluated indicated no change (0%) or negligible change (<5%) in redd cohorts exposed (Table 11-2D-85). There would be no biologically meaningful effects on spawning success attributable to the project.

Table 11-2D-85. Differences between Model Scenarios in Dewatering Risk of River Lamprey Redd Cohorts[a]

Location	Comparison[b]	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Sacramento River at Keswick	Difference	2	-1
	Percent Difference	6%	-3%
Sacramento River at Red Bluff	Difference	3	0
	Percent Difference	8%	0%
Trinity River downstream of Lewiston	Difference	-2	0
	Percent Difference	-3%	0%
Feather River Below Thermalito Afterbay	Difference	-3	-3
	Percent Difference	-4%	-4%
American River at Nimbus	Difference	6	-3
	Percent Difference	11%	-5%
American River at Sacramento River confluence	Difference	13	1
	Percent Difference	22%	1%

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey redd cohorts experiencing a month-over-month reduction in flows of greater than 50%.
[b] Positive values indicate a higher value in A2D_ELT than in EXISTING CONDITIONS or NAA_ELT).

River lamprey generally spawn between February and June (Beamish 1980, Moyle 2002). Using Pacific lamprey as a surrogate, eggs are assumed to hatch in 18-49 days depending on water temperature (Brumo 2006) and are, therefore, assumed to be present during roughly the same period and locations as spawners. Moyle et al. (1995) indicate that river lamprey "adults need…

temperatures [that] do not exceed 25°C," although there is no mention of thermal requirements for eggs in this or any existing literature. Meeuwig et al. (2005) reported that, for Pacific lamprey eggs, significant reductions in survival were observed at 22°C (71.6°F). Therefore, for this analysis, both temperatures, 22°C (71.6°F) and 25°C (77°F), were used as upper thresholds of river lamprey eggs. The analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) or 25°C (77°F) using daily data from USRWQM. For other rivers, the analysis predicted the number of consecutive two-month periods during which at least one month exceeds 22°C (71.6°F) or 25°C (77°F) using monthly averaged data from the Bureau's temperature model. Each individual day or month starts a new "egg cohort" such that there are 12,320 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from February 1 through June 30, and 405 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Spawning locations of river lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

For both thresholds, there would be few differences in egg cohort exposure between NAA_ELT and A2D_ELT among all sites (Table 11-2D-86). Differences of 7 cohorts in the Sacramento River at Hamilton City are negligible to the population considering the total number of cohorts is 12,320. In the Feather River below Thermalito Afterbay, there would be 16 more cohorts (123% increase) exposed to the 71.6°F threshold under Alternative 2D relative to NAA_ELT, although differences at the 77°F threshold would be negligible. In addition, there would be no differences between NAA_ELT and Alternative 2D in egg exposure at the Fish Barrier Dam in the Feather River. Overall, except at one location in the Feather River for the more conservative threshold temperature (71.6°F), these results indicate that there would be no differences in egg exposure to elevated temperatures under Alternative 2D.

Table 11-2D-86. Differences (Percent Differences) between Model Scenarios in River Lamprey Egg Cohort Temperature Exposure

Location	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
71.6°F Threshold		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	108 (NA)	7 (7%)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	2 (NA)	1 (100%)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	20 (222%)	16 (123%)
American River at Nimbus	13 (260%)	-1 (-5%)
American River at Sacramento River Confluence	14 (50%)	-15 (-26%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	11 (1,100%)	0 (0%)
77°F Threshold		
Sacramento River at Keswick	0 (NA)	0 (NA)
Sacramento River at Hamilton City	0 (NA)	0 (NA)
Trinity River at Lewiston	0 (NA)	0 (NA)
Trinity River at North Fork	0 (NA)	0 (NA)
Feather River at Fish Barrier Dam	0 (NA)	0 (NA)
Feather River below Thermalito Afterbay	2 (NA)	2 (NA)
American River at Nimbus	2 (NA)	1 (100%)
American River at Sacramento River Confluence	3 (NA)	0 (0%)
Stanislaus River at Knights Ferry	0 (NA)	0 (NA)
Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Difference and percent difference between model scenarios in the number of Pacific lamprey egg cohorts experiencing water temperatures above 71.6°F and 77°F during February to June on at least one day during a 49-Day incubation period in the Sacramento River or for at least one month during a 2-month incubation period for each model scenario in other rivers. Positive values indicate a higher value in the proposed project than in EXISTING CONDITIONS or NAA_ELT.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because it does not have the potential to substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. Alternative 2D would cause minor effects to river lamprey redd dewatering and exposure to elevated water temperatures that would not be substantial.

CEQA Conclusion: In general, Alternative 2D would not affect the quantity and quality of river lamprey spawning habitat relative to the Existing Conditions.

Lower flows can reduce the instream area available for spawning and rapid reductions in flow can dewater redds leading to mortality. Effects of Alternative 2D on flow reductions during the river lamprey spawning period from February to June in the Sacramento River and American River consist of increases in river lamprey redd cohort dewatering risk relative to Existing Conditions

(Table 11-2D-85). Changes would be most substantial for the American River (increased risk of dewatering exposure to 6 cohorts or 11% at Nimbus Dam, and 13 cohorts or 22% at the confluence). For the Trinity River there are 2 fewer redd cohorts (-3%), and for the Feather River there are 3 fewer redd cohorts (-4%), predicted to experience a month-over-month change in flow of greater than 50% for Alternative 2D relative to Existing Conditions.

In most locations, the number of ammocoete cohorts exposed to each threshold under Alternative 2D would be similar to or lower than those under NAA_ELT (Table 11-2D-86). Biologically meaningful exceptions include the Feather River below Thermalito Afterbay for the 71.6°F threshold. In this case, there would be another location within the river that would have similar or lower exceedances under Alternative 2D.

Summary of CEQA Conclusion

Collectively, the results of the Impact AQUA-184 CEQA analysis indicate that there would be less than significant effects to river lamprey spawning conditions because there would be minor effects of the alternative on redd dewatering risk and temperature exposure in all rivers. No mitigation is necessary.

Impact AQUA-185: Effects of Water Operations on Rearing Habitat for River Lamprey

In general, Alternative 2D would not affect the quantity and quality of river lamprey rearing habitat relative to NAA_ELT.

Flow-related effects on river lamprey rearing habitat were evaluated by estimating effects of flow alterations on ammocoete exposure, or stranding risk, as described for Pacific lamprey. Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Effects of Alternative 2D on flow were evaluated in the Sacramento River at Keswick and Red Bluff, the Trinity River, Feather River, and the American River at Nimbus Dam and at the confluence with the Sacramento River. As for Pacific lamprey, the analysis of river lamprey ammocoete stranding was conducted by analyzing a range of month-over-month flow reductions from CALSIM II outputs, using the range of 50%–90% in 5% increments. A cohort of ammocoetes was assumed to be born every month during their spawning period (February through June) and spend 5 years rearing upstream. Therefore, a cohort was considered stranded if at least one month-over-month flow reduction was greater than the flow reduction at any time during the period. Comparisons of flow reductions for A2D_ELT relative to NAA_ELT for the Sacramento River at Keswick (Table 11-2D-87) predicted either no effect (0%) or negligible effects (±5%) in the occurrence of flow reductions attributable solely to the project, which would have beneficial effects on rearing success.

Table 11-2D-87. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Keswick

-65%	1	-4
-70%	0	-5
-75%	4	3
-80%	7	0
-85%	111	0
-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of A2D_ELT.

Results of comparisons for the Sacramento River at Red Bluff (Table 11-2D-88) provided similar conclusions, with slightly more variability in results. A2D_ELT compared to NAA_ELT indicated no change (0%), negligible effects (±5%), and small increases (to 6%) attributable to the project for different flow reduction categories. Based on the general decrease in frequency of most of the flow reduction categories, the small increases (to 6%) predicted for the 50% and 55% flow reduction event would not have biologically meaningful effects on rearing success.

Table 11-2D-88. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Sacramento River at Red Bluff

-90%	NA	NA

NA = could not be calculated because the denominator was 0.
[a] Negative values indicate reduced cohort exposure, a benefit of A2D_ELT.

Comparisons for the Trinity River indicate small increases in occurrence of 80 through 90% flow reductions under Alternative 2D relative to NAA_ELT (Table 11-2D-89). Occurrences of 50 to 75% flow reductions indicates no effect (0%) or (negligible changes ±5%) attributable to the project.

Table 11-2D-89. Percent Difference between Model Scenarios in the Number of River Lamprey Ammocoete Cohorts Exposed to Month-over-Month Flow Reductions, Trinity River at Lewiston

[a] Negative values indicate reduced cohort exposure, a benefit of A2D_ELT.

Flow reduction comparisons for the American River at Nimbus Dam (Table 11-2D-91) and at the confluence with the Sacramento River (Table 11-2D-92) indicated no effect (0%), negligible increases (<5%), small increases (<13%) or substantial decreases (to -55%) attributable to the project, with increases of 19 to 32% for 75 to 80%, flow reduction categories, at Nimbus Dam and the confluence. Based on the general decrease in frequency of most of the flow reduction categories, the 19 to 32% increases predicted for a three flow reduction categories (75%, 80, and 85%) would not have biologically meaningful effects.

[a] Negative values indicate reduced cohort exposure, a benefit of A2D_ELT.

River lamprey generally spawn between February and June (Beamish 1980, Moyle 2002). Using Pacific lamprey as a surrogate, eggs are assumed to hatch in 18-49 days depending on water temperature (Brumo 2006) and are, therefore, assumed to be present during roughly the same period and locations as spawners. Moyle et al. (1995) indicate that river lamprey "adults need… temperatures [that] do not exceed 25°C," although there is no mention of thermal requirements for eggs in this or any existing literature. Meeuwig et al. (2005) reported that, for Pacific lamprey eggs, significant reductions in survival were observed at 22°C (71.6°F). Therefore, for this analysis, both temperatures, 22°C (71.6°F) and 25°C (77°F), were used as upper thresholds of river lamprey eggs. The analysis predicted the number of consecutive 49 day periods for the entire 82-year CALSIM period during which at least one day exceeds 22°C (71.6°F) or 25°C (77°F) using daily data from SRWQM. For other rivers, the analysis predicted the number of consecutive two-month periods during which at least one month exceeds 22°C (71.6°F) or 25°C (77°F) using monthly averaged data from the Bureau's temperature model. Each individual day or month starts a new "egg cohort" such that there are 12.320 cohorts for the Sacramento River, corresponding to 82 years of eggs being laid every day each year from February 1 through June 30, and 405 cohorts for the other rivers using monthly data over the same period. The incubation periods used in this analysis are conservative and represent the extreme long end of the egg incubation period (Brumo 2006). Also, the utility of the monthly average time step is limited because the extreme temperatures are masked; however, no better analytical tools are currently available for this analysis. Spawning locations of river lamprey are not well defined. Therefore, this analysis uses the widest range in which the species is thought to spawn in each river.

In the Sacramento River at Hamilton City, there would be 1,460 fewer cohorts (-25%) exposed to the 71.6°F threshold under Alternative 2D relative to NAA_ELT, although there would be 4,647 more exposed to the 77°F threshold (Table 11-2D-93) There would be 25 more (100% increase) and 95 more (37% increase) cohorts exposed to the 71.6°F threshold in the Trinity River at North Fork and in the Feather River below Thermalito Afterbay, respectively. There would also be increase in exposure to the 77°F threshold in the Feather and American Rivers. However, none of these increases is expected to be biologically meaningful due to the relatively small magnitude relative to the total number of cohorts and the lack of effect in the majority of locations.

Table 11-2D-93. Differences (Percent Differences) between Model Scenarios in River Lamprey Ammocoete Cohorts Exposed to Temperatures in the Feather River Greater than 71.6°F and 77°F in at Least One Month

Location	EXISTING CONDITIONS vs. A2D_ELT_	NAA_ELT vs. A2D_ELT_

Stanislaus River at Riverbank	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] Positive values indicate a higher value in the preliminary proposal than in EXISTING CONDITIONS or NAA_ELT.

[b] Based on daily data; all other locations use monthly data; 1922–2003.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because it does not have the potential to substantially reduce rearing habitat or substantially reduce the number of fish as a result of ammocoete mortality. Alternative 2D would not affect river lamprey ammocoete stranding relative to the NEPA baseline. Further, increases in exposure to water temperatures under Alternative 2D would not be biologically meaningful.

CEQA Conclusion: In general, Alternative 2D would not affect the quantity and quality of river lamprey rearing habitat relative to the Existing Conditions.

Lower flows can reduce the instream area available for rearing and rapid reductions in flow can strand ammocoetes leading to mortality. Comparisons of Alternative 2D to Existing Conditions for the Sacramento River at Keswick indicate small increases (to 7%), negligible increases (<5%) in the occurrence of flow reductions for all flow reduction categories (Table 11-2D-87) with the exception of a substantial increase (11%) in month-over-month flow reductions of 85%. Comparisons for the Sacramento River at Red Bluff indicate slightly more variable results with no effect (0%) or negligible effects (<5%) for all flow reduction categories except for increases (19% and 23%) in the 75% and 80% flow reduction categories, respectively (Table 11-2D-88).

Comparisons for the Trinity River indicated no effect (0%) for flow reduction categories from 50% to 70%, and increases ranging from 27% to 49% for the higher flow reduction categories (Table 11-2D-89).

Comparisons for the Feather River indicated no effect or reductions in frequency of occurrence for all flow reduction categories (Table 11-2D-90).

Comparisons for the American River at Nimbus Dam (Table 11-2D-91) and at the confluence with the Sacramento River (Table 11-2D-92) indicated increased chance of occurrence of flow reductions between 70 and 90% for Alternative 2D compared to Existing Conditions, with the exception of predicted 100% decrease of occurrence for 90% flow reduction at the confluence; meaningful (>5%) predicted increases are from 35 to 292% for Nimbus Dam and from 24 to 270% for the confluence.

The number of ammocoete cohorts exposed to 71.6°F under Alternative 2D would be substantially higher than those under Existing Conditions in most locations examined (Table 112D-93). The number of ammocoete cohorts exposed to 77°F under Alternative 2D would be similar at all locations except the Feather River below Thermalito Afterbay and at both locations in the American River, at which exposure would increase by 50 to 130 cohorts.

Summary of CEQA Conclusion

Contrary to the NEPA conclusion set forth above, the results of the Impact AQUA-185 CEQA analysis indicate that that the difference between the CEQA baseline and Alternative 2D could be significant because, under the CEQA baseline, the alternative could substantially reduce rearing habitat and substantially reduce the number of fish as a result of ammocoete mortality. There would be substantial increases in stranding risk in the Trinity and American Rivers under Alternative 2D relative to the Existing Conditions. Increased stranding risk in these rivers would increase the risk of desiccation and reduce survival of ammocoete cohorts. Additionally, the risk of exposure to elevated water temperatures in the Feather and American Rivers would increase under Alternative 2D relative to the Existing Conditions. Increased water temperatures would increase stress and reduce survival of lamprey ammocoetes.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on flows, reservoir storage, and water temperatures during the months and locations analyzed would be minimal. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the effects of Alternative 2D on river lamprey rearing habitat conditions would be less than significant and no mitigation is necessary.

Impact AQUA-186: Effects of Water Operations on Migration Conditions for River Lamprey

In general, Alternative 2D would have negligible effects on river lamprey migration conditions relative to NAA_ELT due to negligible effects on mean monthly flows. There would be beneficial effects due to moderate increases in mean monthly flow for some months and water year types but these generally would be offset by flow reductions in other months.

Macropthalmia

After 3 to 5 years river lamprey ammocoetes migrate downstream and become macropthalmia once they reach the Delta. River lamprey migration generally occurs September through November (USFWS unpubl. data). The effects of water operations on seasonal migration flows for river lamprey macropthalmia were assessed using CALSIM II flow output. Flow rates along the likely migration pathways of river lamprey during the likely migration period (September through November) were examined to predict how Alternative 2D may affect migration flows for outmigrating macropthalmia.

Analyses were conducted for the Sacramento River at Red Bluff, Feather River at the confluence with the Sacramento River, and the American River at the confluence with the Sacramento River.

Sacramento River

Comparisons for the Sacramento River at Red Bluff for September through November indicate variable effects of Alternative 2D depending on the month and the water year type. Alternative 2D indicates variable effects, with project-related decreases (-5% and -17%) for September in all water year types except critical years indicate negligible effects, negligible effects (with <5% difference) in all water year types in October, and decreases in flows for all year types (-6% to -18%) in November. Decreases in wetter years in September would less detrimental because flows are higher; the decreases in drier water years would be more detrimental for outmigration. Decreases (to 18%) in November would affect migration conditions during that month, which is the last month in the relatively short migration period.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River for September through November indicate decreases in flow during most water year types in September (-16, -18, -32, and -7% for wet, above normal, below normal, dry respectively) and increases in flow during critical years (14%). The increases in flow during critical years for September would have a positive effect on migration when flow conditions are most critical. There would also be project-related increases in flow during October in all water years, ranging from 5 to 15% depending on water year type. Project-related effects during November would be negligible (<5%) in all water year types. These results indicate Alternative 2D would not affect migration in the Feather River.

American River

Comparisons for the American River at the confluence with the Sacramento River for September through November indicate decreased flows for September in generally all water year types (-9% to -27% depending on year type) except dry years indicate negligible effects, decreased flows during October in wetter water years (to -7%) and dry years (-8%) and increased flows (19% and 27%, below normal and critical years, respectively), and negligible project-related changes during dry and critical years during November and decreased flows (to 15%) for wetter years. These results indicate Alternative 2D would not affect migration conditions in the American River.

Overall conclusions are that, with some variation in results by location, month, and water year type, Alternative 2D would generally not have biologically meaningful effects on macropthalmia migration based on negligible effects (<5%), decreases in flow during wetter water year types that would not have biologically meaningful effects, and increases in flow during drier water years that would have a beneficial effect on migration.

Adults

Effects of Alternative 2D on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

NEPA Effects: Collectively, these results indicate that is not adverse because it would not substantially reduce the amount of suitable habitat or substantially interfere with the movement of fish. Flows under Alternative 2D would not be reduced from NAA_ELT in any waterway analyzed that would affect river lamprey macropthalmia or adults in a biologically meaningful way. There would be small to moderate increases in mean monthly flow for some months and water year types that would have beneficial effects on migration conditions.

CEQA Conclusion: In general, under Alternative 2D water operations, the quantity and quality of suitable migration habitat for river lamprey would not be affected relative to the CEQA baseline.

Macropthalmia

Sacramento River

Comparisons for the Sacramento River at Red Bluff for September through November indicate variable effects of Alternative 2D during September, with increases in mean monthly flow for wetter water year types (21 to 28%) that would have beneficial effects on migration conditions, and decreases for drier water year types (-6 to -24% for below normal, dry, and critical years). Alternative 2D would result in decreases (-5% to -18%) for October in all water year types. Alternative 2D would result in small to moderate decreases in mean monthly flows compared to Existing Conditions for all water year types in November (-8 to -18%). Persistent small to moderate reductions in flow in drier water years for two of the three months in the migration period could affect migration conditions in the Sacramento River.

Feather River

Comparisons for the Feather River at the confluence with the Sacramento River for September through November indicate variable results by month and water year type, with increases for wetter years and decreases in drier years in September except critical years indicates increases (14%), increases in dry years (19%)) in October that would have a small beneficial effect on migration, and negligible effects for water year types in November except for small decreases (-5%) in wet years. Decreased mean monthly flows in September and November during drier water years could affect migration conditions; increases in these water year types in September would have a beneficial effect.

American River

Comparisons for the American River at the confluence with the Sacramento River for September through November indicate reductions in flow for most months and most water year types, ranging from -8 to -43%, with the exception of a 10% and 17% increases in mean monthly flow for below normal and critical water years during October. The predominance of decreased flows for Alternative 2D compared to Existing Conditions would affect migration conditions, with substantial decreases for dry and critical years in September (-30 and -47%, respectively) and November (-23 and -17%, respectively).

Overall, these results indicate that Alternative 2D would cause decreases in mean monthly flow during all or portions of the river lamprey macropthalmia migration period in the Sacramento River (to -22% in dry years), Feather River (to -28%), and American River (to -43%).

Adults

Effects of Alternative 2D on flow during the adult migration period, September through November, would be the same as described for the macropthalmia migration period, September through November, above.

Summary of CEQA Conclusion

Contrary to the NEPA conclusion set forth above, the results of the Impact AQUA-186 CEQA analysis indicate that the difference between the CEQA baseline and Alternative 2D could be significant because, under the CEQA baseline, the alternative could substantially reduce the amount of suitable habitat and substantially interfere with the movement of fish. Reductions in flows during the macropthalmia and adult migration periods would reduce migration ability of both life stages. For macropthalmia, reduced migration ability could increase straying risk and delay initiation of the oceanic life stage. For adults, reduced flows could reduce the ability to sense olfactory cues if adults use such cues to return to natal spawning grounds.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the

2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of the results between the alternative and NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, effects of Alternative 2D on flows, reservoir storage, and water temperatures during the months and locations analyzed would be minimal. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in flows and water temperatures under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, the effects of Alternative 2D on river lamprey migration habitat conditions would be less than significant and no mitigation is necessary.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-187: Effects of Construction of Restoration Measures on River Lamprey

Impact AQUA-188: Effects of Contaminants Associated with Restoration Measures on River Lamprey

Impact AQUA-189: Effects of Restored Habitat Conditions on River Lamprey

Impact AQUA-190: Effects of Methylmercury Management on River Lamprey (Environmental Commitment 12)

Impact AQUA-193: Effects of Localized Reduction of Predatory Fish on River Lamprey (Environmental Commitment 15)

Impact AQUA-194: Effects of Nonphysical Fish Barriers on River Lamprey (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on river lamprey for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Non-Covered Aquatic Species of Primary Management Concern

Construction and Maintenance of Water Conveyance Facilities

The effects of construction and maintenance of CM1 under Alternative 2D would be similar for all non-covered species; therefore, the analysis below is combined for all non-covered species instead of analyzed by individual species.

Impact AQUA-199: Effects of Construction of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

The potential effects of the construction of water conveyance facilities on non-covered species of primary management concern would be similar to those described for Alternative 4A (Impact AQUA-199) except that Alternative 2D would include two additional north Delta intakes (i.e., five intakes instead of three), with the result that the effects (e.g., pile driving; see Table 11-mult-1 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS) would be proportionally greater. The same measures applied to Alternative 4A would be applied to Alternative 2D in order to avoid and minimize the effects to non-covered species of primary management concern.

NEPA Effects: As concluded for Alternative 4A, Impact AQUA-199, the effect would not be adverse for non-covered species of primary management concern.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-199, the impact of the construction of the water conveyance facilities on non-covered aquatic species of primary management concern would be less than significant except for construction noise associated with pile driving. Implementation of Mitigation Measures AQUA-1a and AQUA 1b would reduce that noise impact to less than significant.

Mitigation Measure AQUA-1a: Minimize the Use of Impact Pile Driving to Address Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1a under Alternative 1A, Impact AQUA-1.

Mitigation Measure AQUA-1b: Monitor Underwater Noise and if Necessary, Use an Attenuation Device to Reduce Effects of Pile Driving and Other Construction-Related Underwater Noise

Please refer to Mitigation Measure AQUA-1b under Alternative 1A, Impact AQUA-1.

Impact AQUA-200: Effects of Maintenance of Water Conveyance Facilities on Non-Covered Aquatic Species of Primary Management Concern

NEPA Effects: The potential effects of the maintenance of water conveyance facilities under Alternative 2D would be the same as those described for Alternative 4A. As concluded in Alternative 4A, Impact AQUA-200, the effect would not be adverse for non-covered aquatic species of primary management concern.

CEQA Conclusion: As described in Alternative 4A, Impact AQUA-200 for non-covered aquatic species of primary management concern, the impact of the maintenance of water conveyance facilities on non-covered aquatic species of primary management concern would be less than significant and no mitigation is required.

Operations of Water Conveyance Facilities

The effects of water operations of water conveyance facilities under Alternative 2D include a detailed analysis of the following species:

- Striped Bass
- American Shad
- Threadfin Shad
- Largemouth Bass
- Sacramento tule perch
- Sacramento-San Joaquin roach – California species of special concern
- Hardhead – California species of special concern
- California bay shrimp

Impact AQUA-201: Effects of Water Operations on Entrainment of Non-Covered Aquatic Species of Primary Management Concern

A revised analysis of Impact AQUA-201 for all alternatives, including Alternative 2D, is provided in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The analysis below for Alternative 2D draws on that analysis.

Striped Bass

NEPA Effects: Under Existing Conditions, striped bass are observed in salvage operations of the south Delta facilities throughout the year, with the majority of juvenile striped bass entrainment occurring during the summer (May through July). As described in Chapter 11, Section 11.3.5 of this RDEIR/SDEIS, in Appendix A, operation of the north Delta intakes under Alternative 2D would be expected to reduce overall entrainment of screenable life stages (i.e., early juveniles and older, around 20 mm long) because of the reduction in use of the south Delta facilities, which do not have the state of the art fish screens proposed for the north Delta intakes. Differences in potential entrainment as a function of exports that were provided for juvenile Sacramento splittail under Impact AQUA-111 are representative of the late spring/early summer reductions in entrainment that could occur for juvenile striped bass. As described in Chapter 11, Section 11.3.5, in Appendix A, eggs and larval striped bass are susceptible to entrainment at the proposed north Delta intakes. Particle tracking modeling results for ten monthly periods during March-June suggested that overall entrainment of eggs and larvae of striped bass originating in the Sacramento River upstream of the Delta and moving downstream into the Delta would increase relative to NAA_ELT (see Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). For Alternative 2D, the mean entrainment was increased from 6.5% of particles to 23% of particles, a 256% increase. Note that entrainment of the early life stages of striped bass at the north Delta intakes may be moderated by real-time operational adjustments being made under Alternative 2D during the spring to benefit covered fishes such as spring-run Chinook salmon. Note also that although the north Delta intake screens are estimated to include larvae or juvenile fish of around 20-22 mm and larger, they may also exclude smaller fish to some extent, based on observations from other fish screens in the Delta (Nobriga et al. 2004). As described in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, density-dependence during the juvenile stages of the striped bass life cycle means that losses of early life stages do not necessarily translate into proportional reductions in abundance of older individuals, and entrainment has not recently been identified as a significant driver of juvenile abundance (Mac Nally et al. 2010; Thomson et al. 2010). Therefore it is concluded with some uncertainty that there would be an adverse effect on striped bass.

CEQA Conclusion: The impact of water operations on entrainment of striped bass would be the same as described immediately above. Relative to Existing Conditions, particle tracking modeling for Alternative 2D showed mean entrainment was increased by around 192% (from 8% to 23%; Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). As described in the NEPA Effects section above, increased losses of striped bass eggs and larvae need not necessarily translate into reductions in abundance of later life stages. Nevertheless it is concluded that the impact is significant and unavoidable.

American Shad

American shad eggs and larvae would be vulnerable to entrainment at the proposed north SWP/CVP Delta intakes as these life stages are passively transported downstream to the north Delta. Most American shad spawning though takes place well upstream of the Delta and juveniles may rear to sufficiently large size to avoid entrainment as state-of-the-art fish screens on the proposed north Delta intakes would exclude juvenile and adult American shad.

NEPA Effects: Differences in potential entrainment as a function of exports that were provided for juvenile Sacramento splittail under Impact AQUA-111 are representative of the late spring/early summer reductions in entrainment that could occur for juvenile American shad. As described in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, eggs and larval American shad are susceptible to entrainment at the proposed north Delta intakes. Particle tracking modeling results for ten monthly periods during March-June suggested that overall entrainment of eggs and larvae of American shad originating in the Sacramento River upstream of the Delta and moving downstream into the Delta would increase relative to NAA_ELT(see Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). For Alternative 2D, scenario NAA_ELT, and as discussed above for striped bass, the mean entrainment was increased from 6.5% of particles to 23% of particles, a 256% increase. As noted for striped bass, entrainment of the early life stages of American shad at the north Delta intakes may be moderated by real-time operational adjustments being made under Alternative 2D during the spring to benefit covered fishes such as spring-run Chinook salmon. Note also that although the north Delta intake screens are estimated to include larvae or juvenile fish of around 20-22 mm and larger, they may also exclude smaller fish to some extent, based on observations from other fish screens in the Delta (Nobriga et al. 2004). As described in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, although American shad early life stages may rear to sufficiently large size above the Delta to avoid entrainment, they could also be entrained in appreciably greater magnitude than currently occurs and therefore it is also concluded that the effects of entrainment on American shad would be adverse.

CEQA Conclusion: The impact of water operations on entrainment of American shad would be the same as described immediately above. Relative to Existing Conditions and as described above for striped bass, particle tracking modeling for Alternative 2D scenario NAA_ELT showed mean entrainment was increased by around 192% (from 8% to 23%; Table 11-mult-5 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). As described in the NEPA Effects section above, American shad early life stages may rear to sufficiently large size above the Delta to avoid entrainment. Nevertheless it is concluded that the impact is significant and unavoidable.

Threadfin Shad

NEPA Effects: The impact and conclusion would be the same as discussed for Alternative 1A (Impact AQUA-201 for Threadfin Shad). Entrainment at the south delta would be reduced due to overall decreased exports from the SWP/CVP south Delta facilities. There would be potential entrainment of threadfin shad eggs and larvae to the north Delta intakes, although this risk is minimal because threadfin shad are most abundant in the south Delta (Baxter et al. 2010; see also discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). Overall, threadfin shad entrainment would be reduced because they are most abundant in the southern Delta and would particularly benefit from reduced south Delta exports. The effect would not be adverse.

CEQA Conclusion: The impact of water operations on entrainment of threadfin shad would be the same as described immediately above in the NEPA Effects section. The impact would be less than significant and no mitigation would be required.

Largemouth Bass

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The impact would be less than significant and no mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The impact would be less than significant and no mitigation would be required

Sacramento-San Joaquin Roach

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The impact would be less than significant and no mitigation would be required.

Hardhead

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The impact would be less than significant and no mitigation would be required

California Bay Shrimp

NEPA Effects: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The effect would not be adverse.

CEQA Conclusion: Please refer to the discussion in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The impact would be less than significant and no mitigation would be required.

Impact AQUA-202: Effects of Water Operations on Spawning and Egg Incubation Habitat for Non-Covered Aquatic Species of Primary Management Concern

See Alternative 1A, Impact AQUA-202 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

In general, the effects of Alternative 2D on the quality and quantity of spawning, egg incubation, and initial rearing habitat conditions for striped bass would not be adverse relative to NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or slightly greater than flows under NAA_ELT during April through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to flows under NAA_ELT during April through June, except in above normal years during April (17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during April through June regardless of water year type (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be moderately to substantially greater than flows under NAA_ELT during April through June, except in critical years during May (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be moderately greater than flows under NAA_ELT during April through June, except in critical years during May (20% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside the range would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-2D-138).

Table 11-2D-138. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay are outside the 59°F to 68°F Water Temperature Range for Striped Bass Spawning, Embryo Incubation, and Initial Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (0%)	-5 (-11%)
Above Normal	-6 (-13%)	-15 (-28%)
Below Normal	-12 (-28%)	-14 (-32%)
Dry	2 (4%)	-7 (-13%)
Critical	8 (21%)	-3 (-6%)
All	-1 (-3%)	-8 (-16%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in striped bass spawning, incubation, or initial rearing habitat. Flows in all rivers examined during the April through June spawning, incubation, and initial rearing period under Alternative 2D would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 2D in any river examined.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for striped bass relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June striped bass spawning, embryo incubation, and initial rearing period. Lower flows could reduce the quantity and quality of instream habitat available for spawning, egg incubation, and rearing.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during April through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during April through June, except in below normal years in April (6% lower) and wet years during May (15% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be up to 13% lower under Existing Conditions during May but similar during April and June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during April through June.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be up to 14% lower than those under Existing Conditions during April through June.

Water Temperature

The percentage of months outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside of the 59°F to 68°F suitable water temperature range for striped bass spawning, embryo incubation, and initial rearing during April through June would be the same as or lower than the percentage under Existing Conditions in all water years except critical years (21% higher on a relative scale; 8% higher on an absolute scale) (Table 11-2D-138). This is a relatively small effect that would not have biologically meaningful negative effects on the striped bass population because it only occurs in one water year type.

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the effect would not be significant because Alternative 2D would not cause a substantial reduction in spawning, incubation, and initial rearing habitat of striped bass relative to Existing Conditions. Therefore, no mitigation is necessary. Flows in all rivers except the San Joaquin and Stanislaus Rivers during the April through June spawning, incubation, or initial rearing period under Alternative 2D would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to striped bass. There would be no substantial temperature effects under Alternative 2D on striped bass.

American Shad

In general, the effects of Alternative 2D on the quality and quantity of spawning and egg incubation habitat conditions for American shad would not be adverse relative to NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during April through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to flows under NAA_ELT during April through June, except in above normal years during April (17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during April through June, regardless of water year type (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D would generally be moderately to substantially greater than flows under NAA_ELT during April through June, except in critical years during May (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be moderately greater than flows under NAA_ELT during April through June, except in critical years during May (20% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT during April through June, regardless of water year type.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside the 60°F to 70°F water temperature range would be lower than the percentage under NAA_ELT regardless of water year type (Table 11-2D-140).

Table 11-2D-140. Difference and Percent Difference in the Percentage of Months during April–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 60°F to 70°F Water Temperature Range for American Shad Adult Migration and Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-6 (-14%)	-3 (-6%)
Above Normal	-3 (-8%)	-15 (-31%)
Below Normal	-2 (-8%)	-7 (-20%)
Dry	-2 (-5%)	-4 (-9%)
Critical	-3 (-8%)	-6 (-14%)
All	-4 (-9%)	-6 (-14%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in American shad spawning or adult migration. Flows in all rivers examined during the April through June adult migration and spawning period under Alternative 2D would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 2D in any river examined.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for American shad relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through June American shad adult migration and spawning period. Lower flows could reduce migration ability and instream habitat quantity and quality for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through June, except in critical years during May (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during April through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during April through June, except in below normal years in April (6% lower) and wet years during May (15% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be up to 13% lower under Existing Conditions during May, but similar during April and June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during April through June. In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be up to 14% lower than those under Existing Conditions during April through June.

Water Temperature

The percentage of months outside of the 60°F to 70°F water temperature range for American shad adult migration and spawning during April through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased adult migrant stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside of the 60°F to 70°F water temperature range would be lower than the percentage under Existing Conditions in all water year types (Table 11-2D-140).

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 2D would not cause a substantial reduction in spawning, incubation, and initial rearing habitat of American shad relative to Existing Conditions. Therefore, no mitigation is necessary. Flows in all rivers except the San Joaquin and Stanislaus Rivers during the April through June spawning, incubation, or initial rearing period under Alternative 2D would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to American shad. There would be no substantial temperature effects under Alternative 2D on American shad.

Threadfin Shad

In general, the effects of Alternative 2D on the quality and quantity of spawning habitat conditions for threadfin shad would not be adverse relative to NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during April through August threadfin shad spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during April through August, except in dry years during August (11% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to flows under NAA_ELT during April through August, except in above normal years during April (17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during April through August, except in critical years during July (14% lower) and in critical years during August (11% greater) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be moderately to substantially greater than flows under NAA_ELT during April through June (to 121% greater), except during critical years in May (7% lower), and moderately to substantially lower than flows under NAA_ELT during July and August (to 45% lower), except during critical years in August (14% greater) (Appendix *B, Supplemental Modeling for New Alternatives*). Based on occurrence late in the spawning period, these flow reductions are not expected to have biologically meaningful effects.

In the American River below Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during April through July, except in May during critical years (20%) and lower flows under NAA_ELT during August (to 20% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). These flow reductions are small to moderate in magnitude and limited to late in the spawning period and, therefore, would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during April through August, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would be similar to those under NAA_ELT during April through August, regardless of water year type.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT below 68°F would be greater than those under NAA_ELT (2% to 20% greater) in all but dry and critical years (Table 11-2D-142). On an absolute scale, there are small increases (≤4%) in wet and above normal water years that would not have biologically meaningful effects, and a small increase that is isolated to below normal water years (11% increase).

Table 11-2D-142. Difference and Percent Difference in the Percentage of Months during April–August in Which Water Temperatures in the Feather River below Thermalito Afterbay fall below the 68°F Water Temperature Threshold for Threadfin Shad Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (0%)	2 (2%)
Above Normal	-9 (-12%)	4 (6%)
Below Normal	-1 (-2%)	11 (20%)
Dry	-29 (-39%)	-6 (-11%)
Critical	-22 (-33%)	-2 (-4%)
All	-11 (-16%)	1 (3%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in threadfin shad spawning habitat. Flows in all rivers examined during the April through August spawning period under Alternative 2D would generally be similar to or greater than flows under the NAA_ELT. Some flow reductions would occur late in the spawning season in the Feather and American Rivers and would be too small in magnitude or frequency to have a biologically meaningful effect on threadfin shad. The percentage of years below the spawning temperature threshold would be similar or lower under Alternative 2D relative to the NAA_ELT, except in below normal years, but this increase is not expected to have a biologically meaningful effect on the threadfin shad population because it occurs in only one water year type and is isolated to the Feather River.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for threadfin shad relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during April through August spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through August, except in wet years during May (10% lower) and in dry and critical years during August (12% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). These are relatively small-magnitude and infrequent flow reductions and would not have biologically meaningful effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through August, except in critical years during May and August (6% and 8% lower, respectively) and in wet years during July (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during April through August (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during April through June, except in below normal years during April (6% lower) and in wet years during May (15% lower), and would be lower than flows under Existing Conditions in dry and critical years during July (28% and 50% lower, respectively) and in below normal and dry years during August (10% and 45% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to flows under Existing Conditions during April and July and lower flows under Existing Conditions during May, June and August (up to 46% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during April and May, and would be up to 23% lower than flows under Existing Conditions during June through August.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would be similar to or up to 14% lower than to those under Existing Conditions during April through August, except for 11% greater flow during June of wet years.

Water Temperature

The percentage of months below 68°F water temperature threshold for the April through August adult threadfin shad spawning period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent successful spawning in these areas. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months below the 68°F water temperature threshold for threadfin shad spawning under A2D_ELT would be similar to or 2% to 29% lower than the percentage under Existing Conditions, depending on water year type (Table 11-2D-142).

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 2D during the threadfin shad spawning period relative to Existing Conditions. Flows would be moderately to substantially lower in the Feather, American, Stanislaus, and San Joaquin rivers during substantial portions of the spawning period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable spawning habitat as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the

alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Largemouth Bass

In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for largemouth bass relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during March through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during March through June, except in above normal years during April (17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during March through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be moderately to substantially greater than flows under NAA_ELT during March through June, except in below normal years during March (13% lower) and in critical years during May (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during March through June, except in May during critically dry years (20% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that in the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside the 59°F to 75°F water temperature range would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-2D-144).

Table 11-2D-144. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 75°F Water Temperature Range for Largemouth Bass Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-2 (-4%)	0 (0%)
Above Normal	-2 (-5%)	0 (0%)
Below Normal	0 (0%)	0 (0%)
Dry	-6 (-12%)	0 (0%)
Critical	-8 (-19%)	-2 (-6%)
All	-3 (-7%)	0 (-1%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in largemouth bass spawning habitat. Flows in all rivers examined during the March through June spawning period under Alternative 2D would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 2D in any river examined.

CEQA Conclusion: In general, Alternative 2D would not reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June largemouth bass spawning period. Lower flows could reduce the quantity and quality of instream spawning habitat.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (7% lower) and in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (6% lower) and in critical years during May (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during March through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during March through June, except in below normal and dry years during March (40% and 14% lower, respectively), in below normal years during April (6% lower), and in wet years during May (15% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during March, April and June, except in critical years during March (7% lower), above normal years during April (5% lower), and in wet and critical years during June (20% and 30% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be lower than flows under Existing Conditions during May (to 13% lower) except in critical years (11% greater). Flow reductions in drier water year types, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude throughout the spawning period and would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or lower (up to 16%) than those under Existing Conditions during March through June, except in wet years during March to May, when flows under A2D ELT would range from 2% to 9% greater.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be up to 23% lower than to those under Existing Conditions during March through June, except during these four months in wet years, in which flows under A2D_ELT would range from 0.3% lower to 11% greater.

Water Temperature

The percentage of months outside of the 59°F to 75°F suitable water temperature range for largemouth bass spawning during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside of the 59°F to 75°F water temperature range for largemouth bass spawning would be the same or lower than the percentage under Existing Conditions in all water year types (Table 11-2D-144).

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 2D would not cause a substantial reduction in largemouth bass spawning habitat relative to Existing Conditions, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus Rivers during the March through June spawning period under Alternative 2D would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to largemouth bass. There would be no substantial temperature effects under Alternative 2D on largemouth bass.

Sacramento Tule Perch

NEPA Effects: The effects of water operations on spawning habitat for Sacramento tule perch under Alternative 2D would be similar to that described for Alternative 1A due to similarities in hydrology. For a detailed discussion, please see Alternative 1A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: As described under Alternative 1A, Impact AQUA-202 the impacts on Sacramento tule perch spawning would be not be significant and no mitigation is required.

Sacramento-San Joaquin Roach – California species of special concern

In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during March through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during March through June, except in above normal years during April (17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during March through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be moderately to substantially greater than flows under NAA_ELT during March through June, except in below normal years during March (13% lower) and in critical years during May 7% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during March through June, except in May during critically dry years (20% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT during March through June, regardless of water year type (Appendix *B, Supplemental Modeling for New Alternatives*).

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation under A2D_ELT would be similar to the percentage under NAA_ELT in all water year types (Table 11-2D-146).

Table 11-2D-146. Difference and Percent Difference in the Percentage of Months during March–June in Which Water Temperatures in the Feather River below Thermalito Afterbay Fall below the 60.8°F Water Temperature Threshold for the Initiation of Sacramento-San Joaquin Roach Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	-8 (-12%)	0 (0%)
Above Normal	-5 (-8%)	0 (0%)
Below Normal	-2 (-4%)	0 (0%)
Dry	-6 (-10%)	0 (0%)
Critical	-8 (-15%)	0 (0%)
All	-6 (-10%)	0 (0%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in Sacramento-San Joaquin roach spawning habitat. Flows in all rivers examined during the March through June spawning period under Alternative 2D would generally be similar to or greater than flows under the NAA_ELT. The occurrence of flow reductions would not be of sufficient magnitude or frequency to have a biologically meaningful effect on roach. There would be no substantial temperature effects under Alternative 2D in any river examined.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the March through June Sacramento-San Joaquin roach spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (7% lower) and in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during March through June, except in below normal years during March (6% lower) and in critical years during May (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during March through June (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during March through June, except in below normal and dry years during March (39% and 17% lower, respectively), in below normal years during April (6% lower), and in wet years during May (15% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during March, April and June, except in critical years during March (7% lower), above normal years during April (5% lower), and in wet and critical years during June (20% and 30% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be lower than flows under Existing Conditions during May (to 13% lower), except in critical years (11% greater) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions in drier water year types, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude throughout the spawning period and would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through June, except during March of below normal and dry water years, when flow under A2D_ELT would be 11% and 12% lower, respectively, and during June of wet and dry water years, when flows would be 16% and 11% lower, respectively.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or lower (up to 16%) than those under Existing Conditions during March through June, except during March to May in wet years, when flows under A2D ELT would range from 2% to 9% greater.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be up to 23% lower than to those under Existing Conditions during March through June, except during these four months in wet years, in which flows under A2D_ELT would range from 0.3% lower to 11% greater.

Water Temperature

The percentage of months below the 60.8°F water temperature threshold for Sacramento-San Joaquin roach spawning initiation during March through June was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures below this threshold could delay or prevent spawning initiation. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers.

In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT in which temperatures would be below the 60.8°F water temperature threshold for roach spawning initiation would be lower than the percentage under Existing Conditions in all water year types (Table 11-2D-146).

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the impact would not be significant because Alternative 2D would not cause a substantial reduction in Sacramento-San Joaquin roach spawning habitat relative to Existing Conditions, and no mitigation is necessary. Flows in all rivers examined except the San Joaquin and Stanislaus Rivers during the March through June spawning period under Alternative 2D would generally be similar to or greater than flows under Existing Conditions. There would be isolated and/or small-magnitude flow reductions for some months and water year types in the San Joaquin and Stanislaus Rivers that would not have biologically meaningful negative effects to Sacramento-San Joaquin roach. There would be no substantial temperature effects under Alternative 2D on Sacramento-San Joaquin roach.

Hardhead – California species of special concern

In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during April and May) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to flows under NAA_ELT during April and May, except in above normal years during April (17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during April and May (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be similar to moderately greater than flows under NAA_ELT during April and May, except in critical years in May (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during April and May, except in critically dry years during May (20% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during April and May, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT during April and May, regardless of water year type.

Water Temperature

The percentage of years outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT, this analysis was not conducted and it was concluded that there would be no temperature-related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of years under A2D_ELT outside the 59°F to 64°F suitable water temperature range would be similar to or lower than the percentage under NAA_ELT in all water year types (Table 11-2D-148).

Table 11-2D-148. Difference and Percent Difference in the Percentage of Months during April–May in Which Water Temperatures in the Feather River below Thermalito Afterbay Would Be outside the 59°F to 64°F Water Temperature Range for Hardhead Spawning[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	2 (3%)	0 (0%)
Above Normal	0 (0%)	-9 (-13%)
Below Normal	18 (42%)	4 (6%)
Dry	6 (10%)	-6 (-8%)
Critical	-8 (-15%)	-8 (-15%)
All	4 (7%)	-3 (-5%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in hardhead spawning habitat. Flows in all rivers examined during the April through May spawning period under Alternative 2D would generally be similar to or greater than flows under the NAA_ELT. There would be no substantial temperature effects under Alternative 2D in any river examined.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for hardhead relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through May hardhead spawning period. Lower flows could reduce the quantity and quality of instream habitat available for spawning.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to flows under Existing Conditions during April through May, except in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through May, except in critical years during May (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under Existing Conditions during April through May, except in critical years during April and May (7% and 6% higher, respectively)(Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during April through May, except in below normal years during April (6% lower) and in wet years during May (15% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April, except in above normal years (5% lower). Flows under A2D_ELT would generally be lower than flows under Existing Conditions during May (to 13% lower). (Appendix *B, Supplemental Modeling for New Alternatives*). These few flow reductions are relatively small in magnitude and, therefore would not have biologically meaningful negative effects.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower (up to 8%) than those under Existing Conditions during April and May.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be lower (up to 12%) than to those under Existing Conditions during April and May.

Water Temperature

The percentage of months outside of the 59°F to 64°F suitable water temperature range for hardhead spawning during April through May was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced spawning success and increased egg and larval stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Because water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions, this analysis was not conducted and it was concluded that there would be no temperature related effects in these rivers. In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside of the 59°F to 64°F water temperature range for hardhead spawning would be greater than the percentage under Existing Conditions in all water years types, except critical years (15% lower) (Table 11-2D-148).

Summary of CEQA Conclusion

Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in hardhead spawning habitat, and no mitigation is necessary. Flows in most rivers examined during the April through May spawning period under Alternative 2D would generally be similar to or greater than flows under Existing Conditions. Flows in the San Joaquin and Stanislaus Rivers would be lower under Alternative 2D, although these reductions would not have population-level effects on hardhead. There would be no substantial temperature effects under Alternative 2D on hardhead.

California Bay Shrimp

NEPA Effects: The effect of water operations on spawning habitat of California bay shrimp under Alternative 2D would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-202) due to similarities in hydrology. For a detailed discussion, please see Alternative 1A, Impact AQUA-202. The effects would not be adverse.

CEQA Conclusion: The impact of water operations on spawning habitat of California bay shrimp would be the same as described immediately above. The impacts would be less than significant and no mitigation would be required.

Impact AQUA-203: Effects of Water Operations on Rearing Habitat for Non-Covered Aquatic Species of Primary Management Concern

Also, see Alternative 1A, Impact AQUA-203 for additional background information relevant to non-covered species of primary management concern. The analysis for striped bass, American shad, and bay shrimp includes new analysis across all alternatives that is described in detail in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS. The analysis below for Alternative 2D draws on that analysis.

Striped Bass

NEPA Effects: The discussion under Alternative 2D, Impact AQUA-202 for striped bass also addressed the embryo incubation and initial rearing period. That analysis indicates that there is no adverse effect on striped bass rearing during that period. As discussed further in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, water operations have the potential to affect striped bass juvenile abundance through changes in the extent of rearing habitat in the Plan Area as indexed by X2 (Kimmerer et al. 2009). Several X2-abundance index or X2-survival index relationships from Kimmerer et al. (2009) were applied to striped bass in order to assess the potential effects on abundance or survival through changes in rearing habitat. Application of these relationships suggested that, in relation to NAA_ELT, there generally would be 5-10% reductions in mean abundance index as a result of change in rearing habitat under Alternative 2D scenarios A2D_ELT (See Table 11-mult-6, Table 11-mult-7, Table 11-mult-8, Table 11-mult-9, and Table 11-mult-10 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). The exception was the mean bay midwater trawl abundance index (11% reduction; Table 11-mult-9). This result- indicates that the operational effects would not be adverse, because they would not result in a substantial reduction in the rearing habitat for striped bass.

CEQA Conclusion: The analysis of potential water operations-related rearing habitat effects illustrated that in relation to Existing Conditions (see Table 11-mult-6, Table 11-mult-7, Table 11-mult-8, Table 11-mult-9, and Table 11-mult 10 in Chapter 11, Section 11.3.5, in Appendix A of this

RDEIR/SDEIS), there could be significant impacts of Alternative 2D on survival or abundance of striped bass, in contrast to the conclusion presented above in the NEPA Effects section. As described in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both Alternative 2D and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur in the ELT, including the projected effects of climate change (precipitation patterns), sea level rise and future water demands. Because Alternative 2D modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. In the case of the X2-related analyses of rearing habitat for striped bass, the effect of sea level rise in particular confounds the interpretation of the effects of the alternatives. Based on the discussion presented above for the NEPA Effects, the change in rearing habitat would be less than significant. No mitigation would be necessary.

American Shad

NEPA Effects: As discussed further in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, water operations have the potential to affect American shad juvenile abundance through changes in the extent of rearing habitat in the Plan Area as indexed by X2 (Kimmerer et al. 2009). Two X2-abundance index relationships from Kimmerer et al. (2009) were applied to American shad in order to assess the potential effects on abundance through changes in rearing habitat. Application of these relationships suggested that, in relation to NAA_ELT, there would be only a small change in mean abundance index (<5%) as a result of change in rearing habitat under Alternative 2D scenario A2D_ELT (See Table 11-mult-11, Table 11-mult-12 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). These modeling results indicate that the operational effects would not be adverse, because they would not result in a substantial reduction in the rearing habitat for American shad.

CEQA Conclusion: Similar to striped bass, the analysis of potential water operations-related rearing habitat effects illustrated that in relation to Existing Conditions, there could be a greater impact of Alternative 2D on abundance of American shad (Table 11-mult-11, Table 11-mult-12 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS), than found in the NEPA Effects section. As noted for striped bass, the comparison to the NAA_ELT is a better approach than comparison to Existing Conditions because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. In the case of the X2-related analyses of rearing habitat for American shad, the effect of sea level rise in particular confounds the interpretation of the effects of the alternatives. Based on the discussion presented above for the NEPA Effects, the change in rearing habitat would be less than significant. No mitigation would necessary.

Threadfin Shad

NEPA Effects: The effects of water operations on rearing habitat for threadfin shad under Alternative 2D would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-203) due to similarities in hydrology. For a detailed discussion, please see Alternative 1A, Impact AQUA-203. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on threadfin shad rearing habitat would be less than significant and no mitigation would be required.

Largemouth Bass

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during April through October with some exceptions (to 17% lower), and would be lower in all water year types during November (to 18% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to flows under NAA_ELT with isolated exceptions, including flow reduction in above normal years during April (to 17% lower) and small flow reductions in above normal years during October (8% lower) and in wet years during November (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT during April through November, except in critical years during August (11% greater) and in critical years during July, September, and October (to 14% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be moderately to substantially greater than flows under NAA_ELT during April through June (to 121% greater), except in critical years during May (to 7% lower); moderately to substantially lower flows under NAA_ELT during July through September (to 49% lower), except in critical years during August and September (to 23% greater); and similar to or greater than flows under NAA_ELT during October and November (to 17% greater) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions during July through September would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during April through July and October, except in above normal and dry years during October (7% and 8% lower, respectively), and would be lower than flows under NAA_ELT during August, September, and November (to 24% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT during April through November, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT during April through November, regardless of water year type.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 88°F under NAA_ELT or A2D_ELT. As a result, there would be no difference between NAA_ELT and A2D_ELT in the percentage of months in which the 88°F water temperature threshold is exceeded (Table 11-2D-150).

Table 11-2D-150. Difference and Percent Difference in the Percentage of Months during April–November in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 88°F Water Temperature Threshold for Juvenile Largemouth Bass Rearing[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during year-round adult largemouth bass residency period. Lower flows could reduce the quantity and quality of instream habitat available for adults.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 12% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT throughout the year, except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be lower than flows under NAA_ELT during July through September, except in critical years in August and September (17% and 23% greater, respectively); would generally be similar to or greater than flows under NAA_ELT during January through June and October, except for below normal years during March (13% lower) and in critical years during May (7% lower); and would generally be similar to or greater than flows under NAA_ELT during November and December (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would be more persistently lower under A2D_ELT relative to NAA_ELT (up to 49% lower) during July, August, and in all water year types except critical years during September. Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal years during January (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 24% lower) during August through November, except in below normal and critical years during October (17% and 24% greater, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass residency period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of habitat and increased stress and mortality for adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA_ELT and A2D_ELT (Table 11-2D-151). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between NAA_ELT and A2D_ELT.

Table 11-2D-151. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Adult Largemouth Bass Survival[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in juvenile largemouth bass rearing and adult residency habitat. Flows in all rivers examined during the year under Alternative 2D are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Regardless of these small changes to flows, water temperatures under Alternative 2D would not increase above the 86°F threshold at a higher frequency than would occur under NAA_ELT. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the largemouth bass population.

CEQA Conclusion: In general, Alternative 2D would not reduce the quality and quantity of upstream habitat conditions for largemouth bass relative to Existing Conditions.

Juveniles

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the April through November juvenile largemouth bass rearing period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile rearing.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through July, except in wet years during May (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would generally be similar to or lower than flows under Existing Conditions during August through November (to 22% lower), except in wet and above normal years during September (to 27% greater) (Appendix *B, Supplemental Modeling for New Alternatives*). There would be primarily small flow reductions in some drier water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April through July, except in critical years during May (6% lower) and in wet years during July (10% lower), and similar to or lower than flows under Existing Conditions during August through November (to 17% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). The persistent, small to moderate flow reductions years during August through November would have a localized effect on rearing conditions.

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions during April through November, except in critical years during September (19% lower) and in below normal years during October (6% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). This flow reduction is a relatively small, isolated effect limited to a single water year type and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during April through June, September, and October, with a few isolated exceptions (to 47% lower)(Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be moderately to substantially lower than flows under Existing Conditions during July, August, and November (to 50% lower), except in wet and above normal years during July and August (to 42% greater) and in above normal years during November (5% greater).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during April, except in above normal years (5% lower), but generally lower, by up to 46%, during May through November (Appendix *B, Supplemental Modeling for New Alternatives*). There would be moderate flow reductions in drier water year types, when effects would be most critical for habitat conditions, for some months/water year types from May through November that would affect rearing conditions at this location.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during April and May and September through November, and would be similar to or up to 23% lower than flows under Existing Conditions during June through August.

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be similar to or up to 14% lower than to those under Existing Conditions during April through July, except for 11% greater flow during June of wet years, and would be similar to or slightly lower than flows under Existing Conditions during August through November.

Water Temperature

The percentage of months above the 88°F water temperature threshold for juvenile largemouth bass rearing during April through November was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of instream habitat available for juvenile rearing and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during the April through November period.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 88°F water temperature threshold for juvenile largemouth bass during the April through November rearing period under Existing Conditions or A2D_ELT (Table 11-2D-150). As a result, there would be no difference in the percentage of months in which the 88°F water temperature threshold is exceeded between A2D_ELT and Existing Conditions.

Adults

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round adult largemouth bass residency period. Lower flows could reduce the quantity and quality of instream habitat available for adults.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through July and December, except in below normal years during March (to 7% lower), and in wet years during May (10% lower), (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would generally be similar to or lower than flows under Existing Conditions during August through November (to 22% lower), except in wet and above normal years during September (20% and 27% greater, respectively). (Appendix *B, Supplemental Modeling for New Alternatives*). There would be primarily small flow reductions in some water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through September and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), and critical years in August and September (8% and 17% lower, respectively). Flows under A2D_ELT would generally be similar to or lower (up to 16%) than flows under Existing Conditions during October and November (Appendix *B, Supplemental Modeling for New Alternatives*). These small flow reductions in some water year types during October and November would not be persistent enough or of a magnitude that would have biologically meaningful negative effects

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during March through June, September, and October, except in below normal and dry years during March (40% and 14% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and dry years during September (35% and 47% lower, respectively), and in wet and below normal years during October (6% and 5% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, February, July, August, November, and December, except in wet and above normal years during July (6% and 7% greater, respectively), in wet years during August (42%

greater), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (5% lower), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, in below normal and dry years during June (18% and 23% greater, respectively), and in below normal and critical years during October (10% and 17% greater, respectively). There would be persistent small to substantial flow reductions that would affect conditions for adults at this location.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through September (up to 23% lower), and would be similar or slightly higher than flows under Existing Conditions during January, February, and October through November (up to 11% greater).

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round adult largemouth bass residency period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of habitat for adults and increased stress and mortality of adults. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 86°F water temperature threshold for adult largemouth bass under Existing Conditions or A2D_ELT (Table 11-2D-151). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between A2D_ELT and Existing Conditions.

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 2D during the adult largemouth bass residency period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce the quantity and quality of habitat for adults as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Sacramento Tule Perch

In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during year-round juvenile and adult Sacramento tule perch occurrence period. Lower flows could reduce the quantity and quality of instream habitat available for rearing.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 12% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT throughout the year, except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be lower than flows under NAA_ELT during July through September, except in critical years in August and September (17% and 23% greater, respectively), and would generally be similar to or greater than flows under NAA_ELT during January through June and October, except for below normal years during March (13% lower) and in critical years during May (7% lower); and would generally be similar to or greater than flows under NAA_ELT during November and December (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would be more persistently lower under A2D_ELT relative to NAA_ELT (up to 49% lower) during July, August, and in all water year types except critical years during September. Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal and critical years during January (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 24% lower) during August through November, except in below normal and critical years during October (17% and 24% greater, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

The analysis for Alternative 2D indicates that there would be no biologically meaningful differences in flows between A2D and NAA because flows would not be reduced enough or frequently enough to affect habitat conditions.

Water Temperature

The percentage of months exceeding water temperature thresholds of 72°F and 75°F for the year-round juvenile and adult Sacramento tule perch occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures exceeding these thresholds could lead to reduced rearing habitat quantity and quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month. In the Feather River below Thermalito Afterbay, the percentage of years under A2D_ELT exceeding the 72°F threshold would be higher than the percentage under NAA_ELT by up to 267% depending on water year type (Table 11-2D-154). Although relative differences are large due to small values in the divisor, the absolute differences in percent exceedance are negligible (≤2%) and, therefore, do not represent biologically meaningful effects to Sacramento tule perch.

The percentage of months under A2D_ELT exceeding the 75°F threshold would be similar to or up to 14% lower than the percentage under NAA_ELT (Table 11-2D-154). As with the 72°F threshold, although relative differences are large due to small values in the divisor, the absolute differences in percent exceedance are negligible (≤1%) and, therefore, do not represent biologically meaningful effects to Sacramento tule perch.

Table 11-2D-154. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed 72°F and 75°F Water Temperature Thresholds for Sacramento Tule Perch Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
72°F Threshold		
Wet	2 (86%)	2 (117%)
Above Normal	1 (NA)	1 (NA)
Below Normal	3 (NA)	3 (NA)
Dry	5 (NA)	4 (267%)
Critical	6 (133%)	2 (27%)
All	3 (238%)	2 (120%)
75°F Threshold		
Wet	0 (NA)	0 (0%)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	3 (500%)	-1 (-14%)
All	1 (600%)	0 (-13%)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in the quantity or quality of Sacramento tule perch habitat. Flows in all rivers examined during the year under Alternative 2D are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the Sacramento tule perch population. There would be no substantial differences in water temperature between Alternative 2D and NAA_ELT in any river examined that would cause a biologically meaningful effect to Sacramento tule perch.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for Sacramento tule perch relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during year-round juvenile and adult Sacramento tule perch occurrence period. Lower flows could reduce the quantity and quality of instream habitat available for tule perch.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through July and December, except in below normal years during March (to 7% lower), and in wet years during May (10% lower), (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would generally be similar to or lower than flows under Existing Conditions during August through November (to 22% lower), except in wet and above normal years during September (20% and 27% greater, respectively). (Appendix *B, Supplemental Modeling for New Alternatives*). There would be primarily small flow reductions in some water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through September and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), and critical years in August and September (8% and 17% lower, respectively) but would generally be similar to or lower than flows under Existing Conditions during October and November (Appendix *B, Supplemental Modeling for New Alternatives*). These small to moderate flow reductions in October and November would not cause a biologically meaningful effect on Sacramento tule perch.

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during March through June, September, and October, except in below normal and dry years during March (40% and 14% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and dry years during September (35% and 47% lower, respectively), and in wet and below normal years during October (6% and 5% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, February, July, August, November, and December, except in wet and above normal years during July (6% and 7% greater, respectively), in wet years during August (42% greater), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (5% lower), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, in below normal and dry years during June (18% and 23% greater, respectively), and in below normal and critical years during October (10% and 17% greater, respectively). There would be persistent small to substantial flow reductions that would affect conditions for adults at this location.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through September (up to 23% lower), and would be similar or slightly above flows under Existing Conditions during January, February, and October through November (up to 11% greater).

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months exceeding water temperatures of 72°F and 75°F for the year-round juvenile and adult Sacramento tule perch occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures exceeding these thresholds could lead to reduced habitat quality and increased stress and mortality. Water temperatures were not modeled in Clear Creek or the San Joaquin River.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month. In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT exceeding 72°F relative to the percentage under Existing Conditions would be similar to or greater, by up to 133% (Table 11-2D-154). However, these relative increases correspond to small absolute increases (≤5%) that are not expected to have biologically meaningful effects.

The percentage of years under A2D_ELT exceeding 75°F would be similar to the percentage under Existing Conditions in all water years except critical years (500% higher) (Table 11-2D-154). As with the 72°F threshold, this increase corresponds to a small absolute increase (3%) that is not expected to have biologically meaningful negative effects.

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 2D during the juvenile and adult Sacramento tule perch occurrence period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable rearing habitat as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Sacramento-San Joaquin Roach

In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period. Lower flows could reduce the quantity and quality of instream habitat for juvenile and adult Sacramento-San Joaquin roach.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 12% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower)(Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT throughout the year, except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be lower than flows under NAA_ELT during July through September, except in critical years in August and September (17% and 23% greater, respectively), and would generally be similar to or greater than flows under NAA_ELT during January through June and October, except for below normal years during March (13% lower) and in critical years during May (7% lower); and would generally be similar to or greater than flows under NAA_ELT during November and December (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would be more persistently lower under A2D_ELT relative to NAA_ELT (up to 49% lower) during July, August, and in all water year types except critical years during September. Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal years during January (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 24% lower) during August through November, except in below normal and critical years during October (17% and 24% greater, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced rearing habitat quality and increased stress and mortality. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D _ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of A2D _ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed 86°F under NAA_ELT or A2D_ELT (Table 11-2D-156). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between NAA_ELT and A2D_ELT.

Table 11-2D-156. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Exceed the 86°F Water Temperature Threshold for Sacramento-San Joaquin Roach Survival[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	0 (NA)	0 (NA)
Above Normal	0 (NA)	0 (NA)
Below Normal	0 (NA)	0 (NA)
Dry	0 (NA)	0 (NA)
Critical	0 (NA)	0 (NA)
All	0 (NA)	0 (NA)

NA = could not be calculated because the denominator was 0.

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in quantity and quality of habitat for juvenile and adult Sacramento-San Joaquin roach. Flows in all rivers examined during the year under Alternative 2D are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on the Sacramento-San Joaquin roach population.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for Sacramento-San Joaquin roach relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period. Lower flows could reduce the quantity and quality of instream habitat for juvenile and adult Sacramento-San Joaquin roach.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through July and December, except in below normal years during March (to 7% lower), and in wet years during May (10% lower), (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would generally be similar to or lower than flows under Existing Conditions during August through November (to 22% lower), except in wet and above normal years during September (20% and 27% greater, respectively). (Appendix *B, Supplemental Modeling for New Alternatives*). There would be primarily small flow reductions in some water year types for some months, but not persistent enough and of a magnitude that would be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through September and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), and critical years in August and September (8% and 17% lower, respectively) but would generally be similar to or lower than flows under Existing Conditions during October through November (Appendix *B, Supplemental Modeling for New Alternatives*). The small flow reductions during these months not be large or frequent enough to cause a biologically meaningful effects to roach.

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to or greater than flows under Existing Conditions throughout the year, except in critical years during September and in below normal years during October (19% and 6% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). This flow reduction is a relatively isolated effect limited to a single water year type in each month and would not be expected to have biologically meaningful negative effects.

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during March through June, September, and October, except in below normal and dry years during March (40% and 14% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and dry years during September (35% and 47% lower, respectively), and in wet and below normal years during October (6% and 5% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be moderately to substantially lower than flows under

Existing Conditions in January, February, July, August, November, and December, except in wet and above normal years during July (6% and 7% greater, respectively), in wet years during August (42% greater), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (5% lower), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, in below normal and dry years during June (18% and 23% greater, respectively), and in below normal and critical years during October (10% and 17% greater, respectively). There would be persistent small to substantial flow reductions that would affect conditions for adults at this location.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through September (up to 23% lower), and would be similar or slightly above flows under Existing Conditions during January, February, and October through November (up to 11% greater).

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months above the 86°F water temperature threshold for year-round juvenile and adult Sacramento-San Joaquin roach occurrence period was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Elevated water temperatures could lead to reduced quantity and quality of habitat and increased stress and mortality for juvenile and adult Sacramento-San Joaquin roach. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, water temperatures would not exceed the 86°F water temperature threshold for Sacramento-San Joaquin roach under Existing Conditions or A2D_ELT (Table 11-2D-156). As a result, there would be no difference in the percentage of months in which the 86°F water temperature threshold is exceeded between A2D_ELT and Existing Conditions.

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 2D during the year-round juvenile and adult Sacramento-San Joaquin roach occurrence period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the rearing period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce suitable rearing habitat as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

Hardhead

In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for hardhead relative to the NAA_ELT.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead occurrence period. Lower flows could reduce the quantity and quality of instream habitat available for juvenile and adult hardhead.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT throughout the year with some exceptions (up to 12% lower), and would be lower in all water year types during November (up to 18% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions in drier water years, when effects on habitat conditions would be more critical, would be inconsistent and/or of small magnitude for all months during the rearing period and, therefore, would not have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under NAA_ELT during the period, except in above normal years in April and October (17% and 8% lower, respectively), and in wet years during November (10% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In Clear Creek at Whiskeytown Dam, flows under A2D_ELT would be similar to flows under NAA_ELT throughout the year except in critical years during July (14% lower), August (11% greater), September (10% lower), and October (7% lower) (Appendix *B, Supplemental Modeling for New Alternatives*).

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would generally be lower than flows under NAA_ELT during July through September, except in critical years in August and September (17% and 23% greater, respectively), and would generally be similar to or greater than flows under NAA_ELT during January through June and October, except for below normal years during March (13% lower) and in critical years during May (7% lower); and would generally be similar to or greater than flows under NAA_ELT during November and December (Appendix *B, Supplemental Modeling for New Alternatives*). Flows would be more persistently lower under A2D_ELT relative to NAA_ELT (up to 49% lower) during July, August, and in all water year types except critical years during September. Flow reductions would be partially offset by increases in flow in the adjoining months.

In the American River at Nimbus Dam, flows under A2D_ELT would be similar to or greater than flows under NAA_ELT during January through July and December, except in below normal years during January (11% lower), and would be similar to or lower than flows under NAA_ELT (up to 24% lower) during August through November, except in below normal and critical years during October (17% and 24% greater, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flow reductions would be offset by increases in some months and/or not persistent within a single water year type. Effects would not be biologically meaningful.

In the San Joaquin River at Vernalis, flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

In the Stanislaus River at the confluence with the San Joaquin River flows under A2D_ELT would be similar to those under NAA_ELT throughout the year, regardless of water year type.

Water Temperature

The percentage of months outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality for juvenile and adult hardhead. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under NAA_ELT. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside the range would be similar to or lower than the percentage under NAA_ELT in all water year except below normal years (7% greater) (Table 11-2D-158).

Table 11-2D-158. Difference and Percent Difference in the Percentage of Months Year-Round in Which Water Temperatures in the Feather River below Thermalito Afterbay Are outside the 65°F to 82.4°F Water Temperature Range for Juvenile and Adult Hardhead Occurrence[a]

Water Year Type	EXISTING CONDITIONS vs. A2D_ELT	NAA_ELT vs. A2D_ELT
Wet	1 (1%)	2 (3%)
Above Normal	-1 (-1%)	-1 (-1%)
Below Normal	1 (1%)	5 (7%)
Dry	-1 (-2%)	-1 (-1%)
Critical	-3 (-5%)	-1 (-1%)
All	-1 (-1%)	1 (1%)

[a] A negative value indicates a benefit (reduction in percentage of months outside suitable range) of the alternative.

NEPA Effects: Collectively, these modeling results indicate that the effect would not be adverse because Alternative 2D would not cause a substantial reduction in the quantity or quality of habitat for juvenile and adult hardhead. Flows in all rivers examined during the year under Alternative 2D are generally similar to or greater than flows under the NAA_ELT in most months. Flows in July or August through November are more likely to be lower for some water year types in some of the locations analyzed, however they are generally of small magnitude, not consistent from month to month within a specific water year type, and/or would be offset by increases in flow in the adjoining months. Therefore, the flow reductions are not expected to have biologically meaningful negative effects on hardhead. There are no temperature-related effects in any other rivers examined.

CEQA Conclusion: In general, Alternative 2D would not affect the quality and quantity of upstream habitat conditions for juvenile and adult hardhead relative to Existing Conditions.

Flows

Flow rates in the Sacramento, Trinity, Feather, American, San Joaquin, and Stanislaus Rivers and in Clear Creek were examined during the year-round juvenile and adult hardhead occurrence period. Lower flows could reduce the quantity and quality of instream habitat for juvenile and adult hardhead.

In the Sacramento River upstream of Red Bluff, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through July and December, except in below normal years during March (to 7% lower), and in wet years during May (10% lower), (Appendix *B, Supplemental Modeling for New Alternatives*)*.* Flows would generally be similar to or lower than flows under Existing Conditions during August through November (to 22% lower), except in wet and above normal years during September (20% and 27% greater, respectively). (Appendix *B, Supplemental Modeling for New Alternatives*)*.* There would be primarily small flow reductions in some water year types for some months, but not persistent enough and of a magnitude that would not be expected to have biologically meaningful negative effects.

In the Trinity River below Lewiston Reservoir, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions during January through September and December, except in below normal years during January (16% lower), in below normal years during March (6% lower), and in critical years during May (6% lower), and critical years in August and September (8% and 17% lower, respectively) but would generally be similar to or lower than flows under Existing

Conditions during October through November (Appendix *B, Supplemental Modeling for New Alternatives*). The small flow reductions during these months not be large or frequent enough to cause a biologically meaningful effects to hardhead.

In the Feather River at Thermalito Afterbay, flows under A2D_ELT would be greater than flows under Existing Conditions during March through June, September, and October, except in below normal and dry years during March (40% and 14% lower, respectively), in below normal years during April (6% lower), in wet years during May (15% lower), in below normal and dry years during September (35% and 47% lower, respectively), and in wet and below normal years during October (6% and 5% lower, respectively) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be moderately to substantially lower than flows under Existing Conditions in January, February, July, August, November, and December, except in wet and above normal years during July (6% and 7% greater, respectively), in wet years during August (42% greater), in above normal years during November (5% greater), and in above normal years during December (18% greater).

In the American River at Nimbus Dam, flows under A2D_ELT would generally be similar to or greater than flows under Existing Conditions in wetter years during January, in wet and below normal years during December, and in most water year types during February through April, except in dry and critical years during February (5% lower), in critical years during March (7% lower), and in above normal years during April (5% lower) (Appendix *B, Supplemental Modeling for New Alternatives*). Flows under A2D_ELT would generally be similar to or lower than flows under Existing Conditions during May through November, in below normal and dry years during June (18% and 23% greater, respectively), and in below normal and critical years during October (10% and 17% greater, respectively). There would be persistent small to substantial flow reductions that would affect conditions for adults at this location.

In the San Joaquin River at Vernalis, flows under A2D_ELT would generally be similar to or slightly lower than those under Existing Conditions during March through September (up to 23% lower) and would be similar to or slightly above flows under Existing Conditions during January, February and October through November (up to 11% greater).

In the Stanislaus River at the confluence with the San Joaquin River, flows under A2D_ELT would generally be similar to or up to 29% lower than to those under Existing Conditions during January through July, except for 17% and 11% greater flow in wet years during February and June, respectively, and would be similar to or slightly lower than flows under Existing Conditions during August through December.

Water Temperature

The percentage of months in which year-round in-stream temperatures would be outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead was examined in the Sacramento, Trinity, Feather, American, and Stanislaus Rivers. Water temperatures outside this range could lead to reduced rearing habitat quality and increased stress and mortality for juvenile and adult hardhead. Water temperatures were not modeled in the San Joaquin River or Clear Creek.

Water temperatures in the Sacramento, Trinity, American, and Stanislaus Rivers under A2D_ELT would generally be the same as those under Existing Conditions. Therefore, there would be no temperature related effects of A2D_ELT in these rivers during any month.

In the Feather River below Thermalito Afterbay, the percentage of months under A2D_ELT outside of the 65°F to 82.4°F suitable water temperature range for juvenile and adult hardhead would be similar to or lower than the percentage under Existing Conditions in all water years (Table 11-2D-158).

Summary of CEQA Conclusion

Collectively, flows would be lower under Alternative 2D during the juvenile and adult hardhead occurrence period relative to Existing Conditions. Flows would be persistently and moderately to substantially lower in several rivers during substantial portions of the rearing period. Therefore, these modeling results indicate that the difference between Existing Conditions and Alternative 2D could be significant because the alternative could substantially reduce habitat for juvenile and adult hardhead as a result of flow reductions.

As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. The comparison to the NAA_ELT is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA_ELT and informed by the NEPA analysis above, flows and water temperatures in all rivers would generally be similar between NAA_ELT and Alternative 2D. These modeling results represent the increment of change attributable to the alternative, demonstrating the general similarities in flows and water temperature under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

California Bay Shrimp

NEPA Effects: As discussed further in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS, water operations have the potential to affect California bay shrimp juvenile abundance through an increase in residual circulation in the estuary with increasing outflow (as indexed by X2) that could translate to more rapid or more complete entrainment into the estuary, or more rapid transport to rearing grounds, both of which presumably could increase survival from hatching to settlement (Kimmerer et al. 2009). An X2-abundance index relationship from Kimmerer et al. (2009) was applied to bay shrimp in order to assess the potential effects on abundance through changes in rearing habitat. Application of these relationships suggested that, in relation to NAA_ELT, there would be a 6% decrease in mean abundance index as a result of change in rearing habitat under Alternative 2D scenario A2D_ELT (See Table 11-mult-13 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS). This result indicates that the operational effects would not be adverse, because they would not result in a substantial reduction in the rearing habitat for California bay shrimp.

CEQA Conclusion: Similar to striped bass and American shad, the analysis of potential water operations-related rearing habitat effects illustrated that in relation to Existing Conditions, there could be a greater impact of Alternative 2D on abundance of California bay shrimp (Table 11-mult-13 in Chapter 11, Section 11.3.5, in Appendix A of this RDEIR/SDEIS), than found in the NEPA Effects section. As noted for striped bass and American shad, the comparison to the NAA_ELT is a better approach than comparison to Existing Conditions because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands. In the case of the X2-related analyses of rearing habitat for California bay shrimp and as noted for striped bass and American shad, the effect of sea level rise in particular confounds the interpretation of the effects of the alternatives. Based on the discussion presented above for the NEPA Effects, the change in rearing habitat would be less than significant. No mitigation would necessary.

Impact AQUA-204: Effects of Water Operations on Migration Conditions for Non-Covered Aquatic Species of Primary Management Concern

See Alternative 1A, Impact AQUA-204 for additional background information relevant to non-covered species of primary management concern.

Striped Bass

NEPA Effects: Under Alternative 2D, average spring (March–May) monthly flows in the Sacramento River downstream of the north Delta intake would be reduced 4–33% during the adult striped bass migration compared to the NEPA baseline (NAA_ELT). Sacramento River flows are highly variable inter-annually, but striped bass are still able to migrate upstream the Sacramento River during years of lower flows. The effect of reduced Sacramento flows under Alternative 2D would not be adverse.

CEQA Conclusion: Impacts would be less than significant because the changes in spring flow under Scenarios A2D_ELT (4–36% lower compared to Existing Conditions) would not interfere substantially with movement of pre-spawning striped bass through the Delta. No mitigation would be required.

American Shad

NEPA Effects: Flows in the Sacramento River below the north Delta diversion facilities under Scenario A2D_ELT would be reduced 4–33% relative to NAA_ELT during March–May, as described above for striped bass. River flows are highly variable inter-annually, and American shad are still able to migrate upstream the Sacramento River during lower flow years. Overall, the impact to American shad migration habitat conditions would not be adverse under Alternative 2D.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because, as described above for striped bass, the changes in flow under Scenario A2D_ELT (4-36% lower compared to Existing Conditions) would not interfere substantially with movement of American shad from the Delta to upstream spawning habitat. No mitigation would be required.

Threadfin Shad

NEPA Effects: Threadfin shad are semi-anadromous, moving between freshwater and brackish water habitats. Threadfin shad found in the Delta do not actively migrate upstream to spawn. Therefore there is no effect on migration habitat conditions.

CEQA Conclusion: Impacts would be as described immediately above and would be less than significant because flow changes in the Delta under Alternative 2D would not alter movement patterns for threadfin shad. No mitigation would be required.

Largemouth Bass

NEPA Effects: Largemouth bass are non-migratory fish within the Delta. Therefore they do not use the Delta as a migration habitat corridor. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes under Alternative 2D would not affect largemouth movements within the Delta. No mitigation would be required.

Sacramento Tule Perch

NEPA Effects: Similar with largemouth bass, Sacramento tule perch are a non-migratory species and do not use the Delta as a migration corridor as they are a resident Delta species. There would be no effect.

CEQA Conclusion: As described immediately above, flow changes would not affect Sacramento tule perch movements within the Delta. No mitigation would be required.

Sacramento-San Joaquin Roach

NEPA Effects: For Sacramento-San Joaquin roach, the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 2D, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to the NEPA baseline. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for Sacramento-San Joaquin roach would be less than significant and no mitigation would be required.

Hardhead

NEPA Effects: For hardhead the overall flows and temperature in upstream rivers during migration to their spawning grounds would be similar to those described under Alternative 2D, Impact AQUA-202 for spawning. As described there, the flows would slightly improve the upstream conditions relative to NAA_ELT. These conditions would not be adverse.

CEQA Conclusion: As described immediately above, the impacts of water operations on migration conditions for hardhead would be less than significant and no mitigation would be required.

California Bay Shrimp

NEPA Effects: The effect of water operations on migration conditions of California bay shrimp under Alternative 2D would be similar to that described for Alternative 1A (see Alternative 1A, Impact AQUA-204). For a detailed discussion, please see Alternative 1A, Impact AQUA-204. The effects would not be adverse.

CEQA Conclusion: As described above the impacts on California bay shrimp migration conditions would be less than significant and no mitigation would be required.

Restoration Measures and Environmental Commitments

Alternative 2D has the same restoration and environmental commitments as Alternative 4A, although with a proportionally greater extent of restoration because there are five north Delta intakes included under Alternative 2D compared to three under Alternative 4A. Nevertheless, the effect mechanisms are sufficiently similar that the following impacts are those presented under Alternative 4A that also apply to Alternative 2D.

Impact AQUA-205: Effects of Construction of Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-206: Effects of Contaminants Associated with Restoration Measures on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-207: Effects of Restored Habitat Conditions on Non-Covered Aquatic Species of Primary Management Concern

Impact AQUA-208: Effects of Methylmercury Management on Non-Covered Aquatic Species of Primary Management Concern (Environmental Commitment 12)

Impact AQUA-211: Effects of Localized Reduction of Predatory Fish on Non-Covered Aquatic Species of Primary Management Concern (Environmental Commitment 15)

Impact AQUA-212: Effects of Nonphysical Fish Barriers on Non-Covered Aquatic Species of Primary Management Concern (Environmental Commitment 16)

NEPA Effects: All of these restoration and environmental commitment impact mechanisms have been determined to result in no adverse effects on non-covered aquatic species of primary management concern for the reasons identified for Alternative 4A.

CEQA Conclusion: All of these restoration and environmental commitment impact mechanisms would be considered less than significant, for the reasons identified for Alternative 4A, and no mitigation would be required.

Upstream Reservoirs

Impact AQUA-217: Effects of Water Operations on Reservoir Coldwater Fish Habitat

NEPA Effects: As discussed in Alternative 1A, Impact AQUA-217 and reported in Table 11-1A-102, this effect would not be adverse because coldwater fish habitat in the CVP and SWP upstream reservoirs under Alternative 2D would not be substantially reduced when compared to the No Action Alternative. Carryover storage thresholds for all CVP and SWP reservoirs would be similar between the No Action Alternative and Alternative 2D.

CEQA Conclusion: As discussed in Alternative 1A, Impact AQUA-217 and reported in Table 11-1A-102, Alternative 2D would reduce the quantity of coldwater fish habitat in the CVP and SWP relative to Existing Conditions. There would be 6 fewer years (7% lower) that exceed the 250 TAF carryover storage threshold in Folsom Reservoir under Alternative 2D relative to Existing Conditions, which could result in a significant impact.

However, this interpretation of the biological modeling results is likely attributable to different modeling assumptions for four factors: sea level rise, climate change, future water demands, and implementation of the alternative. As discussed in Section 11.3.3, because of differences between the CEQA and NEPA baselines, it is sometimes possible for CEQA and NEPA significance conclusions to vary between one another under the same impact discussion. The baseline for the CEQA analysis is Existing Conditions at the time the NOP was prepared. Both the action alternative and the NEPA baseline (NAA_ELT) models anticipated future conditions that would occur at 2025 (ELT implementation period), including the projected effects of climate change (precipitation patterns), sea level rise and future water demands, as well as implementation of required actions under the 2008 USFWS BiOp and the 2009 NMFS BiOp. Because the action alternative modeling does not partition the effects of implementation of the alternative from the effects of sea level rise, climate change, and future water demands, the comparison to Existing Conditions may not offer a clear understanding of the impact of the alternative on the environment. This suggests that the comparison of results between the alternative and NAA is a better approach because it isolates the effect of the alternative from those of sea level rise, climate change, and future water demands.

When compared to NAA and informed by the NEPA analysis above, there would be negligible effects on reservoir storage. These modeling results represent the increment of change attributable to the alternative, demonstrating the similarities in reservoir storage under Alternative 2D and the NAA_ELT, and addressing the limitations of the CEQA baseline (Existing Conditions). Therefore, this impact is found to be less than significant and no mitigation is required.

4.4.8 Terrestrial Biological Resources

Alternative 2D is generally similar to Alternative 4A except that it includes two additional intakes (Intakes 1 and 4) along the Sacramento River and operates under a different operational scenario. Like Alternative 4A, this alternative would not serve as an NCCP/HCP and thus the analysis below only considers the conveyance facilities and operations and only includes the environmental commitments necessary to fully mitigate the projects impacts under CEQA and NEPA. Other than the increased impacts from the intakes and associated restoration actions, the effects from Alternative 2D are relatively the same as those under Alternative 4A and therefore Alternative 2D is considered here in a summary fashion. The reader is referred to the discussion of Alternative 4A for a detailed analysis of impacts that would be associated with implementing Alternative 2D. The impacts associated with Alternatives 2D and 4A were derived by comparing the alternative with the No Action Alternative for NEPA purposes, and with Existing Conditions for CEQA purposes.

Operations under Alternative 2D would be similar, but not identical, to those described under Operational Scenario B (see Chapter 3, Section 3.6.4.2, *North Delta and South Delta Water Conveyance Operational Criteria*, of the Draft EIR/EIS). These operations would include both new and existing water conveyance facilities once the new north Delta facilities are completed and become operational, thereby enabling joint management of north and south Delta diversions. Operations included in this alternative for south Delta export facilities would replace the south Delta operations currently implemented in compliance with the FWS (2008) and NMFS (2009) BiOps. The north Delta intakes and the head of Old River barrier would be new facilities for the SWP and CVP and would be operated as described in Chapter 3, Section 3.6.4.2 of the Draft EIR/EIS. Alternative 2D operations include a preference for south Delta pumping in July through September to provide limited flushing for improving general water quality conditions and reduced residence times. The operational scenario under Alternative 2D would have a greater operational capacity compared to Alternative 4A (15,000 cfs compared to 9,000 cfs).

Comparative Differences in Effects for Alternatives 2D and 4A

The principal differences in effects between these two alternatives would be related to the differing construction footprints of the water conveyance facilities and the differences in proposed restoration efforts. The Alternative 2D water conveyance facilities would entail construction of two additional north Delta intakes (Intakes 1 and 4). Intake 1 is located northeast of Clarksburg on the east side of the river and Intake 4 is located just south of Hood, also on the east side of the river. There is also a large RTM disposal area and a new permanent transmission line between Intakes 1 and 2. The operational scenario for Alternative 2D (Scenario B) is also different from Alternative 4A (Scenario H3–H4), but the difference in water operations would not significantly change the operational effects on terrestrial biological resources in the study area.

As a result of the greater impacts from Alternative 2D additional restoration and protection acreages would be required under the environmental commitments to achieve the applicable regulatory standards under ESA Section 7 and CESA Section 2081(b). The restoration actions would themselves result in effects on natural communities where they are likely to occur. Specific locations for implementing many of the restoration commitments have not been identified at this time. Therefore, the analysis considers typical activities that would be undertaken for implementation of the habitat restoration and provides an estimate of what acreages of natural communities would be lost or converted by these activities. These activities under Alternative 2D would generally be the same as those under Alternative 4A but would result in additional impacts on valley foothill riparian and cultivated lands. The effects from these activities are summarized below in Table 4.4.8-1.

Due to the addition of the two intakes and their associated pumps and pipelines, the additional RTM disposal area, and the additional restoration under the environmental commitments, Alternative 2D would create differences in the permanent and temporary loss of natural communities and cultivated lands when compared with Alternative 4A (Table 4.4.8-1). Alternative 2D would permanently remove 11 more acres of valley/foothill riparian habitat along the Sacramento River, 10 acres more of grassland, 75 acres more of managed wetlands, 6 more acres of tidal perennial aquatic, and 867 acres more of cultivated land when compared to Alternative 4A.

During the water conveyance facilities construction process, Alternative 2D would involve more temporary loss of natural communities when compared with Alternative 4A mostly because of the temporary work areas associated with the two additional intakes and the additional pipelines from the intakes. The differences would include greater impacts on cultivated lands east of the river (76 acres more), grassland along the river levee (8 acres more), tidal perennial aquatic within the river channel (25 acres more), tidal freshwater emergent wetland (1 acre more), and valley/foothill riparian along the river levee (3 acres more). No temporary impacts from restoration actions are anticipated because all restoration activities will take place within in the footprint of the proposed restoration site.

These differences in permanent loss of habitat associated with water conveyance construction and restoration would create some differences in effects on wildlife, primarily birds that utilize croplands for foraging and some species that utilize managed wetlands in the north Delta. The increase in permanent loss of cultivated land (primarily irrigated pasture and other hay crops) associated with Alternative 2D would result in a larger loss of foraging habitat for species such as tricolored blackbird, greater sandhill crane, Swainson's hawk, white-tailed kite, short-eared owl, loggerhead shrike, northern harrier, and California horned lark. The increase in impacts on managed wetland would result in increased impacts on white-tailed kite, northern harrier, yellow-head blackbird, and short-eared owl but the particular area of managed wetland that would be affected is not identified as suitable for greater sandhill crane (i.e., is not included as part of the species' modeled habitat). Alternative 2D would also result in an increase in the loss of riparian habitat along the Sacramento River, which would affect nesting habitat for Swainson's hawk, white-tailed kite, cormorants, herons, egrets, and migratory habitat for birds moving along the Sacramento River corridor.

The slightly larger temporary losses of cultivated land, grassland and valley/foothill riparian natural communities associated with Alternative 2D would also increase the effects on special-status species that use these communities. There would be more foraging habitat temporarily lost under Alternative 2D for greater sandhill crane when compared to Alternative 4A because of the cultivated land loss.

Alternative 2D would also affect 51 more acres of jurisdictional wetlands and waters as regulated by Section 404 of the CWA, when compared to Alternative 4 (Table 4.4.8-2). Refer to Table 12-4A-68 for a summary of Alternative 4A jurisdictional waters and wetlands impacts. The majority of this difference is due to impacts on tidal channel and scrub-shrub wetlands (as mapped for the wetland delineation) by the construction of the intakes along the Sacramento River.

The environmental commitments described in Section 4.1.3.3 and the acreages of these commitments presented in Table 4.1-5 would provide for protection, enhancement, and restoration of habitats affected under Alternative 2D. In addition, the Resource Restoration and Performance Principles in Table 4.1-8 would further guide the environmental commitments in mitigating the effects on terrestrial biological resources, the AMMs 1–7, 10, 12–15, 18, 20–25, 27, 30, and 37–39 described in part in Appendix 3.C, *Avoidance and Minimization Measures*, of the Draft BDCP and in Appendix D*, Substantive BDCP Revisions,* of this RDEIR/SEIS would be available to further avoid and minimize impacts, and preparation of an adaptive management and monitoring program as would likely be required during the ESA Section 7 and CESA Section 2081(b) process would further avoid, minimize, and mitigate the effects of Alternative 2D.

Table 4.4.8-1 Alternative 2D Effects on Natural Communities Relative to Alternative 4A (acres)

	Permanent Impacts from Alt. 2D								
Natural Community	Water Conveyance	EC 4 – Tidal Restoration	EC 7 – Riparian Restoration	EC8 – Grassland Restoration	EC 10 – Nontidal Restoration	*Permanent Impact Total*	Permanent Impact Difference from Alternative 4A	Temporary Impacts Alt. 2D	Temporary Impact Difference from Alternative 4A
Tidal perennial aquatic	213	0	0	0	0	*213*	6	*2,123*	25
Tidal brackish emergent wetland	0	0	0	0	0	*0*	0	*0*	0

Table 4.4.8-2 Alternative 2D Effects on Jurisdictional Wetlands and Waters Relative to Alternative 4A (acres)

	Alternative 2D Impacts on Jurisdictional Wetlands and Waters				
Wetland/Water Type	Permanent Impact	Temporary Impacts Treated as Permanent[a]	Temporary Impact[b]	Total Impact[c]	Difference from 4A[d]
Agricultural Ditch	48.6	18.6	0	67.2	4.3
Alkaline Wetland	20.3	0.1	0	20.4	0
Clifton Court Forebay	258.0	0	1,931.0	258.0	0
Conveyance Channel	8.0	2.9	0	10.8	0
Depression	29.3	8.5	0	37.8	1.4
Emergent Wetland	57.3	32.3	0	89.6	0.9
Forest	9.0	9.1	0	18.0	1.2
Lake	23.2		0	23.2	0
Scrub-Shrub	25.3	6.1	0	31.4	13.3
Seasonal Wetland	114.6	25.1	0	139.7	0
Tidal Channel	25.3	104.9	0	130.2	30.3
Vernal Pool	0.3	18.6	0	0.3	0
Total	619	207	1,931	827	51.3

[a] Temporary impacts treated as permanent are temporary impacts expected to last over one year. These impact sites will eventually be restored to pre-project conditions; however, due to the duration of effect, compensatory mitigation will be included for these areas.
[b] Temporary impacts would result from dredging Clifton Court Forebay.
[c] Total does not include temporary impacts on Clifton Court Forebay because these would be temporary disturbance to open water, which typically does not require compensatory mitigation.
[d] Difference in total impacts between 5A and 4A.

NEPA Effects: Alternative 2D would not have adverse effects on the terrestrial natural communities, special-status species and common species that occupy the study area. As with Alternative 4A, this alternative also would not substantially disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 4A, Alternative 2D would result in existing habitat converted by water conveyance construction and restoration actions but to a slightly larger degree. The temporarily affected habitat would be restored to its pre-project condition and the restoration under the environmental commitments (Environmental Commitments 3, 4, 6–10) would permanently replace primarily cultivated land with tidal and nontidal marsh, grassland, and riparian vegetation. The environmental commitments would result in the protection of 14,958 acres and restoration of 2,802 acres of natural communities to offset effects. Where environmental commitments would not fully offset effects, AMMs 1–7, 10, 12–15, 18, 20–25, 27, 30, and 37-39, and in some cases specific mitigation measures have been developed to avoid and minimize adverse effects. Alternative 2D would not require mitigation measures beyond what is proposed for Alternative 4A to offset effects.

CEQA Conclusion: Alternative 2D would not have significant and unavoidable impacts on the terrestrial natural communities, special-status species, and common species that occupy the study area. As with Alternative 4A, this alternative also would not significantly disrupt wildlife movement corridors, significantly increase the risk of introducing invasive species, reduce the value of habitat for waterfowl and shorebirds, or conflict with plans and policies that affect the study area. As with Alternative 4A, existing habitat would be converted during construction of water conveyance facilities and the associated restoration to offset these impacts. The temporarily affected habitat would be restored to its pre-project condition and the restoration conservation measures (Environmental Commitments 3, 4, 6–10) would permanently replace primarily cultivated land with tidal and nontidal marsh, grassland, and riparian vegetation. The environmental commitments would result in the protection of 14,958 acres and restoration of 2,802 acres of natural communities and, together with AMMs 1–7, 10, 12–15, 18, 20–25, 27, 30, and 37–39, and in some cases specific mitigation measures would mitigate the projects impacts to a less-than significant-level. Alternative 2D would not require mitigation measures beyond what is proposed for Alternative 4A to offset effects.

As with Alternative 4A, Alternative 2D would require several mitigation measures to be adopted to reduce all effects on terrestrial biological resources to less-than-significant levels. These mitigation measures would be needed beyond the Environmental Commitments provided and AMMs provided by Alternative 2D. The relevant mitigation measures, which are included in detail in the analysis of Alternative 4A, are as follows:

- Mitigation Measure BIO-42: Avoid Impacts on Delta Green Ground Beetle and its Habitat
- Mitigation Measure BIO-43: Avoid and Minimize Loss of Callippe Silverspot Butterfly Habitat
- Mitigation Measure BIO-55: Conduct Preconstruction Surveys for Noncovered Special-Status Reptiles and Implement Applicable AMMs
- Mitigation Measure BIO-66: California Least Tern Nesting Colonies Shall Be Avoided and Indirect Effects on Colonies Will Be Minimized
- Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds
- Mitigation Measure BIO-117: Avoid Impacts on Rookeries
- Mitigation Measure BIO-146: Active Bank Swallow Colonies Shall Be Avoided and Indirect Effects on Bank Swallow Will Be Minimized
- Mitigation Measure BIO-147: Monitor Bank Swallow Colonies and Evaluate Winter and Spring Flows Upstream of the Study Area
- Mitigation Measure BIO-162: Conduct Preconstruction Survey for American Badger
- Mitigation Measure BIO-166: Conduct Preconstruction Surveys for Roosting Bats and Implement Protective Measures
- Mitigation Measure BIO-170: Avoid, Minimize, or Compensate for Impacts on Noncovered Special-Status Plant Species
- Mitigation Measure BIO-176: Compensatory Mitigation for Fill of Waters of the U.S.

4.4.9 Land Use

Impact LU-1: Incompatibility with Applicable Land Use Designations, Goals, and Policies as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: The nature of impacts related to incompatibility with land use regulations stemming from the construction of water conveyance structures under Alternative 2D would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS because the alignments are the same. However, whereas Alternative 4 includes Intakes 2, 3, and 5, Alternative 2D includes Intakes 1 through 5. Because Alternative 2D would include the same physical/structural components as Alternative 4 and two additional intakes, impacts would be of a slightly greater magnitude.

Like Alternative 4, Alternative 2D would place temporary and permanent structures on lands designated for other uses by the general plans of Sacramento, San Joaquin, Contra Costa, and Alameda Counties. However, because Alternative 2D includes five intakes, it is anticipated that more acres would be impacted than under Alternative 4. The construction of the water conveyance facilities would require land use activities that would be incompatible with land use designations, goals and policies ascribed to the study area and for the purposes of reducing environmental impacts. To the extent that constructing Alternative 2D would result in incompatibilities with land use designations, goals and policies designed to avoid or reduce environmental effects, these potential incompatibilities are described in Alternative 4 of Chapter 13, *Land Use*, Section 13.3.3.9, Impact LU-1 in Appendix A of this RDEIR/SDEIS. As discussed in Section 13.3.2, *Determination of Effects*, of the Draft EIR/EIS, to the extent that alternatives are incompatible with such land use designations, goals, and policies, any related environmental effects are discussed in other chapters.

CEQA Conclusion: These incompatibilities indicate the potential for a physical consequence to the environment. As discussed in Section 13.3.2, *Determination of Effects*, of the Draft EIR/EIS, the physical effects they suggest are discussed in other chapters throughout this document. The relationship between plans, policies, and regulations and impacts on the physical environment is discussed in Section 13.3.1, *Methods for Analysis*, of the Draft EIR/EIS.

Impact LU-2: Conflicts with Existing Land Uses as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: The nature of effects related to conflicts with existing land uses under Alternative 2D would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS because the alignments are the same. However, whereas Alternative 4 includes Intakes 2, 3, and 5, Alternative 2D includes Intakes 1 through 5. Because Alternative 2D would include the same physical/structural components as Alternative 4 and two additional intakes, there would be a greater impact related to construction two additional intakes. As for Alternative 4, construction and operation of physical facilities for water conveyance would create temporary or permanent conflicts with existing land uses (including displacement of existing structures and residences) because of the construction of permanent features of the facility. Because Alternative 2D includes five intakes, it is anticipated that more structures would be impacted than under Alternative 4. Indirect impacts would primarily happen as a result of incompatibility with adjacent land uses or the loss or increased difficultly of access to parcels. Table 13-12 in Appendix A of this RDEIR/SDEIS, summarizes the estimated number of structures affected across structure type and alternative and

Mapbook Figure M13-4 in the Mapbook Volume of the Draft EIR/EIS shows the distribution of these effects across the Modified Pipeline/Tunnel conveyance alignment.

The removal of a substantial number of existing permanent structures as a result of constructing the water conveyance facility would be considered a direct, adverse socioeconomic effect of this alternative under NEPA. When required, the project proponents would provide compensation to property owners for losses due to implementation of the alternative, which would reduce the severity of economic effects related to this physical impact, but would not reduce the severity of the physical impact itself. Project conflicts with existing public structures under Alternative 4 are addressed in Section 4.3.16, *Public Services and Utilities*, of this RDEIR/SDEIS; potential adverse effects on the environment related to the potential release of hazardous materials contained in structures to be demolished are addressed in 4.3.20, *Hazards and Hazardous Materials*, of this RDEIR/SDEIS; and potential adverse effects on traditional cultural properties are addressed in Section 4.3.14, *Cultural Resources*, of this RDEIR/SDEIS.

CEQA Conclusion: Construction of the proposed water conveyance facility would necessitate the removal of a substantial number of existing permanent structures. The removal of existing structures is not, in itself, considered an environmental impact, though removal might entail economic impacts. Significant environmental impacts would only result if the structures qualified as "historical resources" or the removal of structures led to physical effects on certain other resources. As discussed in Section 13.3.2, *Determination of Effects*, of the Draft EIR/EIS, such effects are discussed in other sections throughout the document. Project conflicts with existing public structures under Alternative 2D are addressed in Section 4.3.16, *Public Services and Utilities*, of this RDEIR/SDEIS; potential impacts on the public and environment related to the potential release of hazardous materials contained in structures to be demolished are addressed in Section 4.3.20, *Hazards and Hazardous Materials*, of this RDEIR/SDEIS; and potential impacts on "historical resources" (including qualifying structures) and traditional cultural properties are addressed in Section 4.3.14, *Cultural Resources*, of this RDEIR/SDEIS. Where applicable, project proponents will provide compensation to property owners for losses due to implementation of Alternative 2D. This compensation would not constitute mitigation for any related physical impact; however, it would reduce the severity of economic effects.

Impact LU-3: Create Physical Structures Adjacent to and through a Portion of an Existing Community as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: Effects related to any potential division of an existing community as a result of the construction of water conveyance facilities under Alternative 2D would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS, but with greater magnitude due to construction of additional intakes. Construction of permanent facilities and associated work areas would be located in and around the community of Hood, in some cases displacing structures in the community and creating linear construction zones between structures within the community. Intake 4 would be constructed along the southern border of the community over a period of approximately four years, altering a point of access to the community. Work areas associated with construction of the conveyance pipeline carrying water from Intakes 1 through 4 to the intermediate forebay would run north to south in the eastern section of the community. Additionally, a temporary work area associated with construction of the conveyance facilities would be built adjacent to Hood on the southern side of the community, and would serve as a staging area during the construction phase. It would consist of facilities such as parking areas, offices, and construction equipment storage. A tunnel carrying water south from Intakes 1 through 3 to the intermediate forebay would be placed under the community. The tunnel would be constructed below the surface and would not interfere with the existing community; therefore, the alignment would not create a physical structure adjacent to or through the existing community. A temporary power line would be constructed around the northern, eastern, and southern sections of the community, which would provide power to the intake work areas during construction. Proposed permanent transmission lines would be constructed to the east of the community to provide power to the intake facilities. Construction and the long-term placement of Intakes 3, 4, and 5, would be built about one-quarter mile north, immediately south, and one-half mile south of Hood, respectively, and would substantially alter the lands to the north and south of the community. While permanent physical structures adjacent to or through Hood are not anticipated to result from this alternative, activities associated with their construction could make it difficult to travel within and around Hood in certain areas for a limited period of time. Additionally, the lasting placement of the intake facilities and intermediate forebay would represent physical structures that would substantially alter the setting of the community and its immediate surroundings, constituting an adverse effect. Mitigation Measures TRANS-1a and TRANS-1b are available to address this effect.

CEQA Conclusion: During the construction of the tunnels between Intakes 1 and 5 and the intermediate forebay, construction activities would occur to the north and south of the community of Hood, and proposed temporary and proposed permanent power lines would cross through portions of the community. Even though access to and from the community would be maintained over the long-term, the nearby construction of the temporary work area would substantially alter the setting of the community in the near term. Similarly, the nearby construction of Intakes 3, 4 and 5, would create permanent physical structures approximately one-quarter mile north, immediately south, and one-half mile south of Hood that would substantially alter the community's surroundings. These structures would therefore result in a significant and unavoidable impact. Implementation of Mitigation Measures TRANS-1a and TRANS-1b would reduce the severity of this impact by supporting continued access to and from the community on transportation routes; however, permanent structures in the community's vicinity would remain, and the impact would be significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Chapter 19, *Transportation*, under Impact TRANS-1 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b in Chapter 19, *Transportation*, under Impact TRANS-1 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Impact LU-4: Incompatibility with Applicable Land Use Designations, Goals, and Policies as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects of Alternative 2D related to incompatibility with applicable land use designations, goals, and policies resulting from implementation of Environmental Commitments3, 4, 6–12, 15, and 16 would be similar in mechanism to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, as described in Section 4.1, *Introduction*, if this RDEIR/SDEIS, Alternative 2D would protect and restore up to 17,766 acres of habitat under Environmental Commitment 3, 4, and 6–10 as compared with 83,800 acres under Alternative 4. Up to 5.5 miles of channel margin habitat would be enhanced under Alternative 2D with Environmental Commitment 6 (compared with 20 miles under Alternative 4). Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 8, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 2D would likely be substantially smaller than those associated with Alternative 4. Because Alternative 2D does not include those Conservation Measures, the BDCP will be treated as a covered activity under the Delta Plan. The consistency between this alternative and the Delta Plan is discussed in detail in Appendix G of this RDEIR/SDEIS.

Because the locations for the implementation of these environmental commitments are unknown at this time, there is some uncertainty about whether new land uses related to these environmental commitments would be incompatible with existing land use designations, goals, and policies. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with the study area, which predominantly consists of agriculture and open space. Most activities would be anticipated to take place on land designated for agriculture, open space, natural preserve and recreation; therefore, local designations, goals, and policies related to preservation of those attributes would likely be compatible with the restoration actions that would take place under these environmental commitments. Additionally, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapter 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to result in substantial incompatibilities with local land use regulations. Impacts would not be adverse.

CEQA Conclusion: Because specific locations for the implementation of many of these land-intensive actions are unknown at this point, there is some uncertainty about whether new land uses related to these environmental commitments would be incompatible with existing land uses. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with the study area, which is a predominantly agricultural area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapter 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to result in substantial incompatibilities with local land use regulations. Impacts would be less than significant because environmental commitment actions would be largely consistent with open space and agricultural uses, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. No mitigation is required.

Impact LU-5: Conflicts with Existing Land Uses as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects related to conflicts with existing land uses under Alternative 2D would be similar in mechanism to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 2D (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS, and under Impact LU-4, above). While the location of each restoration and/or enhancement action is not known at this time, it is possible that implementing these measures may result in temporary (e.g., construction activities that may conflict with land designated as open space) or permanent (e.g., displacement of existing residents and removal of existing structures) physical conflicts with existing land uses in or immediately adjacent to the study area.

Because the locations for the implementation of these environmental commitments are unknown at this time, there is some uncertainty about whether new land uses related to these environmental commitments would be incompatible with existing land uses. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with land uses within and adjacent to the study area, which predominantly consists of agriculture and open space. Most activities would be anticipated to take place on land designated for agriculture, open space, natural preserve and recreation; therefore, land uses related to preservation of those attributes would likely be compatible with the restoration actions that would take place under these environmental commitments. Additionally, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapter 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to result in substantial incompatibilities with local land use regulations. Impacts would not be adverse.

CEQA Conclusion: Because specific locations and types of restoration to be implemented are unknown at this point, there is some uncertainty about whether new land uses related to these environmental commitments would conflict with existing land uses or result in the permanent conversion of land uses. However, the restoration associated with these environmental commitments would be consistent with open space, and would generally be compatible with the study area, which is a predominantly agricultural area. Specific impacts to agriculture or wildlife habitat are evaluated in Chapters 13, *Agricultural Resources*, and 11, *Terrestrial Resources*. Therefore, implementation of this alternative is not anticipated to conflict with existing land uses. Impacts would be less than significant because environmental commitment actions would be largely consistent with open space and agricultural uses, actions would be limited compared to other BDCP alternatives, and actions would be dispersed across the study area. No mitigation is required.

Impact LU-6: Create Physical Structures Adjacent to and through a Portion of an Existing Community as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects related to the physical division of an existing community under Alternative 2D would be similar in mechanism to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS, but to a substantially smaller magnitude based on the conservation activities proposed under Alternative 2D (and as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS, and under Impact LU-4, above). Because the locations for the implementation of these habitat restoration and enhancement activities are unknown at this point, a conclusion about this alternative's potential to divide an existing community cannot be made; however, because, large-scale restoration actions that take place in areas suitable for open space, resource conservation, and habitat are not likely to create permanent physical divisions in existing communities, this impact is not anticipated to be adverse.

CEQA Conclusion: Because the locations for the implementation of habitat restoration and enhancement activities are unknown at this point, a conclusion about this alternative's potential to divide an existing community cannot be made; however, because, large-scale restoration actions that take place in areas suitable for open space, resource conservation, and habitat are not likely to create permanent physical divisions in existing communities, this impact is anticipated to be less than significant.

4.4.10 Agricultural Resources

Impact AG-1: Temporary Conversion, Short-Term Conversion, and Permanent Conversion of Important Farmland or of Land Subject to Williamson Act Contracts or in Farmland Security Zones as a Result of Constructing the Proposed Water Conveyance Facility

NEPA Effects: The temporary and short-term conversion and permanent conversion of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones to nonagricultural uses would be similar to those described under Alternative 4 (as described in Chapter 14, *Agricultural Resources*, Section 14.3.3.9 in Appendix A of this RDEIR/SDEIS) and would constitute an adverse effect on the physical environment. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher agricultural conversion effects when compared to Alternative 4. Disposal and reuse of RTM (described in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS), along with Mitigation Measure AG-1, would be available to reduce these effects.

CEQA Conclusion: Construction of physical structures associated with the water conveyance facility proposed under this alternative would occupy Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones, directly precluding agricultural use for the duration of construction. As described above and in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS, it is anticipated that the RTM and dredged material would be removed from RTM storage areas (which represent a substantial portion of the permanent impact areas) and reused, as appropriate, as bulking material for levee maintenance, as fill material for habitat restoration projects, or other beneficial means of reuse identified for the material. Because these activities would convert a substantial amount of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones to nonagricultural uses, however, they are considered significant impacts on the environment. Implementation of Mitigation Measure AG-1 would reduce these impacts by implementing activities such as siting project footprints to encourage continued agricultural production; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. However, these impacts remain significant and unavoidable after implementation of this measure for the same reasons provided under Alternative 4. For further discussion of potential incompatibilities with land use designations, see Section 4.4.9, *Land Use*, in this RDEIR/SDEIS.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in the Draft EIR/EIS.

Impact AG-2: Other Effects on Agriculture as a Result of Constructing and Operating the Proposed Water Conveyance Facility

Effects associated with construction and operation of the water conveyance facility under this alternative would be similar to those described under Alternative 4 in terms of effects related to seepage from the operation of forebays and from disruption of drainage and irrigation facilities during construction of water conveyance facilities. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher effects related to disruption of agricultural infrastructure when compared to Alternative 4. These activities could create indirect but adverse effects on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation in localized areas adjacent to forebays and through disruption of drainage and irrigation facilities.

Under Alternative 2D, Operational Scenario B, the operation of new physical facilities combined with hydrodynamic effects of habitat restoration activities could indirectly affect agriculture by causing changes to the quality of irrigation water in parts of the study area. Relative to Existing Conditions, Alternative 2D would potentially result in an increase in the number of days the Bay-Delta WQCP EC objectives would be exceeded in the Sacramento River at Emmaton, and in the San Joaquin River at San Andreas Landing (Table EC-9 in Appendix B of this RDEIR/SDEIS). The percent of days the Emmaton EC objective would be exceeded for the entire period modeled (1976–1991) would increase from 6% under Existing Conditions to 16% and the percent of days out of compliance would increase from 11% under Existing Conditions to 25%. The percent of days the San Andreas Landing EC objective would be exceeded would remain at 1% under Alternative 2D, but the percent of days out of compliance with the EC objective for San Andreas Landing would increase from 1% to 2%. San Andreas Landing average EC would decrease 6% for the entire period modeled, but would increase 2% during the drought period modeled, relative to Existing Conditions (Table EC-16 in Appendix B of this RDEIR/SDEIS). Alternative 2D is not expected to have adverse effects on EC in the San Joaquin River at San Andreas Landing, relative to Existing Conditions.

As discussed in Section 4.4.4, *Water Quality*, of this RDEIR/SDEIS, sensitivity analyses suggest that many of these modeled exceedances are a result of modeling artifacts or a result of operating rules used by the CALSIM II model under extreme hydrologic and operational conditions where there is not enough water supply to meet all requirements. In these cases, CALSIM II uses a series of operating rules to reach a solution that is a simplified version of the very complex decision processes that SWP and CVP operators would use in actual extreme conditions. Thus, it is unlikely that the Emmaton objective would actually be violated due to dead pool conditions, as suggested by modeling results. In the case of San Andreas Landing, the small number of modeled exceedances not attributable to modeling artifacts would be small in magnitude, last only a few days, and could be addressed with real time operations of the SWP and CVP (see Chapter 8, *Water Quality,* Section 8.3.1.1, in Appendix A of this RDEIR/SDEIS for a description of real time operations of the SWP and CVP). However, the results at Emmaton indicate that water supply could be either under greater stress or under stress earlier in the year, and EC levels at Emmaton and in the western Delta may increase as a result, leading to EC degradation and increased possibility of adverse effects on agricultural beneficial uses.

In general, the changes in frequency of exceedances of EC objectives relative to the No Action Alternative (ELT) would be similar to those discussed above relative to Existing Conditions, and thus the conclusions of the sensitivity analyses discussed above extend to the comparison to the No Action Alternative (ELT). Long-term monthly average EC levels at Emmaton would increase 1–12% for the entire period modeled (1976–1991) and 4–33% during the drought period modeled (1987–1991), relative to the No Action Alternative (ELT) (Table EC-16 in Appendix B of this RDEIR/SDEIS). The largest increases in EC would occur during the summer months of the drought period, and more generally in dry and critical water year types. During these periods, additional flow in the Sacramento River at Emmaton would reduce or eliminate increases in EC. It is expected that for

May–September of dry and critical water years, less pumping from the north Delta intakes and greater reliance on south Delta intakes would allow for enough flow in the Sacramento River at Emmaton to reduce water quality degradation to levels closer to the No Action Alternative (ELT). Alternative 2D is not expected to have adverse effects on EC in the San Joaquin River at San Andreas Landing relative to the No Action Alternative.

NEPA Effects: Considered together, construction and operation of the water conveyance facility under this alternative could create indirect but adverse effects on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation in localized areas and disruption of drainage and irrigation facilities. Water quality modeling results indicate that there could be increased long-term and drought period average EC levels during the summer months that would occur in the western Delta (i.e., in the Sacramento River at Emmaton) under this alternative relative to the No Action Alternative (ELT), that could contribute to adverse effects on the agricultural beneficial uses. Implementation of Mitigation Measures AG-1, GW-1, GW-5, and WQ-11 will reduce the severity of these adverse effects.

CEQA Conclusion: Water conveyance facility construction and operation could create a significant adverse impact on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation in localized areas and disruption of drainage and irrigation facilities. Modeling results indicate that relative to Existing Conditions, average EC levels at Emmaton would increase during the drought period with the largest increase occurring during the summer months of the drought period, and more generally in dry and critical water year types. These increases would potentially impact agricultural beneficial uses in the western Delta. As discussed in Section 4.4.4, *Water* Quality, the comparison to Existing Conditions reflects changes in EC due to both Alternative 2D operations and climate change/sea level rise. The EC effects expected to occur at Emmaton would be due in part to the effects of climate change/sea level rise, and in part due to Alternative 2D operations.

Implementation of Mitigation Measures AG-1, GW-1, GW-5, and WQ-11 will reduce the severity of these impacts by implementing activities such as siting project footprints to encourage continued agricultural production; monitoring changes in groundwater levels during construction; offsetting water supply losses attributable to construction dewatering activities; monitoring seepage effects; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. Implementation of Mitigation Measure WQ-11 would be expected to reduce the EC effects to a less than significant level. However, the impacts related to conversion of Important Farmland would remain significant and unavoidable after implementation of these measures for the same reasons provided under Alternative 4.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS.

Mitigation Measure GW-1: Maintain Water Supplies in Areas Affected by Construction Dewatering

Please see Mitigation Measure GW-1 under Impact GW-1 in the discussion of Alternative 1A in Chapter 7, *Groundwater*, of the Draft EIR/EIS.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A in Chapter 7, *Groundwater*, of the Draft EIR/EIS.

Mitigation Measure WQ-11: Avoid, Minimize, or Offset, as Feasible, Reduced Water Quality Conditions

Please see Mitigation Measure WQ-11 under Impact WQ-11 in the discussion of Alternative 1A in Chapter 8, *Water Quality*, of the Draft EIR/EIS.

Impact AG-3: Temporary Conversion, Short-Term Conversion, and Permanent Conversion of Important Farmland or of Land Subject to Williamson Act Contracts or in Farmland Security Zones as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 2D related to the conversion of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones associated with these environmental commitment activities would be similar to those described for Alternative 4A in Section 4.3.10 of this RDEIR/SDEIS. However, as described in Section 4.1, *Introduction*, of this RDEIR/SDEIS, Alternative 2D would protect and restore up to 17,766 acres of habitat under Environmental Commitment 3, 4, and 6-10 as compared with 83,800 acres under Alternative 4. Up to 5.5 miles of channel margin habitat would be enhanced under Alternative 2D with Environmental Commitment 6 (compared with 20 miles under Alternative 4). Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 8, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 2D would likely be substantially smaller than those associated with Alternative 4.

NEPA Effects: Because locations have not been selected for many of these habitat restoration and enhancement activities, the precise extent of this effect is unknown. However, based on the large proportion of land in the Conservation Zones designated as Important Farmland and/or subject to Williamson Act contracts or in Farmland Security Zones, it is anticipated that a substantial area of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones would be directly converted to habitat purposes under this alternative, resulting in an adverse effect on the environment. While conflicts with or cancellation of Williamson Act contracts would not—by itself—constitute an adverse effect on the quality of the human environment, the related conversion of the underlying agricultural resource would result in such an effect. Mitigation Measure AG-1 would be available to lessen the severity of these potential effects. Also, under the provisions of Government Code §51223, it may be feasible to rescind Williamson Act contracts for agricultural use, and enter into open space contracts under the Williamson Act, or open space easements pursuant to the Open Space Easement Act. To the extent this mechanism is used, it would eliminate the Williamson Act conflicts otherwise resulting from changes from agriculture to restoration and mitigation uses. For further discussion of potential incompatibilities with land use policies, see Section 4.4.9, *Land Use*, of this RDEIR/SDEIS.

CEQA Conclusion: Implementation of Environmental Commitments could result in conversion of a substantial amount of Important Farmland and conflict with land subject to Williamson Act contracts or in Farmland Security Zones, resulting in a significant impact on agricultural resources in the study area. Implementation of Mitigation Measure AG-1 will reduce the severity of these impacts by implementing activities such as siting features to encourage continued agricultural production; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. However, these impacts remain significant and unavoidable after implementation of this measure for the same reasons provided under Alternative 4.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS.

Impact AG-4: Other Effects on Agriculture as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 2D related to the conversion of Important Farmland and land subject to Williamson Act contracts or in Farmland Security Zones associated with these environmental commitment activities would be similar to those described for Alternative 4A. However, the acreages associated with some of these commitments would be somewhat higher than those proposed under Alternative 4A, as described in Impact AG-3 above.

NEPA Effects: Implementation of conservation actions under this alternative could create indirect but adverse effects on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation and seepage or disruption of drainage and irrigation facilities. Further evaluation of these effects would depend on additional information relating to the location of these activities and other detailed information. However, implementation of Mitigation Measures AG-1 and GW-5 will reduce the severity of these adverse effects.

CEQA Conclusion: Implementation of Environmental Commitments under this alternative could create a significant impact on agriculture by converting substantial amounts of Important Farmland to other uses through changes to groundwater elevation and seepage or disruption of drainage and irrigation facilities. Further evaluation of these effects would depend on additional information relating to the location of these activities and other detailed information. Implementation of Mitigation Measures AG-1 and GW-5 will reduce the severity of these impacts by implementing activities such as siting features to encourage continued agricultural production; monitoring seepage effects; relocating or replacing agricultural infrastructure in support of continued agricultural activities; engaging counties, owners/operators, and other stakeholders in developing optional agricultural stewardship approaches; and/or preserving agricultural land through offsite easements or other agricultural land conservation interests. However, these impacts remain significant and unavoidable after implementation of these measures for the same reasons provided under Alternative 4.

Mitigation Measure AG-1: Develop an Agricultural Lands Stewardship Plan (ALSP) to Maintain Agricultural Productivity and Mitigate for Loss of Important Farmland and Land Subject to Williamson Act Contracts or in Farmland Security Zones

Please see Mitigation Measure AG-1 under Impact AG-1 in the discussion of Alternative 4 in Chapter 14, *Agricultural Resources*, of the Draft EIR/EIS.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A in Chapter 7, *Groundwater*, of the Draft EIR/EIS.

4.4.11 Recreation

Impact REC-1: Permanent Displacement of Existing Well-Established Public Use or Private Commercial Recreation Facility Available for Public Access as a Result of the Location of Proposed Water Conveyance Facilities

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4 in Appendix A of this RDEIR/SDEIS, except that it would include two additional intakes compared to Alternative 4. The extent of the permanent displacement of public use or private commercial recreation areas located within the Delta occurring under Alternative 2D as a result of the location of the intakes would be the same as described for Alternative 2, as described in Chapter 15, *Recreation* of the Draft EIR/EIS. The proposed location of the Alternative 2A five intake facilities, tunnels, and associated water conveyance facilities would not lie within the designated boundaries of an existing public use recreation site. The post-construction location of the water conveyance facilities would not result in long-term disruption or reduction of any well-established recreation activity or site, including parks, marinas, or other designated areas. Therefore, there would be no adverse effects. The extent of the permanent displacement of public use or private commercial recreation areas under Alternative 2D as a result of the conveyance facilities located along the rest of the alignment past the intakes, would be the same as described for Alternative 4, as described in Chapter 15, *Recreation*, Section 15.3.3.9 in Appendix A of this RDEIR/SDEIS.

CEQA Conclusion: The extent of permanent displacement of public use or private commercial recreation areas as a result of the location of the intakes under Alternative 2D would be the same as discussed for Alternative 2 because the location of proposed intakes are similar between the two alternatives. The alternative would not locate alternative facilities that would result in the permanent displacement of any well-established public use or private commercial recreation facility available for public access. The extent of permanent displacement of public use or private commercial recreation areas as a result of the location of the rest of the alignment past the intakes under Alternative 2D would be the same as discussed for Alternative 4 because the location of proposed alignments are similar between the two alternatives. Therefore, impacts are considered less than significant. No mitigation is required.

Impact REC-2: Result in Long-Term Reduction of Recreation Opportunities and Experiences as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: The extent of the long-term reduction of recreation experiences within the Delta as a result of construction the water conveyance facilities under Alternative 2D would be the same as described for Alternative 2A in relation to construction of Intakes 1, 2, 3, and 4, and the same as Alternative 4 in relation to construction of Intakes 3 and 5 as well as the rest of the alignment past the intakes. Clarksburg Boat Launch and Stone Lakes National Wildlife would be affected by long-term noise and visual disturbances from the construction of the intakes, as described under Alternative 2. Two recreation sites, Clifton Court Forebay and Cosumnes River Preserve, are within the potential construction footprint and six recreation sites or areas (Stone Lakes National Wildlife Refuge, Clarksburg Boat Launch, Wimpy's Marina, Delta Meadows, Bullfrog Landing Marina, and Lazy M Marina) are within the 1,200- to 1,400-foot indirect impact area, as described in Alternative 4. Potential indirect effects on recreation include loss of access, construction noise, and changes in the visual character of the area surrounding the recreation sites.

As discussed in detail under Alternative 1A (Alternative 2 refers to Alternative 1A for detailed discussion of impacts), Stone Lakes National Wildlife Refuge would be affected by noise and visual disturbances as a result of construction of and associated work areas related to Intakes 1 through 4.

As discussed in detail under Alternative 4, impacts on recreation occurring within the Stone Lakes NWR would be attributable to noise and changes in visual character as a result of temporary work areas, RTM storage, geotechnical exploration, construction of Intakes 2 and 3, and construction of the temporary transmission lines. Recreation activities that could be adversely affected include wildlife and environmental education.

The Clarksburg Boat Launch is on the west bank of the Sacramento River across the river from the site of Intake 3. Although access to the boat launch would be maintained during the construction period, noise generated during construction and geotechnical testing could adversely affect use of the public access areas near the boat launch for fishing or other activities.

As discussed under Alternative 4, impacts on recreation opportunities occurring within the Cosumnes River Preserve would include disruption of wildlife viewing and docent-guided tours. Although no recreation opportunities would be permanently displaced, recreation opportunities occurring within portions of the preserve could be adversely affected during construction as result of the introduction of noise, light, and temporary facilities such as access roads, safe haven work sites, and tunnel shaft with temporary work areas.

Wimpy's Marina is a private boating facility located on the south fork of the Mokelumne River southeast of Walnut Grove. Geotechnical exploration would occur along the tunnel corridor for approximately 2.5 years and would introduce noise that would adversely affect recreation occurring at the marina.

As discussed in detail under Alternative 4, recreation occurring at Delta Meadows could be affected by geotechnical testing and construction and operation of the intermediate forebay and spillway. These features would generate noise and introduce visual disturbances to the recreation site.

Recreation occurring at the Bullfrog Landing Marina on Middle River could be affected by noise and visual disturbance as a result of constructing the water conveyance across Bacon Island. This would include impacts from constructing a temporary access road on the island as well as a temporary safe haven work area. Anglers on the river between the marina and the construction area would also experience noise and visual disturbances during construction.

On-water recreation opportunities not associated with formal recreation sites could be affected by the introduction of noise and light during the construction period. The quality of recreation opportunities in the vicinity of construction sites may be adversely affected by noise and changes in visual character.

As discussed in detail under Alternative 4, recreation opportunities, including fishing and hunting, could be adversely affected by expanding Clifton Court Forebay. Recreation would be adversely affected because access to the forebay would not be allowed during construction.

Construction of Alternative 2D intakes and water conveyance facilities would result in disruption to recreational opportunities. Indirect effects on recreation experiences may occur as a result of impaired access, construction noise, or negative visual effects. Overall, construction and geotechnical exploration may occur year-round and last from 2.5 to 13.5 years at individual construction sites near recreation sites or areas and in-river construction would be primarily limited to June 1 through October 31 each year, which would result in a long-term reduction of recreational opportunities or experiences. Mitigation measures (REC-2, BIO-75, AES-1a, AES-1b, AES-1c, AES-1d, AES-1e, AES-1f, AES-1g, AES-2D, AES-4b, AES-4c, TRANS-1a, TRANS-1b, TRANS-1c, NOI-1a, and NOI-1b) are available to address adverse effects on recreation resulting from introduction of noise and light and the loss of access. However, due to the length of time that construction would occur and the dispersed effects across the Delta, the direct and indirect effects related to temporary disruption of existing recreational activities at facilities within the impact area would be adverse.

CEQA Conclusion: Construction of the Alternative 2D intakes and related water conveyance facilities would result in permanent and long-term (i.e., lasting over 2 years) impacts on well-established recreational opportunities and experiences in the study area because of access, noise, and visual setting disruptions that could result in loss of public use. These impacts would occur year-round. The mitigation measures described below, in combination with environmental commitments, would reduce some construction-related impacts by compensating for effects on wildlife habitat and species; minimizing the extent of changes to the visual setting, including nighttime light sources; manage construction-related traffic; and implementing noise reduction and complaint tracking measures. However, the level of impact would not be reduced to a less-than-significant level because it is not certain the mitigation would reduce the level of these impacts to less than significant in all the instances occurring within the entire study area. Therefore, these impacts are considered significant and unavoidable.

Mitigation Measure REC-2: Provide Alternative Bank Fishing Access Sites

Please see Mitigation Measure REC-2 under Impact REC-2 in the discussion of Alternative 4 in Chapter 15, *Recreation*, of the Draft EIR/EIS.

Mitigation Measure BIO-75: Conduct Preconstruction Nesting Bird Surveys and Avoid Disturbance of Nesting Birds

Please see Mitigation Measure BIO-75 under Impact BIO-75 in the discussion of Alternative 4 in Chapter 12, *Biological Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please see Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please see Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please see to Mitigation Measure AES-1c under Impact AES-1in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please see to Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please see Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please see Mitigation Measure AES-1f under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please see Mitigation Measure AES-1g under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-2D: Limit Construction to Daylight Hours within 0.25 Mile of Residents

Please see Mitigation Measure AES-2D under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Please see Mitigation Measure AES-4b under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Please see Mitigation Measure AES-4c under Impact AES-4 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please see Mitigation Measure TRANS-1b under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please see Mitigation Measure TRANS-1c under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact REC-3: Result in Long-Term Reduction of Recreational Navigation Opportunities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: The extent of the long-term reduction in recreational navigation opportunities as a result of constructing the proposed water conveyance facilities under Alternative 2D would be similar to Alternative 2A in relation to construction of Intakes 1, 2, 3, and 4, and Alternative 4 in relation to Intakes 2, 3, and 5 as well as the rest of the alignment. Construction activities associated with constructing five intakes on the Sacramento River, siphons near Clifton Court Forebay, Head of Old River barrier and operating barges and constructing temporary barge unloading facilities at Snodgrass Slough, Potato Slough, San Joaquin River, Middle River, Connection Slough, Old River, and the West Canal would disrupt boat passage and navigation at and near these sites. Although implementing Mitigation Measure TRANS-1a and helping to fund measures to reduce aquatic weeds would reduce impacts on recreational navigation, these effects would remain adverse because of the long duration of construction which would continually reduce recreation opportunities and distract from experiences occurring near construction activity.

CEQA Conclusion: Impacts on recreational navigation during construction of the water conveyance facilities under Alternative 2D would be similar to those described under Alternatives 2A and 4. Impeding boat passage and navigation and resulting impacts on recreation would occur during construction of the intakes, temporary barge unloading facilities, and siphons. Although Mitigation Measure TRANS-1a would reduce impacts on navigation associated with barge unloading facilities and participating in the aquatic weed reduction program would help address impacts on navigation, the impact of constructing the water conveyance facilities would be considered significant and unavoidable.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact REC-4: Result in Long-Term Reduction of Recreational Fishing Opportunities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: The extent of changes in sport fishing opportunities occurring within the study area under Alternative 2D would be similar to Alternative 2A in relation to construction of Intakes 1, 2, 3, and 4, and Alternative 4 in relation to Intakes 2, 3, and 5 as well as the rest of the alignment. Constructing water intakes, siphons, and operable barrier and placement and use of barge unloading facilities during tunnel/pipeline construction would result in temporary water quality effects (e.g., turbidity, accidental spills, disturbance of contaminated sediments); elevated underwater noise (associated with pile driving and other construction activities); fish exposure to stranding and direct physical injury; and temporary exclusion or degradation of spawning and rearing habitats. Expanding Clifton Court Forebay would restrict access to bank fishing sites during the construction period. Although fish populations likely would not be affected to the degree that the abundance of sport fish would be substantially reduced, construction conditions would introduce noise and visual disturbances that would affect the recreation experience for anglers.

Although construction would occur for more than 2 years and cause a long-term reduction in fishing opportunities at one recreational site, construction of the proposed water conveyance facilities would not affect most fishing opportunities throughout the Delta. Additionally, mitigation measures are available to enhance and ensure access to nearby fishing sites and to address noise and visual disturbances.

Construction of the water conveyance facilities would not result in a long-term adverse effect on fishing opportunities because the effects would be limited to construction sites and would not limit fishing opportunities occurring in other parts of the Delta. Mitigation Measures REC-2, NOI-1a, NOI-1b, AES-1a, AES-1b AES-1c AES-1d, AES-1e, AES-1f, and AES-1g would help reduce or avoid impacts on recreational fishing occurring at construction sites.

CEQA Conclusion: The impact on recreational fishing opportunities as a result of constructing the water conveyance facilities under Alternative 2D would be similar to Alternative 2A in relation to construction of Intakes 1, 2, 3, and 4, and Alternative 4 in relation to Intakes 2, 3, and 5 as well as the rest of the alignment. The combined impact on recreational fishing opportunities would be considered significant. Implementing mitigation measures REC-2, NOI-1a, NOI-1b, AES-1a, AES-1b AES-1c AES-1d, AES-1e, AES-1f, and AES-1g would reduce the impact on recreational fishing to a less-than-significant level by providing alternate fishing sites, reducing noise generated during construction activities, and limiting changes in the visual character of recreational fishing sites.

Mitigation Measure REC-2: Provide Alternative Bank Fishing Access Sites

Please see Mitigation Measure REC-2 under Impact REC-2 in the discussion of Alternative 4 in Chapter 15, *Recreation*, of the Draft EIR/EIS.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under, Alternative 1A in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please see Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please see Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please see Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please see Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please see Mitigation Measure AES-1e under AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please see Mitigation Measure AES-1f under AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please see Mitigation Measure AES-1g under AES-1 in the discussion of Alternative 4 in Chapter 17, *Aesthetics and Visual Resources*, of the Draft EIR/EIS.

Impact REC-5: Result in Long-Term Reduction of Recreational Fishing Opportunities as a Result of the Operation of the Proposed Water Conveyance Facilities

NEPA Effects: The effects of operating the water conveyance facilities on recreational fishing opportunities under Alternative 2D would be similar to Alternative 2A in relation to the location of Intakes 1, 2, 3, and 4, and Alternative 4 in relation to Intakes 2, 3, and 5 as well as the rest of the alignment. Operation of Alternative 2D may result in changes in entrainment, spawning, rearing, and migration. However, effects on fish species that are popular for recreational fishing are not of a nature/level that will adversely affect recreational fishing. While there are some significant impacts on specific non-listed species, as discussed in Section 4.3.7, *Fish and Aquatic Resources*, of this RDEIR/SDEIS, they are typically limited to specific rivers and not the population of that species as a whole. The effect is not adverse because it would not result in a substantial long-term reduction in recreational fishing opportunities.

CEQA Conclusion: The potential impact on covered and non-covered sport fish species from operation of Alternative 2D would be considered less than significant because any impacts on fish and, as a result, impacts on recreational fishing, are anticipated to be isolated to certain areas and would not affect the abundance of popular sport fish.

Impact REC-6: Cause a Change in Reservoir or Lake Elevations Resulting in Substantial Reductions in Water-Based Recreation Opportunities and Experiences at North- and South-of-Delta Reservoirs

NEPA Effects: The methodology for assessing effects on recreation at major upstream storage reservoirs for Alternative 2D is the same as applied to Alternative 2A. However, Alternative 2A only analyzes Operational Scenario B Late Long Term compared to No Action Alternative Late Long Term (2060). Alternative 2D analyzes Operational Scenario B Early Long Term compared to No Action Alternative Early Long Term (2025). The results of this assessment are shown in Tables 4.3.11-1 and 4.3.11-2 below.

Existing Conditions (CEQA Baseline) Compared to Alternative 2D ELT (2025)

Under Alternative 2D Operational Scenario B recreation thresholds would be exceeded more frequently at Trinity, Shasta, Oroville, Folsom, and San Luis Reservoirs relative to Existing Conditions. These changes represent a greater than 10% increase in the frequency the recreation thresholds are exceeded under Operational Scenario B Early Long Term at Trinity, Shasta, Oroville, Folsom, and San Luis Reservoirs compared to Existing Conditions. However, as discussed in Section 15.3.1, *Methods for Analysis*, of the Draft EIR/EIS these changes in SWP/CVP reservoir elevations are primarily attributable to change in demand and other external factors such as sea level rise and climate change. It is not possible to specifically define the exact extent of the changes due to implementation of the action alternative using these model simulation results. Thus, the precise contributions of the external factors to the total differences between Existing Conditions and Alternative 2D Operational Scenario B Early Long Term cannot be isolated in this comparison. Please refer to the comparison of the No Action Alternative (ELT) to Alternative 2D for a discussion of the potential effects on end-of-September reservoir and lake elevations attributable to operation of Alternative 2D.

Existing Conditions (CEQA Baseline) Compared to Alternative 2D LLT (2060)

Existing Conditions compared to Alternative 2D LLT (2060) results are the same as described under Alternative 2A.

No Action Alternative (ELT) Compared to Alternative 2D

The comparison of Alternative 2D to the No Action Alternative (ELT) condition most closely represents changes in reservoir elevations that may occur as a result of operation of Alternative 2D because both conditions external factors such as change in demand and sea level rise and climate change (see Appendix 5A, *BDCP EIR/EIS Modeling Technical Appendix*, of the Draft EIR/EIS). As shown in Table 4.3.11-1 and Table 4.3.11-2, below, Alternative 2D Operational Scenario B Early Long Term would result in changes in the frequency with which the end-of-September reservoir levels at Trinity, Shasta, Oroville, Folsom, and San Luis Reservoirs would fall below levels identified as important water-dependent recreation thresholds. The CALSIM II modeling results indicate that reservoir levels under Alternative 2D ELT operations would either not change or would fall below the individual reservoir recreation thresholds less frequently than under No Action Alternative (ELT) conditions at Trinity, Shasta, and Oroville Reservoirs. Operation of Alternative 2D would not adversely affect water-dependent or water-enhanced recreation at these reservoirs. Overall, these conditions represent improved recreation conditions for ELT results under operation of Alternative 2D because there would be slightly fewer years in which end-of-September reservoir levels would fall below the recreation thresholds thus indicating better boating opportunities, when compared to No Action Alternative (ELT) conditions.

The ELT modeling result for Folsom Reservoir indicates there could be 4 additional years under Alternative 2D, during which the reservoir level would fall below the reservoir's boating threshold at the end of September. The change would not exceed the 10% increase in the frequency threshold that would indicate an adverse impact on recreation occurring at the reservoir.

The ELT modeling result for New Melones Reservoir indicates there could be 1 additional year under Alternative 2D, during which the reservoir level would fall below the reservoir's boating threshold at the end of September. The change would not exceed the 10% increase in the frequency threshold that would indicate an adverse impact on recreation occurring at the reservoir.

The ELT modeling results for San Luis Reservoir indicate there could be 26 additional years under Alternative 2D, during which the reservoir level would fall below the reservoir boating threshold at the end of September relative to the No Action Alternative (ELT) condition. This is a greater than 10% change and would be considered a substantial reduction in recreational boating opportunities at San Luis Reservoir. Shoreline fishing would still be possible, and other recreation activities at the reservoir—picnicking, biking, hiking, and fishing—would be available. The reduction in surface elevations at San Luis Reservoir under Operational Scenarios H3 and H4 would result in an adverse impact on recreation occurring at the reservoir by restricting access by boaters. Mitigation Measure REC-6 would be available to address this effect.

CEQA Conclusion: This impact on water-dependent and water-enhanced recreation opportunities at north- and south-of-Delta reservoirs would be less than significant because, with the exception of San Luis Reservoir, the CALSIM II modeling results indicate that reservoir levels attributable to

Alternative 2D operations would either slightly decrease (Folsom and New Melones Reservoirs) or would fall below the individual reservoir thresholds less frequently than under No Action Alternative (ELT). These changes in reservoir and lake elevations would result in a less-than-significant impact on recreation opportunities and experiences at Trinity, Shasta, Oroville, Folsom, and New Melones Reservoirs. At Trinity and Oroville Reservoirs, because there would be fewer years in which the reservoir or lake levels fall below the recreation threshold relative to No Action Alternative (ELT) conditions, these effects would be considered beneficial to recreation opportunities and experiences. Operation of Alternative 2D would not substantially affect water-dependent or water-enhanced recreation at these reservoirs. At San Luis Reservoir at ELT, the reduction in reservoir access by boaters would be significant because it is a greater than 10% change and could result in a significant impact on recreation. Mitigation Measure REC-6 would reduce this impact to less than significant.

Mitigation Measure REC-6: Provide a Temporary Alternative Boat Launch to Ensure Access to San Luis Reservoir

Consistent with applicable recreation management plans, DWR and Reclamation will work with DPR to establish a boat ramp extension at or near the Basalt boat launch or other alternative boat ramp site at San Luis Reservoir to maintain reservoir access in years when access becomes unavailable.

Table 4.3.11-1. Summary of Years with Reduced SWP and CVP Reservoir Recreation Opportunities (End-of September Elevations below Recreation Thresholds) for Alternative 2D

	Recreation Threshold[a]								
	Trinity Lake			Shasta Lake			Lake Oroville		
	<2,270 ft Elevation			<967 ft Elevation			<700 ft Elevation		
Scenario	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative (ELT) (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative (ELT) (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative (ELT) (CEQA/ NEPA)
Existing Condition (CEQA)	21			17			17		
No Action Alternative (ELT)	32	11		22	5		26	9	
Alternative 2D (ELT)									
Operational Scenario B	31	10	-1	22	5	0	20	3	-6
Alternative 2D (LLT)									
Operational Scenario B	43	22		29	12		29	12	

[a] Recreation thresholds selected for the analysis represent the reservoir surface water elevation at which recreation opportunities become diminished due to restricted access to boat ramps, exposure of previously submerged islands or shoals that affect boater safety, and shoreline degradation.

[b] The number of years out of the 82 simulated when the September end-of-month elevation is less than the recreation elevation threshold for the selected project alternative scenario. An elevation less than the recreation threshold indicates occurrences during which recreation opportunities may be diminished (see note a, above).

[c] The change values are the number of years of the simulated conditions that the selected alternative differs from the comparison condition (i.e., the Existing Condition or No Action Alternative ELT). A positive change would indicate more years with reduced recreation opportunities.

Table 4.3.11-2. Summary of Years with Reduced SWP and CVP Reservoir Recreation Opportunities (End-of September Elevations below Recreation Thresholds) for Alternative 2D

	Recreation Threshold[a]								
	Folsom Lake <405 ft Elevation			New Melones Lake <900 ft Elevation			San Luis Reservoir <360 ft Elevation		
Scenario	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative ELT (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative ELT (CEQA/ NEPA)	Years[b]	Change Relative to Existing Condition (CEQA)[c]	Change Relative to No Action Alternative ELT (CEQA/ NEPA)
Existing Condition (CEQA)	22			9			3		
No Action (ELT)	33	11		8	-1		9	6	
Alternative 2D (ELT)									
Operational Scenario B	37	15	4	9	0	1	35	32	26
Alternative 2D (LLT)									
Operational Scenario B	44	22		12	3		34	31	

[a] Recreation thresholds selected for the analysis represent the reservoir surface water elevation at which recreation opportunities become diminished due to restricted access to boat ramps, exposure of previously submerged islands or shoals that affect boater safety, and shoreline degradation.
[b] The number of years out of the 82 simulated when the September end-of-month elevation is less than the recreation elevation threshold for the selected project alternative scenario. An elevation less than the recreation threshold indicates occurrences during which recreation opportunities may be diminished (see note a, above).
[c] The change values are the number of years of the simulated conditions that the selected alternative differs from the comparison condition (i.e., the Existing Condition or No Action ELT). A positive change indicates more years with reduced recreation opportunities relative to the comparison condition. A negative change indicates fewer years with reduced recreation opportunities relative to the comparison condition.

Impact REC-7: Result in Long-Term Reduction in Water-Based Recreation Opportunities as a Result of Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: The effects of maintaining the water conveyance facilities on water-based recreation under Alternative 2D would be the same as described under Alternative 4. These potential effects would occur as a result of regular maintenance activities of the intakes. The effect on boating is not considered adverse because the boat passage around the intakes would be maintained and disruption of boat access in the immediate vicinity of the intakes would be short-term.

CEQA Conclusion: Effects on recreation resulting from the maintenance of intake facilities would be short-term and intermittent and would not result in significant impacts on boat passage, navigation, or water-based recreation within the vicinity of the intakes.

Impact REC-8: Result in Long-Term Reduction in Land-Based Recreation Opportunities as a Result of Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: The effects of maintaining the water conveyance facilities on land-based recreation under Alternative 2D would be the same as described under Alternative 4. Maintenance activities would be short-term and intermittent, occur within the immediate vicinity of water conveyance facility, and are not expected to generate noise that would distract from adjacent recreation opportunities. Therefore, there would be no effects on recreation opportunities as a result of maintenance of the proposed water conveyance facilities.

CEQA Conclusion: Maintenance of conveyance facilities would be short-term and intermittent and would not result in any changes to land-based recreational opportunities. Therefore, there would be no impact and no mitigation would be required.

Impact REC-9: Result in Long-Term Reduction in Fishing Opportunities as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementing conservation and stressor reduction components as part of Alternative 2D would result in effects on fishing opportunities similar to those described for Alternative 4. The magnitude of the effects occurring under Alternative 2D would be much less than under Alternative 4 because the total acreage that would be affected by the conservation and stressor reduction actions (Environmental Commitments 3, 4, 6–12, 15, and 16) occurring in the Plan Area would be much less than the conservation measures proposed under Alternative 4. Construction, operation, and maintenance of the conservation and stressor reduction components could have affects that would be similar in nature to those discussed above for construction, operation, and maintenance of proposed water conveyance facilities. Although similar in nature, the potential intensity of any effects would likely be substantially lower because the nature of the activities associated with implementing the conservation and stressor reduction components would be much less when compared to Alternative 4. In addition, the conservation and stressor reduction components would be expected to result in long-term benefits to aquatic species.

During the implementation stage, construction activity associated with the conservation and stressor reduction components could result in adverse effects on recreation by temporarily or permanently limiting access to fishing sites and disturbing fish habitat. The impact on fishing opportunities as the conservation and stressor reduction components are constructed would not be considered adverse because the actions would be small and localized. In the long term, the impact on fishing opportunities would be considered beneficial because the conservation and stressor reduction measures could benefit aquatic habitat and fish abundance.

CEQA Conclusion: Conservation and stressor reduction components would be expected to improve fishing opportunities within the Plan Area. The adverse and beneficial impacts would be similar to those described under Alternative 4, however the extent of those impacts would be much less because the restoration actions occurring under Alternative 2D would include much less acreage and a smaller geographic scope than the conservation measures described under Alternative 4. The impact on fishing opportunities as the conservation and stressor reduction components are constructed would be considered less than significant because the actions would be small and localized. In the long term, the impact on fishing opportunities would be considered beneficial because the conservation and stressor reduction measures could benefit aquatic habitat and fish abundance.

Impact REC-10: Result in Long-Term Reduction in Boating-Related Recreation Opportunities as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementing conservation and stressor reduction components as part of Alternative 2D would result in effects on boating-related recreation similar to the effects discussed under Alternative 4 for implementing conservation measures. However, the extent of the effects on boating under Alternative 2D would be much less because the total acreage that would be affected by the conservation and stressor reduction actions occurring in the Plan Area would be much less when compared to Alternative 4. Restoration of channel margin enhancement, riparian natural community, and nontidal marsh could provide increased boating opportunities within the study area.

CEQA Conclusion: Channel modification and other activities associated with implementation of some of the conservation and stressor reduction components may limit some opportunities for boating and boating-related recreation by reducing the extent of navigable water available to boaters. However, overall the conservation and stressor reduction components would also lead to an enhanced boating experience by expanding the extent of waterways available to boaters. Overall, these measures would not be anticipated to result in a long-term reduction in boating-related recreation activities; therefore, this impact is considered less than significant.

Impact REC-11: Result in Long-Term Reduction in Upland Recreational Opportunities as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: Implementing conservation and stressor reduction components as part of Alternative 2D would result in effects on upland recreational opportunities similar to Alternative 4. However, the extent of these effects occurring under Alternative 2D would be much less than under Alternative 4 because the total acreage that would be affected by the conservation and stressor reduction actions occurring in the Plan Area would be much less. The actions could benefit the same types of recreation opportunities (e.g., hunting, hiking, walking, wildlife viewing, botanical viewing, nature photography, picnicking, and sightseeing) as described for Alternative 4, however the recreational benefits accruing from these actions would be much less because of the smaller acreage that would be restored. Conversely, the conservation and stressor reduction actions could adversely affected established recreation activities that would no longer be possible or compatible with restoration. These potential adverse effects would be would be similar to those described under Alternative 4, however the effects are expected to be much less because of the smaller total acreage that would be restored.

Implementing the conservation and stressor reduction components could result in an adverse effect on recreation opportunities by reducing the extent of upland recreation sites and activities available to hiking, nature photography, or other similar activity. However, implementation of the measures would also restore or enhance new potential sites for upland recreation thereby potentially improving the quality of recreational opportunities.

CEQA Conclusion: Similar to Alternative 4, site preparation and earthwork activities occurring under Alternative 2D required to implement the conservation and stressor reduction components could temporarily limit or disrupt opportunities for upland recreational. These impacts on upland recreational opportunities would be considered less than significant because—similar to Alternative 4—environmental commitments incorporated into the project would require the project proponents to consult with CDFW to expand wildlife viewing, angling, and hunting opportunities as an element of the conservation and stressor reduction components. These components would not be anticipated to result in a substantial long-term disruption of upland recreational activities; thus, this impact is considered less than significant.

Impact REC-12: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Federal, State, or Local Plans, Policies, or Regulations Addressing Recreation Resources

NEPA Effects: Similar to Alternative 4, constructing the water conveyance facilities and implementing the conservation and stressor reduction components under Alternative 2D could result in incompatibilities with plans and policies that address recreation. A number of plans and policies that coincide with the study area provide guidance for recreation resource issues are overviewed in Chapter 15, *Recreation*, Section 15.2, *Regulatory Setting*, of the Draft EIR/EIS. This overview of plan and policy compatibility evaluates whether Alternative 2D is compatible or incompatible with such enactments, rather than whether impacts are adverse or not adverse or significant or less than significant. If the incompatibility relates to an applicable plan, policy, or regulation adopted to avoid or mitigate recreation effects, then an incompatibility might be indicative of a related significant or adverse effect under CEQA and NEPA, respectively. Such physical effects of Alternative 2D on recreation resources are addressed in Impacts REC-1 through REC-11, and in other sections, such as Section 4.3.19, *Noise*, and Section 4.3.13, *Aesthetics and Visual Resources*, of this RDEIR/SDEIS. A summary of the compatibility evaluations related to recreation resources for plans and policies is contained in the analysis of Alternative 4 and is applicable to Alternative 2D. Generally the evaluation found that implementing Alternative 2D would not be compatible with some provisions of The Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992 and some policies of the Sacramento, San Joaquin, Contra Costa, and Alameda Counties general plans that address recreation.

CEQA Conclusion: The incompatibilities identified in the analysis indicate the potential for a physical consequence to the environment. The physical effects are discussed in Alternative 2D, impacts REC-1 through REC-11, and no additional CEQA conclusion is required related to the compatibility of the alternative with relevant plans and polices.

4.4.12 Socioeconomics

Impact ECON-1: Temporary Effects on Regional Economics and Employment in the Delta Region during Construction of the Proposed Water Conveyance Facilities

The regional economic effects on employment and income in the Delta region during construction of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are similar. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher project-related employment effects when compared to Alternative 4. Conversely, adverse effects associated with agricultural employment would also be somewhat higher due to the additional acreages of agricultural land that would be affected by construction of five intake facilities.

NEPA Effects: Because construction of water conveyance facilities would result in an increase in construction-related employment and labor income, this would be considered a beneficial effect. However, these activities would also be anticipated to result in a decrease in agricultural-related employment and labor income, which would be considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Construction of the proposed water conveyance facilities would temporarily increase total employment and income in the Delta region. The change would result from expenditures on construction, increasing employment, and from changes in agricultural production, decreasing employment. Changes in recreational expenditures and natural gas well operations could also affect regional employment and income, but these have not been quantified. The total change in employment and income is not, in itself, considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause physical impacts. Such effects are discussed in other sections throughout this RDEIR/SDEIS. Removal of agricultural land from production is addressed in Section 4.4.10, *Agricultural Resources*, Impacts AG-1 and AG-2; changes in recreation related activities are addressed in Section 4.4.11, *Recreation,* Impacts REC-1 through REC-4; abandonment of natural gas wells is addressed in Section 4.4.22, *Minerals*, Impact MIN-1. When required, DWR would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-2: Effects on Population and Housing in the Delta Region during Construction of the Proposed Water Conveyance Facilities

Effects on population and housing in the Delta region during construction of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are similar. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher project-related changes in population and housing demand when compared to Alternative 4. Construction of five intakes under this alternative would also be anticipated to result in slightly higher effects associated with displacement of residential structures, which could create additional demand for housing in localized areas.

The construction workforce would most likely commute daily to the work sites from within the five-county region; however, if needed, there are about 53,000 housing units available to accommodate workers who may choose to commute on a workweek basis or who may choose to temporarily relocate to the region for the duration of the construction period. In addition to the available housing units, there are recreational vehicle parks and hotels and motels within the five-county region to accommodate any construction workers. As a result, and as discussed in more detail in Section 4.4.26, *Growth Inducement and Other Indirect Effects*, of this RDEIR/SDEIS, construction of the proposed conveyance facilities is not expected to substantially increase the demand for housing within the five-county region.

NEPA Effects: Within specific local communities, there could be localized effects on housing. However, given the availability of housing within the five-county region, predicting where this impact might fall would be speculative. In addition, new residents would likely be dispersed across the region, thereby not creating a burden on any one community. Because these activities would not result in permanent concentrated, substantial increases in population or new housing, they would not be considered to have an adverse effect.

CEQA Conclusion: Construction of the proposed water conveyance facilities would result in minor population increases in the Delta region with adequate housing supply to accommodate the change in population. Therefore, the minor increase in demand for housing is not anticipated to lead to a reasonably foreseeable adverse physical changes constituting a significant impact on the environment.

Impact ECON-3: Changes in Community Character as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to changes in community character in the Delta region during construction of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are similar. However, under Alternative 2D two additional intake facilities would be constructed, which would result in additional localized effects on community character when compared to Alternative 4, particularly in and around the communities of Clarksburg, Hood, and Courtland.

Under Alternative 2D, additional regional employment and income could create net positive effects on the character of Delta communities. In addition to potential demographic effects associated with changes in employment, however, property values may decline in areas that become less desirable in which to live, work, shop, or participate in recreational activities. For instance, negative visual- or noise-related effects on residential property could lead to localized abandonment of buildings. While water conveyance construction could result in beneficial effects relating to the economic welfare of a community, adverse social effects could also arise as a result of declining economic stability in communities closest to construction effects and in those most heavily influenced by agricultural and recreational activities. Implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce adverse effects (see Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS).

CEQA Conclusion: Construction of water conveyance facilities under Alternative 2D could affect community character in the Delta region. However, because these impacts are social in nature, rather than physical, they are not considered impacts under CEQA. To the extent that changes to community character would lead to physical impacts involving population growth, such impacts are described under Impact ECON-2 and in Section 4.4.26, *Growth Inducement and Other Indirect Effects*, of this RDEIR/SDEIS. Furthermore, notable decreases in population or employment, even if limited to specific areas, sectors, or the vacancy of individual buildings, could result in alteration of community character stemming from a lack of maintenance, upkeep, and general investment. However, implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce the extent of these effects such that a significant impact would not occur (see Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

Impact ECON-4: Changes in Local Government Fiscal Conditions as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to changes in local government fiscal conditions during construction of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives would be similar. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in higher project-related effects on property tax and assessment revenue when compared to Alternative 4. However, California Water Code Section 85089 subdivision (b) specifies that the entities constructing and operating a new Delta conveyance facility will fully mitigate for the loss of property tax revenues or assessments levied by local governments or special districts. The Water Code requirement will ensure that forgone tax revenues as a result of transferring land from private to public ownership will be fully offset In addition, as discussed under Impact ECON-1, construction of the water conveyance facilities would be anticipated to result in a net temporary increase of income and employment in the Delta region. This would also create an indirect beneficial effect through increased sales tax revenue for local government entities that rely on sales taxes.

CEQA Conclusion: Under Alternative 2D, construction of water conveyance facilities would result in the removal of a portion of the property tax base for various local government entities in the Delta region. The potential losses would be offset by the provisions in the California Water Code that require entities constructing and operating new Delta water conveyance facilities to fully mitigate for the loss of property tax or assessment levied by local governments or special districts. It is anticipated that the Water Code requirement will ensure that forgone tax revenues will be fully offset. In addition, CEQA does not require a discussion of socioeconomic effects except where they would result in reasonably foreseeable physical changes. The potential for a physical change to the environment as a result of changes in tax revenues would be avoided by offsetting the potential losses in tax revenues.

Impact ECON-5: Effects on Recreational Economics as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: As described and defined in Section 4.4.11, *Recreation*, Impacts REC-1 through REC-4, construction of water conveyance facilities under Alternative 2D would be similar to those under Alternative 4, and would include elements that would be permanently located in two existing recreation areas. Additionally, substantial disruption of other recreational activities considered temporary and permanent would occur in certain areas during the construction period. Were it to occur, a decline in visits to Delta recreational sites as a result of facility construction would be expected to reduce recreation-related spending, creating an adverse effect throughout the Delta region. Additionally, if construction activities shift the relative popularity of different recreational sites, implementation of Alternative 2D may carry localized beneficial or adverse effects.

Access would be maintained to all existing recreational facilities, including marinas, throughout construction. As part of Mitigation Measure REC-2, project proponents would enhance nearby fishing access sites and would incorporate public recreational access into design of the intakes along the Sacramento River. Implementation of this measure along with separate, non-environmental commitments as set forth in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS relating to the enhancement of recreational access and control of aquatic weeds in the Delta would reduce these effects. Environmental commitments would also be implemented to reduce some of the effects of construction activities on the recreational experience. Similarly, mitigation measures proposed throughout other sections of this document, and listed under Impact REC-2 in Section 4.4.11, *Recreation*, of this RDEIR/SDEIS would also contribute to reducing construction effects on recreational experiences in the study area. Overall, however, the multi-year schedule and geographic scale of construction activities and the anticipated decline in recreational spending would be considered an adverse effect. The commitments and mitigation measures cited above would contribute to the reduction of this effect.

CEQA Conclusion: Construction of the proposed water conveyance facilities under Alternative 2D could affect recreational revenue in the Delta region if construction activities result in fewer visits to the area. Fewer visits would be anticipated to result in decreased economic activity related to recreational activities. This section considers only the economic effects of recreational changes brought about by construction of the proposed water conveyance facilities. Potential physical changes to the environment relating to recreational resources are described and evaluated in Section 4.4.11, *Recreation,* Impacts REC-1 through REC-4, in this RDEIR/SDEIS.

Impact ECON-6: Effects on Agricultural Economics in the Delta Region during Construction of the Proposed Water Conveyance Facilities

Effects on agricultural economics related to construction of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives are similar. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher effects on agricultural economics when compared to Alternative 4.

NEPA Effects: Because construction of the proposed water conveyance facilities would lead to reductions in crop acreage and in the value of agricultural production in the Delta region, this is considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural*

Resources, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Construction of the proposed water conveyance facilities would reduce the total value of agricultural production in the Delta region. The removal of agricultural land from production is addressed in Section 4.4.10, *Agricultural Resources,* Impacts AG-1 and AG-2, in this RDEIR/SDEIS. The reduction in the value of agricultural production is not considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause physical impacts. Such effects are discussed in other chapters throughout this RDEIR/SDEIS. When required, DWR would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-7: Permanent Regional Economic and Employment Effects in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

Permanent effects on regional economics during operation and maintenance of the proposed water conveyance facilities would be similar to those described under Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are similar and, in the context of the regional economy, operational outcomes related to water supply, water quality, recreation, or fisheries would be similar between the two alternatives. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher effects on employment effects when compared to Alternative 4. Increased expenditures related to operation and maintenance of water conveyance facilities would be expected to result in a permanent increase in regional employment and income, while the permanent removal of agricultural land following construction would have lasting negative effects on agricultural employment and income.

NEPA Effects: Because continued operation and maintenance of water conveyance facilities would result in an increase in operations-related employment and labor income, this would be considered a beneficial effect. However, the long-term footprint of facilities would lead to a continued decline in agricultural-related employment and labor income, which would be considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Operation and maintenance of the proposed water conveyance facilities would increase total employment and income in the Delta region. The net change would result from expenditures on operation and maintenance and from changes in agricultural production. The total change in income and employment is not, in itself, considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause physical impacts. Such effects are discussed in other chapters throughout this RDEIR/SDEIS. Removal of agricultural land from production is addressed in Section 4.4.10, *Agricultural Resources*, Impacts AG-1 and AG-2; and changes in recreation related activities are addressed in Section 4.4.11, *Recreation,* Impacts REC-5 through REC-8 in this RDEIR/SDEIS. When required, DWR would provide compensation to landowners as a result of acquiring lands for the proposed conveyance facilities. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-8: Permanent Effects on Population and Housing in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

Permanent effects on population and housing during operation and maintenance of the proposed water conveyance facilities would be similar to those described under Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are similar. It is anticipated that non-local workers would relocate to the five-county region, thus adding to the local population. However, this additional population would constitute a minor increase in the total 2025 projected regional population of 4.6 million and be distributed throughout the region. It is anticipated that most of the operational workforce would be drawn from within the five-county region. Consequently, operation of the conveyance facilities would not result in impacts on housing.

NEPA Effects: Because these activities would not result in concentrated, substantial increases in population or new housing, they would not be considered to have an adverse effect.

CEQA Conclusion: Operation and maintenance of the proposed water conveyance facilities would result in minor population increases in the Delta region with adequate housing supply to accommodate the change in population and therefore significant impacts on the physical environment are not anticipated.

Impact ECON-9: Changes in Community Character during Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: Under Alternative 2D, effects on community character would be similar in nature, location, and magnitude to those described under Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives are similar. However, under Alternative 2D two additional intake facilities would be constructed, which would result in additional localized effects on community character when compared to Alternative 4, particularly in and around the communities of Clarksburg, Hood, and Courtland.

While water conveyance operation and maintenance could result in beneficial effects relating to the economic welfare of a community, lasting adverse social effects, including effects on community cohesion, could also arise in communities closest to physical features and in those most heavily influenced by agricultural and recreational activities. Implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation would reduce adverse effects (see Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS).

CEQA Conclusion: Operation and maintenance of water conveyance facilities under Alternative 2D could affect community character in the Delta region. However, because these impacts are social in nature, rather than physical, they are not considered impacts under CEQA. To the extent that changes to community character would lead to physical impacts involving population growth, such impacts are described under Impact ECON-8 and in Section 4.4.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS. Furthermore, notable decreases in population or employment, even if limited to specific areas, sectors, or the vacancy of individual buildings, could result in alteration of community character stemming from a lack of maintenance, upkeep, and general investment. However, implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce the extent of these effects such that a significant impact would not occur (see Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

Impact ECON-10: Changes in Local Government Fiscal Conditions during Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to changes in local government fiscal conditions during operation and maintenance of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the water conveyance facilities proposed under these alternatives would be similar. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in higher project-related effects on property tax and assessment revenue when compared to Alternative 4. For the reasons discussed under ECON-4 above, adverse effects on property tax and assessment revenues would be offset by the requirement of the California Water. In addition, as discussed under Impact ECON-1, continued operation and maintenance of the water conveyance facilities would be anticipated to result in a net increase of income and employment in the Delta region. This would also create an indirect beneficial effect through increased sales tax revenue for local government entities that rely on sales taxes.

CEQA Conclusion: Under Alternative 2D, the ongoing operation and maintenance of water conveyance facilities would restrict property tax revenue levels for various local government entities in the Delta region. Some losses could be offset, at least in part, by an anticipated increase in sales tax revenue. For the reasons discussed under ECON-4 above, adverse effects on property tax and assessment revenues would be offset by the requirement of the California Water.

Impact ECON-11: Effects on Recreational Economics during Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: As discussed in Section 4.4.11, *Recreation,* Impacts REC-5 through REC-8, in this RDEIR/SDEIS, operation and maintenance activities associated with the proposed water conveyance facilities under Alternative 2D are anticipated to create minor effects on recreational resources. Maintenance of conveyance facilities, including intakes, would result in periodic temporary but not substantial adverse effects on boat passage and water-based recreational activities. Because effects of facility maintenance would be short-term and intermittent, substantial economic effects are not anticipated to result from operation and maintenance of the facilities.

CEQA Conclusion: Operation and maintenance activities associated with the proposed water conveyance facilities under Alternative 2D are anticipated to create minor effects on recreational resources and therefore, are not expected to substantially reduce economic activity related to recreational activities. This section considers only the economic effects of recreational changes. Potential physical changes to the environment relating to recreational resources are described and evaluated in Section 4.4.11, *Recreation,* Impacts REC-5 through REC-8, in this RDEIR/SDEIS.

Impact ECON-12: Permanent Effects on Agricultural Economics in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

Effects on agricultural economics during operation and maintenance of Alternative 2D would be similar to those described for Alternative 4 in Chapter 16, *Socioeconomics*, Section 16.3.3.9, in Appendix A of this RDEIR/SDEIS, because the physical water conveyance facilities proposed under these alternatives would be similar and, in the context of the regional agricultural economy, outcomes related to water quality would be similar between the two alternatives. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher effects on agricultural economics when compared to Alternative 4.

NEPA Effects: The footprint of water conveyance facilities would result in lasting reductions in crop acreage and in the value of agricultural production in the Delta region; therefore, this is considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: During operation and maintenance of the proposed water conveyance facilities the value of agricultural production in the Delta region would be reduced. The permanent removal of agricultural land from production is addressed in Section 4.4.10, *Agricultural Resources,* Impacts AG-1 and AG-2 of this RDEIR/SDEIS. The reduction in the value of agricultural production is not considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause reasonably foreseeable physical impacts. Such physical effects are discussed in other chapters throughout this RDEIR/SDEIS. When required, DWR would provide compensation to property owners for economic losses due to implementation of the alternative. While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical effect. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-13: Effects on the Delta Region's Economy and Employment Due to the Implementation of Environmental Commitments 3, 4, 6–12, 15, and16

The effects on the economy of the Delta region associated with implementation of these Environmental Commitments would be similar to those described for Alternative 4A in Section 4.3.12, *Socioeconomics*, of this RDEIR/SDEIS. However, the acreages associated with some of these commitments would be somewhat higher than those proposed under Alternative 4A.

NEPA Effects: Because implementation of these Environmental Commitments would be anticipated to result in an increase in construction and operation and maintenance-related employment and labor income, this would be considered a beneficial effect. However, implementation of these components would also be anticipated to result in a decrease in agricultural-related and natural gas production-related employment and labor income, which would be considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite. Additionally, measures to reduce impacts on natural gas wells are discussed in Chapter 26, *Mineral Resources*, Section 26.3.3.2, Impact MIN-5, in Appendix A of this RDEIR/SDEIS.

CEQA Conclusion: Implementation of the proposed Environmental Commitments would affect total employment and income in the Delta region. The change in total employment and income in the Delta region is based on expenditures resulting from implementation of the habitat enhancement and restoration activities and any resulting changes in agricultural production, recreation, and natural gas production. The total change in employment and income is not, in itself, considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause physical impacts. Such effects are discussed in other chapters throughout this RDEIR/SDEIS. Removal of agricultural land from production is addressed in Section 4.4.10, *Agricultural Resources*, Impacts AG-3 and AG-4; changes in recreation-related activities are addressed in Section 4.4.11, *Recreation,* Impacts REC-9 through REC-11; and abandonment of natural gas wells is addressed in Section 4.4.22, *Minerals*, Impact MIN-5. When required, the project proponents would provide compensation to property owners for economic losses due to implementation of the alternative*.* While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts and impacts on natural gas wells are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, and Chapter 26, *Mineral Resources*, Section 26.3.3.2, Impact MIN-5, in Appendix A of this RDEIR/SDEIS.

Impact ECON-14: Effects on Population and Housing in the Delta Region as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: In the Delta region, implementation of habitat enhancement and restoration activities could increase employment and convert land from existing uses, including possible displacement of residential housing and business establishments. The effects on population and housing in the Delta region would be similar to those described for Alternative 4A. However, the acreages associated with some of these commitments would be somewhat higher than those proposed under Alternative 4A. In general, the changes in population and housing would include increases in population from the construction and operation and maintenance-related activity and declines in residential housing and business establishments as a result of lands converted or impaired. Because these activities would not result in concentrated, substantial increases in population or new housing, they would not be considered to have an adverse effect.

CEQA Conclusion: Implementation of the proposed habitat enhancement and restoration activities could affect total population and housing in the Delta region. The change in total population and housing in the Delta region is based on employment resulting from implementation of the proposed conservation activities. The change in population and housing is expected to be minor relative to the five-county Delta region, and dispersed throughout the region. Therefore, significant impacts on the physical environment are not anticipated to result.

Impact ECON-15: Changes in Community Character as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: As noted under Impacts ECON-13 and ECON-14, conservation activities designed to restore, conserve, or enhance natural habitat would be anticipated to create economic effects similar to, but slightly higher than those described for Alternative 4A, including increases to employment and changes in land use that could trigger the disruption of agricultural and recreational economies.

They could also affect the possible displacement of residences and businesses. The effects these activities would create with regard to community character would depend on the nature of each measure along with its specific location, size, and other factors that are not yet defined.

Under Alternative 2D, temporary construction associated with implementation of these measures could lead to demographic changes and resulting effects on the composition and size of Delta communities. Earthwork and site preparation associated with environmental commitments could also detract from the rural qualities of the Delta region; however, their implementation would take place in phases over time, which would limit the extent of effects taking place at any one point in time.

Implementation of these measures could also alter community character over the long term. Conversion of agricultural land to restored habitat would result in the erosion of some economic and social contributions stemming from agriculture in Delta communities. However, in the context of the Delta region, a substantial proportion of land would not be converted. Additionally, restored habitat could support some rural qualities, particularly in terms of visual resources and recreational opportunities. These effects could attract more residents to some areas of the Delta, and could replace some agricultural economic activities with those related to recreation and tourism. To the extent that agricultural facilities and supportive businesses were affected and led to vacancy, alteration of community character could result from these activities. However, protection of cultivated lands would ensure the continuation of agricultural production on a substantial area of land in the Delta. If necessary, implementation of mitigation measures and environmental commitments related to transportation, agriculture, and recreation would be anticipated to reduce these adverse effects (see Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

CEQA Conclusion: Implementation of habitat enhancement and restoration activities under Alternative 2D could affect community character within the Delta region. However, because these impacts are social in nature, rather than physical, they are not considered impacts under CEQA. To the extent that changes to community character are related to physical impacts involving population growth, these impacts are described in Section 4.4.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS*.* Furthermore, notable decreases in population or employment, even if limited to certain areas, sectors, or the vacancy of individual buildings, could result in decay and blight stemming from a lack of maintenance, upkeep, and general investment. However, implementation of mitigation measures and environmental commitments related to noise, visual effects, transportation, agriculture, and recreation, would reduce the extent of these effects such that a significant impact would not occur (see Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS). Specifically, these include commitments to develop and implement erosion and sediment control plans, develop and implement hazardous materials management plans, provide notification of maintenance activities in waterways, develop and implement a noise abatement plan, develop and implement a fire prevention and control plan, and prepare and implement mosquito management plans.

Impact ECON-16: Changes in Local Government Fiscal Conditions as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

As discussed in relation to construction of water conveyance facilities, habitat restoration and enhancement activities under Alternative 2D would also take place, in part, on land held by private owners and from which local governments derive revenue through property taxes and assessments. In particular, environmental commitments related to protection and restoration of natural communities would require the acquisition of multiple parcels of land.

The loss of a substantial portion of an entity's tax base would represent an adverse effect on an agency, resulting in a decrease in local government's ability to provide public goods and services. Under Alternative 2D, property tax and assessment revenue forgone as a result of Environmental Commitment implementation would be similar to that described under Alternative 4A in Section 4.3.12, *Socioeconomics*, of this RDEIR/SDEIS. As described for Alternative 4A, impacts on tax revenues would be avoided as a result of the requirements stipulated in California Water Code that requires entities constructing or operating new Delta conveyance facilities to fully mitigate for the loss of property tax or assessments levied by local governments or special districts.

NEPA Effects: Overall, habitat enhancement and restoration activities would remove many acres of private land from local property tax and assessment rolls. This economic effect would be considered adverse; however, project proponents would offset forgone property tax and assessments levied by local governments and special districts on private lands converted to habitat. As described under Impact ECON-13, regional economic effects from the implementation of these activities would be mixed. While activities associated with construction and establishment of habitat areas could boost regional expenditures and sales tax revenue, reduced agricultural activities may offset these gains. Changes in recreation spending and related sales tax revenue could be positive or negative, depending on the implementation of the measures.

CEQA Conclusion: Under Alternative 2D, implementation of habitat enhancement and restoration activities would result in the removal of a portion of the property tax base for various local government entities in the Delta region. As discussed in Alternative 4A, these losses would be offset by the requirements stipulated in the California Water Code. CEQA does not require a discussion of socioeconomic effects except where they would result in physical changes. The potential for a physical change in the environment would be avoided by offsetting the potential losses in tax revenues

Impact ECON-17: Effects on Recreational Economics as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Implementation of habitat enhancement and restoration activities under this alternative would be anticipated to create an adverse effect on recreational resources by limiting access to facilities, restricting boat navigation, and disturbing fish habitat while restoration activities are taking place. These measures may also permanently reduce the extent of upland recreation sites. However, these components could also create beneficial effects by enhancing aquatic habitat and fish abundance, expanding the extent of navigable waterways available to boaters, and improving the quality of existing upland recreation opportunities. Therefore, the potential exists for the creation of adverse and beneficial effects related to recreational economics. Adverse effects would be anticipated to be primarily limited to areas close to restoration areas and during site preparation and earthwork phases. These effects could result in a decline in visits to the Delta and reduction in recreation-related spending, creating an adverse economic effect throughout the Delta. Beneficial recreational effects would generally result during later stages of restoration implementation as environmental conditions supporting recreational activities are enhanced. These effects could improve the quality of recreational experiences, leading to increased economic activities related to recreation, particularly in areas where habitat enhancement or restoration could create new recreational opportunities.

CEQA Conclusion: Site preparation and earthwork activities associated with a number of environmental commitments would limit opportunities for recreational activities where they occur in or near existing recreational areas. Noise, odors, and visual effects of construction activities would also temporarily compromise the quality of recreation in and around these areas, leading to potential economic impacts. However, over time, implementation could improve the quality of existing recreational opportunities, leading to increased economic activity. This section considers only the economic effects of recreational changes brought about by implementation of habitat enhancement and restoration activities. CEQA does not require a discussion of socioeconomic effects except where they would result in reasonably foreseeable physical changes. Potential physical changes to the environment relating to recreational resources are described and evaluated in Section 4.4.11, *Recreation,* Impacts REC-9 through REC-11 in this RDEIR/SDEIS.

Impact ECON-18: Effects on Agricultural Economics in the Delta Region as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Habitat enhancement and restoration activities would convert land from existing agricultural uses. These direct effects on agricultural land are described qualitatively in Section 4.4.10, *Agricultural Resources,* Impacts AG-3 and AG-4 in this RDEIR/SDEIS. Effects on agricultural economics would include effects on crop production and agricultural investments resulting from restoration actions on agricultural lands. The effects would be similar in kind to those described for lands converted due to construction and operation of the conveyance features and facilities. The total acreage and crop mix of agricultural land potentially affected is not specified at this time, but when required, the project proponents would provide compensation to property owners for losses due to implementation of the alternative. Because implementation of habitat enhancement and restoration activities would be anticipated to lead to reductions in crop acreage and in the value of agricultural production in the Delta region, this is considered an adverse effect. Mitigation Measure AG-1, described in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS, would be available to reduce these effects by preserving agricultural productivity and compensating offsite.

CEQA Conclusion: Implementation of habitat enhancement and restoration activities would reduce the total value of agricultural production in the Delta region. The permanent removal of agricultural land from production is addressed in Section 4.4.10, *Agricultural Resources,* Impacts AG-3 and AG-4 of this RDEIR/SDEIS. The reduction in the value of agricultural production is not considered an environmental impact. Significant environmental impacts would only result if the changes in regional economics cause physical impacts. Such effects are discussed in other chapters throughout this RDEIR/SDEIS. When required, the project proponents would provide compensation to property owners for economic losses due to implementation of the alternative*.* While the compensation to property owners would reduce the severity of economic effects related to the loss of agricultural land, it would not constitute mitigation for any related physical impact. Measures to reduce these impacts are discussed in Chapter 14, *Agricultural Resources*, Section 14.3.3.2, Impact AG-1, in Appendix A of this RDEIR/SDEIS.

Impact ECON-19: Socioeconomic Effects in the South-of-Delta Hydrologic Regions

As described in Section 4.4.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS, the operational components of water conveyance facilities under Alternative 2D could result in a number of effects in areas receiving SWP and CVP water deliveries outside of the Delta. Generally, these effects would be similar to those described for Alternative 2A (Operational Scenario B) in Chapter 16, *Socioeconomics*, Section 16.3.3.5, of the Draft EIR/EIS, because the incremental change in Delta exports is similar, when compared to the relevant No Action condition.

Under Operational Scenario B as considered for Alternative 2D (at the ELT), Delta exports would increase by 14%when compared to the No Action Alternative (ELT), as shown in Table B.1-6 in Appendix B of this RDEIR/SDEIS. Under Operational Scenario B as considered for Alternative 2A (LLT), Delta exports would also increase by 14% when compared to the No Action Alternative (LLT), as shown in Table 5-6 in Appendix A of this RDEIR/SDEIS.

Changes in the amount, cost, or reliability of water deliveries could create socioeconomic effects in the hydrologic regions. To the extent that unreliable or insufficient water supplies currently represent obstacles to agricultural production, Alternative 2D may support more stable agricultural activities by enabling broader crop selection or by reducing risk associated with uncertain water deliveries. As a result of an increase in water supply and supply reliability, farmers may choose to leave fewer acres fallow and/or plant higher-value crops. While the locations and extent of any increases in production would depend on local factors and individual economic decisions, a general increase in production would be anticipated to support growth in seasonal and permanent on-farm employment, along with the potential expansion of employment in industries closely associated with agricultural production. These include food processing, agricultural inputs, and transportation. Generally, these effects would be most concentrated in hydrologic regions where agriculture is a primary industry and where agricultural operations depend most heavily on SWP and CVP deliveries.

NEPA Effects: Changes in water deliveries associated with operation of Alternative 2D could result in beneficial socioeconomic effects in areas receiving water from the SWP and CVP. In hydrologic regions where water deliveries are predicted to increase when compared with the No Action Alternative, more stable agricultural activities could support employment and economic production associated with agriculture. Where M&I deliveries increase, population growth could lead to general economic growth and support water-intensive industries. Such changes could also lead to shifts in the character of communities in the hydrologic regions with resultant beneficial or adverse effects. Likewise, growth associated with deliveries could require additional expenditures for local governments while also supporting increases in revenue.

CEQA Conclusion: As described above, the operational components of the proposed water conveyance facilities could result in a number of socioeconomic effects in areas receiving SWP and CVP water deliveries outside of the Delta. However, because these impacts are social and economic in nature, rather than physical, they are not considered environmental impacts under CEQA. To the extent that changes in socioeconomic conditions in the hydrologic regions would lead to physical impacts, such impacts are described in Section 4.4.26, *Growth Inducement and Other Indirect Effects*, in this RDEIR/SDEIS.

4.4.13 Aesthetics and Visual Resources

Impact AES-1: Substantial Alteration in Existing Visual Quality or Character during Construction of Conveyance Facilities

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4 in Appendix A of this RDEIR/SDEIS, except that it would include two additional intakes compared to Alternative 4. The potential under Alternative 2D to create substantial alteration in visual quality or character during construction of conveyance facilities would be greater than those impacts described under Alternative 4 and would constitute an adverse effect on existing visual character because of the long-term nature of construction, combined with the proximity to sensitive receptors, effects on residences and agricultural buildings, removal of vegetation, and changes to topography through grading. The primary features that would affect the existing visual quality and character under Alternative 2D, once the facility has been constructed, would be Intakes 1, 2, 3, 4, and 5, the intermediate forebay and expanded Clifton Court Forebay, resulting landscape effects left behind from spoil/borrow and RTM areas, the operable barrier and transmission lines. These changes would be most evident in the northern portion of the study area, which would undergo extensive changes from the permanent establishment of large industrial facilities and the supporting infrastructure along and surrounding the segment of the Sacramento River from Clarksburg to north of Courtland where the intakes would be situated. Mitigation Measures AES-1a through AES-1g are available to address visual effects resulting from construction of Alternative 2D water conveyance facilities.

CEQA Conclusion: Construction of Alternative 2D would substantially alter the existing visual quality and character present in the study area in a similar manner as described for Alternative 4 in Appendix A of this RDEIR/SDEIS. The long-term nature of construction of the five intakes, operable barrier, pipeline/tunnel, work areas, spoil/borrow and RTM areas, shaft sites, barge unloading facilities, and operable barrier; presence and visibility of heavy construction equipment; proximity to sensitive receptors; relocation of residences and agricultural buildings; removal of riparian vegetation and other mature vegetation or landscape plantings; earthmoving and grading that result in changes to topography in areas that are predominantly flat; addition of large-scale industrial structures (intakes and related facilities); remaining presence of large-scale borrow/spoil and RTM area landscape effects; and introduction of tall, steel transmission lines would all contribute to this impact. This impact would be significant because of the substantial visual changes that would result from conveyance facility construction. Mitigation Measures AES-1a through AES-1g would partially reduce impacts, but not to a less-than-significant level because not all of the visual changes could be eliminated and permanent changes would be made to the regional landscape. Thus, Alternative 2D would result in significant and unavoidable impacts on the existing visual quality and character in the study area.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please see Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please see Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please see Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please see Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please see Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please see Mitigation Measure AES-1f under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please see Mitigation Measure AES-1g under Impact AES-1 in the discussion of Alternative 4.

Impact AES-2: Permanent Effects on a Scenic Vista from Presence of Conveyance Facilities

NEPA Effects: Effects related to scenic vistas under Alternative 2D would be similar to but greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. During construction, the introduction of construction equipment and removal of vegetation would alter the scenic elements that contribute to the viewing experience from scenic vistas. The five intakes would introduce visually dominant and discordant features in the foreground and middleground views in vistas that would be very noticeable to all viewer groups in areas of low to high landscape sensitivity levels. As described for Alternative 4, the effects of permanent access roads effects on scenic vistas would not be adverse. The effects of shaft site pads and access hatches on scenic vistas could be adverse. The large scale of intakes, the visual presence of large-scale borrow/spoil and RTM area landscape effects, and transmission lines may result in adverse effects on scenic vistas (see discussions under 17.3.1.2 and 17.3.1.3). Overall, effects on scenic vistas associated with Alternative 2D would be adverse because some elements of the conveyance facilities would permanently change views to scenic vistas. Mitigation Measures AES-1a, AES-1c, and AES-1e are available to address these effects.

CEQA Conclusion: Construction of conveyance facilities under Alternative 2D would have effects on scenic vistas similar to and greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. Because proposed permanent access roads generally follow existing ROWs, they would have less-than-significant impacts on scenic vistas. The presence of the intake structures and pumping plants, large-scale borrow/spoil and RTM area landscape effects, shaft site pads and access hatches, and transmission lines would result in significant impacts on scenic vistas because construction and operation would result in a reduction in the visual quality in some locations and introduce dominant visual elements that would result in noticeable changes in the visual character of scenic vistas in the study area. Mitigation Measure AES-1a, AES-1c, and AES-1e would partially reduce these impacts but not to a less-than-significant level. Thus, impacts on scenic vistas associated with Alternative 2D would be significant and unavoidable.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please refer to Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please refer to Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please refer to Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4.

Impact AES-3: Permanent Damage to Scenic Resources along a State Scenic Highway from Construction of Conveyance Facilities

NEPA Effects: Effects on state scenic highways under Alternative 2D would be similar to but greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. Intakes 1.2, 3, 4, and 5, the RTM area north of Intake 2, and the intermediate forebay would be immediately and prominently visible in the foreground from SR 160 and would result in an overall noticeable effect on viewers relative to their current experience of the study area's scenic resources along SR 160 and River Road, where the landscape sensitivity level is high. As described for Alternative 4, the visual elements introduced by the intakes, RTM area north of Intake 2, and intermediate forebay associated with Alternative 2D would conflict with the existing forms, patterns, colors, and textures along River Road and SR 160; would dominate riverfront available from SR 160; and would alter broad views and the general nature of the visual experience presently available from River Road and SR 160. These changes would reduce the visual quality near intake structure locations and result in noticeable changes in the visual character of scenic vista viewsheds in the study area. This effect would be adverse for the same reasons discussed for Alternative 4. Mitigation Measures AES-1a, AES-1c, and AES-1e are available to address these effects.

CEQA Conclusion: Construction of conveyance facilities under Alternative 2D would have effects on scenic highways similar to but greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. Because proposed permanent access roads generally follow existing ROWs, they would have less-than-significant impacts on scenic vistas. The presence of the intake structures and pumping plants, RTM area landscape effects, shaft site pads and access hatches, and transmission lines would result in significant impacts on scenic vistas because construction and operation would result in a reduction in the visual quality in some locations and introduce dominant visual elements that would result in noticeable changes in the visual character of scenic vista viewsheds in the study area. Mitigation Measures AES-1a, AES-1c, and AES-1e would partially reduce these impacts but not to a less-than-significant level for the same reasons identified for Alternative 4. Thus, impacts on scenic vistas associated with Alternative 2D would be significant and unavoidable.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please refer to Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please refer to Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please refer to Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4.

Impact AES-4: Creation of a New Source of Light or Glare That Would Adversely Affect Views in the Area as a Result of Construction and Operation of Conveyance Facilities

NEPA Effects: Effects resulting from light and glare under Alternative 2D would be similar to but greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. Intakes 1, 2, 3, 4, and 5 and their associated facilities would create noticeable effects relating to light and glare (Figures 17-85 through 17-86b). Overall, because the study area currently experiences low levels of light and because there are a larger number of viewers in and around the waterways, intake structures, and forebay that would be affected by these noticeable changes that contrast with the existing rural character, effects associated with new sources of daytime and nighttime light and glare are considered adverse. Mitigation Measures AES-4a through AES-4c are available to address these effects.

CEQA Conclusion: Construction of conveyance facilities under Alternative 2D would have effects, related to light and glare similar to but greater, than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. The impacts associated with light and glare under Alternative 2D are significant because there are a larger number of viewers in and around the waterways, intake structures, and intermediate forebay; project facilities would increase the amount of nighttime lighting in the Delta above existing ambient light levels; and the study area currently experiences low levels of light because there are fewer light/glare producers than are typical in urban areas. Mitigation Measures AES-4a through AES-4c would partially reduce these impacts but not to a less than significant level because all instances of light and glare impacts would not be reduced by the available mitigation measures. Thus, the new sources of daytime and nighttime light and glare associated with Alternative 2D would result in significant and unavoidable impacts on public views in the project vicinity.

Mitigation Measure AES-4a: Limit Construction to Daylight Hours Within 0.25 Mile of Residents

Please refer to Mitigation Measure AES-4a under Impact AES-4 in the discussion of Alternative 4.

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Please refer to Mitigation Measure AES-4b under Impact AES-4 in the discussion of Alternative 4.

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Please refer to Mitigation Measure AES-4c under Impact AES-4 in the discussion of Alternative 4.

Impact AES-5: Substantial Alteration in Existing Visual Quality or Character during Conveyance Facility Operation

NEPA Effects: Effects on the visual environment through operations and maintenance of the water conveyance facilities under Alternative 2D would be similar to and greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. The greatest visual effects resulting from operations would be maintenance of the intakes and dredging the forebays. However, all activities would maintain the visual character of the facilities, once built, and would not act to further change the visual quality or character of the facilities or surrounding visual landscape during operation. These effects on the existing visual quality and character during operation would not be adverse because the activities would not result in further substantial changes to the existing natural viewshed or terrain, alter existing visual quality of the region or eliminate visual resources, or obstruct or permanently reduce visually important features.

CEQA Conclusion: Operation of Alternative 2D would have visual quality effects similar to but greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. Maintenance of the conveyance facilities (i.e., intakes, tunnels, forebays and transmission lines) would be required periodically and would involve painting, cleaning, and repair of structures; dredging at forebays; vegetation removal and care along embankments; tunnel inspection; and vegetation removal within transmission line ROWs. These activities could be visible from the water or land by sensitive viewers in proximity to these features. All activities would maintain the visual character of the facilities, once built, and would not act to further change the visual quality or character of the facilities or surrounding visual landscape during operation. Maintenance and operation of Alternative 2D once constructed, would not result in further substantial changes to the existing natural viewshed or terrain, alter existing visual quality of the region or eliminate visual resources, or obstruct or permanently reduce visually important features. Thus, overall, operation and maintenance of Alternative 2D would have a less-than-significant impact on existing visual quality and character in the study area because operations would not change the visual quality of the environment and maintenance activities would be minor and intermittent. No mitigation is required.

Impact AES-6: Substantial Alteration in Existing Visual Quality or Character during Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 2D related to the potential for alteration of existing visual quality or character from implementing these environmental commitments would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, as described under Section 4.1, *Introduction*, in this RDEIR/SDEIS, Alternative 2D would restore up to 17,766 acres of habitat under Environmental Commitments 3, 4, 6-10 as compared with 83,800 acres under Alternative 4. Similarly, Environmental Commitments 15 and 16 would be implemented only at limited locations.

Conservation Measures 2, 5, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 2D would likely be smaller than those associated with Alternative 4.

NEPA Effects: Effects on the existing visual character, scenic vistas, scenic highways, and light and glare would be similar to those under Alternative 4 (in Appendix A of this RDEIR/SDEIS) because restored/enhanced lands would result in incremental and site-specific changes to the landscape in a similar manner. Because only portions of the restoration environmental commitments and fewer of the other stressor reduction environmental commitments would be implemented under Alternative 2D, it is likely that the visual and aesthetic effects would be less than those presented for Alternative 4. However, these visual and aesthetic impacts are considered to be adverse because site-specific, localized adverse visual effects could occur at the sites of projects implemented under the Alternative 2D environmental commitments. Mitigation Measures AES-1a through AES-1g and Mitigation Measures AES-4a through AES-4c are available to address effects from implementation of the Environmental Commitments.

CEQA Conclusion: Implementation of environmental commitments under Alternative 2D would have similar but less impacts than identified for Alternative 4 in Appendix A of this RDEIR/SDEIS. Alternative 2D has the potential to affect existing visual quality and character, views of scenic vistas, views from scenic highways, and introduce new sources of light and glare in the study area. These potential impacts are considered to be significant because construction of environmental commitments could potentially change views from public areas, negatively affect sensitive receptors and require multiple year construction at specific locations that are currently unknown.

Implementing mitigation measures AES 1a–1g would partially reduce the impacts of Alternative 2D on aesthetic and visual resources but not to a less-than-significant level because restoration and other actions implemented under this alternative could create considerable changes to the visual character of sensitive receptors that may not be fully mitigated by these mitigation measures. Thus, implementation of environmental commitments under Alternative 2D would result in significant and unavoidable impacts on the existing visual quality and character in the study area.

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Please refer to Mitigation Measure AES-1a under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Please refer to Mitigation Measure AES-1b under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Please refer to Mitigation Measure AES-1c under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Please refer to Mitigation Measure AES-1d under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Please refer to Mitigation Measure AES-1e under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Please refer to Mitigation Measure AES-1f under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Please refer to Mitigation Measure AES-1g under Impact AES-1 in the discussion of Alternative 4.

Mitigation Measure AES-4a: Limit Construction to Daylight Hours Within 0.25 Mile of Residents

Please refer to Mitigation Measure AES-4a under Impact AES-4 in the discussion of Alternative 4.

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Please refer to Mitigation Measure AES-4b under Impact AES-4 in the discussion of Alternative 4.

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Please refer to Mitigation Measure AES-4c under Impact AES-4 in the discussion of Alternative 4.

Mitigation Measure AES-6a: Underground New or Relocated Utility Lines Where Feasible

Please refer to Mitigation Measure AES-6a under Impact AES-6 in the discussion of Alternative 4.

Mitigation Measure AES-6b: Develop and Implement an Afterhours Low-Intensity and Lights Off Policy

Please refer to Mitigation Measure AES-6b under Impact AES-6 in the discussion of Alternative 4.

Mitigation Measure AES-6c: Implement a Comprehensive Visual Resources Management Plan for the Delta and Study Area

Please refer to Mitigation Measure AES-6c under Impact AES-6 in the discussion of Alternative 4.

Impact AES-7: Compatibility of the Proposed Water Conveyance Facilities and Other Environmental Commitments with Federal, State, or Local Plans, Policies, or Regulations Addressing Aesthetics and Visual Resources

NEPA Effects: Constructing water conveyance facilities and implementing other environmental commitments under Alternative 2D would generally have the same potential for incompatibilities with one or more plans and policies related to preserving the visual quality and character of the Delta as described for Alternative 4 in Appendix A of this RDEIR/SDEIS. As described for Alternative 4, potential incompatibility with plans and policies could exist related to preserving the visual quality and character of the Delta (i.e., The Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992, Delta Protection Commission Land Use and Resource Management Plan for the Primary Zone of the Delta, Delta Plan, Brannan Island and Franks Tract State Recreation Areas General Plan). In addition, with the exception of Solano County, the alternative may be incompatible with county general plan policies that protect visual resources in the study area.

CEQA Conclusion: The potential incompatibilities with plans and policies listed above indicate the potential for a physical consequence to the environment. The physical effects they suggest are discussed in impacts AES-1 through AES-6, above and no additional CEQA conclusion is required related to the compatibility of Alternative 2D with relevant plans and policies.

4.4.14 Cultural Resources

Impact CUL-1: Effects on Identified Archaeological Sites Resulting from Construction of Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4 with the addition of two river intakes. Constructing the water conveyance facilities under Alternative 2D would result in impacts on identified archaeological sites greater than those disclosed under Alternative 4 in Appendix A of this RDEIR/SDEIS. This encompasses the previously recorded archeological sites occurring in the footprint of the conveyance facility. Site descriptions summarizing available information regarding these resources, are provided in Appendix 18B, *Identified Cultural Resources Potentially Affected by BDCP Alternatives*, Section B.1.2 *Archaeological Site Descriptions*, of the Draft EIR/EIS.

The significance of the identified archeological sites is the same as described for Alternative 4. Because many of these resources are large (typically in excess of 30 meters across), they are each likely to contain sufficient integrity to yield artifacts in their original associations in a manner that will convey the significance themes outlined in the Alternative 4 discussion in Appendix A of this RDEIR/SDEIS. These resources are likely to qualify as historical resources under CEQA and historic properties under the NRHP.

The mechanisms that could impact the archeological sites under Alternative 2D would be similar to those described for Alternative 4. These resources occur within the footprint of both temporary work areas and permanent surface impacts and would be subject to the same types of disturbance described under Alternative 4. Construction of the water conveyance facilities has the potential to materially impair these resources under CEQA and to adversely affect the resources as defined by Section 106 of the NHPA.

NEPA Effects: Construction may disturb and damage NRHP and CRHR-eligible archaeological resources. This effect is considered adverse because the damage may impair the integrity of these resources and thus reduce their ability to convey their significance

CEQA Conclusion: Construction of conveyance facilities would affect identified archaeological resources that occur in the footprint of this alternative. DWR identified these resources and found that they are likely to qualify as historical resources under CEQA (see the individual site descriptions in Appendix 18B, *Identified Cultural Resources Potentially Affected by BDCP Alternatives*, Section B.1.2 *Archaeological Site Descriptions*, of the Draft EIR/EIS). This impact would be significant because construction could materially alter or destroy the physical integrity of the resources and/or their potential to yield information useful in archaeological research through excavation and disruption of the spatial associations that contain meaningful information. Identified but currently inaccessible resources may also be significant under other register criteria; indirect effects such as introduction of inconsistent changes to the setting may also diminish the significance of these resources. Mitigation Measure CUL-1 would reduce this impact, by recovering data at affected significant archeological sites and by monitoring and protecting resources during construction. However, this measure would not ensure preservation of the physical integrity of the resources or ensure that all of the scientifically important material would be retrieved because feasible archaeological excavation only typically retrieves a sample of the deposit, and portions of the site containing important information may remain after treatment. The impact on identified archaeological sites is considered significant and unavoidable because construction could damage the remaining portions of the deposit.

Mitigation Measure CUL-1: Prepare a Data Recovery Plan and Perform Data Recovery Excavations on the Affected Portion of the Deposits of Identified and Significant Archaeological Sites

Please see Mitigation Measure CUL-1 under Impact CUL-1 in the discussion of Alternative 4.

Impact CUL-2: Effects on Archaeological Sites to Be Identified through Future Inventory Efforts

The potential effects of constructing water conveyance facilities on archaeological sites identified through future inventories would be greater under Alternative 2D when compared to Alternative 4. These future impacts could occur because most of the area crossed by the proposed water conveyance facility is not currently legally accessible and as such has not been surveyed for the presence of archaeological sites. Alternative 2D would also require more geotechnical testing than Alternative 4 because of the larger footprint. This testing could damage or destroy archaeological sites. Although the majority of the footprint of the water conveyance facility has not been surveyed, sensitive resources have been located within and near the portions of the alignment that have been surveyed. For this reason, additional prehistoric archaeological resources are likely to be found in the portion of the footprint where surveys have not yet been conducted. For the reason enumerated under Alternative 4, these sites are likely to qualify as historical resources or unique archaeological resources under CEQA and historic properties under Section 106 of the NHPA.

The potential effects on historic sites under Alternative 2D would be greater than those disclosed for Alternative 4. In summary, historic sites are likely to be associated with the historic-era themes of settlement, reclamation, agriculture, and flood management in the Delta region and as such contributed to the economic base for developing urban centers. These historic sites are likely to qualify as historical resources or unique archaeological resources under CEQA and historic properties under Section 106 of the NHPA.

Absent mitigation, ground-disturbing construction is likely to physically damage many of these resources by disrupting the spatial associations that convey data useful in research or changing the setting such that the resource no longer contains its significance. These impacts would materially impair these resources within the meaning of CEQA and adversely affect the resources within the meaning of Section 106 of the NHPA. These effects would be adverse.

NEPA Effects: Alternative 2D has the potential to damage previously unidentified archaeological sites. Because these sites may qualify for the NRHP or CRHR, damage to these sites may diminish their integrity. For these reasons this effect would be adverse.

CEQA Conclusion: The footprint for Alternative 2D is sensitive for both prehistoric and historic-era resources that cannot be identified at this time because much of the footprint is not legally accessible. Because many of these resources are likely to have data useful in prehistoric and historic archaeological research, as well as the integrity to convey this significance, they are likely to qualify as historical resources or unique archaeological sites under CEQA or historic properties under the Section 106 of the NHPA. Ground-disturbing construction may materially alter the significance of these resources by disrupting the spatial associations that could yield important data, resulting in a significant effect. Mitigation Measure CUL-2 would address the impacts of both prehistoric and historic resources through conducting inventories, evaluating significance, and proposing treatment of archeological and historic resources as well as monitoring during the construction phase. However, this mitigation cannot guarantee that all eligible or significant resources would be preserved in place, or that all important data would be retrieved before construction destroys these resources. The scale of the project, investment into existing designs, and the presence of other important environmental resources such as habitat, natural communities, and wetlands that should be avoided are constraints on the flexibility and feasibility of avoidance. For these reasons this impact is significant and unavoidable.

Mitigation Measure CUL-2: Conduct Inventory, Evaluation, and Treatment of Archaeological Resources

Please see Mitigation Measure CUL-2 under Impact CUL-2 in the discussion of Alternative 4.

Impact CUL-3: Effects on Archaeological Sites That May Not Be Identified through Inventory Efforts

The potential effects of construction of the water conveyance facilities on archaeological sites that may not be identified during inventory efforts under Alternative 2D would be greater when compared to Alternative 4 because of the larger footprint. Although surveys will be completed for the water conveyance footprint, such surveys cannot guarantee that all sites will be identified prior to construction.

Ground-disturbing activities occurring under Alternative 2D, including the construction of surface features such as intakes, subterranean tunnel boring operations, and access may disturb and damage these resources before they can be identified and avoided during monitoring efforts required under Mitigation Measure CUL-3. This damage and disturbance may materially impair these resources within the meaning of CEQA or adversely affect the resources within the meaning of Section 106 because this disturbance would impair the ability of these resources to yield data useful in research. While Mitigation Measure CUL-3 would reduce the potential for this impact, it would not guarantee the impact would be avoided entirely. Therefore, this impact is adverse.

NEPA Effects: Constructing Alternative 2D has the potential to damage previously unidentified archaeological sites that also may not necessarily be identified prior to construction. While cultural resource inventories will be completed once legal access is secured, no inventory can ensure that all resources are identified prior to construction. Because these sites may qualify for the NRHP or CRHR, damage to these sites may diminish their integrity. For these reasons this effect would be adverse.

CEQA Conclusion: This impact on archeological resources not identified during inventory efforts would be considered significant for the same reasons described for Alternative 4. Construction has the potential to disturb previously unidentified archaeological sites qualifying as historical resources, historic properties, or unique archaeological resources. Mitigation Measures CUL-3 would reduce but not entirely avoid the potential for this impact, by implementing construction worker training, monitoring and discovery protocols. This impact would remain significant and unavoidable because all archaeological resources may not be identified prior to disturbance.

Mitigation Measure CUL-3: Implement an Archaeological Resources Discovery Plan, Perform Training of Construction Workers, and Conduct Construction Monitoring

Please see Mitigation Measure CUL-3 under Impact CUL-3 in the discussion of Alternative 4.

Impact CUL-4: Effects on Buried Human Remains Damaged during Construction

Effects on buried human remains during construction of Alternative 2D would be greater than Alternative 4 because the footprint of the water conveyance facilities would be larger. As describe in greater detail for Alternative 4, the footprint of the water conveyance facilities is sensitive for buried historic and prehistoric human remains While inventory and monitoring efforts are prescribed by Mitigation Measures CUL-2 and CUL-3, the large land area subject to disturbance under Alternative 2D make exhaustive sampling to identify all buried and isolated human remains technically and economically infeasible. For these reasons the potential remains that such resources may be damaged or exposed before they can be discovered through inventory or monitoring.

NEPA Effects: Buried human remains may be damaged by constructing Alternative 2D because such remains may occur either in isolation or as part of identified and previously unidentified archaeological resources where construction will occur. This effect would be adverse.

CEQA Conclusion: Damage to buried human remains during construction of Alternative 2D would be considered a significant impact for the same reasons described for Alternative 4 in Appendix A of this RDEIR/SDEIS. The project area is sensitive for buried human remains and construction of Alternative 2D would likely result in disturbance of these features. Disturbance of human remains, including remains interred outside of cemeteries is considered a significant impact in the CEQA Appendix G checklist. Mitigation measure CUL-4 would reduce the severity of this impact by following state and federal guidelines, including notifying the county coroner and NAHC, if human remains are discovered during construction. This impact is considered significant and unavoidable, because mitigation would not guarantee that these features could be discovered and treated in advance of construction and the scale of construction makes it technically and economically infeasible to perform the level of sampling necessary to identify all such resources prior to construction.

Mitigation Measure CUL-4: Follow State and Federal Law Governing Human Remains if Such Resources Are Discovered during Construction

Please see Mitigation Measure CUL-4 under Impact CUL-4 in the discussion of Alternative 4.

Impact CUL-5: Direct and Indirect Effects on Eligible and Potentially Eligible Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Effects of constructing the water conveyance facilities on built-environment resources under Alternative 2D would be greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. As described in greater detail in Appendix 18B, *Identified Cultural Resources Potentially Affected by BDCP Alternatives*, of the Draft EIR/EIS, a total of 17 built-environment resources have the potential to be directly or indirectly affected by constructing the water conveyance facilities. These effects would materially impair the resources within the meaning of CEQA and result in adverse effects within the meaning of Section 106 because they would diminish the characteristics that convey the significance of the resources.

NEPA Effects: Alternative 2D would result in direct and indirect effects on NRHP and CRHR eligible built environment resources. These alterations may diminish the integrity of these resources. For these reasons this effect would be adverse.

CEQA Conclusion: Alternative 2D could result in greater impacts on identified historic-era built-environment resources than described for Alternative 4 in Appendix A of this RDEIR/SDEIS. The impacts on -environment resource are considered significant because construction may require demolition or alter the character of the resource to such a degree that each resource may no longer be able to convey its significance. Mitigation measure CUL-5 would reduce the impact by implementing a built environment treatment plan that includes preparing an HSR, assessing preconstruction conditions, implementing protection measures, and preparing HABS records for CRHR and NRHP-eligible historic buildings and structures that will be demolished. The impact on historic-era built-environment resources would remain significant and unavoidable because even with mitigation, the scale of the project and the constraints imposed by other environmental resources make avoidance of all significant effects unlikely.

Mitigation Measure CUL-5: Consult with Relevant Parties, Prepare and Implement a Built Environment Treatment Plan

Please see Mitigation Measure CUL-5 under Impact CUL-5 in the discussion of Alternative 4.

Impact CUL-6: Direct and Indirect Effects on Unidentified and Unevaluated Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Effects of constructing the water conveyance facilities on unidentified and unevaluated historic architectural and built-environment resources under Alternative 2D would likely be greater than those described for Alternative 4 in Appendix A of this RDEIR/SDEIS because the footprint of the water conveyance facility would be greater. As described in detail for Alternative 4, although DWR does not have legal access to the majority of the footprint for the water conveyance, historical documentation suggests numerous additional resources occur in the footprint of the water conveyance facilities that have not been identified or which cannot currently be accessed and evaluated. Construction may result in direct demolition of these resources, damage through vibration, or indirect effects such as changes to the setting.

The resources may exhibit significance under both CEQA (State CEQA Guidelines Section 15064.5[a][3]) and the NRHP (30 CFR 60.4). In addition, because many of the historic-era structures in the Delta region are intact, and retain their rural agricultural setting, many of these resources are likely to have integrity within the meaning of CEQA and the NRHP (14 CCR Section 4852[c], 30 CFR 60.4). Because many unidentified resources are likely to have significance and integrity, they may qualify as historical resources under CEQA and historic properties under Section 106 of the NHPA.

NEPA Effects: Alternative 2D may result in direct modification or indirect changes to the setting for inaccessible and NRHP and CRHR-eligible resources. These changes may diminish the integrity of these resources. For these reasons, this effect would be adverse.

CEQA Conclusion: Alternative 2D may result in greater impacts on unidentified and unevaluated historic architectural and built-environment resources than described for Alternative 4. Construction may also result in permanent indirect effects such as changes to the setting. Direct demolition or changes to the setting would be material alterations because they would either remove the resource or alter the resource character, resulting in an inability of the resource to convey its significance. Many of these resources are likely to qualify as historic properties or historical resources under the NHPA and CEQA. Mitigation measure CUL-6 would reduce these impacts by requiring surveys be conducted on previously inaccessible properties to determine if constructing the water conveyance facilities would impact the properties and if so, requiring the development and implementation of treatment plans. The scale of the project and the constraints imposed by other environmental resources make avoidance of all significant effects unlikely. For these reasons this impact remains significant and unavoidable even with implementation of the following mitigation measures.

Mitigation Measure CUL-6: Conduct a Survey of Inaccessible Properties to Assess Eligibility, Determine if These Properties Will Be Adversely Impacted by the Project, and Develop Treatment to Resolve or Mitigate Adverse Impacts

Please see Mitigation Measure CUL-6 under Impact CUL-6 in the discussion of Alternative 4.

Impact CUL-7: Effects of Environmental Commitments on Cultural Resources

Implementing conservation and stressor reduction components at part of Alternative 2D would result in impacts on cultural resources similar to those described under Alternative 4. The extent of these impacts occurring under Alternative 2D would be much less than under Alternative 4 because the total acreage that would be affected by the habitat restoration and enhancement activities would be substantially less. The following Environmental Commitments could result in impacts on cultural resources because they involve ground-disturbing activities.

- *Environmental Commitment 3: Natural Communities Protection and Restoration*
- *Environmental Commitment 4: Tidal Natural Communities Restoration*
- *Environmental Commitment 6: Channel Margin Enhancement*
- *Environmental Commitment 7: Riparian Natural Community Restoration*
- *Environmental Commitment 8: Grassland Natural Community Restoration*
- *Environmental Commitment 9: Vernal Pool and Alkali Seasonal Wetland Complex Restoration*
- *Environmental Commitment 10: Nontidal Marsh Restoration*

These Environmental Commitments would result in effects on cultural resources when ground-disturbing work is performed to construct improvements and enhance or restore natural communities. Similar to Alternative 4, direct effects would occur through demolition or destruction of NRHP-, CRHR-, and/or local registry-eligible prehistoric and historic archaeological sites, unique archaeological sites, TCPs, human remains, and built-environment resources. In addition, indirect effects may occur where changes to the setting alter the existing setting in a manner that is inconsistent with the feeling and association of the resource. Because the ability of the resources to convey their significance would be lost, this effect would materially alter these resources under CEQA and would be adverse under NEPA. For example, reclaimed agricultural landscapes that are converted to habitat may no longer convey the themes of agriculture and settlement, and thus would be inconsistent with remaining features associated with rural historic landscapes created by reclamation, cultivation, and ranching.

Mitigation Measure CUL-7 below addresses the impact on cultural resources as a result of implementing the conservation and stressor reduction environmental commitments. Because of the large acreages of land included in all these commitments, it is unlikely that all effects on NRHP-, CRHR-, and /or local registry-eligible resources and unique archaeological sites could be avoided. Therefore, this impact would be adverse.

NEPA Effects: Implementation of environmental commitments will result in ground disturbing work and introduction of new infrastructure to the project area. These physical modifications may result in direct effects on NRHP and CRHR eligible resources and therefore reduce the integrity of these resources. For these reasons these effects would be adverse.

CEQA Conclusion: Implementing environmental commitments would require ground-disturbing activities that could alter the significant characteristics of NRHP, CRHR, and/or local registry-eligible cultural resources, including prehistoric and historic archaeological sites, TCPs, and built-environment resources such as historic architectural structures and rural historic landscapes. The same construction may damage unique archaeological sites. This construction would likely result in materially adverse changes for the following reasons.

- Ground-disturbing construction in archaeological sites disrupts the spatial associations that contain data useful in research, thus diminishing or destroying the basis for the significance of the resource.
- Ground-disturbing construction may either directly demolish or indirectly affect the setting of built-environment resources, resulting in an inability of the resource to convey its significance.
- Ground-disturbing construction may either directly demolish or change the setting of TCPs resulting in an inability of the resource to convey its significance.
- Ground-disturbing construction may inadvertently disturb human remains.

The alteration of a resource that changes the characteristics that convey its significance is a material alteration under CEQA. The inadvertent disturbance of human remains is a significant impact under CEQA under the Appendix G checklist. Because this construction would materially alter these categories of resources and disturb human remains it would result in a significant impact. Mitigation measure CUL-7 would reduce these impacts by identifying and evaluating resources, avoiding resources where possible, and developing treatment where avoidance is not possible. In addition construction would be monitored. However, because of the acreage that could be disturbed as a result of implementing the components, as well as the multiple constraints associated with other environmental resources that require mitigation or avoidance, it is unlikely that all cultural resources could be avoided. Therefore, this impact remains significant and unavoidable.

Mitigation Measure CUL-7: Conduct Cultural Resource Studies and Adopt Cultural Resource Mitigation Measures for Cultural Resource Impacts Associated with Implementation of Environmental Commitments 3, 4, 6, 7, 9–12, 15, and 16

Please see Mitigation Measure CUL-7 under Impact CUL-7 in the discussion of Alternative 4.

Impact CUL-8: Compatibility of the Proposed Water Conveyance Facilities and Environmental Commitments with Plans and Policies

Similar to Alternative 4 (as described in Appendix A of this RDEIR/SDEIS), constructing the proposed water conveyance facilities and implementing conservation and stressor reduction environmental commitments under Alternative 2D could result in the potential for incompatibilities with plans and policies adopted to protect the cultural resources of the Delta. A number of plans and policies that coincide with the study area provide guidance for protection of cultural resources as overviewed in Section 18.2.3, *Regional and Local Plans, Policies, and Regulations,* of the Draft EIR/EIS. The policies include the Alameda County East Area Plan, Contra Costa County General Plan, San Joaquin County General Plan, Sacramento County General Plan, Solano County General Plan, and the Yolo County General Plan. A detailed summary of the policies is provided in Alternative 4. Similar to Alternative 4, the construction of the water conveyance facilities and conservation and stressor reduction environmental commitments under Alternative 2D would be compatible with the cultural resource protection policies indicated in the Alameda County East Area Plan, San Joaquin County General Plan, Yolo County General Plan and potentially incompatible with the Contra Costa County General Plan, Sacramento County General Plan and Solano County General Plan. Similar to Alternative 4, restoration actions under Alternative 2D would be compatible with policies that emphasize mitigation and incompatible with policies that emphasize preservation.

It should be noted that, as described in *Land Use*, Section 13.2.3 of the Draft EIR/EIS, state and federal agencies are not subject to local land use regulations. Furthermore, policy incompatibility, by itself is not a physical impact on the environment.

NEPA Effects: Because federal agencies are not regulated by local land use policy, the project alternatives would not result in a conflict with local land use laws.

CEQA Conclusion: As with Alternative 4 in Appendix A of this RDEIR/SDEIS, constructing the proposed water conveyance facilities under Alternative 2D is governed by cultural resource management policies adopted by the various counties with jurisdiction in this region. For policies that emphasize preservation or mitigation Alternative 2D will be compatible with these policies because DWR and appropriate federal agencies will implement cultural resource management practices that will identify significant resources, preserve such resources where feasible, and complete mitigation to reduce significant effects where preservation is not feasible. For policies that emphasize preservation, the project is incompatible in some instances because multiple constraints governing the location of proposed facilities makes preservation of all significant cultural resources unlikely. It should be noted that, as described in *Land Use*, Section 13.2.3, of the Draft EIR/EIS, state and federal agencies are not subject to local land use regulations. Furthermore, policy incompatibility, by itself is not a physical impact on the environment.

4.4.15 Transportation

Impact TRANS-1: Increased Construction Vehicle Trips Resulting in Unacceptable LOS Conditions

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, traffic volumes generated by construction of non-intake features would be similar to Alternative 4, whereas traffic volumes generated by construction of the intakes would be similar to Alternative 1A. Increased traffic volumes generated during construction of Alternative 2D would therefore range between those generated under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-1 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 19-8 and 19-25 in Appendix A of this RDEIR/SDEIS, under baseline plus background growth (BPBG) conditions[1], Alternative 1A would exacerbate an already unacceptable LOS under BPBG conditions on **22** roadway segments and Alternative 4 would exacerbate conditions on **15** roadway segments. The estimated number of vehicles generated by Alternative 2D would be higher compared to Alternative 4 due to the increase in the number of intakes. Localized impacts identified under Alternative 1A in the vicinity of Intakes 1 and 5 would occur under Alternative 2D. The effect of increased traffic volumes in excess of LOS thresholds would be adverse.

Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of the necessary improvements. If an improvement that is identified in any mitigation agreement(s) contemplated by Mitigation Measure TRANS-1c is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of unacceptable LOS would occur. Therefore, this effect would be adverse. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion**:** Construction under Alternative 2D would add hourly traffic volumes to study area roadways that would exceed acceptable LOS thresholds. This would be a significant impact. Mitigation Measures TRANS-1a through TRANS-1c would reduce the severity of this impact, but not to less-than-significant levels. The project proponents cannot ensure that required roadway capacity improvements outlined under TRANS-1c will be fully funded or constructed prior to the project's contribution to the impact. If an improvement identified in the mitigation agreement(s) contemplated by Mitigation Measure TRANS-1c is not fully funded and constructed before the project's contribution to the impact is made, a significant impact in the form of unacceptable LOS would occur. Accordingly, this impact would be significant and unavoidable. If, however, all improvements required to avoid significant impacts prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, impacts would be less than significant.

[1] Background traffic growth was included for the traffic operations analysis based on the anticipated year of construction activity. The final result is a set of volumes representing baseline plus background growth (BPBG) and baseline plus background growth plus project (BPBGPP) traffic conditions.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-2: Increased Construction Vehicle Trips Exacerbating Unacceptable Pavement Conditions

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, traffic volumes generated by construction of non-intake features structures would be similar to Alternative 4, whereas traffic volumes generated by construction of the intakes would be similar to Alternative 1A. Increased traffic volumes generated during construction of Alternative 2D would therefore range between those generated under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-2 under Alternatives 1A and Alternative 4.

NEPA Effects: As shown in Tables 19-9 and 19-26 in Appendix A of this RDEIR/SDEIS, construction of Alternatives 1A and 4 would deteriorate existing pavement conditions to less than the acceptable pavement condition index (PCI) or similar applicable threshold on a total of **46** roadway segments. Damage to roadway pavement is also expected throughout the study area on various local and state roads, as well as on a few interstates. The effect of roadway damage in excess of PCI thresholds would be adverse.

Mitigation Measures TRANS-2a through TRANS-2c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents cannot ensure that the agreements or encroachment permits will be obtained from the relevant transportation agencies. If an agreement or encroachment permit is not obtained, an adverse effect in the form of deficient pavement conditions would occur. Accordingly, this effect could remain adverse. If, however, mitigation agreement(s) or encroachment permit(s) providing for the improvement or replacement of pavement are obtained and any other necessary agreements are completed, adverse effects could be avoided.

CEQA Conclusion**:** Construction under Alternative 2D would add traffic trips to study area roadways that would exacerbate unacceptable pavement conditions. This would be a significant impact. Mitigation Measures TRANS-2a through TRANS-2c would reduce the severity of this impact, but not necessarily to less-than-significant levels, as the project proponents cannot ensure that the agreements or encroachment permits will be obtained from the relevant transportation agencies. If an agreement or encroachment permit is not obtained, a significant impact in the form of deficient pavement conditions would occur. Accordingly, this impact could be significant and unavoidable. If, however, mitigation agreement(s) or encroachment permit(s) providing for the improvement or replacement of pavement are obtained and any other necessary agreements are completed, impacts would be reduced to less than significant.

Mitigation Measure TRANS-2a: Prohibit Construction Activity on Physically Deficient Roadway Segments

Please refer to Mitigation Measure TRANS-2a under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-2b: Limit Construction Activity on Physically Deficient Roadway Segments

Please refer to Mitigation Measure TRANS-2b under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-2c: Improve Physical Condition of Affected Roadway Segments as Stipulated in Mitigation Agreements or Encroachment Permits

Please refer to Mitigation Measure TRANS-2c under Impact TRANS-1 in the discussion of Alternative 4 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-3: Increase in Safety Hazards, Including Interference with Emergency Routes during Construction

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, traffic volumes generated by construction of non-intake features structures would be similar to Alternative 4, whereas traffic volumes generated by construction of the intakes would be similar to Alternative 1A. The potential for Alternative 2D to increase safety hazards during construction would therefore be similar to those impacts described under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-3 under Alternatives 1A and 4.

NEPA Effects: Increases in heavy construction traffic on local roadways could increase safety hazards, such as conflicts with recreational and commuter traffic and with farming operations. The increase in heavy construction traffic using emergency routes could also interfere with emergency service response times. Minor delays and congestion created by rerouted traffic during the temporary realignment of Byron Highway/South Pacific Railroad could create localized interferences with emergency service response times in the vicinity of Bryon Highway. The effect of increased safety hazards from increased heavy construction traffic on local roadways and emergency routes would be adverse.

Mitigation Measure TRANS-1c is available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of increased safety hazards would occur. Accordingly, this effect would be adverse. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion: Construction of Alternative 2D would increase the amount of trucks using the transportation system in the study area, which could increase the potential for safety hazards, including conflicts with farming operations, emergency services, and recreational and commuter traffic. Minor delays and congestion created by rerouted traffic during the temporary realignment of Byron Highway/South Pacific Railroad could also create localized interferences with emergency service response times in the vicinity of Bryon Highway. This would be a significant impact.

Mitigation Measure TRANS-1c will reduce the severity of this impact, but not to less-than-significant levels since the project proponents cannot ensure that the improvements will be fully funded or constructed prior to the project's contribution to the impact. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the impact is made, a significant impact in the form of increased safety hazards would occur. If, however, all improvements required to avoid significant impacts prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, impacts would be less than significant.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-4: Disruption of Marine Traffic during Construction

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, marine traffic generated by construction of non-intake features structures would be similar to Alternative 4, whereas marine traffic generated by construction of the intakes would be similar to Alternative 1A. The potential for Alternative 2D to disrupt marine traffic during construction would therefore be similar to those impacts described under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-4 under Alternatives 1A and 4.

NEPA Effects: Commercial barges would be used to transport tunnel segments from three concrete precast yards to temporary barge unloading facilities on Bouldin Island and at the Clifton Court Forebay. Tugboats would also be used during intake and forebay construction. The number of barge trips required to carry tunnel segments would be similar to Alternative 4 (approximately 5,500 trips). This potential effect is not considered adverse because construction of Alternative 2D would not require modification to existing deep water channels, interfere with Port of Stockton navigation, or substantially increase the volume of barge movement within the study area, such that existing marine traffic would be disrupted. Barge routes and landing sites will be selected to maximize continuous waterway access and a minimum waterway width greater than 100 feet. Moreover, Mitigation Measure TRANS-1a would also reduce any potential disruptions as it includes stipulations to notify the commercial and leisure boating community of proposed barge operations in the waterways.

CEQA Conclusion: Construction of Alternative 2D would not require modification to existing deep water channels, interfere with Port of Stockton navigation, or substantially increase the volume of barge movement within the study area such that existing marine traffic would be disrupted (on average, only eight additional barge trips per day are expected through the segment hauling period). Accordingly, this impact would be less than significant. While no mitigation is required, it is important to note that Mitigation Measure TRANS-1a (implemented to reduce effects from Impact TRANS-1) would reduce any potential disruptions as it includes stipulations to notify the commercial and leisure boating community of proposed barge operations in the waterways.

Impact TRANS-5: Disruption of Rail Traffic during Construction

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, traffic volumes generated by construction of non-intake features structures would be similar to Alternative 4, whereas traffic volumes generated by construction of the intakes would be similar to Alternative 1A. The potential for Alternative 2D to disrupt rail traffic during construction would therefore be similar to those impacts described under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-5 under Alternatives 1A and 4.

NEPA Effects: The water conveyance alignment crosses under the existing BNSF/Amtrak San Joaquin line between Bacon Island and Woodward Island and would therefore have no effect on freight service. Similarly, construction of the Clifton Court Forebay would not disrupt UPRR Tracy Subdivision service since the line is currently inactive. However, if the UPRR Tracy Subdivision branch line is reopened, construction activities may adversely affect new service. Mitigation Measure TRANS-1a, which includes stipulations to coordinate with rail providers to develop alternative transportation modes (e.g., trucks or buses) is available to address this effect.

***CEQA Conclusion*:** Construction of Alternative 2D would not physically cross or require modification to an active railroad. However, if the UPRR Tracy Subdivision branch line is reopened, construction activities at the Clifton Court Forebay may affect new service. This would be a significant impact. Mitigation Measure TRANS-1a, which includes stipulations to coordinate with rail providers to develop alternative transportation modes (e.g., trucks or buses) would reduce this impact to less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-6: Disruption of Transit Service during Construction

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, traffic volumes generated by construction of non-intake features structures would be similar to Alternative 4, whereas traffic volumes generated by construction of the intakes would be similar to Alternative 1A. The potential for Alternative 2D to disrupt transit service during construction would therefore be similar to those impacts described under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-6 under Alternatives 1A and 4.

NEPA Effects: Construction activities associated with Alternative 2D would decrease LOS below applicable thresholds, as well as exacerbate already unacceptable LOS conditions (refer to Impact TRANS-1). Increased congestion resulting from construction traffic would result in an adverse effect on transit routes and schedules, particularly along the SCT Link/Delta Route and Greyhound bus lines.

Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of disruptions to transit service would occur. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

***CEQA Conclusion*:** Construction activities associated with Alternative 2D would decrease LOS below applicable thresholds, as well as exacerbate already unacceptable LOS conditions. Increased congestion resulting from construction traffic would result in a significant impact on transit routes and schedules, particularly along the SCT Link/Delta Route and Greyhound bus lines. Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this impact, but not necessarily to a level that would not be less than significant, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the effect is made, a significant and unavoidable impact in the form of disruptions to transit service would occur. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the impact is made, impacts would be less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-7: Interference with Bicycle Routes during Construction

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, traffic volumes generated by construction of non-intake features structures would be similar to Alternative 4, whereas traffic volumes generated by construction of the intakes would be similar to Alternative 1A. The potential for Alternative 2D to interfere with bicycle routes during construction would therefore be similar to those impacts described under Alternative 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-7 under Alternatives 1A and 4.

NEPA Effects: Increased traffic and vehicle delays during construction could temporarily disrupt bicycle routes on SR 160/River Road and potentially on SR 12. The effect of disruption to bicycle routes during construction would be adverse. Mitigation Measure TRANS-1a, which requires alternative access routes via detours or bridges be provided to maintain continual circulation for bicyclists, is available to reduce this effect.

CEQA Conclusion**:** Increased traffic and vehicle delays during construction could temporarily disrupt bicycle routes on SR 160/River Road and potentially on SR 12, resulting in a significant impact. However, Mitigation Measure TRANS-1a would reduce the severity of this impact to less-than-significant levels because project proponents would provide alternate access routes via detours or bridges to maintain continual circulation for local travelers in and around construction zones, including bicycle riders.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-8: Increased Traffic Volumes and Delays during Operations and Maintenance

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Traffic volumes generated during operation of Alternative 2D would therefore be slightly higher than Alternative 4, as described below. See the discussion of Impact TRANS-8 under Alternative 4.

NEPA Effects: Based on the number of employees required for routine operations and yearly maintenance under Alternative 4 (40 and 35, respectively) and the estimated number of employees required to maintain two additional intakes (10), Alternative 2D would require 50 and 35 employees for routine operations and yearly maintenance, respectively. While the labor force would be slightly greater than under Alternative 4, given the limited number of workers involved and the large number of work sites, it is not anticipated that routine operations and maintenance activities or major inspections would result in substantial increases of traffic volumes or roadway congestion. The impact of increased traffic volumes and delays during project operations would not be adverse.

CEQA Conclusion**:** Given the limited number of workers involved and the large number of work sites, it is not anticipated that routine operations and maintenance activities or major inspections under Alternative 2D would result in substantial increases of traffic volumes or roadway congestion. The impact of increased traffic volumes and delays during operations would therefore be less than significant. No mitigation is required.

Impact TRANS-9: Permanent Alteration of Transportation Patterns during Operations and Maintenance

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Traffic volumes generated during operation of Alternative 2D would therefore be slightly higher than Alternative 4, as described above under Impact TRANS-8. See the discussion of Impact TRANS-9 under Alternative 4.

NEPA Effects: Impacts on public roadways would be limited to the intake areas and would not substantially alter traffic patterns. The design and construction of all project components (i.e., conveyances, intakes, and forebays) would provide for on-going continuity of all rail operations following completion of construction. Impediments to boat traffic associated with the intakes would continue for the life of the project, but would not substantially affect boat passage or usage. The effect of permanent alteration of transportation patterns during operations would therefore not be adverse.

CEQA Conclusion**:** Impacts on public roadways would be limited to the intake areas and would not substantially alter traffic patterns. The design and construction of all project components (i.e., conveyances, intakes, and forebays) would provide for on-going continuity of all rail operations following completion of construction. Impediments to boat traffic associated with the intakes would continue for the life of the project, but would not substantially affect boat passage or usage. Accordingly, the impact of permanent alteration of transportation patterns during operations would be less than significant. No mitigation is required.

Impact TRANS-10: Increased Traffic Volumes during Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Effects of Alternative 2D related to increased traffic volumes during implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be similar to, but less than, those described for Alternative 4. See the discussion of Impact TRANS-10 under Alternative 4 in Appendix A in this RDEIR/SDEIS.

NEPA Effects: Habitat restoration and enhancement activities that require personnel or heavy-duty equipment transport would generate traffic on area roadways. Roads and highways in and around Suisun Marsh could experience increases in traffic volumes, resulting in localized congestion and conflicts with local traffic. Maintenance and monitoring of the restoration areas would also generate some vehicle trips. This would be an adverse effect. The magnitude of the effect would vary according to the amount of traffic generated by implementation of the specific environmental commitment, the location and timing of the actions called for in the environmental commitment, and the roadway and traffic conditions at the time of implementation.

Alternative 2D would restore up to 17,766 acres of habitat under Environmental Commitments 3, 4, 6-10 as compared with 83,839 acres under Alternative 4. Therefore, the magnitude of traffic volumes and associated traffic impacts under Alternative 2D would be smaller than those associated with Alternative 4. Nevertheless, the effect of increased traffic volumes during construction and maintenance of Environmental Commitments 3, 4, 6-10 would be adverse.

Mitigation Measures TRANS-1a through TRANS-1c are available to reduce this effect, but not necessarily to a level that would not be adverse, as the project proponents are not solely responsible for the timing, nature, or complete funding of required improvements. If an improvement that is identified in any mitigation agreement(s) contemplated by Mitigation Measure TRANS-1c is not fully funded and constructed before the project's contribution to the effect is made, an adverse effect in the form of unacceptable LOS would occur. Therefore, this effect would be adverse. If, however, all improvements required to avoid adverse effects prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, effects would not be adverse.

CEQA Conclusion**:** Impacts on roadways could result in circulation delays or the inability to maintain adequate vehicular access in or around restoration or enhancement work zones. Roads and highways in and around Suisun Marsh could experience increases in traffic volumes, resulting in localized congestion and conflicts with local traffic. Maintenance and monitoring of the restoration areas would also generate some vehicle trips. The impact of increased traffic volumes during implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would be significant. Mitigation Measures TRANS-1a through TRANS-1c would reduce the severity of this impact, but not to less-than-significant levels. The project proponents cannot ensure that the improvements will be fully funded or constructed prior to the project's contribution to the impact. If an improvement identified in the mitigation agreement(s) is not fully funded and constructed before the project's contribution to the impact is made, a significant impact would occur. Therefore, the project's impacts on roadway segment LOS would be conservatively significant and unavoidable. If, however, all improvements required to avoid significant impacts prove to be feasible and any necessary agreements are completed before the project's contribution to the effect is made, impacts would be less than significant.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please refer to Mitigation Measure TRANS-1a in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1b: Limit Hours or Amount of Construction Activity on Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1b in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Mitigation Measure TRANS-1c: Make Good Faith Efforts to Enter into Mitigation Agreements to Enhance Capacity of Congested Roadway Segments

Please refer to Mitigation Measure TRANS-1c in Alternative 4, Impact TRANS-1 in Chapter 19, *Transportation*, of the Draft EIR/EIS.

Impact TRANS-11: Compatibility of the Proposed Water Conveyance Facilities and Environmental Commitments with Plans and Policies

Constructing the proposed water conveyance facilities and environmental commitments could result in the potential for incompatibilities with plans and policies related to transportation and circulation. These inconsistencies may result from increases in traffic volumes in excess of regional forecasts, modification of transportation infrastructure, or disruption in regional circulation patterns. Since traffic volumes generated during construction of Alternative 2D would range between those generated under Alternative 1A and those described for Alternative 4, Alternative 2D would generally have the same potential for incompatibilities with one or more transportation plans and policies as described for Alternatives 1A and 4 (which are similar) in Appendix A of this RDEIR/SDEIS. See the discussion of Impact TRANS-11 under Alternative 4.

NEPA Effects: As described for Alternative 4, the project would be constructed with regulations related to transportation and circulation enforced by local (including the local metropolitan planning organizations [MPOs]) and federal (including the FHWA [Federal Highway Administration] and FAA [Federal Aviation Administration]) agencies. The project would also be consistent with the Delta Protection Act of 1992 and Delta Plan. See the discussion of Impact TRANS-11 under Alternative 4 for additional information. Accordingly, there would be no adverse effect.

CEQA Conclusion: The potential incompatibilities with plans and policies listed above indicate the potential for a physical consequence to the environment. The physical effects they suggest are discussed in impacts TRANS-1 and TRANS-10, above and no additional CEQA conclusion is required related to the compatibility of Alternative 2D with relevant plans and policies.

Impact TRANS-12: Potential Effects on Navigation from Changes in Surface Water Elevations Caused by Construction of Water Conveyance Facilities

The potential impacts to navigation caused by changes in surface water elevation during construction of the proposed intakes under Alternative 2D would be similar to those described for Alternative 4A. Although Alternative 2D includes two additional intakes (Alternative 2D includes five intakes compared to three for Alternative 4A), the effects to surface water elevation caused by construction of the proposed intakes is highly localized, and therefore, the higher number of intakes would not result in a greater level of impacts to navigation.

Alternative 2D would include the construction of five fish-screened intakes on the west bank of the Sacramento River. Alternative 2D, however, could potentially entail two different intake and intake pumping plant locations. As an alternative to Intakes 1–5, intake locations 1, 2, 3, 6, and 7 are being considered. Unlike the other intakes, Intakes 6 and 7 would be downstream of Sutter and Steamboat Sloughs. Construction of the intakes would be accomplished using coffer dams at each location. Coffer dams will isolate each construction area from the Sacramento River and will be used to de-water the construction area. Intakes and screens have been designed and located on-bank to minimize changes to river flow characteristics. Nevertheless, some localized water elevation changes will occur upstream and adjacent to each coffer dam at these intake sites due to facility location within the river. These localized surface elevation changes will not exceed an increase of 0.10 feet at any intake location even at high river flows (when surface elevation changes would be expected to be highest). This represents the highest surface upstream elevation increase after coffer dam removal and during intake operation. Because this maximum increase in elevation is entirely localized, downstream surface elevation changes during intake construction would be insignificant and changes to river depth and width at any location will be insignificant. As a result, boat passage and river use, including Sacramento River tributaries, will not be affected.

As explained in Chapter 6, *Surface Water*, construction of facilities within or adjacent to waterways could change surface water elevations or runoff characteristics. Alternative 2D would have potential impacts associated with alterations to drainage patterns, stream courses, and runoff, and potential for increased surface water elevations in the rivers and streams from construction of facilities located within the waterway, as described under Alternative 1A. Construction of the facilities under Alternative 2D would not result in a substantial decrease in surface water elevations on any navigable waterways and therefore would not have an adverse effect on navigation. Although the increase in surface water elevations in rivers and streams under Alternative 2D creates a potential impact regarding flooding (which is considered less-than-significant with implementation of Mitigation Measure SW-4) the changes in surface water elevation would not have any adverse effects on navigation. See Chapter 6, *Surface Water*, for additional information regarding changes to surface water under Alternative 2D.

NEPA Effects: Water surface changes and potential impacts associated with intake construction are not considered adverse to navigation. Water depth and surface elevations will not be substantially effected during construction of the water conveyance facilities (either localized or downstream of the intake structures). Although some construction activities and in-water features (i.e., cofferdams) may cause minor changes in surface water elevations, these effects are highly localized and surface water elevations would not increase by more than .10 feet at any location, even during flood events. These changes would not result in a substantial decrease in surface water elevations on any navigable waterways. Therefore, surface water changes associated with construction of the water conveyance facilities would not cause an adverse impact to navigation.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in surface water elevation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in surface water elevation during construction of the intakes will not have a significant impact on navigation.

Impact TRANS-13: Potential Effects of Navigation from Changes in Surface Elevations Caused by Operation of Intakes

The potential impacts to navigation caused by changes in surface water elevation during operation of the proposed intakes under Alternative 2D would be identical to those described for Alternative 4A, despite the fact that Alternative 2D includes five intakes (two more than Alternative 4A) and despite the fact that Alternative 2D has a 15,000 cfs total conveyance capacity (compared to 9,000 cfs for Alternative 4A). This is because the hydraulic modeling scenario and analysis included five intakes because that is the maximum number of intakes included under any alternative. The modeling also assumed the highest North Delta diversion capacity allowed under any alternative (15,000 cfs).

With respect to Alternative 2D, operation of Intakes 1, 2, 3, 4, and 5, or Intakes 1, 2, 3, 6, and 7 may have localized effects on water surface elevation during certain operational regimes and at various river flows. While intake operations and pumping levels are dictated by many factors, Sacramento River diversions are limited during low flows by operational rules. The nature and extent of impacts caused by diversions at an intake are dependent in large part on the location of the intake on the river. To minimize the intake effects on river surface elevations, intakes were designed as on-bank structures and were placed so that river flood and flow characteristic will be minimally altered. Based on hydrologic modelling, even at the lowest river flows (taking into account both seasonal and tidal variations) and at maximum intake operation (full diversions at each of five alternative intakes), estimates are that boat draft depths of at least 16.5 feet will be maintained within the Sacramento River. (*Planning and Design of Navigation Locks* United States Army Corps of Engineers, EM 1110-2-2602 (September 30, 1995) pages 3-8.) This river depth has occurred historically and has been adequate to support navigation along the Sacramento River. Additionally, under these same intake divisions/river flows, water surface elevations would be lowered by no more than 0.7 feet, which represents a localized and maximum estimate. Surface elevations downstream of the intakes would be affected less, and during higher river flow and lower intake diversions, river depths would be greater than the minimum estimate.

The minimal changes in surface water elevation anticipated under Alternative 2D, even assuming a maximum lowering of 0.7 feet, would not likely expose any currently unexposed natural or man-made features that would affect or impede navigation and there would be no new snags or obstructions that would impede navigation.

Moreover, even when operating at maximum capacity, the intakes would not alter flows in a way that would affect commercial vessels or recreational watercraft. The intakes are designed to ensure pumping velocities will have minimal impacts to aquatic species. It is unlikely that changes in flow velocity would be perceptible to operators of marine vessels or recreational watercraft and would have no effect on navigation.

Additional information regarding changes to surface water elevations can be found in Chapter 6, *Surface Water*.

NEPA Effects: Water surface changes and potential impacts associated with intake operation are not considered adverse. Water depth and surface elevations will not be significantly effected (either localized or downstream of the intake structures) and will therefore not have an adverse effect on navigation.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in surface water elevation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in surface water elevation during operation of the intakes will not have a significant impact on navigation.

Impact TRANS-14: Potential Effects on Navigation Caused by Sedimentation from Construction of Intakes

The potential impacts to navigation caused by sedimentation under Alternative 2D would be similar to those described for Alternative 4A. Although Alternative 2D includes two additional intakes (Alternative 2D includes five intakes compared to three for Alternative 4A), the effects to sedimentation caused by construction of the proposed intakes is highly localized, and therefore, the higher number of intakes would not result in a greater level of impacts to navigation.

Construction for Intakes 1, 2, 3, 4, and 5 or Intakes 1, 2, 3, 6, and 7 would be accomplished using coffer dams at each intake location. Coffer dams will isolate each construction area from the Sacramento River and will be used to de-water the construction area. Construction of coffer dams would require sheet pile driving that would result in incremental suspension of bed sediments. These effects would be temporary and would not have an effect on navigation. Sheet piles at the edge of the levee embankment would likely change eddy currents locally, but rock slope in the transition zone would limit those currents and potential changes to bed load dynamics. As a result, erosion and sedimentation into the Sacramento River during intake construction would be minimal

Moreover, potential sedimentation effects will be further minimized by limiting the duration of in-water construction activities and through implementing the environmental commitments described in Appendix 3B, *Environmental Commitments,* including the commitment to *Develop and Implement Erosion and Sediment Control Plans* to control short-term and long-term erosion and sedimentation effects and to restore soils and vegetation in areas affected by construction activities following construction. This commitment is related to Avoidance and Minimization Measure (AMM) 4, *Erosion and Sediment Control Plan*, described in BDCP Appendix 3.C. It is anticipated that multiple erosion and sediment control plans will be prepared for construction activities, each taking into account site-specific conditions such as proximity to surface water, erosion potential, drainage, etc. The plans will include all the necessary state requirements regarding erosion control and will implement BMPs for erosion and sediment control that will be in place for the duration of construction activities.

Implementation of Mitigation Measure SW-4 (Implement Measures to Reduce Runoff and Sedimentation) will further ensure that impacts from sedimentation are minimal.

NEPA Effects: Construction of coffer dams and intake construction would not have an adverse effect on navigation through increased sedimentation and erosion/deposition in the navigable channel.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in sedimentation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in sedimentation during construction of the intakes will not have a significant impact on navigation.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please refer to Mitigation Measure SW-4 in Alternative 1A, Impact SW-4.

Impact TRANS-15: Potential Effects on Navigation Caused by Sedimentation from Construction of Barge Facilities

The potential impacts to navigation caused by sedimentation under Alternative 2D would be similar to those described for Alternative 4A. Although Alternative 2D includes a greater number of barge fleeting facilities, the effects to sedimentation caused by construction of the facilities is highly localized, and therefore, the greater number of barge facilities would not result in a greater level of impacts to navigation.

Alternative 2D includes six barge unloading facilities to be built on or near the tunnel alignment similar to those described for Alternative 2A. The facilities would be used to transfer pipeline construction equipment and materials to and from construction sites and would be removed after construction was completed. The facilities would likely include in-water and over-water structures, such as piling dolphins, docks, ramps, and possibly conveyors for loading and unloading materials; and vehicles and other machinery. Construction of the facilities would involve piles at each location.

To address potential erosion and sedimentation impacts from barge facility construction associated with Alternative 2D, the project proponents will ensure that a Barge Operations Plan is developed and implemented for facility construction. The requirements for the Barge Operations Plan are described in Draft EIR/EIS Appendix 3B, *Environmental Commitments*. This commitment is related to AMM7, *Barge Operations Plan*, described in BDCP Appendix 3.C. This plan will be developed and submitted by the construction contractors per standard DWR contract specifications. Erosion control measures during construction activities at project locations are provided in Appendix 3B, *Environmental Commitments*, as noted above in the discussion of the intakes. Fleeting facilities will be either docking facilities built through pile and wharves or loaded and unloaded using landward positioned cranes. In either case, through AMM7 and the Environmental Commitments, impacts to sedimentation through construction related activities will be localized and minimal.

Implementation of Mitigation Measure SW-4 (Implement Measures to Reduce Runoff and Sedimentation) will further ensure that impacts from sedimentation are minimal.

***NEPA Effects*:** Construction and operation of the barge facilities under Alternative 2D would not have an adverse effect on navigation.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in sedimentation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in sedimentation from the temporary barge facilities will not have a significant impact on navigation.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please refer to Mitigation Measure SW-4 in Alternative 1A, Impact SW-4.

Impact TRANS-16: Potential Effects on Navigation Caused by Sedimentation from Construction of Clifton Court Forebay

The potential impacts to navigation from sedimentation at Clifton Court Forebay under Alternative 2D would be identical to those described for Alternative 4A. Clifton Court Forebay would be dredged and redesigned to provide an area where water flowing from the new north Delta facilities will be isolated from water diverted from south Delta channels. While Clifton Court Forebay is a "navigable water," use of the forebay is limited to maintenance operations and is not open to commercial or recreational navigation.

NEPA Effects: No effect.

CEQA Conclusion: No impact.

Impact TRANS-17: Potential Effects on Navigation Caused by Sedimentation from Operation of Intakes

The potential impacts to navigation caused by sedimentation under Alternative 2D would be similar to those described for Alternative 4A. Although Alternative 2D includes two additional intakes (Alternative 2D includes five intakes compared to three for Alternative 4A), the effects to sedimentation during operation of the proposed intakes under Alternative 2D would be similar to those described for alternative 4A for the reasons described below.

Sediment loads are present in the Sacramento River as bed loads or distributed within the water column. The Sacramento River is sediment "starved" for most of the year since upstream reservoirs act as settling basins for suspended sediments. In most cases, sediment load is concentrated on the river bed and this bed load depends on several factors including particle size, particle density and flow velocity. To exclude bed loads from entering intake structures during operation, design criteria for the intakes require that the lowest point of the screen is placed above the river bed in such a way that there is no change in bed sediment erosion/distribution patterns. Additionally, screen locations for this alternative are placed on the outer bends of the river to minimize scour, erosion and sediment loading at those locations. Flow control baffles at intakes would be adjusted to control sedimentation near the screens as needed and air jets at screens are proposed to re-suspend sediments as needed.

Implementation of Mitigation Measure SW-4 (Implement Measures to Reduce Runoff and Sedimentation) will further ensure that impacts from sedimentation are minimal.

NEPA Effects: Operational criteria and design specifications for intake operations will result in no change to water column or bed load sediment dynamics. Erosion and deposition patterns will change little if any during intake operation. As a result, there will be no adverse effect on navigation either near or downstream of the intake locations.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation caused by changes in sedimentation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, changes in sedimentation during operation of the proposed intakes will not have a significant impact on navigation.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please refer to Mitigation Measure SW-4 in Alternative 1A, Impact SW-4.

Impact TRANS-18: Potential Effects on Navigation from Construction and Operations of Head of Old River Barrier

Under Alternative 2D, an operable barrier would be placed at the head of Old River at the confluence with the San Joaquin River. The potential navigation impacts from construction and operations of Head of Old River barrier would be identical to those described for Alternative 4A.

Alternative 2D proposes work at the Head of Old River including the construction of fish and flow control gates as well as a small boat lock to allow recreational boat passage. An analysis of potential impacts of this work on navigation was completed in 2005 by Jones and Stokes (South Delta Improvements Program Vol I: Environmental Impact Statement/Environmental Impact Report. Draft. October. (J&S 020533.02.) State Clearinghouse #2002092065. Sacramento, CA.) ("SDIP EIS/EIR"). The SDIP EIS/R analyzed whether the proposed barrier/gates facility and locks would cause a change in south Delta flows or water level, river flows or surface water elevations that would result in substantial changes to existing recreational or commercial boating activity and opportunities.

The changes in access to Delta waterways by boats and other vessels during construction and operation of the gates, during channel dredging activities, and attributable to changes in water levels/depths were addressed. Most of the waterways in the immediate project vicinity are public waterways navigable by recreational craft, including rowboats, large houseboats, and cabin cruisers. These waterways are also navigable by smaller commercial vessels, including towing and salvage vessels, clamshell dredges, dredges for repair and maintenance of levees and channels, and pile-driving vessels. Boat access points in the project area include River's End Marina, located on the south side of the DMC, at the confluence with Old River; Tracy Oasis Marina Resort, located on the east side of Tracy Boulevard and the north side of Old River; and possibly at Heinbockle Harbor, located at Tracy Boulevard, on the south side of Grant Line/Fabian and Bell Canal.

According to a California Department of Parks and Recreation (DPR) survey, minimal boat launching and use occurs in the project area. The channels within the project area are too small to accommodate large commercial vessels, and because the channels are also part of an existing temporary barriers project, larger vessels cannot use these channels when the barriers are in place. A boat lock at the proposed facility would ensure boat access upstream of the gate regardless of gate operations. In this regard, upstream boat access could improve over current conditions. Additionally, from June 16 through September 30, the gates will be open and no boat lock operations will be necessary.

With respect to both recreational and commercial navigation, and based on analysis provided in the SDIP EIS/EIR, boat access impacts during facility construction will be less than significant (p. 5.8-14, 5.8-18, 5.8-21), impacts to navigation caused by water level changes during barrier operation will be less than significant (p. 5.8-15. 5.8-19, 5.8-22), impact to non-recreational boaters due to temporary dredging operation will be less than significant (p. 5.8-16, 5.8-19, 5.8-22), and impacts on recreation as a result of constructing and operating any of the alternatives will not be significant (p. 7.4-1).

Construction of the operable barrier could result in increased sedimentation near the gates. Maintenance dredging around the gate would be necessary to clear out sediment deposits. Dredging around the gates would be conducted using a sealed clamshell dredge. Depending on the rate of sedimentation, maintenance would occur every 3 to 5 years. A formal dredging plan with further details on specific maintenance dredging activities will be developed prior to dredging activities. Guidelines related to dredging activities, including compliance with in-water work windows and turbidity standards are described further in Appendix 3B, *Environmental Commitments*, under *Disposal and Reuse of Spoils, Reusable Tunnel Material (RTM), and Dredged Material*. These activities would ensure that sedimentation would not result in an adverse impact to navigation.

NEPA Effects: With respect to construction and operations of the Head of Old River barrier, Alternative 2D would have no adverse effect on either commercial or recreational navigation activities.

CEQA Conclusion: Because it does not involve a physical change in the environment, effects to navigation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, construction and operations of the Head of Old River barrier will not have a significant impact on navigation.

Impact TRANS-19: Potential Cumulative Effects on Navigation from Construction and Operations of Water Conveyance Facilities

As explained above and with respect to the construction and operation of these facilities, Alternative 2D would not result in an adverse effects to navigation due to water level elevation changes or altered sedimentation patterns. It is highly unlikely that other projects would combine with these impacts of the project to result in cumulative effects on navigation. This is because the minimal effects of these elements of the project on navigation are localized and would combine only with probable future projects if the projects were located immediately adjacent to the project components. There are no other reasonably foreseeable projects proposed to be located near or adjacent to the planned Alternative 2D facilities.

NEPA Effects: Alternative 2D in combination with other reasonably foreseeable projects would not have a cumulatively adverse effect on navigation.

CEQA Conclusion**:** Because it does not involve a physical change in the environment, effects to navigation, by themselves, are not considered environmental impacts under CEQA. Any secondary physical environmental impacts that may result are covered under other impacts. Nonetheless, as explained above, Alternative 2D in combination with other reasonably foreseeable projects would not have a cumulatively significant impact on navigation.

4.4.16 Public Services and Utilities

Impact UT-1: Increased Demand on Law Enforcement, Fire Protection, and Emergency Response Services from New Workers in the Project Area as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to the provision of law enforcement, fire protection, and emergency response services as a result of construction of the proposed water conveyance facilities would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS, but slightly greater due to the need for additional workers to build the two additional intakes. Increased service demands would be experienced in the communities in which new construction workers relocate and in the areas in which construction would take place. However, it is anticipated that many construction jobs would be filled from the existing labor force in the five-county project area region. Effects on services from the presence of new workers in the project area would be anticipated to be marginally greater for this alternative because they would extend to an additional location with the potential construction of an operable barrier at the Head of Old River. The minor increase in construction workers relocating into the project area for specialized jobs (e.g., tunnel construction) during the construction period of approximately 13.5 years would be spread across a large multi-county area. Increases in demand for law enforcement, fire protection and medical services related to this small change in population in any one county are expected to be negligible.

Similarly, the scale and duration of construction required for Alternative 2D could result in increased demand on law enforcement services, especially near major construction sites. Incorporation of an environmental commitment that would provide 24-hour onsite private security at construction sites (Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS) would ensure there would be no adverse effect on local law enforcement agencies associated with construction property protection. Incorporation of environmental commitments that would minimize construction-related accidents associated with hazardous materials spills, contamination, and fires would reduce adverse effects related to the potential demand for law enforcement, fire protection, or emergency services (Appendix 3B, *Environmental Commitments* in Appendix A of the RDEIR/SDEIS).

Construction of Alternative 2D would not increase the demand on law enforcement, fire protection, and emergency response services from new workers in the project area such that it would result in the need for, new or physically altered governmental facilities. Impacts to emergency response times from construction traffic using emergency routes are discussed in Chapter 19 Impact TRANS-3. Accordingly, there would be no adverse effect.

CEQA Conclusion: The potential for impacts on law enforcement and fire services and facilities is not expected to be significant because the estimated increase in population in the project area associated with construction of the alternative during peak construction would be distributed over multiple cities and counties within the project area. In addition, environmental commitments would be incorporated into the alternative to reduce effects related to demand for law enforcement, fire protection, and emergency response services at or near construction sites from new construction workers in the project area, and effects on local law enforcement agencies associated with construction property protection. Construction of Alternative 2D would not require new or physically altered governmental facilities to support the needs of new workers in the project area. These impacts would be considered less than significant. No mitigation is required.

Impact UT-2: Displacement of Public Service Facilities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Under Alternative 2D, a proposed 28-foot interior diameter single-bore tunnel would be constructed more than 100 feet below the surface of Hood. It would connect north of Hood to pipelines running from Intakes 2 and 3, and south of Hood to the intermediate forebay. There are no public facilities in the proposed tunnel location. Construction of the tunnel is not anticipated to disturb the surface and would not conflict with any public facilities, nor would it require the construction or major alteration of such facilities. This effect would not be adverse.

CEQA Conclusion: Construction of the proposed water conveyance facilities under Alternative 2D would not require the construction or major alteration of public service facilities. Therefore, this impact would be less than significant. No mitigation is required.

Impact UT-3: Effects on Public Schools as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: As discussed under Alternative 4 in Appendix A of this RDEIR/SDEIS, because most of the project construction jobs would be filled by workers from within the existing five-county labor force, it is anticipated that school-aged children from those families would already have planned to attend schools in school districts within the project area and there would be no increased demand for public school services from these workers (see Table 20A-4, Appendix 20A). As shown in Table 20A-4, a small number of schools have current enrollments which are already in excess of the available capacity. Although some workers who relocate from outside of the project area could have school-age children, resulting in an increase in public school enrollment, this minor increase in population in the project area for a limited time, and the likelihood that they would be distributed among multiple schools and districts, would not be expected to result in an increase in enrollment numbers substantial enough to exceed the capacity of any individual district, or to warrant construction of a new facility within the project area. There would not be an adverse effect.

CEQA Conclusion: The majority of construction jobs are expected to be filled by workers from the five-county labor force. The incremental increase in school-age children of construction personnel moving into the area for specialized construction jobs (e.g., tunnel construction) would likely be distributed through a number of schools within the project area. This increase in school enrollment would not be substantial enough to exceed the capacity of any individual district, or to warrant construction of a new facility within the project area. The impact on public schools is less than significant. No mitigation is required.[2]

Impact UT-4: Effects on Water or Wastewater Treatment Services and Facilities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Effects related to the need for expanded water or wastewater treatment facilities would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. For purposes of this analysis, the amount of water supply required under this alternative would be greater than the amount required under Alternative 4 due to two additional intakes. Considered

[2] Under California law, the rules governing what constitutes adequate mitigation for impacts on school facilities is governed by legislation. Pursuant to the operative statutes, impacts on schools, with some exceptions, are sufficiently mitigated, as a matter of law, by the payment of school impact fees by residential developers. (See Cal. Gov. Code, §§ 65995[h], 65996[a].)

across the alternative, potable water supply needs are substantial in volume; however, these requirements would need to be met over a construction period of approximately 13.5 years, and would be anticipated to be met with non-municipal water sources without any need for new water supply entitlements. If there are no existing water lines in the vicinity, then field offices will require construction of a water tank. Water for construction will be provided by available sources to the extent possible; if needed, water may be brought to the construction sites in water trucks. Also similar to Alternative 4, wastewater created as a result of tunnel boring and concrete batching would be provided by temporary facilities and treated onsite. Construction of Alternative 2D would not require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities. As discussed under Alternative 4, as part of the Environmental Commitments (Appendix 3B) for each alternative, DWR will be required to conduct project construction activities in compliance with the State Water Board's *NPDES Stormwater General Permit for Stormwater Discharges Associated with Construction and Land Disturbance Activities* (Order No. 2009-0009-DWQ/NPDES Permit No. CAS000002). This General Construction NPDES Permit requires the development and implementation of a SWPPP that outlines the temporary construction-related BMPs to prevent and minimize erosion, sedimentation, and discharge of other construction-related contaminants, as well as permanent post-construction BMPs to minimize adverse long-term stormwater related–runoff water quality effects. This effect would not be adverse.

CEQA Conclusion: While construction of this alternative would require a substantial supply of water, this supply could be met by non-municipal sources such as non-municipal water wells or water trucks. Additional needs for wastewater treatment and potable water could also be served by non-municipal entities. Construction of Alternative 2D would not require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities. This impact would be less than significant. Mitigation is not required.

Impact UT-5: Effects on Landfills as a Result of Solid Waste Disposal Needs during Construction of the Proposed Water Conveyance Facilities

NEPA Effects: Potential effects associated with an increased demand for solid waste management providers in the project area and surrounding communities as a result of waste generated from construction of the proposed water conveyance facilities would be similar to those described under Alternative 4 in Appendix A of this RDEIR/SDEIS. Minor additional needs for landfill services may be generated by the construction of an operable barrier as well as two additional intakes. However, the construction waste that could be generated by implementing Alternative 2D would not result in an adverse effect on the capacity of available landfills because 50% or more of construction waste generated by this alternative would be diverted (in accordance with diversion requirements set forth by the State Agency Model Integrated Waste Management Act (IWMA) and BMP 13 [Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS]), and the construction debris and excavated material that would require disposal at a landfill could be accommodated by, and would have a negligible effect, on the remaining permitted capacity of project area landfills. This alternative is not expected to affect the lifespan of area landfills, because over 70% of the remaining permitted capacity is associated with landfills with expected lifespans of between 18 and 70 years—well beyond the expected timeframe for construction of project facilities, when solid waste disposal services would be needed. This effect would not be adverse.

CEQA Conclusion: Based on the capacity of the landfills in the region, and the waste diversion requirements set forth by the State of California, it would be expected that construction of the proposed water conveyance facilities would not cause any exceedance of landfill capacity. RTM resulting from construction of tunnel segments would be treated in designated RTM work areas. Debris from structure demolition, power poles, utility lines, piping, and other materials would be diverted from landfills to the maximum extent feasible at the time of demolition. This alternative is not expected to affect the lifespan of area landfills, because over 70% of the remaining permitted capacity is associated with landfills with expected lifespans of between 18 and 70 years—well beyond the expected timeframe for construction of project facilities, when solid waste disposal services would be needed. Further, implementation of BMP 13 (Appendix 3B, *Environmental Commitments*, in Appendix A of the RDEIR/SDEIS) would require development of a project-specific construction debris recycling and diversion program to achieve a documented 50% diversion of construction waste. Construction of Alternative 2D would not create solid waste in excess of the permitted capacity of area landfills, nor would it adversely affect the expected lifespan of these solid waste facilities. Therefore, there would be a less-than-significant impact on solid waste management facilities.

Impact UT-6: Effects on Regional or Local Utilities as a Result of Constructing the Proposed Water Conveyance Facilities

NEPA Effects: Disruption of utility services or relocation of existing facilities would be similar to that described under Alternative 4 in Appendix A of this RDEIR/SDEIS. While the two additional intakes associated with Alternative 2D may interfere with additional utilities, the rest of the alignment past the intakes would have the same amount of interferences as Alternative 4: 12 overhead power/electrical transmission lines (Figure 24-6 in the Draft EIR/EIS), 6 natural gas pipelines (Table 20-5 and Figure 24-3 in the Draft EIR/EIS), 11 inactive oil or gas wells (Figure 24-5 in the Draft EIR/EIS), the Mokelumne Aqueduct, and 43 miles of agricultural delivery canals and drainage ditches, including approximately 13 miles on Byron Tract, and 7 miles on Bouldin Island. Additionally, active gas wells may need to be plugged and abandoned. Relocation of additional facilities near proposed forebays, RTM, and borrow or spoils areas could also be necessary. The potential damage and disruption to buried and overhead electric transmission lines would be similar for telecommunication infrastructure. Because relocation and disruption of existing utility infrastructure would be required under this alternative and would have the potential to create environmental effects, this effect would be adverse.

Mitigation Measures UT-6a, UT-6b, and UT-6c are available to reduce the severity of this effect. If coordination with all appropriate utility providers and local agencies to integrate with other construction projects and minimize disturbance to communities were successful under Mitigation Measure UT-6b, the effect would not be adverse.

CEQA Conclusion: Under this alternative, most features would avoid disrupting existing facilities by crossing over or under infrastructure. However, construction of facilities would conflict with existing utility facilities in some locations. Regional power transmission lines and one natural gas pipeline would require relocation. Because the relocation and potential disruption of utility infrastructure would be required, this impact would be significant.

Mitigation Measures UT-6a, UT-6b, and UT-6c are available to reduce these impacts through measures that could avoid disruption of utility infrastructure. If coordination with all appropriate utility providers and local agencies to integrate with other construction projects and minimize disturbance to communities were successful under Mitigation Measure UT-6b, the impact would be less-than-significant. However, because coordination with a third party is required in order to carry out this mitigation, a conservative assessment of significant and unavoidable is being made.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6b: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Operational Reliability

Please see Mitigation Measure UT-6b under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Impact UT-7: Effects on Public Services and Utilities as a Result of Operation and Maintenance of the Proposed Water Conveyance Facilities

NEPA Effects: The proposed water conveyance facilities under this alternative would be operated to provide diversions up to a total of 15,000 cfs from five new north Delta intakes, rather than 9,000 cfs from three intakes under Alternative 4. However, potential effects associated with operation and maintenance of water conveyance facilities would be similar to those described under Alternative 4.

Operation and maintenance activities would require minimal labor. Impacts under Alternative 2D would be similar to those discussed under Alternative 4 in Appendix A of this RDEIR/SDEIS. A few additional workers would be needed given the need to operate the two additional intakes. However, given the limited number of workers involved and the large number of work sites, it is not anticipated that routine operations and maintenance activities or major inspections would result in substantial demand for law enforcement, fire protection, or emergency response services. In addition, operation and maintenance would not place service demand on public schools or libraries. The operation and maintenance of the proposed water conveyance facilities would not result in the need for new or physically altered government facilities as a result of increased need for public services.

Potential effects associated with operation and maintenance of water conveyance facilities would be similar to those described under Alternative 4. Therefore, Alternative 2D would not result in physical effects associated with the provision of new or physically altered government facilities.

Operation and maintenance of Alternative 2D facilities would involve use of water for pressure washing intake screen panels and basic cleaning of building facilities and other equipment. Impacts would be similar to those under Alternative 4, but slightly greater due to the need to maintain two additional intakes. The operation and maintenance of the proposed water conveyance facilities would not result in the need for new water supply entitlements, or require construction of new water or wastewater treatment facilities or expansion of existing facilities.

Similar to Alternative 4, the operation and maintenance activities associated with the proposed water conveyance facilities would not be expected to generate solid waste such that there would be an increase in demand for solid waste management providers in the project area and surrounding communities. Therefore, there would be no or minimal effect on solid waste management facilities.

As with Alternative 4, operation and maintenance of proposed water conveyance facilities under this alternative would require new transmission lines for intakes, pumping plants, operable barriers, boat locks, and gate control structures throughout the various proposed conveyance alignments and construction of project facilities. Points of interconnection would be located similarly to Alternative 4.

Construction of permanent transmission lines would not require improvements to the existing physical power transmission system. As such, operation and maintenance activities associated with the proposed water conveyance facilities would not be expected to result in the disruption or relocation of utilities. Effects associated with energy demands of operation and maintenance of the proposed water conveyance facilities are addressed in Chapter 21, *Energy*, of the Draft EIR/EIS.

Overall, operation and maintenance of the conveyance facilities under Alternative 2D would not result in adverse effects on service demands, water supply and treatment capacity, wastewater and solid waste facilities nor conflict with local and regional utility lines. There would not be an adverse effect.

CEQA Conclusion: Operation and maintenance activities associated with the Alternative 2D proposed water conveyance facilities would not result in the need for the provision of, or the need for, new or physically altered government facilities from the increased need for public services; construction of new water and wastewater treatment facilities or generate a need for new water supply entitlements; generate solid waste in excess of permitted landfill capacity; or result in the disruption or relocation of utilities. The impact on public services and utilities would be less than significant. No mitigation is required.

Impact UT-8: Effects on Public Services and Utilities as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Effects of Alternative 2D related to the potential for effects on public services and utilities from implementing applicable conservation and other stressor reductions would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, as described in Section 4.1, *Introduction*, Alternative 2D would protect and restore up to 17,766 acres of habitat under Environmental Commitment 3, 4, and 6–10 as compared with 83,800 acres under Alternative 4. Up to 5.5 miles of channel margin habitat would be enhanced under Alternative 2D with Environmental Commitment 6 (compared with 20 miles under Alternative 4). Similarly, Environmental Commitments 11, 12, 15, and 16 would be implemented only at limited locations. Conservation Measures 2, 5, 8, 13, 14, and 17–21 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 2D would be smaller than those associated with Alternative 4.

Public Services

Potential effects of implementing conservation and other stressor reductions under Alternative 2D on law enforcement, fire protection, and emergency response services would primarily involve demand for services related to construction site security and construction-related accidents. The effect would be similar to those described under Alternative 4 in Appendix A of this RDEIR/SDEIS, but because the habitat restoration and enhancement activities under Alternative 2D would be of a smaller magnitude than the Conservation Measures under Alternative 4, it is likely that the effects on public services would be less than those presented for Alternative 4. This effect would not be considered adverse with the implementation of environmental commitments to provide onsite private security services at construction areas and environmental commitments that would minimize the potential for construction-related accidents associated with hazardous materials spills, contamination, or fires, as described in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS. These environmental commitments would be incorporated into this alternative and would provide for onsite security at construction sites and minimize construction-related accidents associated with hazardous materials spills, contamination, and fires that may result from construction of the habitat restoration and enhancement activities.

Utilities

Water and Wastewater

Implementation of some of the Environmental Commitments, in particular those involved with restoration and enhancement of some habitat types, could require a water supply, but would not require city or county treated water sources. Effects would be similar to, but less in magnitude than that those discussed under Alternative 4 in Appendix A of this RDEIR/SDEIS, because Alternative 2D involves smaller acreage amounts of restoration and conservation. Additionally, some components that would require water supply under Alternative 4 are not a part of Alternative 2D (CM5, CM8 of the Draft BDCP). Environmental Commitments that could increase need for water supply are restoration of natural tidal communities (Environmental Commitment 4), channel margin (Environmental Commitment 6), riparian (Environmental Commitment 7), vernal pool and alkali seasonal wetland complex (Environmental Commitment 9), and nontidal marsh habitats (Environmental Commitment 10); and maintenance of these habitats. Measures related to the reduction of stressors on covered species that are a part of Alternative 2D would not generally require a treated water supply or generate wastewater. Because the location and construction or operational details (i.e., water consumption and water sources associated with habitat restoration and enhancement activities) of these facilities and programs have not yet been developed, the need for new or expanded water or wastewater treatment facilities is uncertain. However, because the habitat restoration and enhancement activities consist of restoration consistent with open space, the need for new or expanded wastewater treatment facilities is unlikely.

Solid Waste

Implementation of some of the habitat restoration and enhancement activities would result in construction debris and green waste. Implementation of habitat restoration and enhancement proposed under Environmental Commitments 4, 6, 7, and 9–11 would involve restoration, enhancement, and management of various types of habitat. Construction activities could require clearing and grubbing, demolition of existing structures (e.g., roads and utilities), surface water quality protection, dust control, establishment of storage and stockpile areas, temporary utilities and fuel storage, and erosion control. Effects would be similar to, but less in magnitude than those described under Alternative 4 in Appendix A of this RDEIR/SDEIS, because Alternative 2D involves smaller acreage amounts of restoration and conservation. The estimated tonnage of construction debris and solid waste that would be generated from construction associated with the proposed habitat restoration and enhancement activities is unknown. However, there is a remaining landfill capacity of over 300 million tons in nearby landfills (Table 20A-6 in Appendix 20A of the Draft EIR/EIS). The disposal of construction debris and excavated material would occur at several different locations depending on the type of material and its origin. Based on the capacity of the landfills in the region, and the waste diversion requirements set forth by the State of California, it is expected that construction and operation of the proposed habitat restoration and enhancement activities would not cause any exceedance of landfill capacity.

Electricity and Natural Gas

Habitat restoration and enhancement activities including habitat restoration and enhancement would, in some cases, involve substantial earthwork and ground disturbance. As discussed above under Impact UT-6, construction could potentially disrupt utility services, and ground disturbance has potential to damage underground utilities. The long-term conversion of existing utility corridors to habitat purposes could require the relocation of utility infrastructure, which could carry environmental effects. Mitigation Measures UT-6a, UT-6b, and UT-6c would be available to reduce the severity of these effects.

Effects would be similar to, but less in magnitude than that under Alternative 4, because Alternative 2D involves smaller acreage amounts of restoration and conservation. The locations, construction, and operational details for these and other habitat restoration and enhancement activities have not been identified. Adverse effects due to the construction, operation and maintenance activities associated with the habitat restoration and enhancement activities are not expected to result in the need for new government facilities to provide public services or the need for new or expanded water or wastewater treatment facilities based on increased demand. Environmental commitments would minimize construction-related accidents associated with hazardous materials spills, contamination, and fires that may result from construction of the habitat restoration and enhancement activities. However, there is a potential for the disruption or relocation of utility infrastructure, which has the potential to result in an adverse effect. Further, no substantive adverse effects on solid waste management facilities are anticipated. Because the location and construction and operational details (i.e., water consumption and water sources associated with habitat restoration and enhancement activities) related to these facilities and programs have not yet been developed, the need for new or expanded water facilities is uncertain. However, because the habitat restoration and enhancement activities consist of restoration consistent with open space, the need for new or expanded wastewater treatment facilities is unlikely. This effect would be adverse.

CEQA Conclusion: Significant impacts could occur if implementation of the proposed habitat restoration and enhancement activities would result in the need for the provision of, or the need for, new or physically altered government facilities from the increased need for public services; construction of new water and wastewater treatment facilities or generate a need for new water supply entitlements; generate solid waste in excess of permitted landfill capacity; or result in the disruption or relocation of utilities.

Implementation of the proposed habitat restoration and enhancement activities under Alternative 2D is not likely to require alteration or construction of new government facilities due to increased need for public services and utilities. Several measures to reduce stressors on covered species could result in water supply requirements, but are not expected to require substantial increases in demand on municipal water and wastewater treatment services.

Construction and operation activities associated with the proposed Environmental Commitments would result in a less-than-significant impact on solid waste management facilities based on the capacity of the landfills in the region, and the waste diversion requirements set forth by the State of California.

Potential impacts of implementing habitat restoration and enhancement activities on law enforcement, fire protection, and emergency response services within the ROAs would be less-than-significant with the incorporation of environmental commitments into this alternative and would minimize construction-related accidents associated with hazardous materials spills, contamination, and fires that may result from construction of the habitat restoration and enhancement activities (Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS).

The need for new or expanded water facilities and the potential to disrupt utilities in the study area as a result of construction of operation of conservation and other stressor reductions is unknown at this time, nor have construction and operational details been settled upon. However, because the habitat restoration and enhancement activities consist of restoration consistent with open space, the need for new or expanded wastewater treatment facilities is unlikely. Mitigation Measures UT-6a, UT-6b, and UT-6c would reduce the significance of impacts on utilities, but potentially not to a less-than-significant level Therefore, this impact would significant and unavoidable.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6b: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Operational Reliability

Please see Mitigation Measure UT-6b under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Chapter 20, *Public Services and Utilities*, in Appendix A of this RDEIR/SDEIS.

4.4.17 Energy

Impact ENG-1: Wasteful or Inefficient Energy Use for Temporary Construction Activities

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A as described in the Draft EIR/EIS. Construction energy use required for Alternative 2D would therefore be slightly higher than Alternative 4, described in Appendix A of this RDEIR/SDEIS, but the potential to result in a wasteful or inefficient energy use would be the same as Alternative 4. Accordingly, the effects from construction energy use under Alternative 2D would be similar to Alternative 4. See the discussion of Impact ENG-1 under Alternative 4.

NEPA Effects: Based on the total construction energy use for Alternative 4 (2,132 GWh) and the estimated demand required to construct two additional intakes (16 GWh), Alternative 2D would require about 2,148 GWh of electricity over the 14-year construction period. Diesel and gasoline consumption by Alternative 2D would be greater than Alternative 4 due to the increased number of intakes, and would likely range between that of Alternatives 1A and 4. Accordingly, the alternative may consume between 104 and 147 million gallons over the construction period.

While Alternative 2D would require slightly more construction energy than Alternative 4, the potential for Alternative 2D to result in a wasteful, inefficient or unnecessary consumption of construction energy would be similar to Alternative 4. Construction best management practices (BMPs) would ensure that only high-efficiency equipment is utilized during construction and that construction activity would not result in an adverse effect on energy resources.

***CEQA Conclusion*:** Energy requirements for construction of the water conveyance facilities associated with Alternative 2D would equate to approximately 2,148 GWh during the construction period. Alternative 2D would also consume between 104 and 147 million gallons of diesel and gasoline. Construction BMPs would ensure that only high-efficiency equipment is utilized during construction and that construction activity would result in a less-than-significant impact on energy resources. No mitigation is required.

Impact ENG-2: Wasteful or Inefficient Energy Use for Pumping and Conveyance

Alternative 2D would have the same operations as Alternative 2A. Accordingly, the effects from operational energy use under Alternative 2D would be similar to Alternative 2A. See the discussion of Impact ENG-2 under Alternative 2A in Appendix A of this RDEIR/SDEIS.

NEPA Effects: As shown in Table 21-12 in Appendix A of this RDEIR/SDEIS, energy use for north Delta intake pumping and tunnel conveyance would be 341 GWh per year under ELT conditions and 328 GWh per year under LLT conditions. Accordingly, increased energy use at the north Delta would be slightly higher under Alternative 2D than estimated for Alternative 4. While Alternative 2D would still increase energy demand at the north Delta, relative to the No Action Alternative, operation of the water conveyance facility would be managed to maximize efficient energy use, including off-peak pumping and use of gravity. Accordingly, implementation of Alternative 2D would not result in a wasteful or inefficient energy use and there would be no adverse effect.

***CEQA Conclusion*:** Operation of Alternative 2D would require an additional 341 GWh per year under ELT conditions and 328 GWh per year under LLT conditions for north Delta pumping, relative to

Existing Conditions. Operation of the water conveyance facility under both scenarios would be managed to maximize efficient energy use, including off-peak pumping and use of gravity. Accordingly, implementation of Alternative 2D would not result in a wasteful or inefficient energy use and this impact would be less than significant. No mitigation is required.

Impact ENG-3: Compatibility of the Proposed Water Conveyance Facilities and Environmental Commitments 3, 4, 6–12, 15, and 16 with Plans and Policies

Constructing the water conveyance facilities and implementing the environmental commitments under Alternative 2D would generally have the same potential for incompatibilities with one or more plans and policies related to energy resources as described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact ENG-3 under Alternative 4.

NEPA Effects: As described for Alternative 4 in Appendix A of this RDEIR/SDEIS, the project would be constructed and operated in compliance with regulations related to energy resources enforced by Federal Energy Regulatory Commission (FERC) and other federal agencies. The project would not conflict with the Warren-Alquist Act or State CEQA Guidelines, Appendix F, *Energy Conservation.* Accordingly, there would be no adverse effect.

***CEQA Conclusion*:** The potential incompatibilities with plans and policies listed above indicate the potential for a physical consequence to the environment. The physical effects they suggest are discussed in impacts ENG-1 and ENG-2, above and no additional CEQA conclusion is required related to the compatibility of Alternative 2D with relevant plans and policies.

4.4.18 Air Quality and Greenhouse Gases

Impact AQ-1: Generation of Criteria Pollutants in Excess of the SMAQMD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4 in Appendix A of this RDEIR/SDEIS, but would include two additional intakes, similar to Alternative 1A. Accordingly, construction emissions generated by Alternative 2D in the Sacramento Metropolitan Air Quality Management District (SMAQMD) would be greater than Alternative 4 due to the increased number of intakes, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-1 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-12 and 22-99 in Appendix A of this RDEIR/SDEIS, nitrogen oxide (NO_X) emissions generated by Alternatives 2D and 4 would exceed SMAQMD's daily threshold for all years between 2018 and 2029, even with implementation of environmental commitments (see Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS). Since NO_X is a precursor to ozone and particulate matter (PM), violations of SMAQMD's daily NO_X threshold could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the national ambient air quality standards (NAAQS) and California ambient air quality standards (CAAQS). Mitigation Measures AQ-1a and AQ-1b would be available to reduce NO_X emissions, and would thus address regional effects related to secondary ozone and PM formation.

***CEQA Conclusion*:** NO_X emissions generated during construction of Alternative 2D would exceed SMAQMD regional threshold of significance. Since NO_X is a precursor to ozone and PM, violations of SMAQMD's daily NO_X threshold could affect both regional ozone and PM formation. The impact of generating NO_X emissions in excess of local air district thresholds would violate applicable air quality standards in the study area and could contribute to or worsen an existing air quality conditions. This would be a significant impact. Mitigation Measures AQ-1a and AQ-1b would be available to reduce NO_X emissions to a less-than-significant level by offsetting emissions to quantities below SMAQMD CEQA thresholds.

Mitigation Measure AQ-1a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants[3]

Please refer to Mitigation Measure AQ-1a under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

[3] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Mitigation Measure AQ-1b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-1b under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-2: Generation of Criteria Pollutants in Excess of the YSAQMD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4, described in Appendix A of this RDEIR/SDEIS, but would include two additional intakes, similar to Alternative 1A. There would be no construction of physical features in the Yolo-Solano Air Quality Management District (YSAQMD). Accordingly, emissions generated in the air district would result from equipment and material transport to construction sites in the SMAQMD. Criteria pollutant emissions generated in YSAQMD would therefore be greater than Alternative 4 due to the increased number of intakes constructed in SMAQMD, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-2 under Alternatives 1A and 4.

NEPA Effects: As shown in Table 22-99 in Appendix A of this RDEIR/SDEIS, criteria pollutant emissions generated by Alternative 4 would not exceed YSAQMD regional thresholds. However, construction emissions under Alternative 1A would exceed YSAQMD regional thresholds for the following pollutants and years, even with implementation of environmental commitments (see Appendix 3B, *Environmental Commitments* in the Draft EIR/EIS).

- NO_X: 2022–2024
- Particulate matter less than 10 microns in diameter (PM10): 2022–2028

Since NO_X is a precursor to ozone and PM, violations of YSAQMD's daily NO_X threshold could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Similarly, exceedances of YSAQMD's PM10 threshold could impede attainment of the NAAQS and CAAQS for PM10. Mitigation Measures AQ-1a and AQ-1b would be available to reduce NO_X emissions, and would thus address regional effects related to secondary ozone and PM formation.

***CEQA Conclusion*:** Construction emission could exceed YSAQMD's regional thresholds for NOx and PM10. Since NO_X is a precursor to ozone and PM, violations of YSAQMD's daily NO_X threshold could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Similarly, exceedances of YSAQMD's PM10 threshold could impede attainment of the NAAQS and CAAQS for PM10. This would be a significant impact. Mitigation Measures AQ-1a and AQ-1b would be available to reduce NO_X and PM10 emissions to a less-than-significant level by offsetting emissions to quantities below YSAQMD CEQA thresholds.

Impact AQ-3: Generation of Criteria Pollutants in Excess of the BAAQMD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Emissions from construction of physical features in the Bay Area Air Quality Management District (BAAQMD) would be similar to those generated by Alternative 4. However, emissions generated by equipment and material transport from the Port of San Francisco would be greater than Alternative 4 due to the increased number of intakes constructed in SMAQMD. Accordingly, total emissions generated in the BAAQMD would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-3 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-12 and 22-99 in Appendix A of this RDEIR/SDEIS, construction emissions generated by Alternatives 1A and 4 would exceed BAAQMD's daily thresholds for the following pollutants and years, even with implementation of environmental commitments (see Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS).

- Reactive organic gases (ROG): 2023–2027 (Alternative 1A); 2020–2028 (Alternative 4)
- NO_X: 2018–2029 (Alternatives 1A and 4)

Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of BAAQMD's ROG and NO_X thresholds could impact both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Mitigation Measures AQ-3a and AQ-3b are available to reduce ROG and NO_X emissions, and would thus address regional effects related to secondary ozone and PM formation.

***CEQA Conclusion*: ** Emissions of ROG and NO_X generated during construction would exceed BAAQMD regional thresholds of significance. Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of BAAQMD's ROG and NO_X thresholds could affect both regional ozone and PM formation. The impact of generating ROG and NO_X emissions in excess of BAAQMD's regional thresholds would therefore violate applicable air quality standards in the Study area and could contribute to or worsen an existing air quality conditions. This would be a significant impact. Mitigation Measures AQ-3a and AQ-3b would be available to reduce ROG and NO_X emissions to a less-than-significant level by offsetting emissions to quantities below BAAQMD CEQA thresholds.

Mitigation Measure AQ-3a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants[4]

Please refer to Mitigation Measure AQ-3a under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-3b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-3b under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

---

[4] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Impact AQ-4: Generation of Criteria Pollutants in Excess of the SJVAPCD Regional Thresholds during Construction of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4 in the San Joaquin Valley Air Pollution Control District (SJVAPCD). Accordingly, emissions from construction of physical features and equipment and material transport in the SJVAPCD would be similar to those generated by Alternative 4. See the discussion of Impact AQ-4 under Alternative 4.

NEPA Effects: As shown in Table 22-99 in Appendix A of this RDEIR/SDEIS, construction emissions would exceed SJVAPCD's regional thresholds for the following pollutants and years, even with implementation of environmental commitments (see Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS).

- ROG: 2020–2025
- NO_X: 2018–2028
- PM less than 10 microns in diameter (PM10): 2019–2025

Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of SJVAPCD's ROG and NO_X thresholds could impact both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Similarly, exceedances of SJVAPCD's PM10 threshold could impede attainment of the NAAQS and CAAQS for PM10. Mitigation Measures AQ-4a and AQ-4b are available to reduce ROG, NO_X, and PM10 emissions, and would thus address regional effects related to secondary ozone and PM formation.

***CEQA Conclusion*:** Emissions of ROG, NO_X, and PM10 generated during construction would exceed SJVAPCD's regional thresholds of significance. Since ROG and NO_X are precursors to ozone and NO_X is a precursor to PM, violations of SJVAPCD's ROG and NO_X thresholds could affect both regional ozone and PM formation, which could worsen regional air quality and air basin attainment of the NAAQS and CAAQS. Similarly, exceedances of SJVAPCD's PM10 threshold could impede attainment of the NAAQS and CAAQS for PM10. The impact of generating ROG, NO_X, and PM10 emissions in excess of SJVAPCD's regional thresholds would therefore violate applicable air quality standards in the Study area and could contribute to or worsen an existing air quality conditions. This would be a significant impact. Mitigation Measures AQ-4a and AQ-4b would be available to reduce ROG, NO_X, and PM10 emissions to a less-than-significant level by offsetting emissions to quantities below SJVAPCD CEQA thresholds.

Mitigation Measure AQ-4a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants[5]

Please refer to Mitigation Measure AQ-4a under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-4b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions

[5] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

within the SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-4b under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-5: Generation of Criteria Pollutants in Excess of the SMAQMD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, operational emissions generated by Alternative 2D in the SMAQMD would be greater than Alternative 4 due to the increased number of intakes, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-5 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-13 and 22-100 in Appendix A of this RDEIR/SDEIS, operational emissions generated by Alternatives 1A and 4 would not exceed SMAQMD's regional thresholds of significance. Accordingly, operation of Alternative 2D would not contribute to or worsen existing air quality violations. There would be no adverse effect.

***CEQA Conclusion*:** Emissions generated during operation and maintenance activities would not exceed SMAQMD regional thresholds of significance. Accordingly, Alternative 2D would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-6: Generation of Criteria Pollutants in Excess of the YSAQMD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

Operations and maintenance emissions generated by Alternative 2D in the YSAQMD would be similar to those generated by Alternative 4. See the discussion of Impact AQ-6 under Alternative 4.

NEPA Effects: As discussed for Alternative 4, no permanent features would be constructed in the YSAQMD that would require routine operations and maintenance. Accordingly, no operational emissions would be generated in the YSAQMD and operation of Alternative 2D would neither exceed the YSAQMD regional thresholds of significance nor result in an adverse effect to air quality.

***CEQA Conclusion*:** No operational emissions would be generated in the YSAQMD. Consequently, operation of Alternative 2D would not exceed the YSAQMD regional thresholds of significance. This impact would be less than significant. No mitigation is required.

Impact AQ-7: Generation of Criteria Pollutants in Excess of the BAAQMD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

The number of equipment and personnel required for routine and annual inspections is influenced by the physical water conveyance footprint (i.e., size and location of the Clifton court forebay). Since the water conveyance footprint in BAAQMD under Alternative 2D would be similar to Alternative 4, operational activities required for Alternative 2D in the BAAQMD would be the same as those required for Alternative 4. See the discussion of Impact AQ-7 under Alternative 4.

NEPA Effects: As shown in Table 22-100 in Appendix A of this RDEIR/SDEIS, operational emissions generated by Alternative 4 during the ELT condition would not exceed BAAQMD's regional thresholds of significance. Accordingly, operation of Alternative 2D would not contribute to or worsen existing air quality violations. There would be no adverse effect.

***CEQA Conclusion*:** Emissions generated during operation and maintenance activities would not exceed BAAQMD regional thresholds of significance. Accordingly, Alternative 2D would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-8: Generation of Criteria Pollutants in Excess of the SJVAPCD Regional Thresholds from Operation and Maintenance of the Proposed Water Conveyance Facility

The number of equipment and personnel required for routine and annual inspections is influenced by the physical water conveyance footprint (i.e., size and location of the tunnel segments). Since the water conveyance footprint in SJVAPCD under Alternative 2D would be similar to Alternative 4, operational activities required for Alternative 2D in the SJVAPCD would be the same as those required for Alternative 4. See the discussion of Impact AQ-8 under Alternative 4.

NEPA Effects: As shown in Table 22-100 in Appendix A of this RDEIR/SDEIS, operational emissions generated by Alternative 4 during the ELT condition would not exceed SJVAPCD's regional thresholds of significance. Accordingly, operation of Alternative 2D would not contribute to or worsen existing air quality violations. There would be no adverse effect.

***CEQA Conclusion*:** Emissions generated during operation and maintenance activities would not exceed SJVAPCD regional thresholds of significance. Accordingly, Alternative 2D would not contribute to or worsen existing air quality conditions. This impact would be less than significant. No mitigation is required.

Impact AQ-9: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of SMAQMD's Health-Based Concentration Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, construction emissions and associated health risks generated by Alternative 2D in SMAQMD would be greater than Alternative 4 due to the increased number of intakes, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-9 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-14 and 22-102 in Appendix A of this RDEIR/SDEIS, construction of Alternatives 1A and 4 would exceed the SMAQMD's 24-hour PM10 threshold at several receptor locations. The exceedances would be temporary and occur intermittently due to soil disturbance (primarily entrained road dust). Mitigation Measure AQ-9 is available to reduce this effect.

***CEQA Conclusion*:** As shown in Tables 22-14 and 22-102 in Appendix A of this RDEIR/SDEIS, construction of Alternatives 1A and 4 would exceed SMAQMD's 24-hour PM10 threshold at several receptor locations. The exceedances would be temporary and occur intermittently due to soil disturbance (primarily entrained road dust). Mitigation Measure AQ-9 is available to reduce impacts to less than significant.

Mitigation Measure AQ-9: Implement Measures to Reduce Re-Entrained Road Dust and Receptor Exposure to PM2.5 and PM10

Please refer to Mitigation Measure AQ-9 under Impact AQ-9 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-10: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of YSAQMD's Health-Based Concentration Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. There would be no construction of physical features in the YSAQMD. Accordingly, increased health risks in the air district would result from equipment and material transport to construction sites in the SMAQMD. Criteria pollutant emissions and associated health risks generated in YSAQMD would therefore be greater than Alternative 4 due to the increased number of intakes constructed in SMAQMD, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-10 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-15 and 22-103 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under both Alternatives 1A and 4 are less than YSAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 2D would not expose of sensitive receptors to adverse localized particulate matter concentrations.

***CEQA Conclusion*:** As shown in Tables 22-15 and 22-103 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under both Alternatives 1A and 4 are less than YSAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 2D would not expose of sensitive receptors to significant localized particulate matter concentrations. This impact would be less than significant. No mitigation is required.

Impact AQ-11: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of BAAQMD's Health-Based Concentration Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Emissions and increased health risks from construction of physical features in the BAAQMD would be similar to those generated by Alternative 4. However, emissions generated by equipment and material transport from the Port of San Francisco would be greater than Alternative 4 due to the increased number of intakes constructed in SMAQMD. Accordingly, total emissions and associated health risks generated in the BAAQMD would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-11 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-16 and 22-104 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 concentrations under both Alternatives 1A and 4 are less than BAAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 2D would not expose of sensitive receptors to adverse localized particulate matter concentrations.

***CEQA Conclusion*:** As shown in Tables 22-16 and 22-104 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 concentrations under both Alternatives 1A and 4 are less than BAAQMD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 2D would not expose of sensitive receptors to significant localized particulate matter concentrations. This impact would be less than significant. No mitigation is required.

Impact AQ-12: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter in Excess of SJVAPCD's Health-Based Concentration Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4 in the SJVAPCD. Accordingly, emissions and associated health risks from construction of physical features and equipment and material transport in the SJVAPCD would be similar to those generated by Alternative 4. See the discussion of Impact AQ-12 under Alternative 4.

NEPA Effects: As shown in Table 22-105 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under Alternative 4 are less than SJVAPCD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 2D would not expose of sensitive receptors to adverse localized particulate matter concentrations.

***CEQA Conclusion*:** As shown in Table 22-105 in Appendix A of this RDEIR/SDEIS, predicted PM2.5 and PM10 concentrations under Alternative 4 are less than SJVAPCD's adopted thresholds. The project would also implement all air district recommended onsite fugitive dust controls, such as regular watering. Accordingly, Alternative 2D would not expose of sensitive receptors to significant localized particulate matter concentrations. This impact would be less than significant. No mitigation is required.

Impact AQ-13: Exposure of Sensitive Receptors to Health Threats from Localized Carbon Monoxide

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. The potential for exposure of sensitive receptors to increased health threats from localized carbon monoxide (CO) would therefore likely range between impacts described under Alternatives 1A and 4. See the discussion of Impact AQ-13 under Alternatives 1A and 4.

NEPA Effects: Given that 1) construction activities typically do not result in CO hot-spots, 2) onsite concentrations must comply with OSHA standards, and 3) CO levels dissipate as a function of distance, equipment-generated CO emissions are not anticipated to result in adverse health threats to sensitive receptors.

With respect to CO hot-spot formation along construction haul routes, as shown in Tables 19-8 and 19-25 in Appendix A of this RDEIR/SDEIS, the highest peak hour traffic volumes under BPBGPP—11,737 vehicles per hour under Alternative 1A and 8,088 vehicles per hour under Alternative 4—would occur on westbound Interstate 80 between Suisun Valley Road and State Route 12. This is about half of the congested traffic volume modeled by BAAQMD (24,000 vehicles per hour) that would be needed to contribute to a localized CO hot-spot, and less than half of the traffic volume modeled by SMAQMD (31,600 vehicles per hour). Accordingly, construction traffic is not anticipated to result in adverse health threats to sensitive receptors.

***CEQA Conclusion*:** Continuous engine exhaust may elevate localized CO concentrations. Receptors exposed to these CO "hot-spots" may have a greater likelihood of developing adverse health effects.

Construction sites are less likely to result in localized CO hot-spots due to the nature of construction activities (Sacramento Metropolitan Air Quality Management District 2014), which normally utilize diesel-powered equipment for intermittent or short durations. Moreover, construction sites must comply with the OSHA CO exposure standards for onsite workers. Accordingly, given that construction activities typically do not result in CO hot-spots, onsite concentrations must comply with the Occupational Safety and Health Administration (OSHA) standards, and CO levels dissipate as a function of distance, equipment-generated CO emissions are not anticipated to result in significant health threats to sensitive receptors. Similarly, peak-hour construction traffic on local roadways would not exceed BAAQMD's or SMAQMD's conservative screening criteria for the formation potential CO hot-spots. This impact would be less than significant. No mitigation is required.

Impact AQ-14: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of SMAQMD's Chronic Non-Cancer and Cancer Risk Assessment Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, construction emissions and associated health risks generated by Alternative 2D in SMAQMD would be greater than Alternative 4 due to the increased number of intakes, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-14 under Alternatives 1A and 4.

NEPA Effects: As shown in Table 22-106 in Appendix A of this RDEIR/SDEIS, neither Alternative 1A nor Alternative 4 would exceed the SMAQMD's chronic non-cancer or cancer thresholds. Therefore, construction of Alternative 2D is not expected to expose sensitive receptors to DPM and health hazards that would be adverse.

***CEQA Conclusion*:** DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. As shown in Table 22-106 in Appendix A of this RDEIR/SDEIS, neither Alternative 1A nor Alternative 4 would exceed the SMAQMD's chronic non-cancer or cancer thresholds. As such, construction emissions generated by Alternative 2D would not expose sensitive receptors to substantial health hazards. This impact would be less than significant. No mitigation is required.

Impact AQ-15: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of YSAQMD's Chronic Non-Cancer and Cancer Risk Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. There would be no construction of physical features in the YSAQMD. Accordingly, increased health risks in the air district would result from equipment and material transport to construction sites in the SMAQMD. Criteria pollutant emissions and associated health risks generated in YSAQMD would therefore be greater than Alternative 4 due to the increased number of intakes constructed in SMAQMD, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-15 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-19 and 22-107 in Appendix A of this RDEIR/SDEIS, neither Alternative 1A nor Alternative 4 would exceed the YSAQMD's chronic non-cancer or cancer thresholds. Therefore, construction of Alternative 2D is not expected to expose sensitive receptors to DPM and health hazards that would be adverse.

CEQA Conclusion**:** DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. As shown in Tables 22-19 and 22-107 in Appendix A of this RDEIR/SDEIS, neither Alternative 1A nor Alternative 4 would exceed the YSAQMD's chronic non-cancer or cancer thresholds. As such, construction emissions generated by Alternative 2D would not expose sensitive receptors to substantial health hazards. This impact would be less than significant. No mitigation is required.

Impact AQ-16: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of BAAQMD's Chronic Non-Cancer and Cancer Risk Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Emissions and increased health risks from construction of physical features in the BAAQMD would be similar to those generated by Alternative 4. However, emissions generated by equipment and material transport from the Port of San Francisco would be greater than Alternative 4 due to the increased number of intakes constructed in SMAQMD. Accordingly, total emissions and associated health risks generated in the BAAQMD would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-16 under Alternatives 1A and 4.

NEPA Effects: As shown in Table 22-108 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the BAAQMD's chronic non-cancer or cancer thresholds. However, Alternative 1A would result in DPM concentrations in excess of BAAQMD's thresholds at adjacent receptors (see Table 22-20). Since proximity to haul routes contributes DPM emissions to the cancer risk, and Alternative 2D would have increased haul truck activity through BAAQMD due to the construction of five intakes in SMAQMD, similar to Alternative 1A, effects would be adverse under Alternative 2D.

Mitigation Measure AQ-16 would be available to reduce exposure to substantial cancer risk by relocating affected receptors. If a landowner chooses not to accept DWR's offer of relocation assistance, an adverse effect in the form excess cancer risk above air district thresholds would occur. Therefore, this effect would be adverse. If, however, all landowners accept DWR's offer of relocation assistance, effects would not be adverse.

CEQA Conclusion**:** DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. As shown in Table 22-108 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the BAAQMD's chronic non-cancer or cancer thresholds. However, Alternative 1A would result in DPM concentrations in excess of BAAQMD's thresholds at adjacent receptors (see Table 22-20). Since proximity to haul routes contributes DPM emissions to the cancer risk, and Alternative 2D would have increased haul truck activity through BAAQMD due to the construction of five intakes in SMAQMD, similar to Alternative 1A, this impact would be significant under Alternative 2D.

Mitigation Measure AQ-16 would be available to reduce exposure to substantial cancer risk by relocating affected receptors. If a landowner chooses not to accept DWR's offer of relocation assistance, a significant impact in the form excess cancer risk above air district thresholds would occur. Therefore, this effect would be adverse. If, however, all landowners accept DWR's offer of relocation assistance, impacts would be less than significant.

Mitigation Measure AQ-16: Relocate Sensitive Receptors to Avoid Excess Cancer Risk

Please refer to Mitigation Measure AQ-16 under Impact AQ-16 in the discussion of Alternative 1A in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-17: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of SJVAPCD's Chronic Non-Cancer and Cancer Risk Thresholds

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Emissions and associated health risks from construction of physical features and equipment and material transport in the SJVAPCD would be similar to those generated by Alternative 4. See the discussion of Impact AQ-17 under Alternative 4.

NEPA Effects: As shown in Table 22-109 in Appendix A of this RDEIR/SDEIS, Alternative 4 would not exceed the SJVAPCD's chronic non-cancer or cancer thresholds and, thus, would not expose sensitive receptors to substantial DPM concentrations. Therefore, the effect of exposure of sensitive receptors to DPM health threats during construction would not be adverse.

***CEQA Conclusion*:** DPM generated during construction poses inhalation-related chronic non-cancer hazard and cancer risk if adjacent receptors are exposed to significant concentrations for prolonged durations. The DPM generated during Alternative 2D construction would not exceed the SJVAPCD's chronic non-cancer or cancer thresholds, and thus would not expose sensitive receptors to substantial pollutant concentrations. Therefore, this impact for DPM emissions would be less than significant. No mitigation is required.

Impact AQ-18: Exposure of Sensitive Receptors to *Coccidioides immitis* (Valley Fever)

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. While construction activities may be slightly greater under Alternative 2D than Alternative 4, the potential for Alternative 2D to expose receptors adjacent to the construction site to spores known to cause Valley Fever would be similar to Alternative 4. See the discussion of Impact AQ-18 under Alternative 4.

***NEPA Effects*:** Earthmoving activities during construction could release *C. immitis* spores if filaments are present and other soil chemistry and climatic conditions are conducive to spore development. Receptors adjacent to the construction area may therefore be exposed to increase risk of inhaling *C. immitis* spores and subsequent development of Valley Fever. Implementation of advanced air-district recommended fugitive dust controls outlined in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS, would avoid dusty conditions and reduce the risk of contracting Valley Fever through routine watering and other controls. Therefore, the effect of exposure of sensitive receptors to increased Valley Fever risk during construction would not be adverse.

***CEQA Conclusion*:** Construction of the water conveyance facility would involve earthmoving activities that could release *C. immitis* spores if filaments are present and other soil chemistry and climatic conditions are conducive to spore development. Receptors adjacent to the construction area may therefore be exposed to increase risk of inhaling *C. immitis* spores and subsequent development of Valley Fever. Implementation of air-district recommended fugitive dust controls outlined in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS, would avoid dusty conditions and reduce the risk of contracting Valley Fever through routine watering and other controls. Therefore, this impact would be less than significant. No mitigation is required.

Impact AQ-19: Creation of Potential Odors Affecting a Substantial Number of People during Construction or Operation of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. While construction activities may be slightly greater under Alternative 2D than Alternative 4, the potential for Alternative 2D to expose receptors to nuisance odors during construction and operation of the water conveyance facilities would be similar to Alternative 4. See the discussion of Impact AQ-19 under Alternative 4.

NEPA Effects: Odors from construction activities would be localized and generally confined to the immediate area surrounding the construction site. Moreover, odors would be temporary and localized, and they would cease once construction activities have been completed. Thus, it is not anticipated that construction of water conveyance facilities would create objectionable odors from construction equipment or asphalt paving. Similarly, drying and stockpiling of removed muck and sediment will occur under aerobic conditions, which will limit any potential decomposition and associated malodorous products. Accordingly, tunnel and sediment excavation would not create objectionable odors. Finally, since Alternative 2D would not result in the addition of odors facilities (e.g., wastewater treatment plants), long-term operation of the water conveyance facility would not result in objectionable odors. There would be no adverse effect.

***CEQA Conclusion*:** Alternative 2D would not result in the addition of major odor producing facilities. Diesel emissions during construction could generate temporary odors, but these would quickly dissipate and cease once construction is completed. Likewise, potential odors generated during asphalt paving would be addressed through mandatory compliance with air district rules and regulations. While tunnel excavation would unearth approximately 27 million cubic yards of muck, geotechnical tests indicate that soils in the project area have relatively low organic constituents. Moreover, drying and stockpiling of the removed muck will occur under aerobic conditions, which will further limit any potential decomposition and associated malodorous products. Accordingly, the impact of exposure of sensitive receptors to potential odors would be less than significant. No mitigation is required.

Impact AQ-20: Generation of Criteria Pollutants in the Excess of Federal *De Minimis* Thresholds from Construction and Operation and Maintenance of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Emissions generated by Alternative 2D would therefore likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-20 under Alternatives 1A and 4.

NEPA Effects: As shown in Tables 22-23 and 22-110 in Appendix A of this RDEIR/SDEIS, implementation of Alternatives 1A and 4 would exceed the following federal *de minimis* thresholds:

<u>Sacramento Federal Nonattainment Area (SFNA)</u>

- ROG: 2023-2027 (Alternative 1A); 2019-2027 (Alternative 4)
- NO_X: 2018-2028 (Alternative 1A only)
- PM10: 2023-2024 (Alternative 1A only)

<u>San Joaquin Valley Air Basin (SJVAB)</u>[6]

- ROG: 2020-2025 (Alternative 4)
- NO_X: 2018-2028 (Alternative 4)

<u>San Francisco Bay Area Air Basin (SFBAAB)</u>

- NO_X: 2024-2025 (Alternative 4 only)

ROG and NO_X are precursors to ozone, for which the SFNA, SJVAB, and SFBAAB are in nonattainment for the NAAQS. The SFNA is also a maintenance area for PM10. Since project emissions exceed the federal *de minimis* thresholds for ROG (SFNA and SJVAB), NO_X, and PM10 (SFNA only), a general conformity determination must be made to demonstrate that total direct and indirect emissions of ROG (SFNA and SJVAB), NO_X, and PM10 (SFNA only) would conform to the appropriate SFNA, SJVAB, and SFBAAB state implementation plans (SIPs) for each year of construction in which the *de minimis* thresholds are exceeded.

NO_X is also a precursor to PM and can contribute to PM formation. Sacramento County and the SJVAB are currently designated maintenance for the PM10 NAAQS, whereas the SJVAB, SFBAAB, and portions of the SFBA are designated nonattainment for the PM2.5 NAAQS. NO_X emissions in excess of 100 tons per year in Sacramento County and SJVAB trigger a secondary PM10 precursor threshold, whereas NO_X emissions in excess of 100 tons per year in the SFNA, SJVAB, or SFBAAB trigger a secondary PM2.5 precursor threshold. Since NOx emissions can contribute to PM formation, NO_X emissions in excess of these secondary precursor thresholds could conflict with the applicable PM10 and PM2.5 SIPs.

As shown in Table 22-12 in Appendix A of this RDEIR/SDEIS, NO_X emissions generated by construction activities in SMAQMD (Sacramento County) under Alternative 1A would exceed 100 tons per year between 2022 and 2027. It is therefore likely that Alternative 2D would trigger the secondary PM10 precursor threshold, requiring all NO_X offsets for 2022 through 2027 to occur within Sacramento County. Alternative 1A also triggers the secondary PM2.5 precursor threshold in 2021, and Alternative 4 triggers the threshold in 2025, requiring all NO_X offsets in these years to occur within the federally-designated PM2.5 nonattainment area within the SFNA. The nonattainment boundary for PM2.5 includes all of Sacramento County and portions of Yolo, El Dorado, Solano, and Placer counties.

With respect to NO_X emissions in SJVAB and SFBAAB, the PM2.5 precursor threshold would be exceeded in the SFBAAB in 2024 and 2025. The PM10 and PM2.5 precursor thresholds would be exceeded in the SJVAB in 2021 and 2022. Accordingly, NO_X offsets for these years must occur within the federally-designated PM10 maintenance (SJVAB only) and PM2.5 nonattainment areas of the SJVAB and SFBAAB, which are consistent with the nonattainment boundary for ozone.

Mitigation Measures AQ-3a, AQ-3b, AQ-4a, and AQ-4b are available to fully offset emissions generated by Alternatives 1A and 4 in excess of the federal *de minimis* thresholds in SFBAAB and SJVAB to net zero. However, within SFNA, given the limited geographic scope available for offsets in 2022 through 2027 (Sacramento County), neither Mitigation Measures AQ-1a nor 1b could feasibly

[6] Emissions from construction of physical features and equipment and material transport in the SJVAPCD would be the same as those generated by Alternative 4. Accordingly, violations of the federal *de minimis* thresholds under Alternative 1A are not listed.

reduce NO_X emissions to net zero for the purposes of general conformity.[7] This impact would be adverse. In the event that Alternative 2D is selected as the APA, Reclamation, USFWS, and NMFS would need to demonstrate that conformity is met for NO_X and secondary PM10 formation in SFNA through a local air quality modeling analysis (i.e., dispersion modeling) or other acceptable methods to ensure project emissions do not cause or contribute to any new violations of the NAAQS or increase the frequency or severity of any existing violations.

Mitigation Measure AQ-1a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-1a under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-1b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SFNA to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-1b under Impact AQ-1 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-3a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants[8]

Please refer to Mitigation Measure AQ-3a under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-3b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the BAAQMD/SFBAAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable BAAQMD CEQA Thresholds for Other Pollutants

Please refer to Mitigation Measure AQ-3b under Impact AQ-3 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-4a: Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General

[7] The secondary PM precursor thresholds are triggered through the General Conformity Regulation (40 CFR 93.153 (a)(1)). Accordingly, confinement of the geographic scope for available offsets only applies to the General Conformity determination and does not influence mitigation feasibility for Impact AQ-1.

[8] In the title of this mitigation measure, the phrase "for other pollutants" is intended to apply to other alternatives, where associated impacts on other pollutants may exceed thresholds other than NO_X.

Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-4a under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-4b: Develop an Alternative or Complementary Offsite Mitigation Program to Mitigate and Offset Construction-Generated Criteria Pollutant Emissions within the SJVAPCD/SJVAB to Net Zero (0) for Emissions in Excess of General Conformity *De Minimis* Thresholds (Where Applicable) and to Quantities below Applicable SJVAPCD CEQA Thresholds for Other Pollutants

Please see Mitigation Measure AQ-4b under Impact AQ-4 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

CEQA Conclusion: SFNA, SJVAB, and SFBAAB are classified as nonattainment and maintenance areas with regard to the ozone and PM10 NAAQS and the impact of increases in criteria pollutant emissions above the air basin *de minimis* thresholds could conflict with or obstruct implementation of the applicable air quality plans. Since construction emissions in the SFNA, SJVAB, and SFBAAB would exceed the *de minimis* thresholds for ROG (SJVAB and SFNA), NO_X, and PM10 (SFNA only) this impact would be significant.

Mitigation Measures AQ-3a, AQ-3b, AQ-4a, and AQ-4b would ensure project emissions would not result in an increase in regional ROG (SJVAB only) or NO_X in the SFBAAB and SJVAB. These measures would therefore ensure total direct and indirect ROG (SJVAB only) and NO_X emissions generated by the project would conform to the appropriate SFBAAB and SJVAB SIPs by offsetting the action's emissions in the same or nearby area to net zero. Accordingly, impacts would be less than significant with mitigation in the SFBAAB and SJVAB.

Although Mitigation Measures AQ-1a and AQ-1b would reduce NO_X in the SFNA, given the magnitude of NO_X emissions and the limited geographic scope available for offsets (Sacramento County), neither measure could feasibly reduce NO_X emissions to net zero for the purposes of general conformity. This impact would be significant and unavoidable in the SFNA.

Impact AQ-21: Generation of Cumulative Greenhouse Gas Emissions during Construction of the Proposed Water Conveyance Facility

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Total GHG emissions generated by construction of Alternative 2D would therefore be slightly higher than Alternative 4, but the potential effect of those emissions would be the same as Alternative 4. See the discussion of Impact AQ-21 under Alternative 4.

NEPA Effects: Based on the total GHG emissions generated by Alternative 4 (3,019,413 metric tons carbon dioxide equivalent [CO_2e]) and emissions that would be generated by construction of two additional intakes (60,000 metric tons CO_2e), Alternative 2D would emit about 3.1 million metric tons CO_2e over the 14-year construction period. This is equivalent to adding 645,000 typical passenger vehicles to the road during construction (U.S. Environmental Protection Agency 2014e). As discussed in Chapter 22, *Air Quality and Greenhouse Gases*, Section 22.3.2, of the Draft EIR/EIS, any increase in emissions above net zero associated with construction of the project water conveyance features would be adverse. Mitigation Measure AQ-21, which would develop a GHG

Mitigation Program to reduce construction-related GHG emissions to net zero, is available address this effect.

***CEQA Conclusion*:** Construction of Alternative 2D would generate about 3.1 million metric tons of GHG emissions. As discussed in Chapter 22, *Air Quality and Greenhouse Gases*, Section 22.3.2, of the Draft EIR/EIS, any increase in emissions above net zero associated with construction of the project water conveyance features would be significant. Mitigation Measure AQ-21 would develop a GHG Mitigation Program to reduce construction-related GHG emissions to net zero. Accordingly, this impact would be less-than-significant with implementation of Mitigation Measure AQ-21.

Mitigation Measure AQ-21: Develop and Implement a GHG Mitigation Program to Reduce Construction Related GHG Emissions to Net Zero (0)

Please see Mitigation Measure AQ-21 under Impact AQ-21 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-22: Generation of Cumulative Greenhouse Gas Emissions from Operation and Maintenance of the Proposed Water Conveyance Facility and Increased Pumping

Alternative 2D would have the same operations from those under Alternative 2A. Accordingly, the potential to result in a cumulative GHG effect during operation and maintenance would be the same as Alternative 2A. See the discussion of Impact AQ-22 under Alternative 2A.

NEPA Effects: Table 4.4.18-1 summarizes long-term operational GHG emissions associated with operations, maintenance, and increased SWP pumping under Alternative 2D at the ELT and LLT timeframes. Emissions are compared to both the No Action Alternative (NEPA point of comparison) and Existing Conditions (CEQA baseline). The equipment emissions presented in Table 4.4.18-1 are representative of project impacts for both the NEPA and CEQA analysis.

Table 4.4.18-1. GHG Emissions from Operation, Maintenance, and Increased SWP Pumping, Alternative 2D

Condition	Equipment CO_2	NEPA Point of Comparison Electricity)	CEQA Baseline (Electricity)	NEPA Point of Comparison (Total)	CEQA Baseline (Total)
ELT	562	204,388	111,643	204,939	112,205
LLT	548	25,621	4,984	26,169	5,532

Note: The *NEPA point of comparison* compares total CO_2e emissions after implementation of Alternative 4 to the No Action Alternative (ELT), whereas the *CEQA baseline* compares total CO_2e emissions to Existing Conditions.

As shown in Table 4.4.18-1, operations, maintenance, and increased SWP pumping under Alternative 2D would generate 26,000 to 205,000 metric tons CO_2e per year, relative to the No Action Alternative. Emissions relative to existing conditions would range from 5,500 metric tons CO_2e per year to 113,000 metric tons CO_2e per year. This increase relative to existing conditions is lower than emissions and potential effects analyzed under the Scenario H1 for Alternative 4 (113,555 metric tons CO_2e).

As discussed in Impact AQ-22 in Chapter 22, *Air Quality and Greenhouse Gases*, of this RDEIR/SDEIS, analysis was undertaken to confirm additional energy demand and associated GHG emissions under Alternative 4 would not impede DWR's ability to achieve their Climate Action Plan (CAP) goals with implementation of BMPs and modification to DWR's Renewable Energy Procurement Program (REEP). The analysis presented in the chapter meets the consistency requirements detailed in the DWR CAP, therefore enabling the project to tier from the environmental document prepared for the CAP pursuant to CEQA Guidelines section 15183.5. Since emissions under Alternative 2D would be lower than those analyzed for Alternative 4 (Scenario H1), and because DWR demonstrated that implementation of Alternative 4 (Scenario H1) would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the CAP, Alternative 2D would be consistent with the analysis performed in the CAP and would not conflict with any of DWR's specific action GHG emissions reduction measures. There would be no adverse effect

CEQA Conclusion: As discussed in Impact AQ-22 in Chapter 22, *Air Quality and Greenhouse Gases*, of this RDEIR/SDEIS, analysis was undertaken to confirm additional energy demand and associated GHG emissions under Alternative 4 would not impede DWR's ability to achieve their CAP goals with implementation of BMPs and modification to DWR's REEP. The analysis presented in the chapter meets the consistency requirements detailed in the DWR CAP, therefore enabling the project to tier from the environmental document prepared for the CAP pursuant to CEQA Guidelines section 15183.5. As shown in Table 22-115, the assessment considers the amount of additional renewable energy that would need to be added to the REPP annually following construction in order for DWR to meet their long-term GHG reduction goals. Since emissions under Alternative 2D ELT conditions would be lower than those analyzed for Alternative 4 ELT conditions, and because DWR demonstrated that implementation of Alternative 4 (Operational Scenario H1) would not adversely affect DWR's ability to achieve the GHG emissions reduction goals set forth in the CAP, Alternative 2D would be consistent with the analysis performed in the CAP and would not conflict with any of DWR's specific action GHG emissions reduction measures. Prior adoption of the CAP by DWR already provides a commitment on the part of DWR to make all necessary modifications to DWR's REEP or any other GHG emission reduction measure in the CAP necessary to achieve DWR's GHG emissions reduction goals. Therefore no amendment to the approved CAP is necessary to ensure the occurrence of the additional GHG emissions reduction activities needed to account for project-related operational emissions. The effect of Alternative 2D with respect to GHG emissions is less than cumulatively considerable and therefore less than significant. No mitigation is required.

Impact AQ-23: Generation of Cumulative Greenhouse Gas Emissions from Increased CVP Pumping as a Result of Implementation of Water Conveyance Facility

Alternative 2D would have the same operations as Alternative 2A. Accordingly, the potential to result in a cumulative GHG effect from increased CVP pumping under LLT conditions would be the same as Alternative 2A. Potential effects under ELT conditions, which were not analyzed for CVP operation under Alternative 2A, would be slightly higher than those estimated under LLT conditions. See the discussion of Impact AQ-23 under Alternative 2A.

NEPA Effects: Under Alternative 2D, operation of the CVP yields the generation of clean, GHG emissions-free, hydroelectric energy. This electricity is sold into the California electricity market or directly to energy users. Implementation of Alternative 2D could result in an increase of up to 109 GWh in the demand for CVP generated electricity at the ELT timeframe, which would result in a reduction of up to 109 GWh or electricity available for sale from the CVP to electricity users (103 GWh under LLT). This reduction in the supply of GHG emissions-free electricity to the California electricity users could result in a potential indirect effect of the project, as these electricity users would have to acquire substitute electricity supplies that may result in GHG emissions (although additional conservation is also a possible outcome).

It is unknown what type of power source (e.g., renewable, natural gas) would be substituted for CVP electricity or if some of the lost power would be made up with higher efficiency. Given State mandates for renewable energy and incentives for energy efficiency, it is possible that a considerable amount of this power would be replaced by renewable resources or would cease to be needed as a result of higher efficiency. However, to ensure a conservative analysis, indirect emissions were quantified for the entire quantity of electricity (up to 109 GWh) using the current and future statewide energy mix (adjusted to reflect RPS).

Substitution of up to 109 GWh of electricity with a mix of sources similar to the current statewide mix would result in emissions of up to 30,447 metric tons of CO_2e; however, under expected future conditions (after full implementation of the RPS), emissions would be up to 23,659 metric tons of CO_2e. These emissions could contribute to a cumulatively considerable effect and are therefore adverse. The emissions would be caused by dozens of independent electricity users, who had previously bought CVP power, making decisions about different ways to substitute for the lost power. These decisions are beyond the control of Reclamation or any of the other project Lead Agencies. Further, monitoring to determine the actual indirect change in emissions as a result of project actions would not be feasible. In light of the impossibility of predicting where any additional emissions would occur, as well as Reclamation's lack of regulatory authority over the purchasers of power in the open market, no workable mitigation is available or feasible.

CEQA Conclusion**:** Operation of the CVP is a federal activity beyond the control of any State agency such as DWR, and the power purchases by private entities or public utilities in the private marketplace necessitated by a reduction in available CVP-generated hydroelectric power are beyond the control of the State, just as they are beyond the control of Reclamation. For these reasons, there are no feasible mitigation measures that could reduce this potentially significant indirect impact, which is solely attributable to operations of the CVP and not the SWP, to a less than significant level. This impact is therefore determined to be significant and unavoidable.

Impact AQ-24: Generation of Regional Criteria Pollutants from Implementation of Environmental Commitments 3, 4, 6–11

Effects of Alternative 2D related to the generation of regional criteria pollutants during implementation of Environmental Commitments 3, 4, 6–11 would be similar to those described for Alternative 4A. See the discussion of Impact AQ-24 under Alternative 4A in Section 4.3.18, *Air Quality and Greenhouse Gases*, in this RDEIR/SDEIS.

NEPA Effects: Habitat restoration and enhancement activities that require physical changes or heavy-duty equipment would generate construction emissions through earthmoving activities and heavy-duty diesel-powered equipment. Criteria pollutants from restoration and enhancement actions could exceed applicable general conformity *de minimis* levels and applicable local thresholds.

The effect would vary according to the equipment used in construction of a specific environmental commitment, the location, the timing of the actions called for in the environmental commitment, and the air quality conditions at the time of implementation. Nevertheless, increases in emissions during implementation of Environmental Commitments 3, 4, 6–11 in excess of applicable general conformity *de minimis* levels and air district regional thresholds could violate air basin SIPs and worsen existing air quality conditions. Mitigation Measure AQ-24 would be available to reduce this effect, but emissions would still be adverse.

CEQA Conclusion**:** Construction and operational emissions associated with the restoration and enhancement actions would result in a significant impact if the incremental difference, or increase, relative to Existing Conditions exceeds the applicable local air district thresholds. Mitigation Measure AQ-24 would be available to reduce this effect, but may not be sufficient to reduce emissions below applicable air quality management district thresholds. Consequently, this impact would be significant and unavoidable.

Mitigation Measure AQ-24: Develop an Air Quality Mitigation Plan (AQMP) to Ensure Air District Regulations and Recommended Mitigation are Incorporated into Future Habitat Restoration and Enhancement Activities and Associated Project Activities

Please see Mitigation Measure AQ-24 under Impact AQ-24 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-25: Exposure of Sensitive Receptors to Health Threats from Localized Particulate Matter, Carbon Monoxide, and Diesel Particulate Matter from Implementation of Environmental Commitments 3, 4, 6–11

The potential for Alternative 2D to expose sensitive land uses to increased health risks from implementation of Environmental Commitments 3, 4, 6–11 would be similar to those described for Alternative 4A. See the discussion of Impact AQ-25 under Alternative 4A in Section 4.3.18, *Air Quality and Greenhouse Gases*, in this RDEIR/SDEIS.

NEPA Effects: Potential health effects from localized pollutant increases would vary according to the equipment used, the location and timing of the actions called for in the environmental commitment, the meteorological and air quality conditions at the time of implementation, and the location of receptors relative to the emission source. Increases in PM, CO, or DPM (cancer and non-cancer-risk) in excess of applicable air district thresholds at receptor locations would be adverse. Mitigation Measures AQ-24 and AQ-25 would be available to reduce this effect.

CEQA Conclusion**:** Construction and operational emissions associated with the restoration and enhancement actions under Alternative 2D would result in a significant impact if PM, CO, or DPM (cancer and non-cancer-risk) concentrations at receptor locations exceed the applicable local air district thresholds. Mitigation Measures AQ-24 and AQ-25 would ensure localized concentrations at receptor locations would be below applicable air quality management district thresholds. Consequently, this impact would be less than significant.

Mitigation Measure AQ-24: Develop an Air Quality Mitigation Plan (AQMP) to Ensure Air District Regulations and Recommended Mitigation are Incorporated into Future Habitat Restoration and Enhancement Activities and Associated Project Activities

Please see Mitigation Measure AQ-24 under Impact AQ-24 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-25: Prepare a Project-Level Health Risk Assessment to Reduce Potential Health Risks from Exposure to Localized DPM and PM Concentrations

Please see Mitigation Measure AQ-25 under Impact AQ-25 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Impact AQ-26: Creation of Potential Odors Affecting a Substantial Number of People from Implementation of Environmental Commitments 3, 4, 6–11

The potential for Alternative 2D to expose sensitive land uses to nuisance odors from implementation of Environmental Commitments 3, 4, 6–11 would be similar to those described for Alternative 4A. See the discussion of Impact AQ-26 under Alternative 4A in Section 4.3.18, *Air Quality and Greenhouse Gases*, in this RDEIR/SDEIS.

NEPA Effects: Diesel emissions from earthmoving equipment could generate temporary odors, but these would quickly dissipate and cease once construction is completed. While restored land uses have the potential to generate odors from natural processes, the odors would be similar in origin and magnitude to the existing land use types in the restored area (e.g., managed wetlands). Accordingly, odor-related effects associated with Environmental Commitments 3, 4, 6–11 would not be adverse.

***CEQA Conclusion*:** Alternative 2D would not result in the addition of major odor producing facilities. Diesel emissions during construction could generate temporary odors, but these would quickly dissipate and cease once construction is completed. Increases in wetland, tidal, and upland habitats may increase the potential for odors from natural processes. However, the origin and magnitude of odors would be similar to the existing land use types in the restored area (e.g., managed wetlands). Accordingly, the impact of exposure of sensitive receptors to potential odors would be less than significant. No mitigation is required.

Impact AQ-27: Generation of Cumulative Greenhouse Gas Emissions from Implementation of Environmental Commitments 3, 4, 6–11

Effects of Alternative 2D related to the generation of GHG emissions during implementation of Environmental Commitments 3, 4, 6–11 would be similar to those described for Alternative 4A. See the discussion of Impact AQ-27 under Alternative 4A in Section 4.3.18, *Air Quality and Greenhouse* Gases, in this RDEIR/SDEIS.

NEPA Effects: Construction equipment required for earthmoving could generate short-term GHG emissions. Implementing Environmental Commitments 3, 4, 6–11 would also affect long-term sequestration rates through land use changes, such as conversion of agricultural land to wetlands, inundation of peat soils, drainage of peat soils, and removal or planting of carbon-sequestering plants. Without additional information on site-specific characteristics associated with each of the restoration components, a complete assessment of GHG flux from Environmental Commitments 3, 4, 6–11 is currently not possible. The effect of carbon sequestration and methane generation would vary by land use type, season, and chemical and biological characteristics. Mitigation Measures AQ-24 and AQ-27 would be available to reduce this effect. However, due to the potential for increases in GHG emissions from construction and land use change, this effect would be adverse.

***CEQA Conclusion*:** The restoration and enhancement actions under Alternative 2D could result in a significant impact if activities are inconsistent with applicable GHG reduction plans, do not contribute to a lower carbon future, or generate excessive emissions, relative to other projects throughout the state. Mitigation Measures AQ-24 and AQ-27 would be available to reduce this impact, but may not be sufficient to reduce to a less-than-significant level. Consequently, this impact is would be significant and unavoidable.

Mitigation Measure AQ-24: Develop an Air Quality Mitigation Plan (AQMP) to Ensure Air District Regulations and Recommended Mitigation are Incorporated into Future Habitat Restoration and Enhancement Activities and Associated Project Activities

Please see Mitigation Measure AQ-24 under Impact AQ-24 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

Mitigation Measure AQ-27: Prepare a Land Use Sequestration Analysis to Quantify and Mitigate (as Needed) GHG Flux Associated with Habitat Restoration and Enhancement Activities and Associated Project Activities

Please see Mitigation Measure AQ-27 under Impact AQ-27 in the discussion of Alternative 4 in Chapter 22, *Air Quality and Greenhouse Gases*, of the Draft EIR/EIS.

4.4.19 Noise

Impact NOI-1: Exposure of Noise-Sensitive Land Uses to Noise from Construction of Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, noise levels generated by construction of non-intake features structures would be similar to Alternative 4, whereas noise levels generated by construction of the intakes would be similar to Alternative 1A. The potential for Alternative 2D to expose noise-sensitive land uses to noise from construction of the water conveyance facilities would therefore range between impacts described under Alternatives 1A and those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact NOI-1 under Alternatives 1A and 4.

NEPA Effects: Noise would be generated by heavy-duty equipment operating at the various construction sites, as well as by haul trucks and worker vehicles traveling on local roadways. Construction noise would also affect onsite workers. However, occupational exposure to noise levels in excess of 85 A-weighted decibels (dBA) requires monitoring and mitigation to protect workers. Given that onsite workers would be protected under OSHA requirements, no adverse impacts would occur to workers. Accordingly, this analysis focuses exclusively on potential noise effects to noise-sensitive land uses adjacent to construction activities.

Potential reasonable worst-case noise levels generated at construction work areas were evaluated against the 60 dBA L_{eq} (1hr) daytime (7 a.m. to 10 p.m.) and 50 dBA L_{max} nighttime (10 p.m. to 7 a.m.) construction thresholds. Construction noise along roadways was evaluated against the 12 decibel (dB) traffic noise threshold. As described in Impact NOI-1 in Appendix A of this RDEIR/SDEIS, Alternative 4 could generate noise levels in excess of daytime and nighttime standards at up to 765 and 1,293 parcels, respectively, depending on the local and land use type. The effect of exposing noise-sensitive land uses to noise increases above established thresholds at intake work areas, conveyance and associated facility work areas, utility construction work areas, borrow/spoil work areas and truck trips and worker commutes would be adverse. Mitigation Measures NOI-1a and NOI-1b would be available to reduce this effect, but not to a level that would avoid adverse conditions.

CEQA Conclusion*:* Construction activities would expose noise-sensitive land uses adjacent to intake, conveyance, forebay, barge facility, utility, and borrow/spoil work areas to noise levels above the 60 dBA L_{eq} (1hr) daytime and 50 dBA L_{max} nighttime threshold. Receptors near haul roads would also be exposed to noise levels in excess of the 12 dB traffic noise threshold. This would be a significant impact. Mitigation Measures NOI-1a and NOI-1b, which require noise-reducing construction practices and development of a complaint/response tracking program, would reduce noise impacts on sensitive land uses. However, it is not anticipated that feasible measures will be available in all situations to reduce construction noise to levels below the applicable thresholds. This impact would therefore be considered significant and unavoidable.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1a in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under Impact NOI-1b in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact NOI-2: Exposure of Sensitive Receptors to Vibration or Groundborne Noise from Construction of Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Construction at the intake sites would involve use of impact pile driving, and tunnel construction would involve the use of tunnel boring machines (TBMs) and tunnel locomotives, both of which would cause groundborne vibration in localized areas. The potential for Alternative 2D to expose noise-sensitive land uses to vibration at the intake sites would be greater than that of Alternative 4, as described in Appendix A of this RDEIR/SDEIS, and similar to that of Alternative 1A. The potential for Alternative 2D to expose noise-sensitive land uses to vibration from tunneling activities would be the same as that of Alternative 4. See the discussion of Impact NOI-2 under Alternatives 1A and 4.

NEPA Effects: Vibration effects from pile driving were evaluated against a threshold of 0.2 inches per second peak particle velocity (in/sec PPV) at residential buildings within 70 feet of pile driving sites. As described under Alternative 1A in the Draft EIR/EIS, groundborne vibration from impact pile driving is predicted to exceed vibration thresholds at 102 residential receptors. The effect of exposing sensitive receptors to groundborne vibration would be adverse. Mitigation Measure NOI-2 is available to reduce this effect, but not to a level that would avoid adverse conditions.

Vibration effects from tunneling locomotives and TBMs were evaluated against a threshold of 0.04 in/sec PPV. As described under Alternative 4 in Appendix A of this RDEIR/SDEIS, groundborne vibrations from the TBMs would not exceed 0.008 in/sec PPV and would therefore not result in adverse vibration effects to nearby sensitive receptors. Similarly, tunnel locomotives would be operated at slow speeds inside of tunnels and would not result in excessive vibrations. Groundborne noise from tunnel locomotive operation during construction is therefore not predicted to exceed groundborne noise thresholds or result in an adverse noise impact on sensitive receptors along the tunnel conveyance.

As outlined in Mitigation Measure NOI-2, the potential for tunneling induced ground vibration effects will be thoroughly analyzed in the preliminary and final design phases of the project, using site-specific geotechnical data and the expected TBM configuration. Potential effects on surface structures and human perception will be evaluated in detail during preliminary design. As additional precautions, and where necessary, a ground vibration monitoring program using seismographs and other high-precision equipment will be implemented during construction to ensure ground vibration is within the required contract limits.

CEQA Conclusion*:* Groundborne vibrations during tunneling would not exceed 0.008 in/sec and would therefore be less than significant. Likewise, locomotives are not expected to generate significant noise levels because they will travel at low speeds between 5 and 10 miles per hour. However, the impact of exposing residential structures to groundborne vibration during intake construction would be significant as reasonable worst-case modeling indicates that up to 102 residential parcels could be exposed to vibration levels in excess of 0.2 in/sec PPV during intake pile driving. Although Mitigation Measure NOI-2 will reduce the impact, it is not anticipated that feasible measures will be available in all situations to reduce vibration to levels below the applicable thresholds. This impact would therefore be considered significant and unavoidable.

Mitigation Measure NOI-2: Employ Vibration-Reducing Construction Practices during Construction of Water Conveyance Facilities

Please see Mitigation Measure NOI-2 under Impact NOI-2 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact NOI-3: Exposure of Noise-Sensitive Land Uses to Noise from Operation of Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes, similar to Alternative 1A. Accordingly, the potential for Alternative 2D to expose sensitive land uses to noise from intake pump operations would be similar to Alternative 1A. Since the number of pumps and noise generating equipment at the combined pumping plant would be the same under Alternative 2D as Alternative 4, noise effects from operation of the combined pumping plant would be similar to impacts described under Alternative 4 in Appendix A of this RDEIR/SDEIS. See the discussion of Impact NOI-3 under Alternatives 1A and 4.

NEPA Effects: Operation of pumping equipment at the intakes and combined pumping plant could result in increases in noise levels affecting nearby communities and residences. Noise would also affect onsite workers, although OSHA monitoring requirements would avoid adverse effects to personnel. Accordingly, this analysis focuses exclusively on potential noise effects to noise-sensitive land uses adjacent to the conveyance facilities.

Potential reasonable worst-case pump noise levels generated during operation of the intake and pump structures were evaluated against the 50 dBA L_{max} daytime (7 a.m. to 10 p.m.) and 45 dBA L_{max} nighttime (10 p.m. to 7 a.m.) operational thresholds. As described under Alternative 1A in the Draft EIR/EIS, operational activities would exceed the daytime and nighttime thresholds at noise-sensitive land uses within 1,400 feet and 2,600 feet, respectively, from intake locations. Various residential, recreational, and agricultural receptors would therefore be exposed to adverse noise levels during operation. Operational activities at the combined pumping plant would exceed the nighttime threshold at noise-sensitive land uses within a distance of up to 2,800 feet. Mitigation Measure NOI-3 is available to address this effect.

CEQA Conclusion: The impact of exposing noise-sensitive land uses during operations to noise levels above the daytime (50 dBA L_{max}) or nighttime (45 dBA L_{max}) noise thresholds would be considered significant. Based on reasonable worst-case modeling, various agricultural parcels would be affected by daytime and nighttime noise levels in excess of the operational threshold. Mitigation Measure NOI-3 would reduce operational noise levels below applicable thresholds, thus resulting in a less-than-significant level.

Mitigation Measure NOI-3: Design and Construct Intake Facilities and Other Pump Facilities Such That Operational Noise Does Not Exceed 50 dBA (One-Hour L_{eq}) during

Daytime Hours (7:00 A.M. to 10:00 P.M.) or 45 dBA (One-Hour L_{eq}) during Nighttime Hours (10:00 P.M. to 7:00 A.M.) or the Applicable Local Noise Standard (Whichever Is Less) at Nearby Noise Sensitive Land Uses

Please see Mitigation Measure NOI-3 under Impact NOI-3 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Impact NOI-4: Exposure of Noise-Sensitive Land Uses to Noise from Implementation of Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

The potential for Alternative 2D to expose noise-sensitive land uses to noise from implementation of Environmental Commitments 3, 4, and 6-10 would be similar to, but less than, those described for Alternative 4. See the discussion of Impact NOI-4 under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: Restoration and enhancement activities that require heavy-duty equipment and construction vehicles would generate increases in ambient noise levels. The effect would vary according to the type of construction equipment and techniques used in construction of the specific environmental commitment, the location and timing of the actions called for in the environmental commitment, and the noise environment at the time of implementation.

Alternative 2D would restore up to 17,766 acres of habitat under Environmental Commitments 3, 4, 6-10 as compared with 83,839 acres under Alternative 4. Therefore, the number of noise generation equipment and magnitude of potential noise impacts under Alternative 2D would be smaller than those associated with Alternative 4. Nevertheless, receptors within 1,200 feet of an active restoration work area could be exposed to construction noise in excess of the daytime (7 a.m. to 10 p.m.) noise threshold of 60 dBA L_{eq} (1hr). The nighttime threshold of 50 dBA L_{max} would be exceeded within a distance of 2,800 feet. The effect of exposing sensitive land uses to increases in construction noise levels above thresholds would be adverse. Mitigation Measures NOI-1a and NOI-1b would be available to address this effect, but not to a level that would avoid adverse conditions.

CEQA Conclusion*:* Noise levels during implementation of Environmental Commitments 3, 4, 6-10 are expected to vary according to the type of construction equipment and techniques used, but may exceed the daytime noise threshold within 1,200 feet of an active restoration work area and the nighttime threshold within 2,800 feet. The impact of exposing receptors to noise increases above established thresholds would be significant. Mitigation Measures NOI-1a and NOI-1b, which require noise-reducing construction practices and development of a complaint/response tracking program, would reduce noise impacts on sensitive land uses. However, it is not anticipated that feasible measures will be available in all situations to reduce construction noise to levels below the applicable thresholds. This impact would therefore be considered significant and unavoidable.

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Please see Mitigation Measure NOI-1a under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Please see Mitigation Measure NOI-1b under Impact NOI-1 in the discussion of Alternative 4 in Chapter 23, *Noise*, of the Draft EIR/EIS.

4.4.20 Hazards and Hazardous Materials

Impact HAZ-1: Create a Substantial Hazard to the Public or the Environment through the Release of Hazardous Materials or by Other Means during Construction of the Water Conveyance Facilities

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4 but would include two additional intakes. The nature of the impacts related to hazards and hazardous materials under Alternative 2D would be similar to those impacts described under Alternative 4 in Appendix A of this RDEIR/SDEIS. However, the potential under Alternative 2D to create substantial hazards through release of hazardous materials during construction of conveyance facilities would be somewhat greater than under Alternative 4 because the geographic extent, magnitude and duration of construction under Alternative 2D would be greater due to two additional intakes. Potential effects include routine use of hazardous materials, possible natural gas accumulation in tunnels, contact with existing contaminants, constituents in RTM, effects of electrical transmission lines, conflicts with utilities containing hazardous materials and routine transport of hazardous materials. Due to the intensity, duration and geographical extent of construction activities associated with constructing the water conveyance facilities under this alternative, this would constitute an adverse effect on the physical environment. In addition to Mitigation Measures HAZ-1a, HAZ-1b, UT-6a, UT-6c, and Trans-1a, implementation of SWPPPs, HMMPs, SPCCPs, SAPs, and a Barge Operations Plan would be available to reduce the severity of these effects.

CEQA Conclusion: During construction of the water conveyance facilities, the potential for direct impacts on construction personnel, the public and/or the environment associated with a variety of hazardous physical or chemical conditions under Alternative 2D would be greater than under Alternative 4 because there would be two additional intakes. The nature of the impacts, however, would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. Impacts related to hazards and/or hazardous materials may arise as a result of the intensity and duration of construction activities at the north Delta intakes, forebays and conveyance pipelines and tunnels, and the hazardous materials that would be needed in these areas during construction. Potential hazards include the routine use of hazardous materials (as defined by Title 22 of the California Code of Regulations, Division 4.5); natural gas accumulation in water conveyance tunnels; the inadvertent release of existing contaminants in soil, sediment, and groundwater, or release of hazardous materials from existing infrastructure; disturbance of electrical transmission lines; and hazardous constituents present in RTM. Many of these physical and chemical hazardous conditions would occur in close proximity to the towns of Hood and Courtland during construction of the north Delta intakes. Additionally, the potential would exist for the construction of the water conveyance facilities to indirectly result in the release of hazardous materials through the disruption of existing road, rail, or river hazardous materials transport routes because construction would occur in the vicinity of three hazardous material transport routes, three railroad corridors, and waterways with barge traffic. These impacts are considered significant because the potential exists for substantial hazard to the public or environment to occur related to conveyance facility construction. However, implementation of Mitigation Measures HAZ-1a and HAZ-1b, UT-6a and UT-6c (described in Chapter 20, *Public Services and Utilities,* of the Draft EIR/EIS), and TRANS-1a (described in Chapter 19, *Transportation,* of the Draft EIR/EIS), along with environmental commitments to prepare and implement SWPPPs, HMMPs, SPCCPs, SAPs, and a Barge Operations Plan (described in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS) would reduce these impacts to a less-than-significant level by identifying and describing potential sources of hazardous materials so that releases can be avoided and materials can be properly handled; detailing practices to monitor pollutants and control erosion so that appropriate measures are taken; implementing onsite features to minimize the potential for hazardous materials to be released to the environment; minimizing risk associated with the relocation of utility infrastructure; and coordinating the transport of hazardous materials to reduce the risk of spills.

Mitigation Measure HAZ-1a: Perform Preconstruction Surveys, Including Soil and Groundwater Testing, at Known or Suspected Contaminated Areas within the Construction Footprint, and Remediate and/or Contain Contamination

Please see Mitigation Measure HAZ-1a under Impact HAZ-1 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure HAZ-1b: Perform Pre-Demolition Surveys for Structures to Be Demolished within the Construction Footprint, Characterize Hazardous Materials and Dispose of Them in Accordance with Applicable Regulations

Please see Mitigation Measure HAZ-1b under Impact HAZ-1 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Impact HAZ-2: Expose Sensitive Receptors Located within 0.25 Mile of a Construction Site to Hazardous Materials, Substances, or Waste during Construction of the Water Conveyance Facilities

NEPA Effects: The potential under Alternative 2D to expose sensitive receptors, such as parks, schools and hospitals within 0.25 mile to hazardous materials, hazardous substances or waste during construction would be slightly greater than under Alternative 4 in Appendix A of this RDEIR/SDEIS, because there are two additional intakes under Alternative 2D relative to Alternative 4. Regardless, Alternative 2D would not have an adverse effect on sensitive receptors because no parks or hospitals are located within 0.25 miles of the construction zone and environmental commitments such as SWPPPs, SPCCPs, and HMMPs would be implemented to minimize potential effects on Excelsior Middle School (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS).

CEQA Conclusion: The potential for exposure of sensitive receptors to hazardous substances or conditions under Alternative 2D would be slightly greater than under Alternative 4 (described in Appendix A of this RDEIR/SDEIS). However, like Alternative 4, there are no parks or hospitals located within 0.25 mile of the water conveyance facilities alignment. However, Excelsior Middle School is located within 0.25 mile of a proposed permanent 230 kV transmission line. Additionally, under this alternative, an operable barrier would be constructed at the head of Old River near the Mossdale Village area of Lathrop, adjacent to land designated for public use and which could include future schools or parks. If a school or park were built prior to the completion of construction of the operable barrier, sensitive receptors would be in close proximity to Alternative 2D construction activities, creating the potential for an impact on those types of sensitive receptors. However, no school or park is currently proposed within 0.25 mile of the proposed operable barrier site.

Construction of the 230 kV transmission line would require the routine use of hazardous materials (e.g., fuels, solvents, oil and grease) because heavy machinery such as cranes, off-road work trucks, and dozers would be required. Consequently, there would be the risk of accidental spills and equipment leaks of these types of hazardous materials during construction of the transmission line. However, the quantities of hazardous materials likely to be used during construction activities are likely to be small. Were hazardous materials to be released inadvertently, spills or equipment leaks would be localized and minimal, and thus there would be no risk to anyone not in immediate proximity to these releases. Further, BMPs to minimize the potential for the accidental release of hazardous materials and to contain and remediate hazardous spills, as part of the SWPPPs, SPCCPs, and HMMPs, would be implemented (described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS). Therefore, staff and students at Excelsior Middle School would not be at risk or adversely affected by exposure to hazardous materials, substances, or waste during construction of the water conveyance facilities. This impact would be less than significant because no sensitive receptors within 0.25 mile of a construction zone would be exposed to hazardous materials, substances or waste. No mitigation is required.

Impact HAZ-3: Potential to Conflict with a Known Hazardous Materials Site and, as a Result, Create a Significant Hazard to the Public or the Environment

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4 but would include two additional intakes. The nature of the impacts related to hazards and hazardous materials under Alternative 2D would be similar to those impacts described under Alternative 4 in Appendix A of this RDEIR/SDEIS. However, the potential under Alternative 2D to create conflicts with, or result in exposure to known hazardous material sites during conveyance facility construction would be somewhat greater than under Alternative 4 due to the two additional intakes because the geographic extent, magnitude and duration of construction. However, because there are no known SOCs within the construction footprint of the water conveyance facility of Alternative 2D, there would be no conflict with known hazardous materials sites during construction of the water conveyance facilities, and therefore, no related hazard to the public or the environment. Therefore, there would be no effect. The potential for encountering unknown hazardous materials sites during the course of construction is discussed under Impact HAZ-1.

CEQA Conclusion: The potential under Alternative 2D to create the potential for conflicts with, or result in exposure to known hazardous material sites during conveyance facility construction would be somewhat greater than under Alternative 4 due to the two additional intakes because the geographic extent, magnitude and duration of construction. However, because there are no known SOCs within the construction footprint of the water conveyance facility under this alternative, there would be no conflict with known hazardous materials sites during construction of the water conveyance facilities, and therefore, no related hazard to the public or the environment. Accordingly, there would be no impact. No mitigation is required. The potential for encountering unknown hazardous materials sites during the course of construction is discussed under Impact HAZ-1.

Impact HAZ-4: Result in a Safety Hazard Associated with an Airport or Private Airstrip within 2 Miles of the Water Conveyance Facilities Footprint for People Residing or Working in the Study Area during Construction of the Water Conveyance Facilities

NEPA Effects: The potential for construction of conveyance facilities under Alternative 2D to result in a safety hazard associated with activities within 2.0 miles of an airport or private airstrip is similar to effects described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, because there would be two additional intakes under Alternative 2D relative to Alternative 4, the geographical extent of Alternative 2D is greater. Three private airports (Borges-Clarksburg Airport, Walnut Grove Airport, and Spezia Airport) and one public airport (Byron Airport) are located within 2 miles of the water conveyance facilities for Alternative 2D. The Borges-Clarksburg Airport, located 2 miles northeast of the town of Clarksburg, is within 0.5 miles of a proposed intake work area (Intake 1) and less than one mile from the intake. These are water conveyance feature construction areas where high-profile construction equipment may be used. Walnut Grove and Spezia Airports, on Andrus Island and Tyler Island, respectively, are within 2 miles of the following proposed features or areas: a temporary 69 kV transmission line; a permanent 230 kV transmission line; a RTM area; the tunnel; a tunnel work area; and the main construction shaft for the tunnel. Byron Airport, less than 1.5 miles west of Clifton Court Forebay, is within 2 miles of a proposed 12 kV temporary transmission line; a proposed 230 kV permanent transmission line; and a borrow and/or spoils area. With the exception of the proposed transmission lines, construction of these features or work in these areas would not require the use of high-profile construction equipment. Because construction of the proposed transmission lines would potentially require high-profile equipment (e.g., cranes), and because construction of the 230 kV transmission line would require the use of helicopters during the stringing phase, the safety of air traffic arriving or departing from either of these airports could be compromised during construction of the proposed transmission lines.

This potential for implementation of Alternative 2D to result in a safety hazard associated with an airport or private airstrip within 2 miles of the water conveyance facility is not considered adverse because, as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, as part of an environmental commitment pursuant to the State Aeronautics Act (described in Section 24.2.2.17 in Chapter 24, *Hazards and Hazardous Materials* in Appendix A of this RDEIR/SDEIS), DWR would coordinate with Caltrans' Division of Aeronautics to eliminate any potential conflicts prior to initiating construction and comply with its recommendations based on its investigations and compliance with the recommendations of the OE/AAA (for Byron Airport).

CEQA Conclusion: The potential for construction of conveyance facilities under Alternative 2D to result in a safety hazard associated with activities within 2.0 miles of an airport or private airstrip is similar in nature to impacts described for Alternative 4 in Appendix A of this RDEIR/SDEIS, although there would be two additional intakes relative to Alternative 4 so the geographical extent of Alternative 2D is greater. The use of helicopters for stringing the proposed 230 kV transmission lines and relocating the existing 230 kV and 500 kV transmission lines, and of high-profile construction equipment (200 feet or taller), such as cranes, for installation of pipelines, and potentially pile drivers, such as would be used during the construction of the intakes, have the potential to result in safety hazards to aircraft during takeoff and landing if the equipment is operated too close to runways. Three private airports (Borges-Clarksburg Airport, Walnut Grove Airport, and Spezia Airport) and one public airport (Byron Airport) are located within 2 miles of the water conveyance facilities for Alternative 2D. The Borges-Clarksburg Airport, located 2 miles northeast of the town of Clarksburg, is within 0.5 miles of a proposed intake work area (Intake 1) and less than one mile from the intake.

As described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, as part of an environmental commitment pursuant to the State Aeronautics Act (described in Section 24.2.2.17 in Chapter 24, *Hazards and Hazardous Materials* in Appendix A of this RDEIR/SDEIS), DWR would coordinate with Caltrans' Division of Aeronautics prior to initiating construction and comply with its recommendations based on its investigations and compliance with the recommendations of the OE/AAA (for Byron Airport). These recommendations, which could include limitations necessary to minimize potential problems such as the use of temporary construction equipment, supplemental notice requirements, and marking and lighting high-profile structures, would reduce potential impacts on air safety. This impact would be less than significant because recommendations to avoid conflicts with existing airports located near construction areas would be implemented by DWR prior to construction as required by Caltrans. No mitigation is required.

Impact HAZ-5: Expose People or Structures to a Substantial Risk of Property Loss, Personal Injury or Death Involving Wildland Fires, Including Where Wildlands Are adjacent to Urbanized Areas or Where Residences Are Intermixed with Wildlands, as a Result of Construction, and Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The potential for construction of conveyance facilities under Alternative 2D to result in exposure of people or structures to risks associated with wildfire would be similar to the impacts described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, because there would be two additional intakes under Alternative 2D relative to Alternative 4, the geographical extent of Alternative 2D is greater. Regardless, this potential effect is not adverse because no portion of Alternative 2D is located in or near an area designated as a High or Very High Fire Hazard Severity Zone and measures to prevent and control wildland fires would be implemented by DWR during construction, operation, and maintenance of the water conveyance facilities in full compliance with Cal-OSHA standards for fire safety and prevention.

CEQA Conclusion: The potential for construction of conveyance facilities under Alternative 2D to result in exposure of people or structures to risks associated with wildfire would be similar to the impacts described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, because there would be two additional intakes under Alternative 2D relative to Alternative 4, the geographical extent of Alternative 2D is greater. People or structures would not be subject to a significant risk of loss, injury or death involving wildland fires during construction or operation and maintenance of the water conveyance facilities because the alternative would comply with Cal-OSHA fire prevention and safety standards; DWR would implement standard fire safety and prevention measures as part of an FPCP (described in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS); and because the water conveyance facilities would not be located in a High or Very High Fire Hazard Severity Zone. This impact would be less than significant because conditions do not exist near construction areas that would result in exposure of people or structures to significant risk of exposure to wildfire and DWR would implement standard fire safety and prevention measures. No mitigation is required.

Impact HAZ-6: Create a Substantial Hazard to the Public or the Environment through the Release of Hazardous Materials or by Other Means during Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4 but would include two additional intakes. The nature of the impacts related to hazards and hazardous materials under Alternative 2D would be similar to those impacts described under Alternative 4 in Appendix A of this RDEIR/SDEIS. However, the potential under Alternative 2D to create substantial hazards through release of hazardous materials during maintenance and operation of the water conveyance facilities would be somewhat greater than under Alternative 4 because the geographic extent and magnitude of O&M activities under Alternative 2D would be greater due to two additional intakes.

The Borges-Clarksburg, Walnut Grove, and Spezia Airports (all private air facilities), and the Byron Airport (a public airport), are within 2 miles of the Alternative 2D construction footprint, as discussed under Impact HAZ-1 for this alternative. With the exception of power transmission lines supplying power to pumps, and other equipment used for water conveyance facilities operation and maintenance, water conveyance facilities operations and maintenance are not anticipated to require high-profile equipment (i.e., equipment with a vertical reach of 200 feet or more), the use of which near an airport runway could result in an adverse effect on aircraft. DWR would adhere to all applicable FAA regulations (14 CFR Part 77) and, as part of an environmental commitment pursuant to the State Aeronautics Act (See Appendix 3B, Environmental Commitments in Appendix A of this RDEIR/SDEIS), DWR would coordinate with Caltrans' Division of Aeronautics prior to initiating maintenance activities requiring high-profile equipment to assess whether a site investigation is necessary. If a site investigation is performed, DWR would adhere to Caltrans' recommendations in order to avoid any adverse effects on air safety. Further, compliance with the results of the OE/AAA for Byron Airport would reduce the risk for adverse effects on air traffic safety by implementing recommendations which could include limitations necessary to minimize potential problems, supplemental notice requirements, and marking and lighting high-profile structures.

During routine operation and maintenance of the water conveyance facilities the potential would exist for the accidental release of hazardous materials and other potentially hazardous releases (e.g., contaminated solids and sediment). Accidental hazardous materials releases, such as chemicals directly associated with routine maintenance (e.g., fuels, solvents, paints, oils), are likely to be small, localized, temporary and periodic; therefore, they are unlikely to result in adverse effects on workers, the public, or the environment. Further, BMPs and measures implemented as part of SWPPPs, SPCCPs, SAPs, and HMMPs would be developed and implemented as part of the project, as described under Impact HAZ-1, and in detail as described in Appendix 3B, *Environmental Commitments*, in Appendix A of this RDEIR/SDEIS, which would reduce the potential for accidental spills to occur and would result in containment and remediation of spills should they occur. Solids collected at solids lagoons and sediment dredged during periodic maintenance dredging at the intakes may contain potentially hazardous constituents (e.g., persistent pesticides, mercury, PCBs). Contaminated solids could pose a hazard to the environment if improperly disposed of, which would be an adverse effect. Implementation of Mitigation Measure HAZ-6 (described below) would help ensure that there are no adverse effects on soil, groundwater or surface water due to improperly disposed of lagoon solids. Dewatered solids may require special management to meet discharge/disposal requirements. To ensure that potentially contaminated sediment from maintenance dredging activities at the intakes would not adversely affect soil, groundwater or surface water, a SAP would be implemented prior to any dredging activities, as described under Impact HAZ-1 for this alternative. All sediment would be characterized chemically prior to reuse and/or disposal to ensure that reuse of this material would not result in a hazard to the public or the environment.

CEQA Conclusion: The potential for operation and maintenance of conveyance facilities under Alternative 2D to result in a substantial hazard to the public or environment would be similar to the effects described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, the potential under Alternative 2D to create substantial hazards through release of hazardous materials during maintenance and operation off conveyance facilities would be somewhat greater than under Alternative 4 because the geographic extent and magnitude of O&M activities under Alternative 2D would be greater due to two additional intakes. The accidental release of hazardous materials (including contaminated solids and sediment) to the environment during operation and maintenance of the water conveyance facilities could result in significant impacts on the public and environment. However, implementation of the BMPs and other activities required by SWPPPs, HMMPs, SAPs, SPCCPs, as well as adherence to all applicable FAA regulations (14 CFR Part 77) and, as part of an environmental commitment pursuant to the State Aeronautics Act (See Appendix 3B, *Environmental Commitments* in Appendix A of this RDEIR/SDEIS), coordination/compliance with Caltrans' Division of Aeronautics when performing work with high-profile equipment within 2 miles of an airport would ensure that impacts are reduced to a less-than-significant level. Contaminated solids could pose a hazard to the environment if improperly disposed of, and would be considered a significant impact because of the large volume of sediment/solids that would be handled and the potential for improper disposal. However, implementation of Mitigation Measure HAZ-6, would reduce this impact to a less-than-significant level by requiring sampling and characterizing solids from the solids lagoons to evaluate options to dispose of material at an appropriate, licensed facility.

Mitigation Measure HAZ-6: Test Dewatered Solids from Solids Lagoons Prior to Reuse and/or Disposal

Please see Mitigation Measure HAZ-6 under Impact HAZ-6 in the discussion of Alternative 4.

Impact HAZ-7: Create a Substantial Hazard to the Public or the Environment through the Release of Hazardous Materials or by Other Means as a Result of Implementing Environmental Commitments 3, 4, 6-12, 15 and 16

Effects of Alternative 2D related to the potential for release of hazardous materials from implementing these environmental commitments would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, as described under Section 4.1, *Introduction*, under Alternative 2D the project would restore up to 17,766 acres of habitat under Environmental Commitments 3, 4, 6-10 as compared with 83,800 acres under Alternative 4. Similarly, Environmental Commitment 16 would be implemented only at limited locations. Conservation Measures 13, 14, and 18 would not be implemented as part of this alternative. Therefore, the magnitude of effects under Alternative 2D would likely be smaller than those associated with Alternative 4.

NEPA Effects: Implementation of portions of Environmental Commitments 3, 4, 6-10, 11, 12, 15, and 16 at limited locations could result in multiple potentially hazardous effects related to the release of or exposure to hazardous materials or other hazards including increased production, mobilization and bioavailability of methylmercury; release of existing contaminants (e.g., pesticides in agricultural land); air safety hazards; and wildfires. These effects are considered adverse because of the potential for substantial hazards to occur while constructing restoration actions. However, implementation of Mitigation Measures HAZ-1a, HAZ-1b, UT-6a, UT-6c, and TRANS-1a, as well as activities required by SWPPPs, HMMPs, SAPs, SPCCPs, and fire prevention and fire control BMPs as part of a FPCP (described under Alternative 4 in Chapter 24, *Hazards and Hazardous Materials,* in Appendix A of this RDEIR/SDEIS) are available to reduce/minimize these potential effects.

CEQA Conclusion: The potential for impacts related to the release and exposure of workers and the public to hazardous substances or conditions during construction, operation, and maintenance of Environmental Commitments 3, 4, 6-12, 15, and 16, is considered significant because implementation of these environmental commitments would involve extensive use of heavy equipment during construction and transporting hazardous chemicals during operations and maintenance (e.g., herbicides for nonnative vegetation control). These chemicals could be inadvertently released, exposing construction workers or the public to hazards. Construction of restoration projects on or near existing agricultural and industrial land and/or SOCs may also result in a conflict with or exposure to known hazardous materials, and the use of high-profile equipment (i.e., 200 feet or higher) in close proximity to airport runways could result in safety hazards to air traffic. However in addition to implementation of SWPPPs, HMMPs, SPCCPs, SAPs, and fire prevention and fire control BMPs as part of a FPCP(described in Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS), Mitigation Measures HAZ-1a, HAZ-1b, UT-6a, UT-6c, and TRANS-1a would be implemented to ensure no substantial hazards to the public or the environment would occur from implementation of Environmental Commitments 3, 4, 6-12, 15, and 16 and that impacts would be reduced to a less-than-significant level.

Mitigation Measure HAZ-1a: Perform Preconstruction Surveys, Including Soil and Groundwater Testing, at Known or Suspected Contaminated Areas within the Construction Footprint, and Remediate and/or Contain Contamination

Please refer to Mitigation Measure HAZ-1a under Impact HAZ-1 in the discussion of Alternative 4. Implementation of this mitigation measure will result in the avoidance, successful remediation or containment of all known or suspected contaminated areas, as applicable, within the construction footprint, which would prevent the release of hazardous materials from these areas into the environment.

Mitigation Measure HAZ-1b: Perform Pre-Demolition Surveys for Structures to Be Demolished within the Construction Footprint, Characterize Hazardous Materials and Dispose of Them in Accordance with Applicable Regulations

Please refer to Mitigation Measure HAZ-1b under Impact HAZ-1 in the discussion of Alternative 4. Implementation of this measure will ensure that hazardous materials present in or associated with structures being demolished will not be released into the environment.

Mitigation Measure UT-6a: Verify Locations of Utility Infrastructure

Please see Mitigation Measure UT-6a under Impact UT-6 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure UT-6c: Relocate Utility Infrastructure in a Way That Avoids or Minimizes Any Effect on Worker and Public Health and Safety

Please see Mitigation Measure UT-6c under Impact UT-6 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Mitigation Measure TRANS-1a: Implement Site-Specific Construction Traffic Management Plan

Please see Mitigation Measure TRANS-1a under Impact TRANS-1 in the discussion of Alternative 4 in Appendix A of this RDEIR/SDEIS.

Impact HAZ-8: Increased Risk of Bird–Aircraft Strikes during Implementation of Environmental Commitments that Create or Improve Wildlife Habitat

Effects of Alternative 2D related to the potential for increased risk of aircraft bird strikes from implementing restoration actions that improve wildlife habitat would be similar to those described for Alternative 4 in Appendix A of this RDEIR/SDEIS. However, as described under Section 4.1, *Introduction*, Alternative 2D would restore up to 17,766 acres of habitat under Environmental Commitments 3, 4, and 6-10 as compared with 83,800 acres with Conservation Measures 3–11 under Alternative 4 of the Draft EIR/EIS. Therefore, the magnitude of effects under Alternative 2D would likely be smaller than those associated with Alternative 4.

NEPA Effects: Implementation of Environmental Commitments 3, 4, 6-10 under Alternative 2D could result in an increase of aircraft bird strikes in the vicinity of restoration areas that attract waterfowl and other birds in proximity to local airports. This effect is considered adverse because of the potential to affect aircraft safety in the vicinity of restoration projects. Mitigation Measure HAZ-8 is available to reduce this effect.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6-10, because they would create or improve wildlife habitat, could potentially attract waterfowl and other birds to areas in proximity to existing airport flight zones, and thereby potentially result in an increase in bird-aircraft strikes. The potential for this impact is considered significant because of the increased wildlife restoration projects that could occur in the vicinity of Travis Air Force Base; Rio Vista Municipal Airport; Funny Farm Airport; Sacramento International Airport; and Byron Airport. Mitigation Measure HAZ-8 could reduce the severity of this impact by minimizing bird strike hazards, but this impact would not be reduced to a less-than-significant level because of the inherent uncertainty related to bird strike risks for these future projects. Therefore this impact is significant and unavoidable.

Mitigation Measure HAZ-8: Consult with Individual Airports and USFWS, and Relevant Regulatory Agencies

Please see Mitigation Measure HAZ-8 under Impact HAZ-8 in the discussion of Alternative 4.

4.4.21 Public Health

Impact PH-1: Increase in Vector-Borne Diseases as a Result of Construction and Operation of the Water Conveyance Facilities

NEPA Effects: The potential for Alternative 2D construction and operation of the water conveyance facilities to increase vector-borne diseases would be similar to that for Alternative 4. Like Alternative 4, Alternative 2D will increase surface water within the study area at an intermediate forebay on Glannvale Tract, and at an expanded Clifton Court Forebay; however, unlike Alternative 4, Alternative 2D has five intakes rather than three intakes (Intakes 2, 3, and 5). Therefore, there would be a greater number of sedimentation basins and solids lagoons under Alternative 2D relative to Alternative 4. These features could provide breeding habitat for mosquitos. However, as described for Alternative 4, the depth, design, and operation of the sedimentation basin and solids lagoons would prevent the development of suitable mosquito habitat. Specifically, the basins would be too deep and the constant movement/circulation of water would prevent mosquitoes from breeding and multiplying. It is unlikely that forebays would provide suitable breeding habitat for mosquitoes given that the water in the forebays would not be stagnant and would generally be too deep to support substantial mosquito habitat. Shallow edges of the forebays could provide some suitable mosquito breeding habitat if emergent vegetation or other aquatic plants (e.g., pond weed) were allowed to grow. However, as part of the regular maintenance of these forebay areas, floating vegetation such as pond weed would be harvested to maintain flow and forebay capacity. To further minimize the potential for impacts related to increasing suitable vector habitat within the study area, DWR would consult and coordinate with San Joaquin County and Sacramento-Yolo County MVCDs and prepare and implement MMPs, as necessary, to control mosquitoes and reduce the likelihood that construction and operation of the water conveyance facilities would require an increase in mosquito abatement activities by the local MVCDs (Appendix 3B, Environmental Commitments, in Appendix A of the RDEIR/SDEIS). BMP activities would be consistent with the CDPH's *Best Management Practices for Mosquito Control* plan (described in Section 25.2.3.4 in the Draft EIR/EIS). Accordingly, Alternative 2D would not substantially increase suitable vector habitat, and would not substantially increase vector-borne diseases. No adverse effects on public health would result because conditions for mosquito breeding at conveyance facilities would be minimized and standard practices to control mosquitos would be implemented.

CEQA Conclusion: The potential for construction and operation of conveyance facilities under Alternative 2D to result in an increase in exposure of people to vector-borne diseases would be similar in nature to the impacts described for Alternative 4. However, because Alternative 2D has 2 more intakes and a greater number of associated sedimentation basins and solids lagoons than Alternative 4, there would be more surface water created under this alternative relative to Alternative 4. Alternative 2D conveyance facilities could create new and increased surface water areas (relative to baseline) at the intakes, intermediate forebay, and the expanded Clifton Court Forebay, and these areas have the potential to provide habitat for vectors that transmit diseases (e.g., mosquitoes) because of the large volumes of water that would be held there. However, during operations, the depth, design, and operation of conveyance facilities would prevent the development of suitable mosquito habitat. Specifically, the water bodies would be too deep to provide suitable mosquito habitat, and the constant movement of water would prevent mosquitoes from breeding and multiplying. To minimize the potential for impacts related to increasing suitable vector habitat within the study area, DWR would consult and coordinate with San Joaquin County and Sacramento-

Yolo County MVCDs and prepare and implement MMPs. BMPs to be implemented as part of the MMPs would help control mosquitoes during construction and operation of the sedimentation basins, solids lagoons, the expanded Clifton Court Forebay, the intermediate forebay, and the intermediate forebay inundation area. Therefore, construction and operation of Alternative 2D would not result in a substantial increase in vector-borne diseases in the study area. This impact is considered to be less than significant because conditions for mosquito breeding at conveyance facilities would be minimized and standard practices to control mosquitos would be implemented. No mitigation is required.

Impact PH-2: Exceedances of Water Quality Criteria for Constituents of Concern Such That There Is an Adverse Effect on Public Health as a Result of Operation of the Water Conveyance Facilities

As described in detail in Section 4.4.4, *Water Quality*, of this RDEIR/SDEIS, the analysis of bromide and DOC (among other constituents) for Alternative 2D in the ELT is based on modeling done for Alternative 4 in the ELT timeframe, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. As described in Section 4.1.3, *Description of Alternative 2D*, CM2 would not be implemented as a part of Alternative 2D and Environmental Commitment 4 would restore approximately 65 acres of tidal wetlands, as opposed to the 65,000 acres contemplated under CM4. As such, the assessment of bromide for Alternative 2D relative to Existing Conditions and the No Action Alternative (ELT) likely overestimates potential increases in bromide, particularly in the west Delta. Regardless, there is uncertainty in the results of all quantitative assessments that refer to modeling results, due to the differing assumptions used in the modeling and the description of Alternative 2D and the No Action Alternative (ELT).

NEPA Effects:

Disinfection Byproducts

As described in Section 4.4.4, *Water Quality*, the effects on DOC concentrations in the Delta under Alternative 2D would be similar to Alternative 4. To the extent that habitat restoration actions alter hydrodynamics within the Delta region these effects are included in this assessment. However, there would be less potential for increased DOC concentrations at western Delta locations associated with habitat restoration and enhancement under this alternative because very little restoration/enhancement would occur relative to Alternative 4.

The geographic extent of effects related to long-term average DOC concentrations within Delta waters with water supply operations under Alternative 2D would be less extensive than Alternative 4 and the magnitude of predicted long-term change and relative frequency of DOC concentration exceedances would be lower than Alternative 4. Relative to the No Action Alternative (ELT), Alternative 2D would result in small increases in long-term average DOC concentrations for the modeled 16-year period and drought period at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, and Contra Costa Pumping Plant #1. The increases in average DOC concentrations would correspond to more frequent concentration threshold exceedances, with the greatest change occurring at Contra Costa Pumping Plant #1.

While Alternative 2D would lead to slightly higher long-term average DOC concentrations at some municipal water intakes and Delta interior locations, the predicted change would not be expected to adversely affect MUN beneficial uses, or any other beneficial use. The change in frequency of threshold concentration exceedances at other assessment locations would be similar or lower. In general, substantial change in ambient DOC concentrations would need to occur before significant changes in drinking water treatment plant design or operations are triggered. The increases in long-term average DOC concentrations estimated to occur at various Delta locations under Alternative 2D are of sufficiently small magnitude that they would not require existing drinking water treatment plants to substantially upgrade treatment for DOC removal above levels currently employed. In the LLT, the primary difference will be changes in the Delta source water fractions due to hydrologic effects from climate change and higher water demands. These effects would occur regardless of the implementation of the alternative and, thus, at the LLT the effects of the alternative on DOC are expected to be similar to those described above. Therefore, changes in DOC concentrations in the Delta resulting from operation of the water conveyance facilities under Alternative 2D are not anticipated to contribute to increases in disinfection byproducts (DBPs).

As described in Section 4.4.4, *Water Quality* of the RDEIR/SDEIS, operations and maintenance of the water conveyance facilities under Alternative 2D, relative to the No Action Alternative (ELT), would result in increases in long-term average bromide concentrations in the South Fork Mokelumne River at Staten Island and decrease at all other assessment locations. However, at South Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island there would be an increased frequency of exceedance of the 50 µg/L bromide threshold (the CALFED Drinking Water Program goal) for protecting against the formation of DBPs in treated drinking water. The greatest increase in frequency of exceedance of the 50 µg/L threshold would occur in the South Fork Mokelumne River and Sacramento River at Emmaton. Other locations would increase in the frequency of exceedance of the 50 µg/L and 100 µg/L threshold. The 100 µg/L threshold is the concentration believed to be sufficient to meet currently established drinking water criteria for DBPs. The greatest increase in frequency of exceedance this threshold would occur at Franks Tract. Unlike Alternative 4, there would be no increased bromide concentration or frequency of exceedance of bromide thresholds in Barker Slough at the North Bay Aqueduct under Alternative 2D. As described for Alternative 4, the effects of Alternative 2D in the LLT in the Delta relative to the No Action Alternative (LLT) would be expected to be similar to that described above. There may be higher bromide concentrations in the LLT in the western Delta, but this would be associated with sea level rise, not Alternative 2D, because the primary source of bromide to the Delta is sea water intrusion. The use of seasonal intakes at these locations is largely driven by acceptable water quality, and thus has historically been opportunistic. The opportunity to use these intakes would remain, and the predicted increases in bromide concentrations at Antioch and Mallard Slough would not be expected to adversely affect municipal beneficial uses, or any other beneficial use, at these locations. Therefore, changes in bromide concentrations in the Delta resulting from operation of the water conveyance facilities under Alternative 2D are not anticipated to contribute to increases in DBPs.

Trace Metals

The changes in modeled trace metal concentrations of primarily human health and drinking water concern (arsenic, iron, manganese) in the Delta under Alternative 2D would be similar to those described for Alternative 4A (see Draft BDCP EIR/EIS, Chapter 8, *Water Quality,* Section 8.3.3.9) because the factors that would affect trace metal concentrations in Delta waters would be the same in the ELT and LLT.

The arsenic criterion was established to protect human health from the effects of long-term chronic exposure, while secondary MCLs for iron and manganese were established as reasonable federal regulatory goals for drinking water quality, and enforceable standards in California. Average concentrations for arsenic, iron, and manganese in the primary source water (Sacramento River, San Joaquin River, and the bay at Martinez) are below these criteria. No mixing of these three source waters could result in a metal concentration greater than the highest source water concentration, and, given that the modeled average water concentrations for arsenic, iron, and manganese do not exceed water quality criteria, more frequent exceedances of drinking water criteria in the Delta would not be an expected result under this alternative. Accordingly, no adverse effect on public health related to the trace metals arsenic, iron, or manganese from drinking water sources is anticipated.

Pesticides

The changes in modeled pesticide concentrations in the Delta under Alternative 2D would be similar to those described for Alternative 4. The average winter and summer flow rates, relative to the No Action Alternative (ELT) are expected to be similar to or less than changes in flow rates under Alternative 4 in the Sacramento River at Freeport, American River at Nimbus, Feather River at Thermalito and the San Joaquin River at Vernalis. The main factor influencing pesticide concentrations in Delta waters (i.e., changes in San Joaquin River, Sacramento River and Delta Agriculture source water fractions at various Delta locations, including Banks and Jones pumping plants) is expected to change by a similar degree. As described in Section 4.4.4, *Water Quality,* of the RDEIR/SDEIS, the percent change in monthly average source water fractions under Alternative 2D would be similar to changes expected under Alternative 4. Modeled changes in the source water fractions of Sacramento River, San Joaquin River, and Delta agriculture water under Alternative 2D would not be of sufficient magnitude to substantially alter beneficial uses of the Delta. Therefore, it is not anticipated that there would be adverse effects on public health related to pesticides from drinking water sources.

Because there would be no increases in DBPs due to increases in bromide or DOC in Delta surface waters, and because the modeled changes in trace metals and pesticide concentrations would not increase substantially in magnitude or frequency in the Delta under Alternative 2D relative to the No Action Alternative (ELT and LLT), there would be no adverse effect on public health as a result of operation of the water conveyance facilities.

CEQA Conclusion: Under Alternative 2D, modeled long-term average pesticide levels in the Delta would be similar to or slightly less that described under Alternative 4 and would not be expected to increase substantially, relative to Existing Conditions, such that beneficial use impairments are made measurably worse. Long-term average bromide concentrations would increase in the South Fork Mokelumne River at Staten Island and decrease at all other assessment locations relative to Existing Conditions. However, there would be an increased frequency of exceedance of the 50 μg/L and 100 μg/L bromide thresholds for protecting against the formation of DBPs in treated drinking water at the South Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. The effects of Alternative 2D in the LLT in the Delta relative to Existing Conditions would be expected to be similar. There may be higher bromide concentrations in the LLT in the western Delta, but this would be associated with sea level rise, not the project alternative, because the primary source of bromide to the Delta is sea water intrusion. The use of seasonal intakes at Antioch and Mallard Island is largely driven by acceptable water quality, and therefore has historically been opportunistic, and the opportunity to use these intakes would remain. Thus, the increased bromide concentrations would not be expected to adversely affect municipal beneficial uses, or any other beneficial use, at these locations, and therefore would not be expected to contribute substantially to

DBP formation. Operations and maintenance activities under Alternative 2D would not cause a substantial long-term change in DOC concentrations in the Delta, although there would be relatively small increases in long-term average DOC concentrations at some interior Delta locations. However, the increases are of sufficiently small magnitude that they would not require existing drinking water treatment plants to substantially upgrade treatment for DOC above levels currently employed, and therefore these increases would not be expected to contribute substantially to DBP formation. Further, there would be predicted improvements in long-term average DOC concentrations at Barker Slough relative to Existing Conditions. Average concentrations of trace metals are not expected to increase substantially under Alternative 2D in the primary source water. Therefore, this alternative is not expected to cause additional exceedances of applicable water quality objectives by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment.

Because there would be no increases in DBPs due to increases in bromide or DOC in Delta surface waters, and because the modeled changes in trace metals and pesticide concentrations would not increase substantially in magnitude or frequency in the Delta with implementation of water supply operations under Alternative 2D relative to Existing Conditions, there would be no significant impact on public health as a result of operation of the water conveyance facilities. No mitigation is required.

Impact PH-3: Substantial Mobilization of or Increase in Constituents Known to Bioaccumulate as a Result of Construction, Operation or Maintenance of the Water Conveyance Facilities

NEPA Effects: As described in Section 4.4.4, *Water Quality*, of the RDEIR/SDEIS, modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 2D would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance.

Five intakes would be constructed and operated under Alternative 2D. Sediment-disturbing activities during construction and maintenance of these intakes and other water conveyance facilities proposed near or in surface waters under this alternative could result in the disturbance of existing constituents in sediment, such as pesticides or methylmercury. In-channel construction activities, such as pile driving during the construction of cofferdams at the intakes and pier construction at the barge unloading facilities, which would occur over a period of 5 months, would result in the localized disturbance of river sediment. In addition, maintenance of the five proposed north Delta intakes and the intermediate forebay would entail periodic dredging for sediment removal at these locations. Sediment accumulation in both the northern and southern portion of the expanded Clifton Court Forebay is expected to be minimal in the ELT period as the need for dredging is anticipated to be every 50 years given the design. However, it is anticipated that there may be some sediment accumulation at the inlet structure of the northern portion of Clifton Court Forebay. Therefore, while overall sediment accumulation in this forebay is not expected to be substantial, some dredging may be required at the inlet structure to maintain an even flow path.

Pesticides

Legacy pesticides, such as organochlorines, have low water solubility; they do not readily volatilize and have a tendency to bond to particulates (e.g., soil and sediment), settle out into the sediment, and not be transported far from the source. If present in sediment within in-water construction areas, legacy pesticides would be disturbed locally and would not be expected to partition into the water column to any substantial degree. Therefore, no significant adverse effect on public health would result from construction.

Numerous pesticides are currently used throughout the affected environment. While some of these pesticides may be bioaccumulative, those present-use pesticides for which there is sufficient evidence of their presence in waters affected by SWP and CVP operations (i.e., organophosphate pesticides, such as diazinon, chlorpyrifos, diuron, and pyrethroids) are not considered bioaccumulative. Thus, changes in their concentrations would not directly cause bioaccumulative problems in aquatic life or humans. The effects of Alternative 2D on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions and the No Action Alternative (ELT) would be similar to or slightly less than those described for the Alternative 4. Alternative 2D would not result in increased tributary flows that would mobilize organochlorine pesticides in sediments. Thus, the change in source water in the Delta associated with the change in water supply operations is not expected to adversely affect public health with respect to bioaccumulation of pesticides.

Methylmercury

If mercury is sequestered in sediments at water facility construction sites, it could become suspended in the water column during construction activities, opening up a new pathway into the food chain. Construction activities (e.g., pile driving and cofferdam installation) at intake sites or barge landing locations would result in a localized, short-term resuspension of sediment and an increase in turbidity that may contain elemental or methylated forms of mercury. Please see Chapter 8, Section 8.1.3.9, *Mercury,* in Appendix A of the RDEIR/SDEIS for a discussion of methylmercury concentrations in sediments.

Changes in methylmercury concentrations under Alternative 2D are expected to be small. As described in Section 4.4.4, *Water Quality,* the greatest annual average methylmercury concentration for drought conditions under Alternative 2D would be 0.166 ng/L for the San Joaquin River at Buckley Cove, which would be slightly lower than the No Action Alternative (ELT) (0.168 ng/L). Fish tissue estimates show only small or no increases for mercury concentrations relative to the No Action Alternative (ELT) based on long-term annual average concentrations in the Delta. Mercury concentrations in fish tissue expected for Alternative 2D (with Equation 1), show increases of 9 percent or less, relative to the No Action Alternative (ELT), in all modeled years. Mercury concentrations in fish tissue expected for Alternative 2D (with Equation 2), are estimated to increase 13 percent at Staten Island relative to the No Action Alternative (ELT), in all modeled years. Because these increases are relatively small, and because it is not apparent that substantive increases are expected throughout the Delta, these estimated changes in mercury concentrations in fish tissue under Alternative 2D are expected to be within the uncertainty inherent in the modeling approach and would not likely be measureable in the environment. See Appendix 8I, *Mercury*, of the Draft EIR/EIS for a discussion of the uncertainty associated with fish tissue estimates of mercury. Therefore, modeled changes in mercury in the Delta and in fish tissues due to operation of Alternative 2D would not be expected to adversely affect public health.

In summary, operation of the water conveyance facilities under Alternative 2D would not alter bioaccumulative pesticide concentrations or mercury concentrations in the Delta such that there would be an effect on public health. As such, there would be no adverse effect.

CEQA Conclusion: Relative to Existing Conditions, operation of the water conveyance facilities under Alternative 2D is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because mercury concentrations are not expected to increase substantially relative to the Existing Conditions, no long-term water quality degradation is expected to occur and, thus, no adverse effects to beneficial uses would occur. As described in Section 4.4.4, *Water Quality*, concentrations of mercury in fish tissue using Equation 1 under Alternative 2D, would increase 9 percent or less in all years relative to the Existing Conditions. Using Equation 2, there would be increases from 10 percent to 13 percent in Mokelumne River (South Fork) at Staten Island, Old River at Rock Slough, and San Joaquin River at Antioch relative to Existing Conditions in all years. Because these increases are relatively small, and because it is not apparent that substantive increases are expected throughout the Delta, these estimated changes in mercury concentrations in fish tissue under Alternative 2D are expected to be within the uncertainty inherent in the modeling approach and would not likely be measureable in the environment. Construction activities (e.g., pile driving and cofferdam installation) at intake sites or barge landing locations would result in a localized, short-term resuspension of sediment and an increase in turbidity that may contain elemental or methylated forms of mercury.

The effects of Alternative 2D on bioaccumulative pesticide levels in the Delta would be similar to or slightly less than those described for the Alternative 4. Alternative 2D would not result in increased tributary flows that would mobilize organochlorine pesticides in sediments. Thus, the change in source water in the Delta associated with the change in water supply operations is not expected to adversely affect public health with respect to bioaccumulation of pesticides. If present in sediment within in-water construction areas, legacy pesticides would be disturbed locally and would not be expected to partition into the water column to any substantial degree.

For these reasons, there would be no significant impact on public health due to mercury or bioaccumulative pesticides as a result of construction of or operation of the water conveyance facilities under Alternative 2D. No mitigation is required.

Impact PH-4: Expose Substantially More People to Transmission Lines Generating New Sources of EMFs as a Result of the Construction and Operation of the Water Conveyance Facilities

NEPA Effects: The potential for Alternative 2D transmission line construction and operation to expose people to new sources of EMFs would be somewhat larger than Alternative 4 because there would be more facilities requiring power (i.e., intakes) under Alternative 2D. As described for Alternative 4, this effect would not be adverse because transmission lines would generally not be located in populated areas or within 300 feet of sensitive receptors and CPUC's EMF design guidelines would be implemented for any new temporary or new permanent transmission lines constructed and operated under Alternative 2D.

CEQA Conclusion: The potential for Alternative 2D transmission line construction and operation to expose people to new sources of EMFs would be somewhat larger relative to Alternative 4 because there would be more facilities requiring power (i.e., intakes) under Alternative 2D. Under this alternative the majority of proposed temporary (69 kV and 230 kV) and permanent (230 kV) transmission lines would be located within the rights-of-way of existing transmission lines; any new temporary or permanent transmission lines not within the right-of-way of existing transmission lines would, for the most part, be located in sparsely populated areas generally away from existing sensitive receptors. None of the proposed temporary or permanent transmission lines would be within 300 feet of sensitive receptors. Further, the temporary transmission lines would be removed when construction of the water conveyance facility features is completed, so there would be no potential permanent effects. Therefore, these transmission lines would not substantially increase people's exposure to EMFs. This impact is considered to be less than significant because transmission lines would generally not be located in populated areas or within 300 feet of sensitive receptors and CPUC's EMF design guidelines would be implemented for any new temporary or permanent transmission lines constructed and operated under Alternative 2D. No mitigation is required.

Impact PH-5: Increase in Vector-Borne Diseases as a Result of Implementing Environmental Commitments 3, 4, 6, 7, 10 and 11

Effects of Alternative 2D related to the potential for increase in vector-borne diseases from implementing Environmental Commitments 3, 4, 6, 7, 10, and 11 would be slightly greater than described for Alternative 4A. As described under Section 4.1.3, *Description of Alternative 2D*, Alternative 2D would restore more habitat under these Environmental Commitments relative to Alternative 4A and, therefore, the potential for vector-borne disease effects under Alternative 2D would likely be greater than the potential associated with Alternative 4A.

NEPA Effects: Implementation of portions of Environmental Commitments 3, 4, 6, 7, 10, and 11 under Alternative 2D would involve protecting and restoring wetland and other surface water habitat that could potentially increase suitable mosquito habitat within the study area. This potential effect would not be adverse because the total restoration acreage of these types of habitat implemented under Alternative 2D would generally not be located near densely populated areas, and management plans under Environmental Commitment 11, *Natural Communities Enhancement and Management*, would be implemented in consultation with the appropriate MVCDs to ensure MMPs are implemented to reduce mosquito breeding. Additionally, BMPs from the guidelines outlined in Appendix 3B, *Environmental Commitments*, of the Draft BDCP EIR/EIS, would be incorporated into Alternative 2D and executed to maintain proper water circulation and flooding during appropriate times of the year (e.g., fall) to prevent stagnant water and habitat for mosquitoes. This consultation would occur when specific restoration and enhancement projects and locations are identified.

CEQA Conclusion: The potential for impacts related to increases of vector-borne disease from mosquitos during construction, operation, and maintenance of portions of Environmental Commitment 3, 4, 6, 7, 10, and 11 under Alternative 2D is considered less than significant because the total restoration acreage of wetland and other surface water areas implemented under this alternative would generally not be located near densely populated areas, and management plans under Environmental Commitment 11, *Natural Communities Enhancement and Management*, would be implemented in consultation with the appropriate MVCDs to ensure MMPs are implemented to reduce mosquito breeding. Additionally, BMPs from the guidelines outlined in Appendix 3B, *Environmental Commitments*, of the Draft BDCP EIR/EIS, would be incorporated and executed to maintain proper water circulation and flooding during appropriate times of the year (e.g., fall) to prevent stagnant water and habitat for mosquitoes. No mitigation is required.

Impact PH-6: Substantial Increase in Recreationists' Exposure to Pathogens as a Result of Implementing the Restoration Environmental Commitments

Effects of Alternative 2D related to the potential for increase in recreationists' exposure to pathogens from implementing portions of the restoration environmental commitments would be slightly greater than those described for Alternative 4A. As described under Section 4.1.3, *Description of Alternative 2D*, Alternative 2D would restore more acres of habitat under Environmental Commitments 3, 4, 6, 7, and 9–11 relative to Alternative 4A.

NEPA Effects: The study area currently supports habitat types, such as tidal habitat, upland wetlands, and agricultural lands that produce pathogens as a result of the biological productivity in these areas (e.g., migrating birds, application of fertilizers, waste products of animals). The study area does not currently have pathogen concentrations that rise to the level of adversely affecting beneficial uses of recreation. However, any potential increase in pathogens associated with the proposed habitat restoration and enhancement environmental commitments under Alternative 2D would be localized and within the vicinity of the actual restoration. This localized increase is not expected to be of sufficient magnitude and duration to result in adverse effects on recreationists because these areas would generally not support livestock and most areas would not have public access.

CEQA Conclusion: The potential for an increase in recreationists' exposure to pathogens under Alternative 2D is considered less than significant because of the localized nature of pathogens and because the rapid die-off of pathogens in water would not create sufficient magnitudes of pathogen generation that could affect recreational beneficial uses. No mitigation is required.

Impact PH-7: Substantial Mobilization of or Increase in Constituents Known to Bioaccumulate as a Result of Implementing Environmental Commitments 4 and 10

Effects of Alternative 2D related to the potential to mobilize contaminants known to bioaccumulate (pesticides and methylmercury) from implementing portions of the restoration environmental commitments would be slightly greater than those described for Alternative 4A. As described in Section 4.1.3, *Description of Alternative 2D,* Alternative 2D would restore more habitat under Environmental Commitments 4 and 10 relative to Alternative 4A. Therefore, the potential for mobilization of contaminants under Alternative 2D would likely be greater than the potential associated with Alternative 4A.

NEPA Effects: The primary concern with habitat restoration regarding constituents known to bioaccumulate is the potential for mobilizing contaminants sequestered in sediments of the newly inundated floodplains and marshes. The mobilization depends on the presence of the constituent and the biogeochemical behavior of the constituent to determine whether it could re-enter the water column or be reintroduced into the food chain. This potential effect would not be adverse because the total tidal and nontidal habitat restoration acreage implemented under Alternative 2D would be relatively small, bioaccumulation of pesticides and/or methylmercury in these restoration areas is not expected to substantially affect public health because of the limited extent of this type of restored habitat under Alternative 2D, the localized nature of pesticide bioaccumulation, and because current OEHHA standards would be enforced. Implementation of Environmental Commitment 12, *Methylmercury Management*, would be implemented to reduce methylmercury production in restored habitats.

CEQA Conclusion: The potential for public health impacts related to mobilization of pesticides and methylmercury in habitat restoration areas related to Environmental Commitments 4 and 10 is considered less than significant because the total tidal and nontidal restoration acreage implemented under Alternative 2D would be relatively small, bioaccumulation of pesticides and/or methylmercury in the these restoration areas is not expected to substantially affect public health because of the limited extent of restored habitat under Alternative 2D, the localized nature of pesticide bioaccumulation, and because current OEHHA standards would be enforced. Environmental Commitment 12, *Methylmercury Management*, would be implemented to reduce methylmercury production in restored habitats. No mitigation is required.

Impact PH-8: Increase in *Microcystis* Bloom Formation as a Result of Operation of the Water Conveyance Facilities.

NEPA Effects: Any modified reservoir operations under Alternative 2D are not expected to promote *Microcystis* production upstream of the Delta relative to the No Action Alternative (ELT and LLT) since large reservoirs upstream of the Delta are typically low in nutrient concentrations, as described in Section 4.4.4, *Water Quality*. Further, in the rivers and streams of the Sacramento River watershed, watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), and the San Joaquin River upstream of the Delta, bloom development would be limited by high water velocity and low hydraulic residence times. These conditions would not be expected to change under Alternative 2D relative to the No Action Alternative (ELT and LLT)

With implementation of water supply operations under Alternative 2D, conditions in the Export Service Areas are not expected to become more conducive to *Microcystis* bloom formation relative to the No Action Alternative (ELT and LLT) because the fraction of water flowing through the Delta that would reach the existing south Delta intakes is not expected to be adversely affected by *Microcystis* blooms.

As indicated in Section 4.4.4, *Water Quality,* of this RDEIR/SDEIS, there was not modeling available that adequately accounted for the effects of operation of the water conveyance facilities and the hydrodynamic impacts of the environmental commitments on long-term average residence times in the Delta for Alternative 2D. Accordingly, the hydrodynamic effects of Alternative 2D on *Microcystis* were determined qualitatively and the effects discussed for the Delta are related entirely to operations and maintenance and not the hydrodynamic effects of the restoration actions. Although there is uncertainty, water supply operations under Alternative 2D are not expected to increase water residence times or ambient water temperatures throughout the Delta, including Banks and Jones pumping plants, relative to the No Action Alternative (ELT and LLT), and therefore Delta waters are not expected to be adversely affected by *Microcystis* blooms.

CEQA Conclusion: Relative to Existing Conditions, operation of the water conveyance facilities under Alternative 2D is not expected to promote *Microcystis* bloom formation in the reservoirs and watersheds upstream of the Delta because large reservoirs upstream are typically low in nutrient concentrations, and high water velocity and low hydraulic residence times in the upstream area limit the development of *Microcystis* blooms.

The potential for *Microcystis* blooms in the Export Service Areas under Alternative 2D would be less than under Alternative 4, but source waters to the south Delta intakes could be affected by *Microcystis* due to an increase in Delta water temperatures associated with climate change and from an increase in water residence times. The impacts from increased water residence times in the Delta would be mostly related to tidal habitat restoration and improvements to the Yolo Bypass, which are assumed to occur separate from Alternative 2D, as well as to climate change and sea level rise. The combined effect of these factors on increasing *Microcystis* in source waters to the south Delta intakes would likely be a greater influence than that of Alternative 2D operations.

Water supply operations under Alternative 2D could result in localized increases in Delta residence times in some locations and decreased residence times in other Delta locations. As indicated in Section 4.4.4, *Water Quality,* of this RDEIR/SDEIS, there is substantial uncertainty regarding the extent that Alternative 2D operations and maintenance would result in a net increase in water residence times relative to Existing Conditions. Regardless of this uncertainty, it is likely that these potential effects under Alternative 2D would be relatively small compared to the combined effects of tidal habitat restoration and Yolo Bypass improvements unrelated to Alternative 2D, and sea level rise and climate change. Climate change in the ELT is expected to result in a 1.3-2.5°F increase in ambient Delta water temperatures relative to Existing Conditions. The combined effects of restoration activities unrelated to Alternative 2D, climate change, and sea level rise on increased water residence time, as well as the effects of climate change on Delta water temperatures, it is possible that *Microcystis* blooms in the Delta would increase in frequency, magnitude, and geographic extent, relative to Existing Conditions. However, although there is considerable uncertainty regarding this impact, the effects on *Microcystis* due to operations under Alternative 2D would be less than significant. No mitigation is required.

Impact PH-9: Increase in *Microcystis* Bloom Formation as a Result of Implementing Environmental Commitment 4.

Effects related to *Microcystis* from implementation of Environmental Commitment 4 under Alternative 2D would be the nearly the same as those described for Alternative 4A because the acreages of tidal natural communities restored under this alternative (65 acres) is nearly the same as under Alternative 4A (59 acres).

NEPA Effects: Under Alternative 2D, Yolo Bypass Fisheries Enhancement would not occur, unlike under Alternative 4. However, improvements in the Yolo Bypass, as well as restoration of 8,000 acres of tidal habitat, would be implemented under a plan separate and distinct from Alternative 2D (see Section 4.1.3, *Description of Alternative 2D*, of this RDEIR/SDEIS). These activities are assumed to occur under both Alternative 2D and the No Action Alternative. Similar to Alternative 4 (under CM 4), there would be tidal habitat restoration in the Delta under Alternative 2D with implementation of Environmental Commitment 4. However, the 65 acres of tidal habitat restored under this alternative would be substantially fewer than under Alternative 4. As discussed in Section 4.4.4, *Water Quality,* of this RDEIR/SDEIS, implementation of Environmental Commitment 4 under Alternative 2D would have negligible effects in terms of the potential for creating conditions conducive to *Microcystis* bloom in the Delta relative to what could result from the development of 8,000 acres of tidal habitat and improvements in the Yolo Bypass in the ELT, which could increase water temperatures and hydraulic residence times relative to the No Action Alternative (LLT). Therefore, implementation of Environmental Commitment 4 under Alternative 2D would not be adverse because it would not increase *Microcystis* bloom formation.

CEQA Conclusion: Implementation of Environmental Commitment 4 (*Tidal Natural Communities Restoration*) under Alternative 2D would result in 65 acres of tidal restoration within the Delta. This would have a negligible effect on creating conditions conducive to *Microcystis* bloom formation, particularly relative to the development of 8,000 acres of tidal habitat and improvements to the Yolo Bypass in the ELT—activities separate and distinct from Alternative 2D. These activities would create shallow backwater areas that could result in a measureable increase in water temperatures and water residence times in the Delta, and therefore *Microcystis*, relative to Existing Conditions. Thus, implementation of Environmental Commitment 4 under Alternative 2D would be less than significant. No mitigation is required.

4.4.22 Minerals

Impact MIN-1: Loss of Availability of Locally Important Natural Gas Wells as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: Alternative 2D would include the same physical/structural components as Alternative 4, described in Appendix A of this RDEIR/SDEIS, with the addition of two river intakes. The configuration of river intakes would be similar to Alternative 1A, described in the Draft EIR/EIS. There are no producing wells within the construction footprint, the temporary construction work areas, or the east-west transmission line alignment option.

Because no producing wells within the construction footprint would be affected, construction of Alternative 2D would not reduce natural gas production in the study area. Alternative 2D would not affect any locally important natural gas wells or result in the loss of any portion of the study area's natural gas production.

CEQA Conclusion: Because no natural gas wells occur in the Alternative 2D water conveyance facility footprint, there would be no change in the number of active natural gas wells or natural gas production. The construction of Alternative 2D would not impact natural gas wells or gas production. No mitigation is required.

Impact MIN-2: Loss of Availability of Extraction Potential from Natural Gas Fields as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: The extent of the construction and permanent footprints of the water conveyance facilities and resulting loss of extraction potential from natural gas fields under Alternative 2D would be the same as described under Alternative 4 in Appendix A of this RDEIR/SDEIS. Constructing the water conveyance facilities would permanently reduce the land surface available for vertical extraction of natural gas from directly underlying gas fields; however most of the affected gas fields could be accessed from other overlying areas. Similarly, effects on potential gas extraction resulting from construction work areas would be small and temporary and would not prevent recovery of natural gas. Therefore, there would be no short or long-term adverse effect on the potential to extract natural gas as a result of constructing the water conveyance facilities.

CEQA Conclusion: Although the Alternative 2D conveyance facilities would reduce the land surface available for vertical extraction of natural gas from underlying gas fields, the proportion of these gas fields affected would be small (less than approximately 3% of the areal extent of natural gas field areas intersected). Additionally, there would be no substantial loss of existing production or permanent loss of access to the resource because the gas fields would continue to be accessible using conventional or directional drilling techniques. The impact is less than significant because the potential to extract natural gas would not be substantially reduced. No mitigation is required.

Impact MIN-3: Loss of Availability of Locally Important Natural Gas Wells as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation and maintenance of the water conveyance facilities under Alternative 2D would be similar to those under Alternative 4, described in Appendix A of this RDEIR/SDEIS, and would include moving water through the new water conveyance infrastructure and in natural channels. These operations would not cause additional effects on natural gas wells beyond those occurring as a result of constructing the water conveyance facilities. Maintenance of these facilities under Alternative 2D would be similar but slightly greater as discussed for Alternative 4. Operation and maintenance activities would occur on or immediately adjacent to the water conveyance facilities. Accordingly, the operation and maintenance associated with the water conveyance facilities would not restrict access to or use of existing active wells. There would be no adverse effect on natural gas wells from operating or maintaining Alternative 2D.

CEQA Conclusion: The operation and maintenance of water conveyance facilities under Alternative 2D would have no impact on access to natural gas wells because operation and routine maintenance such as painting, cleaning, repairs, levee and landscape maintenance and similar activities would occur on or immediately adjacent to the facilities and would not require the abandonment of wells, eliminate access to wells, or reduce natural gas production. Therefore, the impact on natural gas wells would be less-than-significant. No mitigation is required.

Impact MIN-4: Loss of Availability of Natural Gas Fields as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 2D would be same as Alternative 2A and would include moving water through the new water conveyance infrastructure and in natural channels. These operations would not cause additional effects on access to natural gas fields beyond those occurring as a result of constructing the water conveyance facilities. Maintenance of the water conveyance facilities under Alternative 2D would be similar but slightly greater than as discussed for Alternative 4 in Appendix A of this RDEIR/SDEIS. Operation and maintenance activities would occur on or immediately adjacent to the water conveyance facilities and as such would not restrict access to or use of existing natural gas fields. There would be no adverse effect on natural gas fields from operating or maintaining Alternative 2D.

CEQA Conclusion: The operation and maintenance of Alternative 2D water conveyance facilities would have no impact on the access to natural gas fields because operation and routine maintenance such as painting, cleaning, repairs, levee and landscape maintenance and similar activities would occur on or immediately adjacent to the facilities. The impact on the availability of natural gas fields is considered less than significant because access to these fields would not be restricted when operation and maintenance of the water conveyance facilities is occurring. No mitigation is required.

Impact MIN-5: Loss of Availability of Locally Important Natural Gas Wells as a Result of Implementing Environmental Commitments 3, 4, 6-12, 15 and 16

The type of effects on locally important natural gas wells associated with Environmental Commitments, 4, 6–12, 15, and 16 would be similar to those described for Alternative 4, described in Appendix A of this RDEIR/SDEIS. However, as described under Section 4.1.3, *Description of Alternative 2D*, of this RDEIR/SDEIS, Environmental Commitments occurring under Alternative 2D would affect much less land within the project area when compared to Alternative 4. Therefore, the magnitude of effects of Alternative 2D on mineral resources within the project area would be smaller than those disclosed under Alternative 4 in Appendix A of this RDEIR/SDEIS.

NEPA Effects: Because locations for these activities have not been determined, the extent of the effect of implementing restoration actions on locally important natural gas wells can only be estimated. It is anticipated that implementing the environmental commitments under Alternative 2D would result in adverse effects on locally important natural gas wells however to a lesser degree than under Alternative 4 because much less land would be restored. Similar to Alternative 4, natural gas wells located in areas that would be permanently inundated could remain productive with the use of protective cages or platforms. However, for those instances, modification and maintenance of wells may not be cost effective. It is likely that any producing wells in proposed permanent inundation areas would need to be abandoned because modifications to these wells would not be feasible.

The number of active wells directly affected would vary, depending on the specific lands inundated by the environmental commitments. The active wells that would be affected could be maintained in place if they were only seasonally inundated. In permanently flooded areas, the active wells could be replaced using conventional or directional drilling techniques at a location outside the inundation zone to maintain production. The likelihood of this replacement would depend on the availability of land for lease and the cost of the new construction. If a large number of wells had to be abandoned and could not be re-drilled, there could be a locally adverse effect related to permanent elimination of a substantial portion of a county's active natural gas wells. Mitigation Measure MIN-5 is available to address this effect.

Natural gas wells in upland areas could remain operational and unaffected if they are avoided when restoration activities are implemented and access to the gas well can be maintained. Maintaining access to an oil or gas well is defined by DOC as (1) maintaining rig access to the well, and (2) not building over, or in close proximity to, the well (California Department of Conservation, Division of Oil, Gas, and Geothermal Resources 2007).

CEQA Conclusion: Although the number of natural gas wells likely to be affected may be a small percentage of the total wells in the study area, and some wells may be relocated using conventional or directional drilling, there is potential to affect a significant number of locally important gas wells. Consequently, this impact is considered significant. Because implementation of Mitigation Measure MIN-5 cannot assure that all or a substantial portion of a county's existing natural gas wells will remain accessible after implementation of this alternative, this impact is significant and unavoidable.

Mitigation Measure MIN-5: Design Environmental Commitments 4 and 10 to Avoid Displacement of Active Natural Gas Wells to the Extent Feasible

During final design of Environmental Commitments 4 and 10, the project proponents will avoid permanent inundation of or construction over active natural gas well sites where feasible to minimize the need for well abandonment or relocation.

Impact MIN-6: Loss of Availability of Extraction Potential from Natural Gas Fields as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Because locations of restoration actions occurring under Alternative 2D have not been determined, the extent of the effect of implementing these actions on natural gas fields within the project area can only be estimated. It is anticipated that restoration actions occurring under Alternative 2D would result in adverse effects on the potential to extract natural gas from these fields although to a lesser degree than under Alternative 4 because less land would be restored. Similar to Alternative 4, described in Appendix A of this RDEIR/SDEIS, some natural gas fields could be permanently inundated resulting in potential losses in production. However, most natural gas fields would still be accessible from outside the inundated areas using either conventional or directional drilling, although feasibility of access would depend on the exact configuration of inundation and the availability of adjacent drilling sites. Although the overall extent of affected natural gas fields in the region is low, there remains the potential for a locally adverse effect on access to natural gas fields because the resource may be permanently inundated or otherwise become inaccessible to recovery. Mitigation Measure MIN-6 is available to lessen this effect.

CEQA Conclusion: The areal extent of lands overlying study area natural gas fields that would be inundated as a result of restoration actions cannot be precisely determined because the final locations for these measures have not been established. Most of these natural gas fields would still be accessible from outside inundated areas using either conventional or directional drilling, although feasibility of access would depend on the exact configuration of the restoration sites the availability of adjacent drilling sites. Although the overall extent of affected natural gas fields in the region is low to moderate, there is potential for a locally significant impact on access to natural gas fields if they are permanently covered (inundated) such that the resource cannot be recovered. Implementation of Mitigation Measure MIN-6 would reduce this impact, but not to a less-than-significant level. Because implementation of Mitigation Measure MIN-6 cannot assure that all or a substantial portion of existing natural gas fields will remain accessible after implementation of Alternative 2D, this impact is significant and unavoidable.

Mitigation Measure MIN-6: Design Environmental Commitments 4 and 10 to Maintain Drilling Access to Natural Gas Fields to the Extent Feasible

During final design of actions to offset the impacts of constructing and operating the water conveyance facilities, the project proponents will identify means to maintain access to natural gas fields that could be adversely affect by implementing Environmental Commitments 4 and 10 where feasible. These could include preserving non-inundated lands either over or adjacent to natural gas fields adequate in size to allow drilling to occur. These measures will ensure that drilling access to natural gas fields is maintained to the greatest extent practicable.

Impact MIN-7: Loss of Availability of Locally Important Aggregate Resource Sites (Mines and MRZs) as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: Because there are no permitted resource extraction mines (including aggregate mines) and no identified MRZs in the Alternative 2D footprint, including within the footprint for the east-west transmission line alignment option, there would be no effect on the availability of aggregate resources.

CEQA Conclusion: Because there are no permitted mines or MRZs in the construction footprint for Alternative 2D, including within the footprint for the east-west transmission line alignment option, there would be no impact. No mitigation is required.

Impact MIN-8: Loss of Availability of Known Aggregate Resources as a Result of Constructing the Water Conveyance Facilities

NEPA Effects: The demand for construction materials, including aggregates and borrow materials for Alternative 2D would be slightly greater than Alternative 4 because of the two additional intakes. The principal demands for construction material would come from the five intakes, Clifton Court Forebay pumping plant and associated facilities, the nearly 40 miles of concrete pipeline tunnels, and forebays. Similar to Alternative 4, described in Appendix A of this RDEIR/SDEIS, this demand would not result in a substantial depletion of construction-grade aggregate within the six regional aggregate production study areas, would not cause remaining supplies to be inadequate for future development, and would not substantially contribute to the need for the development of new aggregate resources. Accordingly, it would not have an adverse effect on the availability of known aggregate resources or borrow materials over the water conveyance facilities construction period.

CEQA Conclusion: The use of large amounts of construction aggregate over the 9-year construction period would not result in a substantial depletion of construction-grade aggregate from the study area, would not cause remaining supplies to be inadequate for future development, and would not contribute to the need for development of new aggregate sources. Consequently, although a substantial amount of available aggregate material may be used to construct Alternative 2D, the impact on aggregate resources would be less than significant. No mitigation is required.

Borrow is not a defined mineral resource and is usually developed on an as-needed basis. Consequently, the amount of borrow required for this alternative would not be a significant impact. No mitigation is required.

Impact MIN-9: Loss of Availability of Locally Important Aggregate Resource Sites (Mines and MRZs) as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 2D would include moving water through both the new water conveyance infrastructure and natural channels. Adverse effects would only occur if operations prevented access to a locally important aggregate resource site; this is not expected to occur because there are no aggregate mines or MRZs in the area where Alternative 2D would operate. Accordingly, operation of Alternative 2D would not block access to existing mines or identified MRZs and similar to Alternative 4, described in Appendix A of this RDEIR/SDEIS, there would be no effect. Similarly, routine facilities maintenance activities such as painting, cleaning, and structure repair, landscape maintenance, road work, and periodic replacement of erosion protection on the levees and embankments would occur at or immediately adjacent to water conveyance facilities and would not cover or block access to existing mines or identified MRZs. Accordingly, the operation and maintenance of the water conveyance facilities under Alternative 2D would not have effects on the availability of aggregate resource sites.

CEQA Conclusion: The operation and maintenance of Alternative 2D water conveyance facilities would have no impact on locally important aggregate resources because operation and routine maintenance such as painting, cleaning, repairs, levee and landscape maintenance and similar activities would be limited to the water conveyance facilities. The impact on locally important aggregate resources is considered less than significant because access to areas containing these resources would not be restricted when operation and maintenance of the water conveyance facilities is occurring. No mitigation is required.

Impact MIN-10: Loss of Availability of Known Aggregate Resources as a Result of Operation and Maintenance of the Water Conveyance Facilities

NEPA Effects: The operation of the water conveyance facilities under Alternative 2D would include moving water through both the new water conveyance infrastructure and natural channels. Adverse effects would only occur if operations prevented access known aggregate resources; this is not expected to occur because there are no known aggregate resources the area where Alternative 2D would operate. Similarly, routine facilities maintenance activities such as painting, cleaning, and structure repair, landscape maintenance, road work, and periodic replacement of erosion protection on the levees and embankments would occur at or immediately adjacent to water conveyance facilities and would not cover or block access known aggregate resources, Accordingly, the operation and maintenance of the water conveyance facilities under Alternative 2D would not have effects on known aggregate resources.

CEQA Conclusion: The operation and maintenance of Alternative 2D water conveyance facilities would have no impact on known aggregate resources because operation and routine maintenance such as painting, cleaning, repairs, levee and landscape maintenance and similar activities would be limited to the water conveyance facilities. The impact on known aggregate resources is considered less than significant because access to areas containing these resources would not be restricted when operation and maintenance of the water conveyance facilities is occurring. No mitigation is required.

Impact MIN-11: Loss of Availability of Locally Important Aggregate Resource Sites (Mines and MRZs) as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15 and 16

NEPA Effects: Implementation of the Environmental Commitments would have the potential to affect locally important aggregate resource sites are those that would inundate large areas of land. The loss of important aggregate resource sites under Alternative 2D would be similar to that described under Alternative 4 in Appendix A of this RDEIR/SDEIS. However, the potential for loss of important aggregate resource sites would be less than Alternative 4 because much less land would be restored within the project area and over a much shorter period. Nevertheless, the potential for inundation and loss of this aggregate resource sites would remain under Alternative 2D and is considered an adverse effect. Mitigation Measure MIN-11 is available to reduce this effect.

CEQA *Conclusion:* As described under Alternative 4, an active mine on Decker Island may fall within the inundation footprints associated with implementing restoration actions associated with tidal natural communities and nontidal marsh. Although less acreage would be restored under Alternative 2D, restoration actions could result in inundation of aggregate resources. Although the impact is expected to be less than under Alternative 4, the potential loss would remain significant impact because it would eliminate the potential to recover aggregate resources. Mitigation Measure MIN-11 is designed to reduce the impact to less than significant.

Mitigation Measure MIN-11: Purchase Affected Aggregate Materials for Use in Project Construction

Please see Mitigation Measure MIN-11 under Impact MIN-11 in the discussion of Alternative 4, described in in Appendix A of this RDEIR/SDEIS.

Impact MIN-12: Loss of Availability of Known Aggregate Resources as a Result of Implementing Environmental Commitments 3, 4, 6-12, 15 and 16

NEPA Effects: Restoration actions occurring under Alternative 2D have the potential to reduce the availability of important aggregate resources. When compared to Alternative 4, loss of aggregate resources under Alternative 2D would be less because the total acreage of restoration occurring with the project area would be substantially less. Similar to Alternative 4, described in in Appendix A of this RDEIR/SDEIS, aggregate and riprap would be used for levee, berm, access road, and rock revetment construction, and rock would be placed for erosion control and stability at levee breaches and toe drain earthworks. The amounts of aggregate and riprap necessary for these activities cannot be calculated at this time because of the programmatic nature and general design of the restoration actions. However, the amount needed would be used over a period of years and would be expected to be within the available resources of the study area and adjacent aggregate resource study areas discussed in Section 26.1.2.1, *Aggregate Resources* of the Draft EIR/EIS and identified in Table 26-1. There would be no depletion (loss of availability) of regional aggregate supplies substantial enough to cause remaining supplies to be inadequate for future development or to require development of new aggregate sources to meet future demand. Therefore, the use of aggregate material for the restoration actions under Alternative 2D would not cause an adverse effect on the availability of aggregate resources.

CEQA Conclusion: Restoration actions occurring under Alternative 2D, would use small amounts of aggregate for levee, berm, and access road construction, and placement of rock revetments or riprap for erosion control and stability at level breaches and toe drain earthworks. The amounts of aggregate are unknown but would be within the available resources of the study area or adjacent aggregate resource study areas. The impact on known aggregate resources would be less than significant because implementing environmental commitments would not use an amount of aggregate that would cause remaining supplies to be inadequate to meet future demands or require developing new sources. No mitigation is required.

4.4.23 Paleontological Resources

Impact PALEO-1: Destruction of Unique or Significant Paleontological Resources as a Result of Construction of Water Conveyance Facilities

Alternative 2D would include the same physical/structural components as Alternative 4, but would include two additional intakes. The potential for Alternative 2D to affect unique or significant paleontological resources would be similar to the impacts described for Alternative 4 in Appendix A of this RDEIR/SDEIS, but could include additional impacts associated with constructing Intakes 1 and 4. Construction activities that could result in adverse effects on paleontological resources include excavation for new intakes, new pumping plants, new forebays, pipelines and tunnels, canals to the Jones and Banks pumping plants, an operable barrier at the head of Old River, other water facility components, roads, and borrow sites. The depth, extent, and location of excavation and other ground-disturbing activities vary greatly across the project area would be similar to the description of the extent of impacts on paleontological resources in Alternative 4 and summarized in Table 27-14 in Appendix A of the RDEIR/SDEIS, with the exception of two additional intakes.

NEPA Effects: The ground-disturbing activities that occur in geologic units sensitive for paleontological resources have the potential to damage or destroy those resources. Direct or indirect destruction of significant paleontological resources as defined by the SVP (2010) would represent an adverse effect because conveyance facility construction could directly or indirectly destroy unknown paleontological resources in geologic units known to be sensitive for these resources.

The shallow excavation and grading in surficial Holocene deposits that would take place for the construction of roads could be addressed through implementation of Mitigation Measures PALEO-1b and 1d.

Mitigation Measures PALEO-1a through PALEO-1d are available to mitigate the effects of the surface-related ground disturbance activities associated with Alternative 2D. However, while these measures could be applied to the excavation of the tunnel shafts, no mitigation is available for the boring activities because they would be conducted deep underground and could not be monitored. Moreover, although boring material could be examined by monitors, such work would be subsequent to boring, and the boring area could not be accessed even if fossils were encountered.

Excavation for new intakes, new pumping plants, new/expanded forebays, pipelines and tunnels, canals to Jones and Banks pumping plants, and other water facility components necessary for Alternative 2D would most likely destroy unique or significant paleontological resources and would constitute an adverse effect under NEPA.

***CEQA Conclusion*:** Construction of water conveyance facilities proposed under Alternative 2D could cause the destruction of unique paleontological resources. The ground-disturbing activities associated with Alternative 2D would occur in geologic units sensitive for paleontological resources and could therefore have the potential to damage or destroy those resources. Direct or indirect destruction of significant paleontological resources as defined by the SVP (2010) would constitute a significant impact because construction of conveyance facilities could substantially affect geologic formations that have potential to contain unique paleontological resources.

Implementation of Mitigation Measures PALEO-1a through PALEO-1d would reduce the effects of surface-related ground disturbance to a less-than-significant level, but excavation for the tunnels necessary for Alternative 2D would most likely destroy unique or significant paleontological resources in the project area and would potentially cause a significant and unavoidable impact.

Mitigation Measure PALEO-1a: Prepare a Monitoring and Mitigation Plan for Paleontological Resources

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4 of the DEIR/DEIS.

Mitigation Measure PALEO-1b: Review 90% Design Submittal and Develop Specific Language Identifying How the Mitigation Measures Will Be Implemented along the Alignment

Please see Mitigation Measure PALEO-1b under Impact Paleo-1 in the discussion of Alternative 4 of the DEIR/DEIS.

Mitigation Measure PALEO-1c: Educate Construction Personnel in Recognizing Fossil Material

Please see Mitigation Measure PALEO-1c under Impact Paleo-1 in the discussion of Alternative 4 of the DEIR/DEIS.

Mitigation Measure PALEO-1d: Collect and Preserve Substantial Potentially Unique or Significant Fossil Remains When Encountered

Please see Mitigation Measure PALEO-1d under Impact Paleo-1 in the discussion of Alternative 4 of the DEIR/DEIS.

Impact PALEO-2: Destruction of Unique or Significant Paleontological Resources Associated with the Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Ground-disturbing activities associated with restoration actions under Alternative 2D would result in impacts that would be similar in nature to those described under Alternative 4 in Appendix A of this RDEIR/SDEIS. However, the extent of these impacts would be much less than under Alternative 4 because less ground disturbing activity would occur. The conservation and stressor reduction environmental commitments are described in detail in Section 4.1.3.3, *Environmental Commitments*, and include natural communities protection and restoration, tidal natural communities restoration, channel margin enhancement, riparian natural community restoration, vernal pool and alkali seasonal wetland complex restoration, and nontidal marsh restoration. Land disturbing activities would be required to implement each of the conservation and stressor reduction measures.

NEPA Effects: If fossils are present in the project area, they could be damaged during excavation required to implement the conservation and stressor reduction environmental commitments. The greater the extent of excavation, the greater the potential effect, although even localized excavation could damage or destroy paleontological resources. Direct or indirect destruction of vertebrate or otherwise scientifically significant paleontological resources as defined by the SVP (2010) would be an adverse effect.

Mitigation Measures PALEO-1b and PALEO-1d are available to mitigate all shallow ground-disturbing environmental commitments. Mitigation Measures PALEO-1a through PALEO-1d would address all deeper ground-disturbing environmental commitments.

CEQA Conclusion: Ground-disturbing activities associated with implementing the conservation and stressor reduction environmental commitments under Alternative 2D could affect paleontological resources. If fossils are present in the project area, they could be damaged during excavation associated with these environmental commitments. The greater the extent of excavation, the greater the potential impact, although even localized excavation could damage or destroy paleontological resources. Direct or indirect destruction of significant paleontological resources as defined by the SVP (2010) would constitute a significant impact because construction activities could substantially affect geologic formations that have potential to contain unique paleontological resources.

Implementation of Mitigation Measures PALEO-1b and PALEO-1d for all shallow ground-disturbing environmental commitments and Mitigation Measures PALEO-1a through PALEO-1d for all deeper ground-disturbing environmental commitments ensure that unique or significant paleontological resources in the alternative footprint are systematically identified, documented, avoided or protected from damage where feasible, or recovered and curated so they remain available for scientific study and would reduce these impacts to a less-than-significant level.

Mitigation Measure PALEO-1a: Prepare a Monitoring and Mitigation Plan for Paleontological Resources

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4.

Mitigation Measure PALEO-1b: Review 90% Design Submittal and Develop Specific Language Identifying How the Mitigation Measures Will Be Implemented along the Alignment

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4.

Mitigation Measure PALEO-1c: Educate Construction Personnel in Recognizing Fossil Material

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4.

Mitigation Measure PALEO-1d: Collect and Preserve Substantial Potentially Unique or Significant Fossil Remains When Encountered

Please see Mitigation Measure PALEO-1a under Impact Paleo-1 in the discussion of Alternative 4.

4.4.24 Environmental Justice

As described in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS some of the resource topics were not considered in the assessment of disproportionate impacts on minority or low-income populations. For the reasons described in Section 28.5.3.1, *Issues Not Analyzed in Detail*, these resources were also not evaluated as part of the Alternative 2D environmental justice impact assessment. The resource topics not evaluated for a disproportionate impact on minority or low income populations are geology and seismicity, hazards and hazardous materials, mineral resources, water supply, surface water, groundwater, water quality, soils, fish and aquatic resources, terrestrial biological resources, agricultural resources, recreation, transportation, energy, and paleontological resources.

4.3.24.1 Land Use

The potential impact on minority and low-income populations resulting from changes in land use for Alternative 2D would be the same as described for Alternative 4. The discussion of Alternative 4 in Chapter 13, *Land Use*, Section 13.3.3.9 of the Draft EIR/EIS identifies effects caused by incompatibility with local land uses, potential for physical division of established communities, and incompatibility with land use policies, By itself, incompatibility with land use policies is not a physical effect on the environment, and, therefore, does not have the potential to result in a disproportionate effect on a minority or low-income populations. Chapter 13, *Land Use*, Section 13.3.3.9 of the Draft EIR/EIS, also addresses the potential for an alternative to result in the relocation of residents, or a physical effect on existing structures, with the consequence that adverse effects on the physical environment would result. The following adverse effects are relevant to this analysis:

Impact LU-2: Conflicts with Existing Land Uses as a Result of Constructing the Proposed Water Conveyance Facility

Impact LU-3: Create Physical Structures Adjacent to and through a Portion of an Existing Community as a Result of Constructing the Proposed Water Conveyance Facility

The extent of land use changes attributable to construction of Alternative 2D that could affect minority and low-income populations would be the same as disclosed for Alternative 4 because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives. Alternative 2D would include the same physical/structural components as Alternative 4 and two additional intakes. Therefore, there would be a greater impact related to construction two additional intakes. As for Alternative 4, construction and operation of physical facilities for water conveyance would create temporary or permanent conflicts with existing land uses (including displacement of existing structures and residences) because of the construction of permanent features of the facility. As discussed in detail under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS, a disproportionate effect on minority populations would occur because construction of intakes would result in the displacement of residential structures and permanent structures within census blocks where the minority population is greater than 50%.

4.3.24.2 Socioeconomics

The potential impact on minority and low-income communities associated with changes in socioeconomic conditions for Alternative 2D would be the same as described for Alternative 4. The discussion of Alternative 4 in Section 13.3.3.9 of the Draft EIR/EIS identified effects on agricultural economics and local employment conditions associated with constructing and operating the water conveyance facility and implementing environmental commitments. These impacts have the potential to disproportionately affect environmental justice populations. The following adverse effects are relevant to this analysis:

Impact ECON-1: Temporary Effects on Regional Economics in the Delta Region during Construction of the Proposed Water Conveyance Facilities

Impact ECON-7: Permanent Regional Economic Effects in the Delta Region during Operation and Maintenance of the Proposed Water Conveyance Facilities

Land use changes that could affect minority and low-income populations for Alternative 2D would be the same as indicated for Alternative 4 because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher project-related employment effects when compared to Alternative 4. Conversely, adverse effects associated with agricultural employment would also be somewhat higher due to the additional acreages of agricultural land that would be affected by construction of five intake facilities. Also, the two additional intake facilities that would be constructed would likely result in slightly higher effects on employment effects when compared to Alternative 4. As discussed in greater detail under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the majority of farm-related employment is represented by minority populations, including those of Hispanic origin, and potentially low-income, loss of agriculture land and loses of associated employment is expected to result in a disproportionate effect on minority populations. While a net increase in employment would occur during construction of the water conveyance facility, it is expected that most new construction jobs would not likely be filled by displaced agricultural workers because the skills required are not comparable. This effect would, therefore, remain adverse because job losses would disproportionately accrue to a minority population.

4.3.24.3 Aesthetics and Visual Resources

The potential impact on minority and low-income communities associated with changes in visual resources for Alternative 2D would be the same as described for Alternative 4. However, the potential under Alternative 2D to create substantial alteration in visual quality or character during construction of conveyance facilities would be slightly greater than those impacts described under Alternative 4 and would constitute adverse effects on existing visual character, on scenic vistas, would create new light or glare, and would substantially alter existing visual character. The discussion of Alternative 4 in Section 17.3.3.9 in the Draft EIR/EIS addresses impacts on aesthetics and visual resources in the study area. The impacts on aesthetics and visual resources have the potential to disproportionately affect environmental justice populations. The following adverse effects and mitigation measures are relevant to this analysis:

Impact AES-1: Substantial Alteration in Existing Visual Quality or Character during Construction of Conveyance Facilities

Impact AES-2: Permanent Effects on a Scenic Vista from Presence of Conveyance Facilities

Impact AES-3: Permanent Damage to Scenic Resources along a State Scenic Highway from Construction of Conveyance Facilities

Impact AES-4: Creation of a New Source of Light or Glare That Would Adversely Affect Views in the Area as a Result of Construction and Operation of Conveyance Facilities

Impact AES-6: Substantial Alteration in Existing Visual Quality or Character during Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

Mitigation Measure AES-1a: Locate New Transmission Lines and Access Routes to Minimize the Removal of Trees and Shrubs and Pruning Needed to Accommodate New Transmission Lines and Underground Transmission Lines Where Feasible

Mitigation Measure AES-1b: Install Visual Barriers between Construction Work Areas and Sensitive Receptors

Mitigation Measure AES-1c: Develop and Implement a Spoil/Borrow and Reusable Tunnel Material Area Management Plan

Mitigation Measure AES-1d: Restore Barge Unloading Facility Sites Once Decommissioned

Mitigation Measure AES-1e: Apply Aesthetic Design Treatments to All Structures to the Extent Feasible

Mitigation Measure AES-1f: Locate Concrete Batch Plants and Fuel Stations Away from Sensitive Visual Resources and Receptors and Restore Sites upon Removal of Facilities

Mitigation Measure AES-1g: Implement Best Management Practices to Implement Project Landscaping Plan

Mitigation Measure AES-2D: Limit Construction to Daylight Hours within 0.25 Mile of Residents

Mitigation Measure AES-4b: Minimize Fugitive Light from Portable Sources Used for Construction

Mitigation Measure AES-4c: Install Visual Barriers along Access Routes, Where Necessary, to Prevent Light Spill from Truck Headlights toward Residences

Mitigation Measure AES-6a: Underground New or Relocated Utility Lines Where Feasible

Mitigation Measure AES-6b: Develop and Implement an Afterhours Low-intensity and Lights off Policy

Mitigation Measure AES-6c: Implement a Comprehensive Visual Resources Management Plan for the Delta and Study Area

The changes in the visual character of the study area that could affect minority and low-income communities under Alternative 2D would be the same as indicated under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives. As described in detail under Alternative 4, changes in the visual character of the study area would occur as a result of the following:

- Landscape scars left behind from spoil borrow and RTM areas, transmission lines, concrete batch plants and fuel stations, and launching, retrieval, ventilation shafts sites.
- Constructing industrial facilities (i.e., Sacramento River intakes, intermediate forebay, expanded Clifton Court Forebay and pumping plant) in the study area.

The change in visual character as a result of the construction of the water conveyance facilities would be evident from the communities of Walnut Grove, Clarksburg, and Hood as well as rural residences located along the entire alignment. Because of the concentration of minority and low income populations in these communities as well as along the entire alignment, a change in visual character of the study area would disproportionately affect these populations. For these reasons, although mitigation is available to reduce the severity of these effects, this effect would be adverse.

Similar to Alternative 4, implementing conservation and stressor reduction measures as part of Alternative 2D, would result in impacts on the study area's visual quality and character. However because the precise location of the conservation and stressor reduction measures are unknown, this impact is not carried forward for further analysis of environmental justice effects.

4.3.24.4 Cultural Resources

The potential impact on minority and low-income communities associated with changes to cultural resources Alternative 2D would be the same as described for Alternative 4, but with slightly greater magnitude due to construction of two additional intakes. The discussion of Alternative 4 in Section 18.3.5.9 of the Draft EIR/EIS addresses cultural resources in the study area. The impacts on cultural resources have the potential to disproportionately affect minority or low-income populations. The following adverse effects and mitigation measures are relevant to this analysis:

Impact CUL-1: Effects on Identified Archaeological Sites Resulting from Construction of Conveyance Facilities

Impact CUL-2: Effects on Archaeological Sites to Be Identified through Future Inventory Efforts

Impact CUL-3: Effects on Archaeological Sites That May Not Be Identified through Inventory Efforts

Impact CUL-4: Effects on Buried Human Remains Damaged during Construction

Impact CUL-5: Direct and Indirect Effects on Eligible and Potentially Eligible Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Impact CUL-6: Direct and Indirect Effects on Unidentified and Unevaluated Historic Architectural/Built-Environment Resources Resulting from Construction Activities

Impact CUL-7: Effects of Environmental Commitments on Cultural Resources

Mitigation Measure CUL-1: Prepare a Data Recovery Plan and Perform Data Recovery Excavations on the Affected Portion of the Deposits of Identified and Significant Archaeological Sites

Mitigation Measure CUL-2: Conduct Inventory, Evaluation, and Treatment of Archaeological Resources

Mitigation Measure CUL-3: Implement an Archaeological Cultural Resources Discovery Plan, Perform Training of Construction Workers, and Conduct Construction Monitoring

Mitigation Measure CUL-4: Follow State and Federal Law Governing Human Remains If Such Resources Are Discovered during Construction

Mitigation Measure CUL-5: Consult with Relevant Parties, Prepare and Implement a Built Environment Treatment Plan

Mitigation Measure CUL-6: Conduct a Survey of Inaccessible Properties to Assess Eligibility, Determine if These Properties Will Be Adversely Impacted by the Project, and Develop Treatment to Resolve or Mitigate Adverse Impacts

Mitigation Measure CUL-7: Conduct Cultural Resource Studies and Adopt Cultural Resource Mitigation Measures for Cultural Resource Impacts Associated with Implementation of CM2–CM21

The impact that the loss of cultural resources from within the study area could have on minority and low-income populations under Alternative 2D would be the same as indicated under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives, but of greater magnitude due to construction of two additional intakes. As discussed in greater detail under Alternative 4 of Chapter 18 of the Draft EIR/EIS, the loss or damage to prehistoric cultural resources would result in a disproportionate effect on Native American populations and potentially other minorities. Despite the required mitigation measures and Native Consultation processes, construction of Alternative 2D is likely to result in adverse effects on prehistoric archaeological resources and human remains because the scale of the construction activities makes avoidance of all eligible resources infeasible. The effect on minority populations that may ascribe significance to cultural resources in the Delta would remain disproportionate even after mitigation because mitigation cannot guarantee that all resources would be avoided, or that effects on affected resources would be reduced. For these reasons this effect would be adverse because the effect would disproportionately accrue to a minority population.

4.3.24.5 Public Services and Utilities

The potential impact on minority and low-income communities associated with changes to the availability of public services and utilities under Alternative 2D would be the same as described for Alternative 4, but of greater magnitude due to construction of two additional intakes. The discussion of Alternative 4 in Section 20.3.3.9 of the Draft EIR/EIS addresses potential effects on utility infrastructure and public service providers, such as fire stations and police facilities. The following adverse effects on public services and utilities are relevant to the analysis:

Impact UT-6: Effects on Regional or Local Utilities as a Result of Constructing the Proposed Water Conveyance Facilities

Impact UT-8: Effects on Public Services and Utilities as a Result of Implementing the Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

The impacts on public services and utilities located within the study area that could disproportionately affect minority and low-income populations under Alternative 2D would be the same as indicated disclosed under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives, but of greater magnitude due to construction of two additional intakes. As discussed in greater detail under Alternative 4, the impact of constructing the proposed water conveyance facilities on public services and utilities would not result in a disproportionate effect on minority or low income populations because relocation of an existing known utility would affect the entire service area of that utility. This effect would not be anticipated to result in a disproportionate effect on a minority or low-income population.

4.3.24.6 Air Quality and Greenhouse Gas Emissions

Alternative 2D would include the same physical/structural components as Alternative 4, described in Appendix A of this RDEIR/SDEIS, but would include two additional intakes, similar to Alternative 1A. Accordingly, construction emissions and associated health risks generated by Alternative 2D in would be similar to but greater than Alternative 4 due to the increased number of intakes, and would likely range between those generated under Alternatives 1A and 4. See the discussion of Impact AQ-14 under Alternatives 1A and 4 of the DEIR/DEIS. The following adverse effects and mitigation measure are relevant to this analysis:

Impact AQ-14: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of SMAQMD's Chronic Non-Cancer and Cancer Risk Assessment Thresholds

Impact AQ-16: Exposure of Sensitive Receptors to Health Threats from Diesel Particulate Matter in Excess of BAAQMD's Chronic Non-Cancer and Cancer Risk Thresholds

Mitigation Measure AQ-14: Relocate Sensitive Receptors to Avoid Excess Cancer Risk

Alternative 4 would not exceed the SMAQMD's or BAAQMD's chronic non-cancer or cancer thresholds. However, Alternative 1A would result in diesel particulate matter (DPM) concentrations in excess of SMAQMD's and BAAQMD's thresholds at adjacent receptors (see Tables 22-18 and 22-20). Since construction of the intakes contributes the majority of DPM emissions to the cancer risk in the SMAQMD, and Alternative 2D would construction five intakes, similar to Alternative 1A, effects would be adverse under Alternative 2D. Since proximity to haul routes contributes DPM emissions to the cancer risk, and Alternative 2D would have increased haul truck activity through BAAQMD due to the construction of five intakes in SMAQMD, similar to Alternative 1A, effects would be adverse under Alternative 2D.

Mitigation Measure AQ-14 would be available to reduce exposure to substantial cancer risk by relocating affected receptors. If a landowner chooses not to accept DWR's offer of relocation assistance, an adverse effect in the form excess cancer risk above air district thresholds would occur. Therefore, this effect would be adverse. If, however, all landowners accept DWR's offer of relocation assistance, effects would not be adverse.

The impacts on air quality during construction of the water conveyance facilities and resulting effects on minority and low-income communities under Alternative 2D would be similar to but greater than Alternative 4 due to the increased number of intakes, and would likely range between those generated under Alternatives 1A and 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives, but of greater magnitude due to construction of two additional intakes. As discussed in greater detail under Alternative 4 in Appendix A of this RDEIR/SDEIS, constructing the water conveyance facilities would result in an adverse impact on air quality that would remain adverse after application of mitigation. Given that the construction and restoration and conservation areas along this alignment are proximate to census blocks and block groups where meaningfully greater minority and low-income populations occur, it is expected that generation of criteria pollutants in excess of local air district thresholds would result in a potentially disproportionate effect on minority and low-income populations.

4.3.24.7 Noise

The potential impact on minority and low-income communities associated with noise occurring under Alternative 2D would be the same as described for Alternative 4, but of greater magnitude due to construction of two additional intakes. The discussion of Alternative 4 in Section 23.4.3.9 of the Draft EIR/EIS identifies the following adverse effects associated with new sources of noise and vibration that would be introduced into the study area under Alternative 4. The following adverse effects and mitigation measure are relevant to this analysis.

Impact NOI-1: Exposure of Noise-Sensitive Land Uses to Noise from Construction of Water Conveyance Facilities

Impact NOI-2: Exposure of Sensitive Receptors to Vibration or Groundborne Noise from Construction of Water Conveyance Facilities

Impact NOI-4: Exposure of Noise-Sensitive Land Uses to Noise from Implementation of Proposed Environmental Commitments 3, 4, 6–12, 15, and 16

Mitigation Measure NOI-1a: Employ Noise-Reducing Construction Practices during Construction

Mitigation Measure NOI-1b: Prior to Construction, Initiate a Complaint/Response Tracking Program

Mitigation Measure NOI-2: Employ Vibration-Reducing Construction Practices during Construction of Water Conveyance Facilities

The impacts of noise and vibration generated during construction of the water conveyance facilities and resulting effects on minority and low-income communities occurring under Alternative 2D would be the same as indicated under Alternative 4 in Chapter 28, *Environmental Justice*, of the Draft EIR/EIS because the period of construction, construction methods, and design of the water conveyance facility would be similar between the two alternatives, but of greater magnitude due to construction of two additional intakes. As discussed in greater detail under Alternative 4, constructing the water conveyance facilities would generate nose in exceedance of daytime and nighttime noise standards in areas zoned as sensitive land uses including residential, natural/recreational, agricultural residential, and schools. Similarly, ground borne vibration from impact pile driving would exceed vibration thresholds in areas zoned for residential, including agricultural residential. This effect of noise and vibration generated during construction would remain adverse after application of mitigation. Because the alignment of the water conveyance facility is proximate to census blocks and block groups where meaningfully greater minority and low-income populations occur it is expected that generation of noise and vibration in exceedance of thresholds would result in a potentially disproportionate effect on minority and low-income populations.

Impacts of implementing conservation and stressor reduction components (Environmental Commitments 3, 4, 6, 7, 9–12, 15, and 16) under Alternative 2D would be expected to be similar to impacts of implementing CM2–CM11 under Alternative 4. However, because fewer acres would be restored under Alternative 2D, it is expected that noise and vibration generated would be less when compared to Alternative 4. Nevertheless, it would be difficult to analyze potential disproportionate effects on environmental justice population because similar to CM3–CM11, the location of the conservation and stressor reduction components are not known. However, because of the distribution of minority and low-income populations in the study area, there is a potential for noise and vibration impacts to disproportionately affect these populations.

4.3.24.8 Public Health

Section 4.4.21, *Public Health*, of this RDEIR/EIS, identifies the potential for construction, operation, and maintenance of Alternative 2D to mobilize or increase constituents known to bioaccumulate. The following adverse effects are relevant to this analysis.

Impact PH-3: Substantial Mobilization of or Increase in Constituents Known to Bioaccumulate as a Result of Construction, Operation or Maintenance of the Water Conveyance Facilities

The amount of habitat restoration completed under Alternative 2D would be substantially less than under Alternative 4. Five intakes would be constructed and operated under Alternative 2D. Sediment-disturbing activities during construction and maintenance of these intakes and other water conveyance facilities proposed near or in surface waters under this alternative could result in the disturbance of existing constituents in sediment, such as pesticides or methylmercury. The effects of Alternative 2D on pesticide levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions and the No Action Alternative (ELT) would be similar to or slightly less than those described for the Alternative 4. Alternative 2D would not result in increased tributary flows that would mobilize organochlorine pesticides in sediments.

If mercury is sequestered in sediments at water facility construction sites, it could become suspended in the water column during construction activities, opening up a new pathway into the food chain. Construction activities (e.g., pile driving and cofferdam installation) at intake sites or barge landing locations would result in a localized, short-term resuspension of sediment and an increase in turbidity that may contain elemental or methylated forms of mercury. Please see Chapter

8, Section 8.1.3.9, *Mercury,* in Appendix A of the RDEIR/SDEIS for a discussion of methylmercury concentrations in sediments.

Changes in methylmercury concentrations under Alternative 2D are expected to be small. As described in Section 4.4.4, *Water Quality,* the greatest annual average methylmercury concentration for drought conditions under Alternative 2D would be 0.166 ng/L for the San Joaquin River at Buckley Cove, which would be slightly lower than the No Action Alternative (ELT) (0.168 ng/L). Fish tissue estimates show only small or no increases for mercury concentrations relative to the No Action Alternative (ELT) based on long-term annual average concentrations in the Delta. Mercury concentrations in fish tissue expected for Alternative 2D (with Equation 1), show increases of 9 percent or less, relative to the No Action Alternative (ELT), in all modeled years. Mercury concentrations in fish tissue expected for Alternative 2D (with Equation 2), are estimated to 13 percent at Staten Island relative to the No Action Alternative (ELT), in all modeled years. See Appendix 8I, *Mercury*, of the Draft EIR/EIS for a discussion of the uncertainty associated with fish tissue estimates of mercury.

Because some of the affected species of fish in the Delta are pursued during subsistence fishing by minority and low-income populations, this increase creates the potential for mercury-related health effects on these populations. Asian, African-American, and Hispanic subsistence fishers pursuing fish in the Delta already consume fish in quantities that exceed the US Environmental Protection Agency reference dose of 7 micrograms (μg) per day total (Shilling et al. 2010:5). This reference dose is set at 1/10 of the dose associated with measurable health impacts (Shilling et al. 2010:6). The highest rates of mercury intake from Delta fish occur among Lao fishers (26.5 μg per day, Shilling et al. 2010:6). Increased mercury was modeled based upon increases modeled for one species: largemouth bass. These effects are considered unmitigable (see Chapter 8, *Water Quality,* Mitigation Measure WQ-13).

The associated increase in human consumption of mercury caused by these alternatives would depend upon the selection of the fishing location (and associated local fish body burdens), and the relative proportion of different Delta fish consumed. Different fish species would suffer bioaccumulation at different rates associated with the specific species, therefore the specific spectrum of fish consumed by a population would determine the effect of increased mercury body burdens in individual fish species. These confounding factors make demonstration of precise impacts on human populations infeasible. However, because minority populations are known to practice subsistence fishing and consume fish exceeding US EPA reference doses, any increase in the fish body burden of mercury may contribute to an existing adverse effect. Because subsistence fishing is specifically associated with minority populations in the Delta compared to the population at large this effect would be disproportionate on those populations for Alternative 2D. This effect would be adverse.

4.3.24.9 Summary of Environmental Justice Effects under Alternative 2D

Alternative 2D would result in disproportionate effects on minority and low-income communities resulting from land use, socioeconomics, aesthetics and visual resources, cultural resources, noise, air quality, and public health effects. Mitigation and environmental commitments are available to reduce these effects; however, effects would remain adverse. For these reasons, effects on minority and low-income populations would be disproportionate and adverse.

4.4.25 Climate Change

This section is organized differently from the other sections above because analyzing how Alternative 2D would affect the Delta's resiliency and adaptability to climate change is a fundamentally different analysis than those presented in other resource analyses. Whereas the other sections are organized to identify effects of Alternative 2D and how to mitigate any significant impacts, this section's function is to analyze and disclose how Alternative 2D would affect the Delta's resiliency and adaptability to expected climate change. While climate change is already ongoing and would occur under the ELT timeframe, effects of Alternative 2D on the resiliency and adaptability would be greater under LLT conditions as climate change effects are expected to be more pronounced[9]. Nevertheless, an assessment of conditions under the ELT timeframe is provided below.

Alternative 2D would provide resiliency and adaptation benefits over the No Action/No Project alternative for dealing with the combined effect of increases in sea level rise and changes in upstream hydrology. The benefits would be similar to those anticipated under Alternative 4A (see Section 4.3.25 in this RDEIR/SDEIS) and are primarily derived from the alternative's dual conveyance structure and location of the north Delta facility, which allow for more flexible water movement and protection from potential salinity intrusion. Alternative 2D would also provide more reliable water supplies and increased flexibility to adaptively manage the Delta so that conditions can be optimized across all Delta water uses and habitat conditions.

In addition to added water management flexibility, Alternative 2D includes several environmental commitments that will improve habitat in certain areas and reduce the effects of stressors. Provided benefits would be similar to those anticipated under Alternative 4A and include expanded habitat options during periods of high or low freshwater inflow, increased habitat connectivity, and potential buffers against rising water temperatures. Alternative 2D would also provide additional adaptability to catastrophic failure of Delta levees. Please refer to Section 4.3.25, *Climate Change*, in this RDEIR/SDEIS for more detailed discussion on anticipated resiliency and adaptation benefits.

As described for Alternative 4A, Alternative 2D would not be anticipated to add resiliency to existing levees; levee fragility would remain high and increase with time as in the No Action/No Project Alternative. Similarly, construction and operation of the proposed water conveyance facilities and implementation of environmental commitments under Alternative 2D would not affect the ability of agencies to implement plans and proactive measures associated with climate change resiliency (see Draft EIR/EIS Chapter 29, *Climate Change,* Section 29.7 for a discussion of individual plans and policies). Accordingly, the project would be compatible with these federal and state plans to address climate change.

[9] The ELT timeframe is modeled at 2025. The LLT timeframe is modeled at 2060.

4.4.26 Growth Inducement and Other Indirect Effects

4.4.26.1 Direct Growth Inducement

Construction Jobs

Construction of Alternative 2D would require a peak of approximately the same number of workers as those described for Alternative 4 in Chapter 30, *Growth Inducement and Other Indirect Effects*, in the Draft EIR/EIS. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher project-related employment effects when compared to Alternative 4. It is estimated that approximately 30 percent of these workers would come from out of state (due to the specialized nature of some of the jobs) and reside temporarily in the vicinity. Given the availability of housing in the project vicinity, out-of-state workers would be readily accommodated by existing housing; therefore the influx of these workers during project construction would not induce substantial new housing development.

Permanent Jobs

Alternative 2D would require permanent operations and maintenance workers, who would be anticipated to live in the Delta region. This number would be similar to those required under Alternative 4. However, under Alternative 2D two additional intake facilities would be constructed, which would likely result in slightly higher effects on employment effects when compared to Alternative 4. It is likely that this small number of new jobs would readily be filled by the local labor force and would not induce additional growth in the area. Assuming some or all of the jobs were specialized and required workers from outside the local labor pool, given the availability of housing in the project vicinity, these workers would be readily accommodated by existing housing; therefore the influx of these workers during project operation would not induce substantial new housing development.

4.4.26.2 Indirect Growth Inducement Associated with Facility Construction and Operation

Access Roads within the BDCP Plan Area

Construction of Alternative 2D water conveyance facilities will be similar to Alternative 4. Effects of construction of access roads for this alternative would be similar to that described for Alternative 4A under Section 4.3.26.2, *Indirect Growth Inducement Associated with Facility Construction and Operation*, of this RDEIR/SDEIS.

Flood Risk Reduction

Actions under Alternative 2D are not anticipated to have any substantial impact or change on potential for flooding within the Plan Area and downstream areas (RDEIR/SDEIS Section 4.4.2. *Surface Water*). Effects of this alternative would be similar to that described for Alternative 4A under Section 4.3.26.2, *Indirect Growth Inducement Associated with Facility Construction and Operation*, of this RDEIR/SDEIS. There is not anticipated to have any indirect effect on growth.

4.4.26.3 Indirect Growth Inducement Potential: Summary of Modeling Results

The following sections highlight changes in SWP and CVP deliveries associated with the BDCP alternatives based on modeling conducted using CALSIM II, focusing on changes in municipal and industrial (M&I) deliveries (also referred to as urban deliveries). Figure 4.4.1-26 summarizes overall changes in SWP deliveries to both agricultural and M&I contractors for Alternative 2D relative to Existing Conditions (the CEQA baseline) and the No Action Alternative (ELT) (which reflects with sea level rise and climate change (i.e., effects of precipitation and snowpack). Figure 4.4.1-25 summarizes changes in CVP deliveries under Alternative 2D relative to Existing Conditions as well as the No Action Alternative (ELT).

For purposes of analyzing the project's potential to induce growth, this analysis focuses on the net increase in annual average deliveries; all information on water deliveries presented below is for average annual deliveries in normal hydrologic years. The SWP modeling results reflected in the tables and figures presented in this section include Table A water as well as Article 21 water.[10]

This analysis does not address potential effects of redistribution of SWP water supply among SWP water contractors that might occur from an SWP contract amendment or funding agreements for implementing BDCP, other than as possible multi-year or permanent agricultural to urban water transfer of SWP water. A SWP contract amendment or funding agreement could include provisions for allocating benefits such as a more reliable water supply, to contractors who pay for BDCP and could create the potential for redistributing SWP water. At this time, because a specific SWP amendment or funding agreement has not been developed, it would be too speculative per Section 15145 of the State CEQA Guidelines to evaluate changes in SWP water distribution at this time. If the SWP amendment or agreement, after it is developed, may have potential to have an environmental effect not already contemplated in the BDCP EIR/EIS, DWR would prepare additional analysis.

As described in Section 4.1.3, Alternative 2D would include the construction of five new intakes, among other facilities and would follow the operational criteria described as Scenario B, which includes the Fall X2 action and less negative south Delta Old and Middle River flows than under Scenario A.

The addition of new north Delta intakes as well as changes to Delta regulatory requirements under Alternative 2D would provide operational flexibility that would allow the SWP and CVP to increase Delta exports compared to operations under Existing Conditions. However, Alternative 2D and the No Action Alternative (ELT) also assume that there would be an increase in M&I water rights demands north of the Delta, which would increase overall system demands and reduce the amount of CVP water available for total export south of the Delta. Consequently, SWP M&I deliveries under

[10] Article 21 water is interruptible water allocated under certain conditions. Water supply under Article 21 becomes available only during wet months of the year (December through March). A SWP contractor must have an immediate use for Article 21 supply or a place to store it outside of SWP; therefore not all SWP contractors can take advantage of this additional supply. Article 21 is a section of the contract between DWR and the water contractor that permits delivery of water in excess of delivery of SWP Table A. It is apportioned to contractors that request it in the same proportion as their SWP Table A water. Article 21 water is allocated under certain conditions: (a) SWP's share of San Luis Reservoir is full or projected to fill in the near term; (b) other SWP reservoirs are full or at their storage targets, or conveyance capacity to fill these reservoirs is maximized; (c) releases from upstream reservoirs plus unregulated inflow exceed the water supply needed to meet Sacramento Valley in-basin uses; (d) SWP Table A deliveries are being fully met; and (e) Banks Pumping Plant has spare capacity (California Department of Water Resources 2008b:32,39).

Alternative 2D are projected to increase due to increased Delta exports, while in some cases CVP deliveries south of Delta are projected to decrease due to increased water rights demands north of Delta.

See Section 4.4.1 of this RDEIR/SDEIS, for more detail on changes in Delta exports and SWP and CVP deliveries under Alternative 2D.

Changes in Deliveries to the Hydrologic Regions.

SWP. Compared to both Existing Conditions and the No Action Alternative (ELT), Alternative 2D would increase deliveries to all hydrologic regions except for the San Joaquin River region, which would experience no change in deliveries. South Coast would realize the largest net increase (between 117.5 and 202.8 TAF) among the regions, and represents 64–65% of the net increase in M&I deliveries. San Francisco Bay represents 11–13% of the increase, and Colorado River represents 8–9% of the increase. For more information, refer to results for Alternative 2A, 2B, and 2C in Table 30-16 in the Public Draft EIR/EIS.

CVP. Alternative 2D would not change M&I deliveries for the Sacramento River, South Coast, South Lahontan and Colorado River regions because there are no affected CVP contractors located in these regions. Alternative 2D may result in increased or decreased deliveries to the other hydrologic regions depending on whether deliveries are compared to Existing Conditions or the No Action Alternative (ELT). San Francisco Bay is projected to realize the largest potential increase (2.4 TAF) and also the largest decrease (4.8 TAF) among the hydrologic regions. For more information, refer to results for Alternative 2A, 2B and 2C in Table 30-17 in the Public Draft EIR/EIS.

Alternatives 2D Compared to Existing Conditions, Early Long Term.

SWP. By 2025, average annual total SWP deliveries to all SWP contractors are projected to increase by 8% relative to ELT and increase 3% at LLT. Under Alternative 2D, average annual total south of Delta SWP deliveries as compared to Existing Conditions, would increase (11%) at ELT and would increase (5%) at LLT.

CVP. By 2025, deliveries to all contractors under Alternative 2D, average annual total CVP deliveries as compared to Existing Conditions, would increase by up to 2% at ELT and decrease by up to 1% at LLT. Under Alternative 2D, average annual total south of Delta CVP deliveries as compared to Existing Conditions, would decrease by up to 2% at ELT and by up to 6% at LLT.

Alternatives 2D Compared to No Action Alternative (ELT).

SWP. By 2025, average annual total SWP deliveries as compared to No Action Alternative (ELT), would increase (by about 15%). Under Alternative 2D, average annual total south of Delta SWP deliveries as compared to No Action Alternative (ELT), would increase (by about 21%).

CVP. By 2025, deliveries to all CVP contractors are projected to increase by 3% relative to the No Action Alternative (ELT) and by up to 2% at LLT. Under Alternative 2D, average annual total south of Delta CVP deliveries as compared to No Action Alternative (ELT), would increase by up to 5%.

4.5 Impacts of Alternative 5A

4.5.1 Water Supply

Facilities construction under Alternative 5A would be identical to that described under Alternative 4, except this alternative would include two fewer intakes. Alternative 5A water conveyance operations would be similar to the operations that would occur under Alternative 5.

Model simulation results for Alternative 5A Early Long-term (ELT) are summarized in Tables B.1-4 and B.1-5 in Appendix B of this RDEIR/SDEIS. Model simulation results for Alternative 5A at Late Long-term (LLT) which are similar to the Alternative 5 (LLT), are summarized in Tables 5-7 through 5-9 in the Draft EIR/EIS.

As indicated in Section 5.3.2, *Determination of Effects*, of Draft EIR/EIS, NEPA adverse effect and CEQA significant impact conclusions are not provided for the impacts discussed in this water supply section.

4.5.1.1 Summary of Water Supply Operations under Alternative 5A

Change in Delta Outflow

Changes in long-term average Delta outflow under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-4 and B.1-5 in Appendix B and Figures 4.4.1-1 through 4.4.1-3 in this RDEIR/SDEIS.

Changes in long-term average Delta outflow under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-3 through 5-5 and Tables 5-7 through 5-9 of the Draft EIR/EIS.

Late-fall and winter outflows remain similar or show minor reductions in Alternative 5A compared to No Action Alternative. In the spring months, outflow would decrease under Alternative 5A as compared to No Action Alternative. SWP and CVP exports in summer months would increase and result in lower outflow as compared to No Action Alternative. In the fall months, outflow under Alternative 5A as compared to No Action Alternative would be similar because of the Fall X2 requirement in wet and above-normal years, and increased or similar outflow in September and October months of all year types due to OMR flow requirements and export reductions.

Long-term average and wet year peak outflows would increase in winter months with a corresponding decrease in spring months because of the shift in system inflows caused by climate change and increased Delta exports as compared to Existing Conditions. In other year types, Alternative 5A would result in higher or similar outflow because of the spring outflow requirements. In summer and fall months, Alternative 5A would result in similar or higher outflow because of changes in export patterns and OMR flow requirements and export reductions in fall months, and also because of the Fall X2 requirements in wet and above normal years. The incremental changes in Delta outflow between Alternative 5A and Existing Conditions would be a function of both the facility and operations assumptions (including north Delta intakes capacity of 15,000 cfs, less negative OMR flow requirements, enhanced spring outflow and/or Fall X2 requirements) and the reduction in water supply availability due to increased north of Delta urban demands, sea level rise and climate change.

Delta outflow under Alternative 5A would likely decrease in winter, spring and summer months, and remain similar or increase in other months, compared to the conditions without the project.

Results for the range of changes in Delta Outflow under Alternative 5A (LLT), which are similar to Alternative 5 (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling Technical Appendix*, of the Draft EIR/EIS.

Change in SWP and CVP Reservoir Storage

Changes in May and September reservoir storage under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Figures 4.4.1-4 through 4.4.1-10 in this RDEIR/SDEIS and Tables B.1-4 and B.1-5 in Appendix B of this RDEIR/SDEIS for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis Reservoir storages are presented in Figures 4.4.1-11 through 4.4.1-14 for completeness.

Changes in May and September reservoir storage under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables 5-7 through 5-9 of Draft EIR/EIS for Trinity Lake, Shasta Lake, Lake Oroville, and Folsom Lake. SWP and CVP San Luis Reservoir storages are presented in Figures 5-13 through 5-16 of Draft EIR/EIS for completeness.

Results for changes in SWP and CVP reservoir storages under Alternative 5A at LLT, which are similar to Alternative 5 (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling Technical Appendix*, of the Draft EIR/EIS.

Trinity Lake

Under Alternative 5A, average annual end of September Trinity Lake storage as compared to No Action Alternative would remain similar in most years at ELT, and decrease (3%) at LLT.

Under Alternative 5A, average annual end of September Trinity Lake storage as compared to Existing Conditions would decrease by 9% at ELT and 19% at LLT. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 5A and the results show that average annual end of September Trinity Lake storage could remain similar or decrease under Alternative 5A as compared to the conditions without the project.

Shasta Lake

Under Alternative 5A, average annual end of September Shasta Lake storage as compared to No Action Alternative would remain similar in most of the years at ELT, and decrease (3%) at LLT.

Under Alternative 5A, average annual end of September Shasta Lake storage as compared to Existing Conditions would decrease by 9% at ELT and 20% at LLT. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 5A and the results show that average annual end of September Shasta Lake storage could remain similar or decrease under Alternative 5A as compared to the conditions without the project.

Lake Oroville

Under Alternative 5A, average annual end of September Lake Oroville storage as compared to No Action Alternative would increase by up to 4% at ELT and 6% at LLT.

Under Alternative 5A, average annual end of September Lake Oroville storage as compared to Existing Conditions would decrease by 18% at ELT and 28% at LLT. This decrease would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 5A and the results show that average annual end of September Lake Oroville storage could increase under Alternative 5A as compared to the conditions without the project.

Folsom Lake

Under Alternative 5A, average annual end of September Folsom Lake storage as compared to No Action Alternative would decrease by about 2%.

Under Alternative 5A, average annual end of September Folsom Lake storage as compared to Existing Conditions decrease by up to 17% at ELT and 29% at LLT. This decrease primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 5A and the results show that average annual end of September Folsom Lake storage could decrease under Alternative 5A as compared to the conditions without the project.

San Luis Reservoir

Under Alternative 5A, average annual end of September San Luis Reservoir storage as compared to the No Action Alternative would mostly decrease, due to changes in export patterns.

Under Alternative 5A, average annual end of September San Luis Reservoir storage as compared to Existing Conditions would decrease. This decrease primarily would occur due to changes in export patterns, sea level rise, climate change, and increased north of Delta demands.

A comparison with storages under the No Action Alternative provides an indication of the potential change due to Alternative 5A and the results show that average annual end of September San Luis Reservoir storage would generally decrease under Alternative 5A as compared to the conditions without the project.

Change in Delta Exports

Changes in average annual Delta exports under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-4 and B.1-5 in Appendix B and Figures 4.4.1-15 through 4.4.1-18 in this RDEIR/SDEIS.

Changes in average annual Delta exports under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-17 through 5-20 and Tables 5-7 through 5-9, of Draft EIR/EIS.

The addition of the north Delta intakes and changes to Delta regulatory requirements under Alternative 5A change SWP and CVP Delta exports as compared to Delta exports under Existing Conditions and the No Action Alternative.

Delta exports would increase in wetter years and either increase (at ELT) or decrease (at LLT) in drier years under Alternative 5A as compared to exports under No Action Alternative because of the additional capability to divert water at the north Delta intakes.

Total long-term average annual Delta exports under Alternative 5A would increase at ELT and decrease by up to 1% at LLT as compared to exports under Existing Conditions reflecting changes in operations due to less negative OMR flows, implementation of Fall X2 and/or spring outflow under Alternative 5A, and sea level rise and climate change.

The incremental change in Delta exports under Alternative 5A as compared to No Action Alternative would be caused by the facility and operations assumptions of Alternative 5A. Delta exports would increase in wetter years and remain similar or decrease in the drier years under Alternative 5A as compared to the conditions without the project.

Change in SWP and CVP Deliveries

Impact WS-1: Changes in SWP CVP Water Deliveries during Construction

NEPA Effects: During construction of water conveyance facilities associated with Alternative 5A, operation of existing SWP and CVP water conveyance would continue. Construction would not affect the timing or amount of water exported from the Delta through SWP and CVP facilities.

***CEQA Conclusion*:** Constructing Alternative 5A water conveyance facilities would not impact operation of existing SWP or CVP facilities.

Impact WS-2: Change in SWP and CVP Deliveries

The addition of the north Delta intakes under Alternative 5A provides operational flexibility compared to deliveries under Existing Conditions and the No Action Alternative.

Changes in SWP and CVP Deliveries under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.1-4 and B.1-5 in Appendix B and Figures 4.4.1-22 through 4.4.1-28 in this RDEIR/SDEIS.

Changes in SWP and CVP Deliveries under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 5-6 through 5-12 and Tables 5-7 through 5-9 of Draft EIR/EIS.

Results for SWP and CVP deliveries under Alternative 5A (LLT), which are similar to Alternative 5 (LLT), are presented in more detail in Appendix 5A, *BDCP EIR/S Modeling Technical Appendix*, of the Draft EIR/EIS.

Total CVP Deliveries

Under Alternative 5A, average annual total CVP deliveries as compared to No Action Alternative, would increase by up to 3% at ELT and by up to 2% at LLT. Under Alternative 5A, average annual total south of Delta CVP deliveries as compared to No Action Alternative, would increase by up to 5%.

Under Alternative 5A, average annual total CVP deliveries as compared to Existing Conditions, would increase by up to 2% at ELT and decrease by up to 1% at LLT. Under Alternative 5A, average annual total south of Delta CVP deliveries as compared to Existing Conditions, would decrease by up to 2% at ELT and by up to 6% at LLT. However, the decrease would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change. Therefore, average annual total CVP deliveries and average annual total CVP south of Delta deliveries would increase under Alternative 5A scenarios as compared to the conditions without the project.

CVP North of Delta Agricultural Deliveries

Under Alternative 5A, average annual CVP north of Delta agricultural deliveries would increase by up to 4% at ELT and by up to 2% at LLT as compared to No Action Alternative.

Under Alternative 5A, average annual CVP north of Delta agricultural deliveries as compared to Existing Conditions, would decrease by up to 17% at ELT and by up to 30% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP north of Delta agricultural deliveries as compared to No Action Alternative would generally increase. Therefore, average annual CVP north of Delta agricultural deliveries would generally increase under Alternative 5A as compared to the conditions without the project.

CVP South of Delta Agricultural Deliveries

Under Alternative 5A, average annual CVP south of Delta agricultural deliveries as compared to No Action Alternative would increase by up to 13% at ELT and by up to 14% at LLT.

Under Alternative 5A, average annual CVP south of Delta agricultural deliveries as compared to Existing Conditions would decrease by up to 1% at ELT and 14% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP south of Delta agricultural deliveries as compared to No Action Alternative would generally increase. Therefore, average annual CVP south of Delta agricultural deliveries would increase under Alternative 5A as compared to the conditions without the project.

CVP Settlement and Exchange Contract Deliveries

There would be negligible change to CVP Settlement Contract deliveries during dry and critical years under Alternative 5A as compared to deliveries under the No Action Alternative.

There would be negligible change to CVP Settlement Contract deliveries during dry and critical years under Alternative 5A at ELT as compared to deliveries under the Existing Conditions. Under Alternative 5A at LLT, CVP Settlement Contract deliveries during dry and critical years as compared to Existing Conditions would decrease. This is due to Shasta Lake storage declining to dead pool more frequently, as described previously, under increased north-of Delta demands and climate change and sea level rise conditions. As described in the methods section in Chapter 5, *Water Supply* of the Draft EIR/EIS, model results and potential changes under these extreme reservoir storage conditions may not be representative of actual future conditions because changes in assumed operations may be implemented to avoid these conditions.

There would be no changes in deliveries to CVP Exchange Contractors under Alternative 5A.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that CVP Settlement Contract and CVP Exchange Contractors deliveries during dry and critical years would remain similar. Therefore, CVP Settlement Contract and CVP Exchange Contractors deliveries during dry and critical years under Alternative 5A would be similar to the deliveries under the conditions without the project.

CVP North of Delta Municipal and Industrial Deliveries

Under Alternative 5A, average CVP north of Delta M&I deliveries as compared to No Action Alternative would remain similar of result in minor increase.

Under Alternative 5A, average annual CVP north of Delta M&I deliveries as compared to Existing Conditions would increase by up to 88% at ELT and 82% at LLT. However, this increase primarily would occur because there would be an increase in north of Delta M&I water rights demands under Alternative 5A and No Action Alternative as compared to demands under Existing Conditions.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP north of Delta M&I deliveries would remain similar or show minor increase under Alternative 5A as compared to the deliveries under the No Action Alternative. Therefore, average annual CVP north of Delta M&I deliveries would remain similar or increase under Alternative 5A as compared to the conditions without the project.

CVP South of Delta Municipal and Industrial Deliveries

Under Alternative 5A, average CVP south of Delta M&I deliveries as compared to No Action Alternative, would increase by about 4%.

Under Alternative 5A, average annual CVP south of Delta M&I deliveries as compared to Existing Conditions would decrease by up to 1% at ELT and by up to 7% at LLT. However, this decrease primarily would occur due to sea level rise and climate change, and increased north of Delta demands.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual CVP south of Delta M&I deliveries would remain similar or increase under Alternative 5A as compared to the deliveries under the No Action Alternative. Therefore, average annual CVP south of Delta M&I deliveries would increase under Alternative 5A as compared to the conditions without the project.

Total SWP Deliveries

Under Alternative 5A, average annual total SWP deliveries as compared to No Action Alternative, would increase (by about 15%). Under Alternative 5A, average annual total south of Delta SWP deliveries as compared to No Action Alternative, would increase (by about 21%).

Under Alternative 5A, average annual total SWP deliveries as compared to Existing Conditions, would increase (8%) at ELT and increase (3%) at LLT. Under Alternative 5A, average annual total south of Delta SWP deliveries as compared to Existing Conditions, would increase (11%) at ELT and would increase (5%) at LLT. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that under Alternative 5A average annual total SWP deliveries would increase. Therefore, average annual total SWP deliveries and average annual total SWP south of Delta deliveries under Alternative 5A would show an increase as compared to the conditions without the project.

SWP Table A Deliveries

Under Alternative 5A, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to No Action Alternative (ELT), would increase (by about 16%). Under Alternative 5A, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to No Action Alternative (ELT), would increase (by about 16%).

Under Alternative 5A, average annual total SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would increase (11%) at ELT and would increase (5%) at LLT. Under Alternative 5A, average annual total south of Delta SWP Table A deliveries with Article 56 (without Article 21) as compared to Existing Conditions, would increase (10%) at ELT and would increase (4%) at LLT. However, the decrease in deliveries primarily would occur due to sea level rise and climate change.

Deliveries under the No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that under Alternative 5A average annual total SWP Table A deliveries with Article 56 (without Article 21) would increase.

SWP Article 21 Deliveries

Under Alternative 5A, average annual total SWP Article 21 deliveries as compared to No Action Alternative, would increase by about 231%.

Under Alternative 5A, average annual total SWP Article 21 deliveries as compared to Existing Conditions, would increase by up to 10% at ELT and by up to 1% at LLT. However, this decrease primarily would occur due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual Article 21 deliveries would increase under Alternative 5A as compared to the deliveries under the No Action Alternative. Therefore, average annual Article 21 deliveries would increase under Alternative 5A as compared to the conditions without the project.

SWP Feather River Service Area

Under Alternative 5A, average annual total SWP Feather River Service Area deliveries during dry and critical years as compared to No Action Alternative would increase or remain similar.

Under Alternative 5A, average annual total SWP Feather River Service Area deliveries during dry and critical years as compared to Existing Conditions, would decrease by up to 4% at ELT and by up to 5% at LLT. The primary cause of this reduction would be change in SWP operations due to sea level rise and climate change.

Deliveries compared to No Action Alternative are an indication of the potential change due to Alternative 5A in the absence of the effects of increased north of delta demands and sea level rise and climate change and the results show that average annual SWP Feather River Service Area deliveries would increase or remain similar under Alternative 5A as compared to the deliveries under No Action Alternative. Therefore, average annual SWP Feather River Service Area deliveries would remain similar under Alternative 5A as compared to the conditions without the project.

NEPA Effects: SWP and CVP deliveries under Alternative 5A as compared to deliveries under No Action Alternative would increase or remain similar. Indirect effects of changes in water deliveries in addition to potential effects on urban areas caused by changes in SWP and CVP water supply deliveries under Alternative 5A, are addressed in Section 4.5.26, *Growth Inducement and Other Indirect Effects,* and other sections addressing specific resources.

CEQA Conclusion: SWP and CVP deliveries under Alternative 5A would decline as compared to deliveries under Existing Conditions. The primary cause of the reduction is increased north of Delta water demands that would occur under No Action Alternative and Alternative 5A and changes in SWP and CVP operations due to sea level rise and climate change. As shown above in the NEPA analysis, SWP and CVP deliveries would generally increase or remain similar under Alternative 5A as compared to deliveries under conditions in 2025 and 2060 without Alternative 5A if sea level rise and climate change conditions are considered the same under both scenarios (Alternative 5A and No Action Alternative). SWP and CVP deliveries under Alternative 5A would generally increase or remain similar as compared to deliveries under Existing Conditions without the effects of increased north of Delta water demands, sea level rise, and climate change. Some reductions in the SWP south of Delta deliveries could occur under Alternative 5A with higher spring outflow requirements. Indirect effects of changes in water deliveries including potential effects on urban areas caused by changes in SWP and CVP water supply deliveries are addressed in Section 4.5.26, *Growth Inducement and Other Indirect Effects,* and other sections addressing specific resources in this RDEIR/SDEIS.

Impact WS-3: Effects of Water Transfers on Water Supply

Alternative 5A increases project water supply allocations as compared to the No Action Alternative, and consequently will decrease cross-Delta water transfer demand compared to the No Action Alternative. Alternative 5A would change the combined SWP Table A and CVP south-of-Delta agricultural water supply allocations as compared to Existing Conditions, and the frequency of years in which cross-Delta transfers are assumed to be triggered would change as well, assuming an estimated cross-Delta transfer supply of 600,000 acre-feet in any one year.

Under Alternative 5A as compared to Existing Conditions, the frequency of years in which cross-Delta transfers would increase, and the average annual volume of those transfers would increase. Under Alternative 5A as compared to the No Action Alternative, the frequency of years in which cross-Delta transfers would occur would decrease.

Alternative 5A provides a separate cross-Delta facility with additional capacity to move transfer water from areas upstream of the Delta to export service areas and provides a longer transfer window than allowed under current regulatory constraints. In addition, the facility provides conveyance that would not be restricted by Delta reverse flow concerns or south Delta water level concerns. As a result of avoiding those restrictions, transfer water could be moved at any time of the year that capacity exists in the combined cross-Delta channels, the new cross-Delta facility, and the export pumps, depending on operational and regulatory constraints, including criteria guiding the operation of water conveyance facilities under Alternative 5A.

NEPA Effects: Alternative 5A would decrease water transfer demand compared to existing conditions. Alternative 5A would decrease conveyance capacity, enabling additional cross-Delta water transfers that could lead to increases in Delta exports when compared to No Action Alternative. Prior to approval, each transfer must go through NEPA review and be evaluated by the export facility agency, and may also be subject to CEQA review and/or SWRCB process. Indirect effects of changes in Delta exports or water deliveries are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, and other sections addressing specific resources.

CEQA Conclusion: Alternative 5A would increase water transfer demand compared to existing conditions. Alternative 5A would increase conveyance capacity, enabling additional cross-Delta water transfers that could lead to increases in Delta exports when compared to existing conditions. Prior to approval, each transfer must go through the CEQA and/or SWRCB process and be evaluated by the export facility agency, and may also be subject to NEPA review. Indirect effects of changes in Delta exports or water deliveries are addressed in Section 4.3.26, *Growth Inducement and Other Indirect Effects*, and other sections addressing specific resources.

4.5.2 Surface Water

Facilities construction under Alternative 5A would be similar to those described under Alternative 4, except Alternative 5A includes only one intake. Alternative 5A water conveyance operations would be similar to the operations that would occur under Alternative 5.

Model simulation results for Alternative 5A Early Long-term (ELT), which are represented by the Alternative 5 (ELT), are summarized in Tables B.2-7 through B.2-12 in Appendix B of the RDEIR/SDEIS. Model simulation results for Alternative 5A at Late Long-term (LLT) which are similar to Alternative 5 (LLT), are summarized in Tables 6-2 through 6-9 in the Draft EIR/EIS.

Section 6.3.2, *Determination of Effects*, of the Draft EIR/EIS describes criteria used for the NEPA adverse effect and CEQA significant impact determinations.

SWP CVP Reservoir Storage and Related Changes to Flood Potential

Impact SW-1: Changes in SWP or CVP Reservoir Flood Storage Capacity

Reservoir storage in Shasta Lake, Folsom Lake, and Lake Oroville during the October through June period is compared to the flood storage capacity of each reservoir to identify the number of months where the reservoir storage is close to the flood storage capacity.

Changes in the number of months where the reservoir storage is close to the flood storage capacity under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-7 through B.2-12 in Appendix B of this RDEIR/SDEIS.

Changes in the number of months where the reservoir storage is close to the flood storage capacity under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Tables 6-2 through 6-7 of Draft EIR/EIS.

NEPA Effects: Under Alternative 5A, the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be similar (or show no more than 10% increase) under the No Action Alternative.

A comparison with storage conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that reservoir storages would not be consistently high during October through June under Alternative 5A as compared to the conditions under the No Action Alternative. Therefore, Alternative 5A would not result in adverse effects on reservoir flood storage capacity as compared to the conditions without the project.

CEQA Conclusion: Under Alternative 5A, the number of months where the reservoir storage is close to the flood storage capacity in Shasta Lake, Folsom Lake, and Lake Oroville would be less than under Existing Conditions. These differences represent changes under Alternative 5A, increased demands from Existing Conditions to No Action Alternative, and changes due to sea level rise and climate change. Alternative 5A would not cause consistently higher storages in the upper Sacramento River watershed during the October through June period. Accordingly, Alternative 5A would result in a less-than-significant impact on flood management. No mitigation is required.

Highest Monthly Flows in Sacramento and San Joaquin Rivers and Related Changes to Flood Potential

Impact SW-2: Changes in Sacramento and San Joaquin River Flood Flows

Changes in highest monthly flows under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-7 through B.2-9 in Appendix B and Figures 4.4.2-1 through 4.4.2-15 in this RDEIR/SDEIS.

Changes in highest monthly flows under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figures 6-8 through 6-22 and Tables 6-2 through 6-4 of Draft EIR/EIS.

Sacramento River at Bend Bridge

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would increase by about 2% of the channel capacity (100,000 cfs) as compared to the flows under Existing Conditions. The increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the Sacramento River at Bend Bridge as compared to the conditions without the project.

Sacramento River at Freeport

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would decrease by about 1% of the channel capacity (110,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the Sacramento River at Freeport as compared to the conditions without the project.

San Joaquin River at Vernalis

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar to (or show less than 1% change with respect to the channel capacity: 52,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar (or show less than 1% change with respect to the channel capacity: 52,000 cfs) as compared to the flows under Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the San Joaquin River at Vernalis as compared to the conditions without the project.

Sacramento River at Location Upstream of Walnut Grove (downstream of north Delta intakes)

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would decrease by about 4% of channel capacity (110,000 cfs) as compared to the flows under the No Action Alternative. This decrease primarily would occur due to the diversion of Sacramento River flow at the north Delta intakes under Alternative 5A.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would decrease by about 3% of channel capacity (110,000 cfs) as compared to the flows under Existing Conditions. This decrease primarily would occur due to the diversion of Sacramento River flow at the north Delta intakes under Alternative 5A.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the Sacramento River upstream of Walnut Grove as compared to the conditions without the project.

Trinity River Downstream of Lewiston Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would increase by about 4% of channel capacity (6,000 cfs) as compared to the flows under Existing Conditions. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the Trinity River downstream of Lewiston Lake as compared to the conditions without the project.

American River Downstream of Nimbus Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar to (or show less than 1% change with respect to the channel capacity: 152,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would increase by no more than approximately 1% of the channel capacity (152,000 cfs) as compared to the flows under Existing Conditions. This increase primarily would occur due to sea level rise, climate change, and increased north of Delta demands.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the American River at Nimbus Dam as compared to the conditions without the project.

Feather River Downstream of Thermalito Dam

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar as compared to the flows under the No Action Alternative depending on the range of spring Delta outflow requirements.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would remain similar as compared to the flows under Existing Conditions. A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the Feather River at Thermalito Dam as compared to the conditions without the project.

Yolo Bypass at Fremont Weir

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A would increase no more than approximately 1% of the channel capacity (343,000 cfs) as compared to the flows under the No Action Alternative.

Average of highest flows simulated (flows with probability of exceedance of 10% or less) under Alternative 5A at ELT would increase no more than 1% of the channel capacity (343,000 cfs) and at LLT would increase no more than 2% of the channel capacity (343,000 cfs) as compared to the flows under the Existing Conditions.

A comparison with flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change and the results show that there would not be a consistent increase in high flow conditions under Alternative 5A as compared to the No Action Alternative. Therefore, Alternative 5A would not result in adverse impacts on flow conditions in the Yolo Bypass at Fremont Weir as compared to the conditions without the project.

NEPA Effects: Overall, Alternative 5A would not result in an increase in potential risk for flood management compared to the No Action Alternative. Highest monthly flows under Alternative 5A in the locations considered in this analysis either were similar to or less than the highest monthly flows that would occur under the No Action Alternative; or the increase in the highest monthly flows would be less than the flood capacity for the channels at these locations.

Therefore, Alternative 5A would not result in adverse effects on flood management.

***CEQA Conclusion*:** Alternative 5A would not result in an increase in potential risk for flood management compared to Existing Conditions when the changes due to sea level rise and climate change are eliminated from the analysis. Highest monthly flows under Alternative 5A in the locations considered in this analysis either were similar to or less than those that would occur under Existing Conditions without the changes in sea level rise and climate change; or the increased highest monthly flows would not exceed the flood capacity of the channels at these locations. Accordingly, Alternative 5A would result in a less-than-significant impact on flood management. No mitigation is required.

Reverse Flows in Old and Middle River

Impact SW-3: Change in Reverse Flow Conditions in Old and Middle Rivers

Changes in average monthly reverse flow conditions for Old and Middle River flows under Alternative 5A (ELT) as compared to the No Action Alternative (ELT) and Existing Conditions are shown in Tables B.2-7 through B.2-9 in Appendix B and Figure 4.3.2-16 in this RDEIR/SDEIS.

Changes in average monthly reverse flow conditions for Old and Middle River flows under Alternative 5A (LLT) [similar to Alternative 5 (LLT)] as compared to the No Action Alternative (LLT) and Existing Conditions are shown in Figure 6-23 and Tables 6-2 through 6-4 of Draft EIR/EIS.

Reverse flow conditions for Old and Middle River flows would be reduced in all months under Alternative 5A on a long-term average basis except in April, compared to reverse flows under both Existing Conditions and the No Action Alternative. Compared to flows under the No Action Alternative, Old and Middle River flows would be generally less positive in April.

NEPA Effects: A comparison with reverse flow conditions under the No Action Alternative provides an indication of the potential change due to Alternative 5A without the effects of sea level rise and climate change. The results show that reverse flow conditions under Alternative 5A would be reduced in all months on a long-term average basis except in April as compared to No Action Alternative. In April the reverse flow conditions would be generally greater than 1% under Alternative 5A as compared to No Action Alternative. The effects to beneficial use of the surface water for water supplies and aquatic resources, is described in this RDEIR/SDEIS in Section 4.3.4, *Water Quality* and Section 4.3.7, *Fish and Aquatic Resources*.

***CEQA Conclusion*:** Alternative 5A would provide positive changes related to reducing reverse flows in Old and Middle Rivers in May through March and negative changes in the form of increased reverse flow conditions in April, compared to Existing Conditions. The increase (more negative) in reverse flow conditions is generally greater than 1% as compared to Existing Conditions. The significance of the impact to beneficial use of the surface water for water supplies and aquatic resources, and appropriate Mitigation Measures for those impacts to beneficial uses is described in this RDEIR/SDEIS in Section 4.3.4, *Water Quality* and Section 4.3.7, *Fish and Aquatic Resources*.

Impact SW-4: Substantially Alter the Existing Drainage Pattern or Substantially Increase the Rate or Amount of Surface Runoff in a Manner That Would Result in Flooding during Construction of Conveyance Facilities

NEPA Effects: Effects associated with construction and operations of facilities under Alternative 5A would be similar to those described under Alternative 1A with the exception of four fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 5A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. However, the measures included in Alternative 1A to avoid adverse effects would be included in Alternative 5A.

Alternative 5A would involve excavation, grading, stockpiling, soil compaction, and dewatering that would result in temporary and long-term changes to drainage patterns, drainage paths, and facilities that would in turn, cause changes in drainage flow rates, directions, and velocities. Construction of cofferdams could impede river flows at the intake locations, but would not increase water surface elevations upstream by more than 0.10 feet during flood events. Potential adverse effects could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages; and changes in sediment accumulation near the intakes. Mitigation Measure SW-4 is available to address effects of runoff and sedimentation.

***CEQA Conclusion*:** Alternative 5A could result in alterations to drainage patterns, stream courses, and runoff; and potential for slightly increased surface water elevations in the rivers and streams during construction and operations of facilities located within the waterway. Although intakes have been designed and located on-bank to minimize changes to river flow characteristics, some localized water elevation changes would occur upstream and adjacent to each cofferdam at the intake sites due to facility location within the river. These localized surface elevation changes would not exceed an increase of 0.10 feet at any intake location even under flood flow conditions. Potential impacts could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages, and from changes in sediment accumulation near the intakes. These impacts are considered significant. Mitigation Measure SW-4 would reduce this impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

Impact SW-5: Substantially Alter the Existing Drainage Pattern or Substantially Increase the Rate or Amount of Surface Runoff in a Manner That Would Result in Flooding during Construction of Habitat Restoration Area Facilities under Environmental Commitments 3, 4, 6-11

NEPA Effects: Alternative 5A would include construction of the restoration area facilities under Environmental Commitments 3, 4, and 6-11.

Riparian habitat restoration is anticipated to occur primarily in association with the restoration of tidal marsh habitat, and channel margin habitat. The restored vegetation has the potential of increasing channel roughness, which could result in increases in channel water surface elevations, including under flood flow conditions, and in decreased velocities. Modified channel geometries could increase or decrease channel velocities and/or channel water surface elevations, including under flood flow conditions. Under existing regulations, the USACE, CVFPB, and DWR would require the habitat restoration projects to be flood neutral. The specific permits/decisions/approvals required are included in Table 1-1 of this RDEIR/SDEIS, and in Table 1-2 of the Draft EIR/EIS. Measures to reduce flood potential could include channel dredging to increase channel capacities and decrease channel velocities and/or water surface elevations.

***CEQA Conclusion*:** Alternative 5A would include construction of the restoration area facilities under Environmental Commitments 3, 4, and 6–11. Alternative 5A could result in alterations to drainage patterns, stream courses, and runoff; and potential for increased surface water elevations in the rivers and streams during construction and operations of facilities located within the waterway. These impacts are considered significant. Under existing regulations, the USACE, CVFPB, and DWR would require the habitat restoration projects to be flood neutral. Measures to reduce flood potential could include channel dredging to increase channel capacities and decrease channel velocities and/or water surface elevations. The specific permits/decisions/approvals required are included in Table 1-1 of this RDEIR/SDEIS, and in Table 1-2 of the Draft EIR/EIS. Mitigation Measure SW-4 would reduce this impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

Impact SW-6: Create or Contribute Runoff Water Which Would Exceed the Capacity of Existing or Planned Stormwater Drainage Systems or Provide Substantial Additional Sources of Polluted Runoff

Effects associated with construction and operations of facilities under Alternative 5A would be similar to those described under Alternative 1A with the exception of four fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 5A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A because there would be fewer construction sites under this alternative.

NEPA Effects: Paving, soil compaction, and other activities would increase runoff during facilities construction and operations. Construction and operation of dewatering facilities and associated discharge of water would result in localized increases in flows and water surface elevations in receiving channels. These activities could result in adverse effects if the runoff volume exceeds the capacities of local drainages. As noted below in the CEQA Conclusion section, compliance with permit design requirements would avoid adverse effects on surface water quality and flows from dewatering activities. The use of dispersion facilities would reduce the potential for channel erosion. Mitigation Measure SW-4 is available to address adverse effects.

***CEQA Conclusion*:** Alternative 5A actions would include installation of dewatering facilities in accordance with permits issued by the Regional Water Quality Control Board and CVFPB (See Section 6.2.2.4 in the Draft EIR/EIS). Alternative 5A would include provisions to design the dewatering system in accordance with these permits to avoid significant impacts on surface water quality and flows. However, increased runoff could occur from facilities sites during construction or operations and could result in significant impacts if the runoff volume exceeds the capacities of local drainages. These impacts are considered significant. Mitigation Measure SW-4 would reduce this potential impact to a less-than-significant level.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

Impact SW-7: Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding Due to the Construction of New Conveyance Facilities

NEPA Effects: Effects associated with construction of conveyance facilities under Alternative 5A would be identical to those described under Alternative 1A with the exception of four fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 5A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A.

Alternative 5A would not result in an increase to exposure of people or structures to flooding due to construction of the conveyance facilities because the project proponents would be required to comply with USACE, CVFPB, and DWR requirements to avoid increased flood potential and levee failure due to construction and operation of the facilities as described in Section 6.2.2.4 in the Draft EIR/EIS. Additionally, DWR would consult with local reclamation districts to ensure that construction activities would not conflict with reclamation district flood protection measures. Determination of design flood elevations would need to consider sea level rise to reduce impacts.

***CEQA Conclusion*:** Alternative 5A would not result in an increase to exposure of people or structures to flooding due to construction of the conveyance facilities because the project proponents would be required to comply with the requirements of USACE, CVFPB, and DWR to avoid increased flood potential and levee failure due to construction and operation of the facilities as described in Section 6.2.2.4 in the Draft EIR/EIS. If the design flood elevations did not consider sea level rise to reduce impacts, these impacts are considered significant. Mitigation Measure SW-7 would reduce this impact to a less-than-significant level.

Mitigation Measure SW-7: Implement Measures to Reduce Flood Damage

Please see Mitigation Measure SW-7 under Impact SW-7 in the discussion of Alternative 1A.

Impact SW-8: Expose People or Structures to a Significant Risk of Loss, Injury, or Death Involving Flooding Due to Habitat Restoration under Environmental Commitments 3, 4, 6-11

Tidal marsh habitat, and channel margin habitat could increase flood potential due to impacts on adjacent levees. The newly flooded areas would have larger wind fetch lengths (unobstructed distance which wind can travel over water and potentially develop large waves caused by wind force not tidal force) compared to the existing fetch lengths of the adjacent leveed channels. An increase in fetch length would result in increases in wave height and velocities that reach the existing levees along adjacent islands and floodplains. These potential increases in wave action could also reach the land-side of the remaining existing levees around the restoration area. In accordance with existing requirements of the USACE, CVFPB, and DWR, Alternative 5A would be designed to avoid increased flood potential as compared to Existing Conditions or No Action Alternative.

NEPA Effects: Alternative 5A would not result in an increase to exposure of people or structures to flooding due to the operation of the Environmental Commitments because the facilities would be required to comply with the requirements of the USACE, CVFPB, and DWR to avoid increased flood potential. However, increased wind fetch near open water areas of habitat restoration could cause potential damage to adjacent levees. This impact could become more substantial with sea level rise and climate change.

***CEQA Conclusion*:** Alternative 5A would not result in an increase to exposure of people or structures to flooding due to the operations of Environmental Commitments because the facilities would be required to comply with the requirements of the USACE, CVFPB, and DWR to avoid increased flood potential. However, increased wind fetch near open water areas of habitat restoration could cause potential damage to adjacent levees. These impacts are considered significant. Mitigation Measure SW-8 would reduce this potential impact to a level of less than significant.

Mitigation Measure SW-8: Implement Measures to Address Potential Wind Fetch Issues

Please see Mitigation Measure SW-8 under Impact SW-8 in the discussion of Alternative 1A.

Impact SW-9: Place within a 100-Year Flood Hazard Area Structures Which Would Impede or Redirect Flood Flows, or Be Subject to Inundation by Mudflow

Effects associated with construction and operations of facilities under Alternative 5A would be identical those described under Alternative 1A with the exception of four fewer intakes, elimination of the pumps at the intake locations, and reduction of the intermediate forebay acreage. Additional pumps would be constructed near Clifton Court Forebay under Alternative 5A as compared to Alternative 1A. Because similar construction methods and similar features would be used as under Alternative 1A, the types of effects would be similar. However, the potential for effects would be less than described under Alternative 1A. The measures included in Alternative 1A to avoid adverse effects would be included in Alternative 5A. As described under Impact SW-1, Alternative 5A would not increase flood potential on the Sacramento River, San Joaquin River, Trinity River, American River, or Feather River, or Yolo Bypass as described under Impact SW-2. Alternative 5A would include measures including Mitigation Measure SW-4 to address potential issues associated with alterations to drainage patterns, stream courses, and runoff and potential for increased surface water elevations in the rivers and streams during construction and operations of facilities.

NEPA Effects: Potential adverse effects could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages; and changes in sediment accumulation near the intakes. These effects are considered adverse. Mitigation Measure SW-4 is available to address these potential effects.

***CEQA Conclusion*:** Alternative 5A would not result in an impedance or redirection of flood flows or conditions that would cause inundation by mudflow due to construction or operations of the conveyance facilities or construction of the habitat restoration facilities because the project proponents would be required to comply with the requirements of USACE, CVFPB, and DWR to avoid increased flood potential as described in Section 6.2.2.4 in the Draft EIR/EIS. Potential adverse impacts could occur due to increased stormwater runoff from paved areas that could increase flows in local drainages, as well as changes in sediment accumulation near the intakes. These impacts are considered significant. Mitigation Measure SW-4 would reduce this potential impact to a less-than-significant level by implementing a number of measures which would prevent an increase in runoff volume and rate from land-side construction areas; and which would prevent an increase in sedimentation in the runoff from the construction areas.

Mitigation Measure SW-4: Implement Measures to Reduce Runoff and Sedimentation

Please see Mitigation Measure SW-4 under Impact SW-4 in the discussion of Alternative 1A.

4.5.3 Groundwater

4.5.3.1 Delta Region

Alternative 5A would include the same physical/structural components as Alternative 4 but would include two fewer intakes. Facilities construction under Alternative 5A would be similar to those described for Alternative 4, but with a smaller footprint due to two fewer intakes.

Impact GW-1: During Construction, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Local Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

Construction activities under Alternative 5A would be similar to those under Alternative 4. The impacts on groundwater levels resulting from dewatering activities are dependent on the local hydrogeology and the depth and duration of dewatering required. Because all of the pump stations associated with the intakes are located in areas of similar geology and hydrogeology, and the dewatering configurations are identical for each of the facilities, it would be expected that the impacts of construction activities on local groundwater levels and associated well yields would be similar. The only difference would be associated with the number of intakes used. This alternative would use one intake instead of three intakes used in Alternative 4. Dewatering activities would result in decreased groundwater level impacts and fewer wells being affected.

NEPA Effects: Similarly to the impacts described under Alternative 4, the sustainable yield of some wells might temporarily be affected by the lower water levels resulting from construction dewatering under Alternative 5A, such that they are not able to support existing land uses. The construction of conveyance features would result in effects on groundwater levels and associated well yields that would be temporary. It should be noted that these estimated impacts reflect a worst-case scenario as the option of installing seepage cutoff walls during dewatering was not considered in the analysis.

CEQA Conclusion: Similarly to the impacts described under Alternative 4, wells in the vicinity of the construction dewatering areas under Alternative 5A could experience significant reductions in yield, if they are shallow wells and may not be able to support existing land uses. The temporary impact on groundwater levels and associated well yields is considered significant because construction-related dewatering might affect the amount of water supplied by shallow wells located near the construction sites. Mitigation Measure GW-1 identifies a monitoring procedure and options for maintaining an adequate water supply for land owners that experience a reduction in groundwater production from wells within the impacted areas due to construction-related dewatering activities. It should be noted that these estimated impacts reflect a worst-case scenario as the option of installing seepage cutoff walls during dewatering was not considered in the analysis. Implementing Mitigation Measure GW-1 would help address these effects; however, the impact may remain significant because replacement water supplies may not meet the preexisting demands or planned land use demands of the affected party. In some cases this impact might temporarily be significant and unavoidable until groundwater elevations recover to pre-construction conditions which could require several months after dewatering operations cease.

Mitigation Measure GW-1: Maintain Water Supplies in Areas Affected by Construction Dewatering

Please see Mitigation Measure GW-1 under Impact GW-1 in the discussion of Alternative 1A.

Impact GW-2: During Operations, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Local Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

See Impact GW-2 under Alternative 4; operations under Alternative 5A would be similar to those under Alternative 4.

NEPA Effects: The new Intermediate Forebay and the expanded Clifton Court Forebay would be constructed to comply with the requirements of the DSD which include design features intended to minimize seepage under the embankments. In addition, the forebays will include a seepage cutoff wall installed to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. Any potential vertical seepage under the smaller Intermediate Forebay would also be captured by the toe drain. However, operation of Alternative 5A would result in groundwater level increases in the vicinity of the expanded Clifton Court Forebay portion at Byron Tract due to groundwater recharge, similar to Alternative 4.

Operation of the tunnel would have no impact on existing wells or yields given the facilities would be located more than 100 feet underground and would not substantially alter groundwater levels in the vicinity.

CEQA Conclusion: The new Intermediate Forebay and the expanded Clifton Court Forebay will include design features intended to minimize seepage under the embankments and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. Any potential vertical seepage under the smaller Intermediate Forebay would also be captured by the toe drain. However, operation of Alternative 5A would result in groundwater level increases in the vicinity of the expanded Clifton Court Forebay portion at Byron Tract due to groundwater recharge, similar to Alternative 4, which would not reduce the yields of nearby wells.

Operation of the tunnel would have no impact on existing wells or yields given these facilities would be located over 100 feet underground and would not substantially alter groundwater levels in the vicinity.

Therefore, this impact would be less than significant. No mitigation is required.

Impact GW-3: Degrade Groundwater Quality during Construction and Operation of Conveyance Facilities

See Impact GW-3 under Alternative 4; the construction and operations activities under Alternative 5A would be similar to those under Alternative 4, with a lesser magnitude, because one intake would be constructed (instead of three).

NEPA Effects: Dewatering would temporarily lower groundwater levels and cause small changes in groundwater flow patterns near the intake pump stations along the Sacramento River, Intermediate Forebay, and Clifton Court Forebay. Since no significant regional changes in groundwater flow directions are anticipated, and the inducement of poor-quality groundwater into areas of better quality is unlikely, it is anticipated that there would be no change in groundwater quality for

Alternative 5A. Further, the planned treatment of extracted groundwater prior to discharge into adjacent surface waters would prevent significant impacts on groundwater quality. There would be no adverse effect.

CEQA Conclusion: No significant groundwater quality impacts are anticipated during construction activities. Because of the temporary and localized nature of construction dewatering, the potential for the inducement of the migration of poor-quality groundwater into areas of higher quality groundwater will be low. Further, the planned treatment of extracted groundwater prior to discharge into adjacent surface waters would prevent significant impacts on groundwater quality.

No significant groundwater quality impacts are anticipated in most areas of the Delta during the implementation of Alternative 5A, because changes to regional patterns of groundwater flow are not anticipated. However, degradation of groundwater quality near the Suisun Marsh area are likely, due to the effects of saline water intrusion caused by slightly rising sea levels. Effects due to climate change are provided for informational purposes only and do not lead to mitigation. This impact would be less than significant. No mitigation is required.

Impact GW-4: During Construction of Conveyance Facilities, Interfere with Agricultural Drainage in the Delta

See Impact GW-4 under Alternative 4; construction activities under Alternative 5A would be similar to those under Alternative 4, with a lesser magnitude, because one intake would be constructed (instead of three).

NEPA Effects: In the absence of seepage cutoff walls intended to minimize local changes to groundwater flow, the lowering of groundwater levels due to construction dewatering would temporarily affect localized shallow groundwater flow patterns during and immediately after the construction dewatering period. For the Byron Tract Forebay site, only a portion of the shallow groundwater flow will be directed inward toward the dewatering operations. Forecasted temporary changes in shallow groundwater flow directions and areas of impacts are minor near the intakes. Therefore, agricultural drainage during construction of conveyance features is not forecasted to result in adverse effects under Alternative 5A. In some instances, the lowering of groundwater levels in areas that experience near-surface water level conditions (or near-saturated root zones) would be beneficial. There would be no adverse effect.

CEQA Conclusion: The forecasted changes in shallow groundwater flow patterns due to construction dewatering activities in the Delta are localized and temporary and are not anticipated to cause significant impacts on agricultural drainage. This impact would be less than significant. No mitigation is required.

Impact GW-5: During Operations of New Facilities, Interfere with Agricultural Drainage in the Delta

See Impact GW-5 under Alternative 4; operations under Alternative 5A would be similar to those under Alternative 4.

NEPA Effects: The Intermediate Forebay and the expanded Clifton Court Forebay will include a seepage cutoff wall to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. These design measures will greatly reduce any potential for seepage onto adjacent lands and avoid interference with agricultural drainage in the vicinity of the Intermediate Forebay. Once constructed, the operation of the forebay would be monitored to ensure seepage does not exceed performance requirements.

However, operation of Alternative 5A would result in local changes in shallow groundwater flow patterns adjacent to the expanded Clifton Court Forebay portion at Byron Tract, where groundwater recharge from surface water would result in groundwater level increases, similar to Alternative 4. If existing agricultural drainage systems adjacent to the forebay are not adequate to accommodate the additional drainage requirements, operation of the forebay could interfere with agricultural drainage in the Delta.

CEQA Conclusion: The Intermediate Forebay and the expanded Clifton Court Forebay will include a seepage cutoff wall to the impervious layer and a toe drain around the forebay embankment, to capture water and pump it back into the forebay. These design measures will greatly reduce any potential for seepage onto adjacent lands and avoid interference with agricultural drainage in the vicinity of the Intermediate Forebay. Once constructed, the operation of the forebay would be monitored to ensure seepage does not exceed performance requirements.

However, operation of Alternative 5A would result in local changes in shallow groundwater flow patterns adjacent to the expanded Clifton Court Forebay portion at Byron Tract, caused by groundwater recharge from surface water, and could cause significant impacts to agricultural drainage where existing systems are not adequate to accommodate the additional drainage requirements, similar to Alternative 4. Implementation of Mitigation Measure GW-5 is anticipated to reduce this impact to a less-than-significant level in most instances, though in some instances mitigation may be infeasible due to factors such as costs that would be imprudent to bear in light of the fair market value of the affected land. The impact is therefore significant and unavoidable as applied to such latter properties.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A.

Impact GW-6: Deplete Groundwater Supplies or Interfere with Groundwater Recharge Alter Local Groundwater Levels Reduce the Production Capacity of Preexisting Nearby Wells, or Interfere with Agricultural Drainage as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: Implementation of the environmental commitments under Alternative 5A could result in additional increased frequency of inundation of areas associated with the proposed tidal habitat, channel margin habitat, and seasonally inundated floodplain restoration actions, which would result in increased groundwater recharge. Such increased recharge could result in groundwater level rises in some areas. More frequent inundation would also increase seepage, which is already difficult and expensive to control in most agricultural lands in the Delta (see Chapter 14, *Agricultural Resources*). Effects associated with the implementation of those environmental commitments be considered adverse. The implementation of Mitigation Measure GW-5 would help address these effects by identifying areas where seepage conditions have worsened and installing additional subsurface drainage measures, as needed.

CEQA Conclusion: Implementation of the environmental commitments under Alternative 5A could result in additional increased frequency of inundation of areas associated with the proposed tidal habitat, channel margin habitat, and seasonally inundated floodplain restoration actions, which would result in increased groundwater recharge. Such increased recharge could result in groundwater level rises in some areas. More frequent inundation would also increase seepage, which is already difficult and expensive to control in most agricultural lands in the Delta (see Chapter 14, *Agricultural Resources*). Impacts associated with the implementation of those environmental commitments would result in significant impacts. This impact would be reduced to a less-than-significant level in most instances, with the implementation of Mitigation Measure GW-5 by identifying areas where seepage conditions have worsened and installing additional subsurface drainage measures, as needed. However, in some instances mitigation may be infeasible due to factors such as costs. The impact is therefore considered significant and unavoidable as applied to such latter properties.

Mitigation Measure GW-5: Agricultural Lands Seepage Minimization

Please see Mitigation Measure GW-5 under Impact GW-5 in the discussion of Alternative 1A.

Impact GW-7: Degrade Groundwater Quality as a Result of Implementing Environmental Commitments 3, 4, 6–12, 15, and16

NEPA Effects: The increased inundation frequency in restoration areas from the environmental commitments under Alternative 5A would increase the localized areas exposed to saline and brackish surface water, which would result in increased groundwater salinity beneath such areas. The flooding of large areas with saline or brackish water would result in an adverse effect on groundwater quality beneath or adjacent to flooded areas. It would not be possible to completely avoid this effect. However, if water supply wells in the vicinity of these areas are not useable because of water quality issues, Mitigation Measure GW-7 is available to address this effect.

CEQA Conclusion: The increased inundation frequency in restoration areas from the environmental commitments under Alternative 5A would increase the localized areas exposed to saline and brackish surface water, which would result in increased groundwater salinity beneath such areas. The flooding of large areas with saline or brackish water would result in significant impacts on groundwater quality beneath or adjacent to flooded areas. It would not be possible to completely avoid this effect. However, if water supply wells in the vicinity of these areas are not useable because of water quality issues, Mitigation Measure GW-7 would help reduce this impact, but the impact would remain significant and unavoidable.

Mitigation Measure GW-7: Provide an Alternate Source of Water

Please see Mitigation Measure GW-7 under Impact GW-7 in the discussion of Alternative 1A.

4.5.3.2 SWP/CVP Export Service Areas

Impact GW-8: During Operations, Deplete Groundwater Supplies or Interfere with Groundwater Recharge, Alter Groundwater Levels or Reduce the Production Capacity of Preexisting Nearby Wells

The groundwater resource impacts of Alternative 5A will be similar to those under Alternative 5, but with the magnitude of the impacts proportional to the change in the quantity of CVP and SWP surface water supplies delivered to the SWP/CVP Export Service Areas compared to the No Action Alternative at ELT.

Table 4.3.3-3 below shows the long-term average SWP and CVP deliveries for Alternative 5A compared to existing conditions and the No Action Alternative at early long-term. See Table 7-7 in Chapter 7, *Groundwater*, of the Draft EIR/EIS for long-term average SWP and CVP surface water deliveries at LLT.

Table 4.3.3-3. Long-Term State Water Project and Central Valley Project Deliveries to Hydrologic Regions Located South of the Delta at Early Long-Term

	Long-Term Average State Water Project and Central Valley Project Deliveries at Early Long Term(TAF/year)		
Alternative	San Joaquin and Tulare Hydrologic Region	Central Coast Hydrologic Region	Southern California Hydrologic Region
Existing Conditions	2,964	47	1,647
No Action Alternative (ELT)	2,682	43	1,580
Alternative 5A ELT	2,924	48	1,746

NEPA Effects: In the San Joaquin and Tulare Hydrologic Region, total long-term average annual water deliveries to the CVP and SWP Service Areas under Alternative 5A at ELT are expected to be higher than the exports under the No Action Alternative at early long-term. Increases in surface water deliveries attributable to project operations from the implementation of Alternative 5A are anticipated to result in a corresponding decrease in groundwater use in the San Joaquin and Tulare Export Service Areas as compared to the No Action Alternative (ELT), as discussed in Section 4.2.4, *Water Supply*, of this RDEIR/DSEIS. Higher groundwater levels associated with reduced overall groundwater use would result in a beneficial effect on groundwater levels. Similarly, total long-term average annual water deliveries to the CVP and SWP Service Areas under Alternative 5A at LLT are expected to be higher than the exports under the No Action Alternative at late long-term.

The total long-term average annual SWP deliveries to Southern California areas under Alternative 5A would be greater than those under the No Action Alternative (ELT) as well as at LLT. Therefore, implementation of Alternative 5A would result in a corresponding decrease in groundwater use. There would be no adverse effects on groundwater levels because of the anticipated decreases in groundwater pumping due to an increase in surface water deliveries.

CEQA Conclusion*:* For the San Joaquin and Tulare Service Areas, total long-term average surface water deliveries under Alternative 5A at ELT would be slightly lower compared to Existing Conditions, largely because of effects due to climate change, sea level rise, and increased water demand north of the Delta. Groundwater pumping under Alternative 5A at ELT is anticipated to be greater than under Existing Conditions, and that groundwater levels in some areas would be lower than under Existing Conditions. Total long-term average surface water deliveries under Alternative 5A at LLT in the San Joaquin Valley and Tulare Basin would be lower compared to Existing Conditions, largely because of effects due to climate change, sea level rise, and increased water demand north of the Delta.

As shown above in the NEPA analysis, SWP and CVP deliveries would increase under Alternative 5A as compared to deliveries under conditions in 2025 without Alternative 5A if sea level rise and climate change conditions are considered the same. For reasons discussed in Section 7.3.1, *Methods for Analysis*, in the Draft EIR/EIS, DWR has identified effects of action alternatives under CEQA separately from the effects of increased water demands, sea level rise, and climate change, which would occur without and independent of the Alternative 5A. Absent these factors, the impacts of Alternative 5A with respect to groundwater levels are anticipated to be less than significant because groundwater pumping is not anticipated to increase due to Alternative 5A.

The total long-term average annual SWP deliveries to Southern California areas under Alternative 5A would be greater than those under Existing Conditions. Therefore, implementation of Alternative 5A would result in a corresponding decrease in groundwater use. Impacts on groundwater levels would be less than significant because of the anticipated decreases in groundwater pumping due to an increase in surface water deliveries.

Impact GW-9: Degrade Groundwater Quality

NEPA Effects: As discussed under Impact GW-8, surface water deliveries to the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin under Alternative 5A are expected to increase as compared to the No Action Alternative (ELT) and at LLT. Increased surface water deliveries could result in a decrease in groundwater use. The decreased groundwater use is not anticipated to alter regional patterns of groundwater flow in these service areas. Therefore, it is not anticipated this would result in an adverse effect on groundwater quality in these areas because similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater as might occur with increased pumping.

Similarly, long-term average annual SWP supplies to Southern California are anticipated to increase under Alternative 5A compared to the No Action Alternative at ELT and LLT, and therefore, groundwater pumping is anticipated to decrease, which would not alter regional groundwater flow patterns. As a result, adverse effects on groundwater quality are not anticipated in this region because similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater.

CEQA Conclusion: As discussed under Impact GW-8 above, the impacts of Alternative 5A with respect to groundwater levels are considered to be less than significant in the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin and in Southern California. Therefore, no significant groundwater quality impacts are anticipated in these areas during the implementation of Alternative 5A because it is not anticipated to alter regional groundwater flow patterns. Therefore, this impact is considered less than significant because groundwater levels and flow patterns would not change compared to Existing Conditions, and similar groundwater flow patterns would not cause poor quality groundwater migration into areas of better quality groundwater.

Impact GW-10: Result in Groundwater Level–Induced Land Subsidence

Groundwater level-induced land subsidence has the highest potential to occur in the San Joaquin and Tulare Export Service Areas, based on historical data, if groundwater pumping substantially increases due to the Alternatives.

NEPA Effects: As discussed under Impact GW-8, surface water deliveries to the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin under Alternative 5A are expected to increase as compared to the No Action Alternative (ELT) as well as at LLT. Increased surface water deliveries could result in a decrease in groundwater pumping. The decreased groundwater pumping would result in higher groundwater levels, and therefore, the potential for groundwater level-induced land subsidence is reduced under Alternative 5A. Operations under Alternative 5A would not result in an adverse effect on the potential for groundwater level-induced land subsidence in these areas because groundwater levels would not decline such that compaction of unconsolidated materials in the unconfined aquifer would occur.

CEQA Conclusion: As discussed under Impact GW-8 above, the impacts of Alternative 5A with respect to groundwater levels are considered to be less than significant in the CVP and SWP Export Service Areas in the San Joaquin Valley and Tulare Basin. Therefore, the potential for groundwater level-induced land subsidence is anticipated to be less than significant in these areas during the implementation of Alternative 5A because it is not anticipated to result in a decline in groundwater levels such that compaction of unconsolidated materials in the unconfined aquifer would occur.

4.5.4 Water Quality

The water quality changes described for Alternative 5A reflect assumed water conveyance facilities operations. The water quality changes described for Alternative 5A are also affected by assumptions regarding the extent of habitat restoration to be implemented. As described in Section 4.1.4, *Description of Alternative 5A*, of this RDEIR/SDEIS, Alternative 5A does not include the full suite of conservation actions included in Alternative 4. Aside from the water conveyance facilities, the most important differences from a water quality perspective are:

- CM2 – Yolo Bypass Improvements: this is included in Alternative 4, but not included in Alternative 5A; and
- CM4 – Tidal Natural Communities Restoration: includes 65,000 acres in Alternative 4, but would be significantly less under Alternative 5A.

This results in somewhat different patterns of water withdrawals from the Delta, and potentially somewhat different effects on water quality and aquatic habitat conditions in the project area than analyzed for Alternative 4. As described in Section 4.1.4, *Description of Alternative 5A*, of this RDEIR/SDEIS, actions associated with Alternative 4 that are not proposed to be implemented under Alternative 5A would continue to be pursued as part of existing, but separate, projects and programs associated with the 2008 USFWS and 2009 NMFS BiOps (e.g., 8,000 acres of tidal habitat restoration and Yolo Bypass improvements), California EcoRestore, and the 2014 California Water Action Plan.

The analysis of boron, bromide, chloride, DOC, EC, and nitrate under Alternative 5A in the ELT is based on modeling conducted for Alternative 5 in the ELT, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. As described above, Yolo Bypass Improvements are not a component of Alternative 5A and the amount of tidal habitat restoration (i.e., Environmental Commitment 4) would be significantly less than that represented in the modeling. In general, the significance of this difference is that the assessment of bromide, chloride, and EC for Alternative 5A, relative to Existing Conditions and the No Action Alternative (ELT), likely overestimates increases in bromide, EC, and chloride that could occur, particularly in the west Delta. Nevertheless, there is notable uncertainty in the results of all quantitative assessments that refer to modeling results, due to the differing assumptions used in the modeling and the description of Alternative 5A and the No Action Alternative (ELT). Due to the reduced suite of environmental commitments in Alternative 5A compared to Alternative 4 (in particular, significantly less tidal restoration), there generally are fewer significant impacts identified for Alternative 5A than for Alternative 4.

Impact WQ-1: Effects on Ammonia Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), substantial point and non-point sources of ammonia-N do not exist upstream of the SRWTP at Freeport in the Sacramento River watershed, in the watersheds of the eastern tributaries (Cosumnes, Mokelumne, and Calaveras Rivers), or upstream of the Delta in the San Joaquin River watershed. Thus, like Alternative 4, operation of the water conveyance facilities under Alternative 5A would have negligible, if any, effect on ammonia concentrations in the rivers and reservoirs upstream of the Delta relative to Existing Conditions and the No Action Alternative (ELT and LLT). Any negligible increases in ammonia-N concentrations that could occur in the water bodies of the affected environment located upstream of the Delta would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the quality of these water bodies, with regard to ammonia.

Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), a substantial decrease in Sacramento River ammonia concentrations is expected under Alternative 5A relative to Existing Conditions, due to planned lowering of ammonia in the SRWTP effluent discharge, and this is expected to decrease ammonia concentrations for all areas of the Delta that are influenced by Sacramento River water. Concentrations of ammonia at locations not influenced notably by Sacramento River water would change little relative to Existing Conditions, due to the similarity in San Joaquin River and San Francisco Bay concentrations and the lack of expected changes in either of these concentrations. Thus, Alternative 5A would not result in substantial increases in ammonia concentrations in the project area, relative to Existing Conditions.

Relative to the No Action Alternative (ELT and LLT), the primary mechanism that could potentially alter ammonia concentrations under Alternative 5A is decreased flows in the Sacramento River, which would lower dilution available to the SRWTP discharge. This flow change would be attributable only to operations of the water conveyance facilities, since the same assumptions regarding SRWTP discharge ammonia concentrations, water demands, climate change, and sea level rise apply to both Alternative 5A and the No Action Alternative (ELT and LLT). A simple mass balance calculation was performed to calculate ammonia concentrations downstream of the SRWTP discharge (i.e., downstream of Freeport) under Alternative 5A and the No Action Alternative (ELT) to assess the effects of the flow changes. Monthly average CALSIM II flows at Freeport and the upstream ammonia concentration (0.04 mg/L-N; Central Valley Water Board 2010a:5) were used, together with the SRWTP permitted average dry weather flow (181 mgd) and seasonal ammonia limitations (1.5 mg/L-N in Apr–Oct, 2.4 mg/L-N in Nov–Mar), to estimate the average change in ammonia concentrations downstream of the SRWTP. Table 4.5.4-1 of this RDEIR/SDEIS shows monthly average and long-term annual average predicted concentrations under Alternative 5A. As Table 4.5.4-1 shows, average monthly ammonia concentrations in the Sacramento River downstream of Freeport (upon full mixing of the SRWTP discharge with river water) under Alternative 5A and the No Action Alternative (ELT) are expected to be similar. In comparison to the No Action Alternative (ELT), minor increases in monthly average ammonia concentrations would occur during January through March, August, September, and November under Alternative 5A. Minor decreases in ammonia concentrations are expected for Alternative 5A in June and October. A minor increase in the annual average concentration would occur under Alternative 5A, compared to the No Action Alternative (ELT). Relative to the No Action Alternative (LLT), Alternative 5A is expected to result in similar minor increases in Sacramento River ammonia concentration, because the increased water demands, climate change, and sea level rise in the LLT would occur under both alternatives, and neither would affect ammonia sources or loading. The estimated ammonia concentrations in the Sacramento River downstream of Freeport under Alternative 5A would be similar to existing source water concentrations for the San Francisco Bay and San Joaquin River. Consequently, changes in source water fraction anticipated under Alternative 5A, relative to the No Action Alternative (ELT and LLT), are not expected to substantially increase ammonia concentrations at any Delta locations.

Ammonia concentrations downstream of Freeport on the Sacramento River under Alternative 5A would be similar to those under Alternative 4 (see Table 8-67 in Appendix A of the RDEIR/SDEIS). As stated for Alternative 4, any negligible increases in ammonia concentrations that could occur at certain locations in the Delta under Alternative 5A would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade the water quality at these locations, with regard to ammonia.

Table 4.5.4-1. Estimated Ammonia (mg/L as N) Concentrations in the Sacramento River Downstream of the Sacramento Regional Wastewater Treatment Plant for the No Action Alternative Early Long-term Timeframe (ELT) and Alternative 5A

	Oct	Nov	Dec	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Annual Average
No Action Alternative (ELT)	0.076	0.082	0.068	0.060	0.057	0.060	0.058	0.062	0.067	0.060	0.067	0.063	0.065
Alternative 5A	0.075	0.086	0.068	0.061	0.058	0.061	0.058	0.062	0.064	0.060	0.068	0.067	0.066

SWP CVP Export Service Areas

As discussed above, for areas of the Delta that are influenced by Sacramento River water, including Banks and Jones pumping plants, ammonia-N concentrations are expected to decrease under Alternative 5A, relative to Existing Conditions (in association with less diversion of water influenced by the SRWTP). Like Alternative 4, this decrease in ammonia-N concentrations for water exported via the south Delta pumps is not expected to result in an adverse effect on beneficial uses or substantially degrade water quality of exported water, with regard to ammonia. Furthermore, as discussed above, for all areas of the Delta, including Banks and Jones pumping plants, ammonia concentrations are not expected to be substantially different under Alternative 5A relative to the No Action Alternative (ELT and LLT). Thus, any negligible increases in ammonia concentrations that could occur at Banks and Jones pumping plants would not be of frequency, magnitude and geographic extent that would adversely affect any beneficial uses or substantially degrade water quality at these locations, with regard to ammonia.

NEPA Effects: In summary, ammonia concentrations in water bodies upstream of the Delta, in the Plan Area, and the waters exported to the SWP/CVP Export Service Areas are not expected to be substantially different under Alternative 5A relative to the No Action Alternative (ELT and LLT). Thus, effects of the water conveyance facilities on ammonia are considered to be not adverse.

CEQA Conclusion: The magnitude and direction of changes in ammonia concentrations in water bodies upstream of the Delta, in the Plan Area, or the waters exported to the SWP/CVP Export Service Areas would be approximately the same as expected under Alternative 4, relative to Existing Conditions. There would be no substantial, long-term increase in ammonia concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the CVP and SWP service areas under Alternative 5A relative to Existing Conditions. As such, Alternative 5A is not expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause adverse effects on any beneficial uses of waters in the affected environment. Because ammonia concentrations are not expected to increase substantially, no long-term water quality degradation is expected to occur and, thus, no adverse effects on beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that could occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-2: Effects on Ammonia Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: Some habitat restoration activities would occur on lands in the Delta formerly used for irrigated agriculture. Although this may decrease ammonia loading to the Delta from agriculture, increased biota in those areas as a result of restored habitat may increase ammonia loading originating from flora and fauna. Ammonia loaded from organisms is expected to be converted rapidly to nitrate by established microbial communities. Thus, these land use changes would not be expected to substantially increase ammonia concentrations in the Delta. Implementation of Environmental Commitments 12, 15, and 16 do not include actions that would affect ammonia sources or loading. Based on these findings, the effects on ammonia from the implementation Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 5A are determined to not be adverse.

***CEQA Conclusion*:** Land use changes that would occur from the environmental commitments are not expected to contribute substantially increase ammonia concentrations, because the amount of area to be converted would be small relative to existing habitat, and any resulting ammonia would likely be rapidly converted to nitrate. Thus, there would be no substantial, long-term increase in ammonia concentrations in the rivers and reservoirs upstream of the Delta, in the Plan Area, or the waters exported to the SWP/CVP Export Service Areas due to implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 relative to Existing Conditions. As such, implementation of these environmental commitments would not be expected to cause additional exceedance of applicable water quality objectives/criteria by frequency, magnitude, and geographic extent that would cause significant impacts on any beneficial uses of waters in the affected environment. Because ammonia concentrations would not be expected to increase substantially from implementation of these environmental commitments, no long-term water quality degradation would be expected to occur and, thus, no significant impact on beneficial uses would occur. Ammonia is not CWA Section 303(d) listed within the affected environment and thus any minor increases that could occur in some areas would not make any existing ammonia-related impairment measurably worse because no such impairments currently exist. Because ammonia is not bioaccumulative, minor increases that could occur in some areas would not bioaccumulate to greater levels in aquatic organisms that would, in turn, pose substantial health risks to fish, wildlife, or humans. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-3: Effects on Boron Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), under Alternative 5A there would be no expected change to the sources of boron in the Sacramento River and east-side tributary watersheds and, thus, resultant changes in flows from altered system-wide operations would have negligible, if any, effects on the concentration of boron in the rivers and reservoirs of these watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease by 1%, relative to Existing Conditions (in association with the different operational components of Alternative 5A in the ELT, climate change, and increased water demands) (Table Bo-1 in Appendix B of this RDEIR/SDEIS). The reduced flow relative to Existing Conditions would result in possible increases in long-term average boron concentrations of up to about 0.5% relative to the Existing Conditions. Flows would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial boron increases relative to the No Action Alternative (ELT). The increased boron concentrations, relative to Existing Conditions, under Alternative 5A in the ELT would not increase the frequency of exceedances of any applicable objectives or criteria and would not be expected to cause further degradation at measurable levels in the lower San Joaquin River, and thus would not cause the existing impairment there to be discernibly worse. Consequently, Alternative 5A in the ELT would not be expected to cause exceedance of boron objectives/criteria or substantially degrade water quality with respect to boron, and thus would not adversely affect any beneficial uses of the Sacramento River, the east-side tributaries, associated reservoirs upstream of the Delta, or the San Joaquin River.

Effects of Alternative 5A in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect boron sources in these areas.

Delta

Effects of water conveyance facilities on boron under Alternative 5A in the Delta would be similar to the effects discussed for Alternative 4. To the extent that habitat restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. However, there would be less potential for increased boron concentrations at western Delta locations associated with restoration environmental commitments under Alternative 5A because very little would occur relative Alternative 4. Other effects of the environmental commitments not attributable to hydrodynamics are discussed in Impact WQ-4. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

The effects of Alternative 5A relative to Existing Conditions and the No Action Alternative (ELT) are discussed together because the direction and magnitude of predicted change are similar. Relative to the Existing Conditions and No Action Alternative (ELT), Alternative 5A would result in increased long-term average boron concentrations for the 16-year period modeled at most of the interior Delta locations (increases up to 6% at the S. Fork Mokelumne River at Staten Island, 3% at Franks Tract, and 4% at Old River at Rock Slough) (Table Bo-10 in Appendix B of this RDEIR/SDEIS). The long-term average boron concentrations at most of the western Delta assessment locations would not change measurably. The long-term annual average and monthly average boron concentrations, for either the 16-year period or drought period modeled, would never exceed the 2,000 μg/L human health advisory objective (i.e., for children) or the 500 μg/L agricultural objective at the majority of assessment locations, which represents no change from the Existing Conditions and No Action Alternative (ELT) (Table Bo-8 in Appendix B of this RDEIR/SDEIS). A small increase in the frequency of exceedances 500 μg/L agricultural objective at the Sacramento River at Mallard Island (i.e., as much as 4% in the drought period relative to the No Action Alternative [ELT]) would not be anticipated to substantially affect agricultural diversions which occur primarily at interior Delta locations. There would be no reduction in long-term average assimilative capacity at Delta locations with respect to the 500 μg/L agricultural objective (Table Bo-12 in Appendix B of this RDEIR/SDEIS). Therefore, the risk of exceeding objectives or adverse effects to municipal and agricultural water supply beneficial uses, or any other beneficial uses, would not occur (Figure Bo-2 in Appendix B of this RDEIR/SDEIS).

Effects of Alternative 5A in the Delta in the LLT, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to those described above for the ELT. Boron concentrations may be higher at western Delta locations due to greater effects of climate change on sea level rise that would occur in the LLT; however, these effects are independent of the alternative. Further, boron is of concern in waters diverted for agricultural use, which primarily occurs in the interior Delta, and based on Delta source water characteristics (see Table 8-42 in Appendix A of the RDEIR/SDEIS), boron concentrations in the interior Delta would be expected to remain suitable for agricultural use.

SWP/CVP Export Service Areas

Under the Alternative 5A, long-term average boron concentrations would decrease at Barker Slough (as much as 15%) and at Banks pumping plant (as much as 12%) relative to Existing Conditions, and the reductions would be similar compared to No Action Alternative (ELT) (Table Bo-10 in Appendix B of this RDEIR/SDEIS) as a result of export of a greater proportion of low-boron Sacramento River water. Commensurate with the decrease in exported boron concentrations, boron concentrations in the lower San Joaquin River may be reduced and would likely alleviate or lessen any expected increase in boron concentrations at Vernalis associated with flow reductions (see discussion of Upstream of the Delta), as well as locations in the Delta receiving a large fraction of San Joaquin River water. Reduced export boron concentrations also may contribute to reducing the existing CWA Section 303(d) impairment in the lower San Joaquin River and associated TMDL actions for reducing boron loading. These same effects on boron at the Banks and Jones pumping plants would be expected in the LLT, because the primary effect of climate change on sea level rise and boron concentrations is expected in the western Delta.

Maintenance of SWP and CVP facilities under Alternative 5A would not be expected to create new sources of boron or contribute towards a substantial change in existing sources of boron in the affected environment.

NEPA Effects: In summary, relative to the No Action Alternative (ELT and LLT), Alternative 5A would result in relatively small increases in long-term average boron concentrations in the Delta, not measurably increase boron levels in the lower San Joaquin River, and reduce boron levels in water exported to the SWP/CVP export service areas. However, the predicted changes would not be expected to cause exceedances of applicable objectives or further measurable water quality degradation, and thus would not constitute an adverse effect on water quality.

CEQA Conclusion: Based on the above assessment, any modified reservoir operations and subsequent changes in river flows under Alternative 5A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in boron levels upstream of the Delta. Small increases in boron levels predicted for interior Delta locations in response to a shift in the Delta source water percentages would not be expected to cause exceedances of objectives, or substantial degradation of these water bodies. Alternative 5A maintenance also would not result in any substantial increases in boron concentrations in the affected environment. Boron concentrations would be reduced in water exported from the Delta to the CVP/SWP Export Service Areas, thus reflecting a potential improvement to boron loading in the lower San Joaquin River.

Boron is not a bioaccumulative constituent, thus any increased concentrations under Alternative 5A would not result in adverse boron bioaccumulation effects to aquatic life or humans. Relative to Existing Conditions, Alternative 5A would not result in substantially increased boron concentrations such that frequency of exceedances of municipal and agricultural water supply objectives would increase. The levels of boron degradation that may occur under Alternative 5A would not be of sufficient magnitude to cause substantially increased risk for adverse effects to municipal or agricultural beneficial uses within the affected environment. Long-term average boron concentrations would decrease in Delta water exports to the SWP and CVP service area, which may contribute to reducing the existing CWA Section 303(d) impairment of agricultural beneficial uses in the lower San Joaquin River. Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-4: Effects on Boron Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

NEPA Effects: The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 for Alternative 5A present no new direct sources of boron to the affected environment, including areas upstream of the Delta, within the Delta region, and in the SWP/CVP Export Service Areas. Habitat restoration activities in the Delta, while involving increased land and water interaction within these habitats, would not be anticipated to contribute boron which is primarily associated with source water inflows to the Delta (i.e., San Joaquin River, agricultural drainage, and Bay source water). Moreover, some habitat restoration would occur on lands within the Delta currently used for irrigated agriculture, thus replacing agricultural land uses with restored habitats. The potential reduction in irrigated lands within the Delta may result in reduced discharges of agricultural field drainage with elevated boron concentrations, which would be considered an improvement compared to the No Action Alternative (ELT and LLT). Consequently, as they pertain to boron, implementation of the environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment.

CEQA Conclusion: Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 for Alternative 5A would not present new or substantially changed sources of boron to the affected environment upstream of the Delta, within Delta, or in the SWP/CVP Export Service Areas. As such, their implementation would not be expected to substantially increase the frequency with which applicable Basin Plan objectives or other criteria would be exceeded in water bodies of the affected environment located upstream of the Delta, within the Delta, or in the SWP/CVP Export Service Areas or substantially degrade the quality of these water bodies, with regard to boron. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-5: Effects on Bromide Concentrations Resulting from Facilities Operations and Maintenance Upstream of the Delta

Upstream of the Delta

As described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), under Alternative 5A in the ELT there would be no expected change to the sources of bromide in the Sacramento River and east-side tributary watersheds. Thus, changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of bromide in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions and would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial bromide increases. Moreover, there are no existing municipal intakes on the lower San Joaquin River, which is the beneficial use most sensitive to elevated bromide concentrations. Consequently, Alternative 5A in the ELT would not be expected to adversely affect the MUN beneficial use, or any other beneficial uses, of the Sacramento River, the San Joaquin River, the eastside tributaries, or their associated reservoirs upstream of the Delta due to changes in bromide concentrations.

Effects of Alternative 5A in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect bromide sources in these areas.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due to water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-6. See Chapter 8, Section 8.3.1.3, *Plan Area* in Appendix A of the RDEIR/SDEIS for more information regarding the modeling methodology.

Estimates of bromide concentrations at Delta assessment locations were generated using a mass balance approach, and using relationships between EC and chloride and between chloride and bromide and DSM2 EC output. See Chapter 8, Section 8.3.1.3, *Plan Area* in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in bromide at Delta assessment locations based on both approaches.

Based on the mass balance modeling approach for bromide, relative to Existing Conditions, Alternative 5A long-term average bromide concentrations would increase in the S. Fork Mokelumne River at Staten Island, and decrease at all other assessment locations (Table Br-3 in Appendix B of this RDEIR/SDEIS). Average bromide concentrations at Staten Island would increase from 50 μg/L under Existing Conditions to 59 μg/L (18% increase) for the modeled 16-year hydrologic period (1976–1991). However, multiple interior and western Delta assessment locations would have an increased frequency of exceedance of 50 μg/L, which is the CALFED Drinking Water Program goal for bromide as a long-term average applied to drinking water intakes (Table Br-3 in Appendix B of this RDEIR/SDEIS). These locations are the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. The greatest increase in frequency of exceedance of the CALFED Drinking Water Program long-term goal of 50 μg/L would occur in the S. Fork Mokelumne River (19% increase) and Sacramento River at Emmaton (3% increase). The increase in frequency of exceedance of the 50 μg/L threshold at the other locations would be 1% or less. Similarly, these locations would have an increased frequency of exceedance of 100 μg/L, which is the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts (Table Br-3 in Appendix B of this RDEIR/SDEIS). The greatest increase in frequency of exceedance of 100 μg/L would occur at Franks Tract (7% increase). The increase in frequency of exceedance of the 100 μg/L threshold at the other locations would be 5% or less.

Changes in long-term average bromide concentrations and changes in threshold exceedance frequencies relative to the No Action Alternative (ELT) are generally of similar magnitude to those previously described relative to Existing Conditions (Table Br-3 in Appendix B of this RDEIR/SDEIS).

Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide were consistent with the discussion above, and assessment of bromide using these modeling results lead to the same conclusions as are presented above for the mass balance approach (Table Br-4 in Appendix B of this RDEIR/SDEIS).

Unlike Alternative 4, there would be no increased bromide concentration or frequency of exceedance of bromide thresholds in Barker Slough at the North Bay Aqueduct under Alternative 5A relative to Existing Conditions and the No Action Alternative (ELT). Also, the magnitude of bromide concentration increases at Mallard Slough and in the San Joaquin River at Antioch during their historical months of use, relative to Existing Conditions and the No Action Alternative (ELT), would be generally similar to those described for Alternative 4 (Tables Br-5 and Br-6 in Appendix B of this RDEIR/SDEIS), and the frequency of exceedance of bromide thresholds would be similar (Tables Br-3 and Br-4 in Appendix B of this RDEIR/SDEIS). As described for Alternative 4, the use of seasonal intakes at these locations is largely driven by acceptable water quality, and thus has historically been opportunistic. Opportunity to use these intakes would remain, and the predicted increases in bromide concentrations at Antioch and Mallard Slough would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, at these locations.

The effects of Alternative 5A in the LLT in the Delta region, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to that described above. There may be higher bromide concentrations in the LLT in the western Delta, but this would be associated with sea level rise, not the project alternative, because the primary source of bromide to the Delta is sea water intrusion.

SWP/CVP Export Service Areas

Under Alternative 5A, long-term average bromide concentrations at the Banks and Jones pumping plants, based on the mass balance modeling approach, would decrease. Long-term average bromide concentrations for the modeled 16-year hydrologic period at the pumping plants would decrease by as much as 27% relative to Existing Conditions and 21% relative to the No Action Alternative (ELT) (Table Br-3 in Appendix B of this RDEIR/SDEIS). As a result, less frequent exceedances of the 50 μg/L and 100 μg/L assessment thresholds would occur and an overall improvement in SWP/CVP Export Service Areas water quality would occur respective to bromide. Commensurate with the decrease in exported bromide, an improvement in lower San Joaquin River bromide would also occur since bromide in the lower San Joaquin River is principally related to irrigation water deliveries from the Delta. Results of the modeling approach which used relationships between EC and chloride and between chloride and bromide are consistent with the mass balance results, and assessment of bromide using these modeling results leads to the same conclusions (Table Br-4 in Appendix B of this RDEIR/SDEIS).

The effects of Alternative 5A in the LLT in the SWP/CVP Export Service Areas, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to that described above, because the sea level rise that could occur in the LLT would not result in substantial bromide contributions to the water exported at Banks and Jones pumping plants.

Maintenance of SWP and CVP facilities under Alternative 5A would not be expected to create new sources of bromide or contribute towards a substantial change in existing sources of bromide in the affected environment. Maintenance activities would not be expected to cause any substantial change in bromide such that MUN beneficial uses, or any other beneficial use, would be adversely affected anywhere in the affected environment.

NEPA Effects: In summary, the operations and maintenance activities under Alternative 5A, relative to the No Action Alternative (ELT and LLT) would result in an increased frequency of exceedance of the 50 μg/L and 100 μg/L bromide thresholds for protecting against the formation of disinfection byproducts in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. However, long-term average bromide concentrations would increase only in the S. Fork Mokelumne River at Staten Island; there would be decreases in long-term average bromide concentrations at the other assessment locations. The long-term bromide concentration in the S. Fork Mokelumne River at Staten Island would be less than the concentration believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts. Thus, this increased bromide concentration is not expected to result in adverse affects to MUN beneficial uses, or any other beneficial use, at these locations. Based on these findings, this effect is determined to not be adverse.

CEQA Conclusion: While greater water demands under Alternative 5A would alter the magnitude and timing of reservoir releases north and east of the Delta, these activities would have negligible, if any, effect on the sources of bromide, and ultimately the concentration of bromide in the Sacramento River, the San Joaquin River, the eastside tributaries, and the various reservoirs of the related watersheds, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS).

Under Alternative 5A there would be an increased frequency of exceedance of the 50 μg/L and 100 μg/L bromide thresholds for protecting against the formation of disinfection byproducts in treated drinking water at the S. Fork Mokelumne River at Staten Island, Franks Tract, Old River at Rock Slough, Sacramento River at Emmaton, San Joaquin River at Antioch, and Sacramento River at Mallard Island. However, long-term average bromide concentrations would increase only in the S. Fork Mokelumne River at Staten Island and decrease at all other assessment locations. The long-term bromide concentration in the S. Fork Mokelumne River at Staten Island (59 μg/L) would be less than the 100 μg/L believed to be sufficient to meet currently established drinking water criteria for disinfection byproducts. Further, as described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), the use of seasonal intakes at Antioch and Mallard Island is largely driven by acceptable water quality, and thus has historically been opportunistic and opportunity to use these intakes would remain. Thus, these increased bromide concentrations would not be expected to adversely affect MUN beneficial uses, or any other beneficial use, at these locations.

The assessment of effects on bromide in the SWP/CVP Export Service Areas is based on assessment of changes in bromide concentrations at Banks and Jones pumping plants. Long-term average bromide concentrations at the Banks and Jones pumping plants are predicted to decrease by as much as 27% relative to Existing Conditions and there would be less frequent exceedance of bromide concentration thresholds.

Based on the above, Alternative 5A would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide. Alternative

5A would not result in any substantial change in long-term average bromide concentration or exceed 50 and 100 µg/L assessment threshold concentrations by frequency, magnitude, and geographic extent that would result in adverse effects on any beneficial uses within affected water bodies. Bromide is not a bioaccumulative constituent and thus concentrations under this alternative would not result in bromide bioaccumulating in aquatic organisms. Increases in exceedances of the 100 µg/L assessment threshold concentration would be 7% or less at all locations assessed, which is considered to be less than substantial long-term degradation of water quality. The levels of bromide degradation that may occur under the Alternative 5A would not be of sufficient magnitude to cause substantially increased risk for adverse effects on any beneficial uses of water bodies within the affected environment. Bromide is not CWA Section 303(d) listed and thus the minor increases in long-term average bromide concentrations would not affect existing beneficial use impairment because no such use impairment currently exists for bromide. Based on these findings, this impact is less than significant. No mitigation is required.

Impact WQ-6: Effects on Bromide Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would present no new sources of bromide to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Areas. Some habitat restoration activities would occur on lands in the Delta formerly used for irrigated agriculture. Such replacement or substitution of land use activity would not be expected to result in new or increased sources of bromide to the Delta. Therefore, as they pertain to bromide, implementation of these environmental commitments would not be expected to adversely affect MUN beneficial use, or any other beneficial uses, of the affected environment.

Environmental Commitment 4 would result in some tidal habitat restoration, however, the areal extent would be small relative to the existing and No Action Alternative tidal area and, thus not expected to appreciably affect the magnitude of daily tidal water exchange at the restoration areas or alter other hydrodynamic conditions in adjacent Delta channels that would result in measurable bromide concentration changes.

In summary, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 5A relative to the No Action Alternative (ELT and LLT), would have negligible, if any, effects on bromide concentrations. Therefore, the effects on bromide from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

***CEQA Conclusion*:** Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 5A would not present new or substantially changed sources of bromide to the affected environment. Some environmental commitments may replace or substitute for existing irrigated agriculture in the Delta. This replacement or substitution would not be expected to substantially increase or present new sources of bromide. Thus, implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would have negligible, if any, effects on bromide concentrations throughout the affected environment, would not cause exceedance of applicable state or federal numeric or narrative water quality objectives/criteria because none exist for bromide, and would not cause changes in bromide concentrations that would result in significant impacts on any beneficial uses within affected water bodies. Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 would not cause significant long-term water quality degradation such that there would be greater risk of significant impacts on beneficial uses, would not cause greater bioaccumulation of bromide, and would not further impair any beneficial uses due to bromide concentrations because no uses are currently impaired due to bromide levels. Based on these findings, this impact is considered less than significant. No mitigation is required.

Impact WQ-7: Effects on Chloride Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 5A on chloride concentrations in reservoirs and rivers upstream of the Delta would be the similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). Chloride loading in these watersheds would remain unchanged and resultant changes in flows from altered system-wide operations would have negligible, if any, effects on the concentration of chloride in the rivers and reservoirs of these watersheds. There would be no expected change to the sources of chloride in the Sacramento River and east-side tributary watersheds, and changes in the magnitude and timing of reservoir releases north and east of the Delta would have negligible, if any, effect on the sources, and ultimately the concentration of chloride in the Sacramento River, the eastside tributaries, and the various reservoirs of the related watersheds. The modeled annual average lower San Joaquin River flow at Vernalis would decrease slightly (1%) compared to Existing Conditions and would remain virtually the same as the No Action Alternative (ELT), and thus flow changes would not result in substantial chloride increases. Moreover, there are no existing municipal intakes on the lower San Joaquin River. Consequently, Alternative 5A in the ELT would not be expected to cause exceedances of chloride objectives/criteria or substantially degrade water quality with respect to chloride, and thus would not adversely affect any beneficial uses of the Sacramento River, the eastside tributaries, associated reservoirs upstream of the Delta, or the San Joaquin River.

Effects of Alternative 5A in reservoirs and rivers upstream of the Delta in the LLT relative to Existing Conditions and the No Action Alternative (LLT) would be expected to be similar, because the climate change and sea level rise that would occur in the LLT would not affect chloride sources in these areas.

Delta

Modeling scenarios included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 5A would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of water quality changes due water conveyance facilities operations and maintenance. Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-8. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Estimates of chloride concentrations at Delta assessment locations were generated using a mass balance approach and EC-chloride relationships and DSM2 EC output. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding these modeling approaches. The assessment below identifies changes in chloride at Delta assessment locations based on both approaches.

Modeling of chloride using both the mass balance approach and EC-chloride relationship predicts that Alternative 5A in the ELT would result in similar or reduced long-term average chloride concentrations, relative to Existing Conditions, for the 16-year period modeled at all assessment locations except for the S. Fork Mokelumne River at Staten Island. The increase in long-term average chloride concentration at Staten Island would be 3 mg/L (17%) based on the mass balance modeling and 1 mg/L (6%) based on the EC-chloride relationship (Tables Cl-20 and Cl-21 in Appendix B of this RDEIR/SDEIS). This differs from Alternative 4, under which there would be increased long-term average chloride concentrations also at the North Bay Aqueduct at Barker Slough. The change in long-term average chloride concentrations relative to the No Action Alternative (ELT) would be similar to those relative to Existing Conditions.

The following outlines the modeled chloride changes relative to the applicable objectives and beneficial uses of Delta waters.

Municipal Beneficial Uses Relative to Existing Conditions

Estimates of chloride concentrations generated using EC-chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses on a basis of the percent of years the chloride objective is exceeded for the modeled 16-year period. The objective is exceeded if chloride concentrations exceed 150 mg/L for a specified number of days in a given water year at Antioch and Contra Costa Pumping Plant #1. The modeled frequency of objective exceedance would decrease at the Contra Costa Pumping Plant #1 from 6.7% of years under Existing Conditions to 0% of years under Alternative 5A in the ELT (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Evaluation of the 250 mg/L Bay-Delta WQCP objective for chloride utilized results from both the mass balance approach and EC-chloride relationship. The basis for the evaluation was the predicted number of days the objective would be exceeded for the modeled 16-year period.

Based on the mass balance approach, there would be a decreased frequency of exceedance of the 250 mg/L objective under Alternative 5A, relative to Existing Conditions, at all locations except in the Sacramento River at Mallard Island, San Joaquin River at Antioch, and the Sacramento River at Emmaton. In the Sacramento River at Mallard Island, the frequency of objective exceedance would increase from 85% under Existing Conditions to 86% under Alternative 5A for the entire period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). In the San Joaquin River at Antioch, there would be an increase in chloride objective exceedance for the entire period modeled, from 66% under Existing Conditions to 68% under Alternative 5A. In the Sacramento River at Emmaton, there would be an increase in chloride objective exceedance during the drought period modeled, from 55% to 57%. The mass balance results also indicate reduced assimilative capacity with respect to the 250 mg/L objective during certain months and at certain locations. In the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in March and April of up to 20% for the 16-year period modeled and 56% for the drought period modeled (Table Cl-22 in Appendix B of this RDEIR/SDEIS). Assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced, in February through April by up to 7%, and in January of the drought period modeled by 77%.

When utilizing the EC-chloride relationship to model chloride concentrations for the 16-year period, trends in frequency of exceedance and use of assimilative capacity would be similar to that discussed when utilizing the mass balance modeling approach (Tables Cl-3 and Cl-23 in Appendix B of this RDEIR/SDEIS). However, the EC-chloride relationships generally predicted changes of lesser magnitude, where predictions of change utilizing the mass balance approach were generally of greater magnitude, and thus more conservative. As discussed in Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS, in cases of such disagreement, the approach that yielded the more conservative predictions was used as the basis for determining adverse impacts.

Based on the long-term average water quality degradation in the western Delta, the potential exists for substantial adverse effects under Alternative 5A in the ELT on the municipal and industrial beneficial uses through reduced opportunity for diversion of water with acceptable chloride levels.

CWA Section 303(d) Listed Water Bodies–Relative to Existing Conditions

Tom Paine Slough in the southern Delta is on the state's CWA Section 303(d) list for chloride with respect to the secondary MCL of 250 mg/L. Monthly average chloride concentrations at the Old River at Tracy Road for the 16-year period modeled, which represents the nearest DSM2-modeled location to Tom Paine Slough, would be generally similar under Alternative 5A in the ELT relative to Existing Conditions, and thus, would not be further degraded on a long-term basis (Figure Cl-5 in Appendix B of this RDEIR/SDEIS).

Suisun Marsh also is on the state's CWA Section 303(d) list for chloride in association with the Bay-Delta WQCP objectives for maximum allowable salinity during the months of October through May, which establish appropriate seasonal salinity conditions for fish and wildlife beneficial uses. With respect to Suisun Marsh, the monthly average chloride concentrations for the 16-year period modeled would generally increase under Alternative 5A in the ELT relative to Existing Conditions in March through May at the Sacramento River at Mallard Island (Figure Cl-6 in Appendix B of this RDEIR/SDEIS) and at Collinsville (Figure Cl-7 in Appendix B of this RDEIR/SDEIS), and increase substantially in October through May at Montezuma Slough at Beldon's Landing (i.e., over a doubling of concentration in December through February) (Figure Cl-8 in Appendix B of this RDEIR/SDEIS). However, modeling of Alternative 5A assumed no operation of the Montezuma Slough Salinity Control Gates, but the project description assumes continued operation of the Salinity Control Gates, consistent with assumptions included in the No Action Alternative. A sensitivity analysis modeling run conducted for Alternative 4 scenario H3 at the LLT with the gates operational consistent with the No Action Alternative resulted in substantially lower EC levels than indicated in the original Alternative 4 modeling results for Suisun Marsh, but EC levels were still somewhat higher than EC levels under Existing Conditions for several locations and months. Although chloride was not specifically modeled in these sensitivity analyses, it is expected that chloride concentrations would be nearly proportional to EC levels in Suisun Marsh. Additionally, although these analyses were only conducted at the LLT, they are expected to generally also apply to the ELT. Another modeling run with the gates operational and restoration areas removed resulted in EC levels nearly equivalent to Existing Conditions (see Appendix 8H Attachment 1 in Appendix A of the RDEIR/SDEIS for more information on these sensitivity analyses). Since Alternative 5A in the ELT includes operation of the gates, and includes very little tidal restoration area, it is anticipated that chloride increases in Suisun Marsh predicted via the modeling would not occur, and that chloride in Suisun Marsh under Alternative 5A in the ELT would be very similar to Existing Conditions. For these reasons, any changes in chloride in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

Municipal Beneficial Uses Relative to No Action Alternative (ELT)

Similar to the assessment conducted for Existing Conditions, estimates of chloride concentrations generated from EC-chloride relationships were used to evaluate the 150 mg/L Bay-Delta WQCP objective for municipal and industrial beneficial uses. For Alternative 5A in the ELT, the modeled frequency of objective exceedance would not change at the Contra Costa Pumping Plant #1--the No

Action Alternative (ELT) and Alternative 5A in the ELT all would have 0% exceedance (Table Cl-1 in Appendix B of this RDEIR/SDEIS).

Based on the mass balance approach, the frequency of exceedance of the 250 mg/L objective under Alternative 5A in the ELT would be the same, or would decrease, at all locations relative to the No Action Alternative (ELT), except in the Old River at Rock Slough and Contra Costa Pumping Plant #1 during the drought period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). The frequency of objective exceedance would increase from 32% to 33% at Rock Slough and from 28% to 30% at Contra Costa Pumping Plant #1. The mass balance results indicate reduced assimilative capacity with respect to the 250 mg/L objective for certain months and locations. In the San Joaquin River at Antioch, there would be a reduction in assimilative capacity in April of 4% for the entire period modeled and 20% for the drought period modeled (Table Cl-22 in Appendix B of this RDEIR/SDEIS). Assimilative capacity at the Contra Costa Pumping Plant #1 also would be reduced in October, January, and April by up to 2% for the entire period modeled. During the drought period modeled, there would be reductions of assimilative capacity of 45% in January and 100% in September (Table Cl-22 in Appendix B of this RDEIR/SDEIS).

When utilizing the EC-chloride relationship to model monthly average chloride concentrations for the 16-year period, trends in frequency of exceedance and use of assimilative capacity would be similar to that discussed for the mass balance modeling approach (Tables Cl-3 and Cl-23 in Appendix B of this RDEIR/SDEIS). However, utilizing the EC-chloride relationships generally predicted changes of lesser magnitude, where predictions of change utilizing the mass balance approach were generally of greater magnitude, and thus more conservative. As discussed in Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS, in cases of such disagreement, the approach that yielded the more conservative predictions was used as the basis for determining adverse impacts.

Figure Cl-18 shows chloride concentrations in April during the five-year drought period (1987–1991) at Antioch, where Table Cl-22 indicated 22% use of assimilative capacity. The figure shows that during two of the five years, chloride concentrations increased relative to the No Action Alternative (ELT) and decreased in the other three years. The absolute differences estimated are fairly small and may be within modeling uncertainty. Figures Cl-19 and Cl-20 show a box and whisker plot and exceedance plot for April at Antioch for all dry and critical water years modeled (not just the 1987–1991 drought period). These graphs show that while the median chloride concentration is slightly increased relative to the No Action Alternative (ELT), the maximum value decreased, while the 25th percentile and 75th percentile values remained about the same. Based on this analysis, long-term degradation is not expected at Antioch in April during drought years.

Figure Cl-21 shows chloride levels in September at Contra Costa Pumping Plant #1 during the drought period (1987–1991), where Table Cl-22 indicated 100% use of assimilative capacity. In general, changes in chloride concentrations relative to the No Action Alternative (ELT) are fairly small, and may be within modeling uncertainty. Figures Cl-22 and Cl-23 show a box and whisker plot and exceedance plot for September at Contra Costa Pumping Plant #1 for all dry and critical water years modeled (not just the 1987–1991 drought period). These graphs show that the median chloride concentration is slightly decreased relative to the No Action Alternative (ELT), and chloride concentrations are generally similar to the No Action Alternative (ELT) throughout the range seen. The 100% use of assimilative capacity was shown because long term averages were just below the criterion, so a very small increase in chloride (that is probably within the modeling uncertainty) resulted in a very high estimate of use of assimilative capacity. Similar results are shown in Figure

Cl-24, Cl-25, and Cl-26 for October at Contra Costa Pumping Plant #1. Median concentrations decreased slightly, and the exceedance plot shows generally similar concentrations throughout the range seen. Figure Cl-24 shows that while some years see increased concentrations (e.g., 1978, 1989), other years see decreased concentrations (e.g., 1980, 1982). Based on this analysis, long-term degradation is not expected at Contra Costa Pumping Plant #1 in September during drought years, or October on a long-term average basis.

Furthermore, sensitivity analyses conducted of Alternative 4 Scenario H3 without restoration areas indicated lower chloride levels in the western Delta than with the restoration areas. It is thus likely that modeling of Alternative 5A that does not include restoration areas would show lower levels of chloride at Antioch in April, and at Contra Costa Pumping Plant #1 in September and October than is shown herein using the Alternative 5 (ELT) modeling.

Based on the low level of water quality degradation estimated for the western Delta, and the lack of exceedance of water quality objectives, Alternative 5A is not expected to have substantial adverse effects on municipal and industrial beneficial uses in the western Delta.

CWA Section 303(d) Listed Water Bodies–Relative to No Action Alternative (ELT)

With respect to the state's CWA Section 303(d) listing for chloride, Alternative 5A would generally result in similar changes to those discussed for the comparison to Existing Conditions. Monthly average chloride concentrations at Tom Paine Slough would not be further degraded on a long-term basis, based on changes that would occur in Old River at Tracy Road (Figure Cl-5 in Appendix B of this RDEIR/SDEIS). Modeling indicated that monthly average chloride concentrations at source water channel locations for the Suisun Marsh would increase substantially in some months during October through May relative to the No Action Alternative (ELT) (Figures Cl-6, Cl-7, and Cl-8 in Appendix B of this RDEIR/SDEIS), but the results of sensitivity analyses performed indicate that chloride increases in Suisun Marsh predicted via the modeling would not occur, and that chloride in Suisun Marsh under Alternative 5A in the ELT would be very similar to the No Action Alternative (ELT). Depending on where tidal restoration areas assumed to be included in the No Action Alternative are located, chloride concentrations under Alternative 5A could be less than under the No Action Alternative (ELT). For these reasons, any changes in chloride in Suisun Marsh are expected to have no adverse effect on marsh beneficial uses.

The effects of Alternative 5A in the LLT in the Delta region, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be similar to effects in the ELT. With greater climate change and sea level rise, additional outflow may be required at certain times to prevent increases in chloride in the west Delta. Small increases in chloride concentrations may occur in some areas, but it is not expected that these increases would cause exceedance of Bay-Delta WQCP objectives of cause substantial long-term degradation that would impact municipal and industrial beneficial uses.

SWP/CVP Export Service Areas

Under Alternative 5A in the ELT, long-term average chloride concentrations at the Banks and Jones pumping plants, based on the mass balance analysis of modeling results for the 16-year period, would decrease relative to Existing Conditions. Chloride concentrations would be reduced by 26% at Banks pumping plant (Table Cl-20 in Appendix B of this RDEIR/SDEIS). At Jones pumping plant, chloride concentrations would be reduced 21% (Table Cl-20 in Appendix B of this RDEIR/SDEIS). The frequency of exceedances of applicable water quality objectives would be the same or decrease relative to Existing Conditions, except for at Jones pumping plant for the drought period modeled (Table Cl-2 in Appendix B of this RDEIR/SDEIS). The frequency of objective exceedance at the Jones pumping plant would increase from 0% to 2%. The chloride concentration changes relative to the No Action Alternative (ELT) would be similar. Consequently, water exported into the SWP/CVP Export Service Areas would generally be of similar or better quality with regard to chloride relative to Existing Conditions and the No Action Alternative (ELT). Results of the modeling approach which utilized a EC-chloride relationship are consistent these results, and assessment of chloride using these modeling output results in the same conclusions as for the mass balance approach (Tables Cl-3 and Cl-21 in Appendix B of this RDEIR/SDEIS).

Commensurate with the reduced chloride concentrations in water exported to the SWP/CVP Export Service Area, reduced chloride loading in the lower San Joaquin River would be anticipated which would likely alleviate chloride concentrations at Vernalis.

The effects of Alternative in the LLT in the SWP/CVP Export Service Areas, relative to Existing Conditions and the No Action Alternative (LLT), would be expected to be very similar to effects in the ELT.

Maintenance of SWP and CVP facilities would not be expected to create new sources of chloride or contribute towards a substantial change in existing sources of chloride in the affected environment. Maintenance activities would not be expected to cause any substantial change in chloride such that any long-term water quality degradation would occur, thus, beneficial uses would not be adversely affected anywhere in the affected environment.

NEPA Effects: In summary, relative to the No Action Alternative (ELT and LLT), Alternative 5A would not result in substantially increased chloride concentrations in the Delta on a long-term average that would result in adverse effects on the municipal and industrial water supply beneficial use, or any other beneficial use. Additional exceedance of the 150 mg/L and 250 mg/L objectives is not expected, and substantial long-term degradation is not expected that would result in adverse effects on the municipal and industrial water supply beneficial use, or any other beneficial use. Based on these findings, this effect is determined to not be adverse.

CEQA Conclusion: Chloride is not a constituent of concern in the Sacramento River watershed upstream of the Delta, thus river flow rate and reservoir storage reductions that would occur under Alternative 5A relative to Existing Conditions, would not be expected to result in a substantial adverse change in chloride levels. Additionally, relative to Existing Conditions, Alternative 5A would not result in reductions in river flow rates (i.e., less dilution) or increased chloride loading such that there would be any substantial increase in chloride concentrations upstream of the Delta in the San Joaquin River watershed.

Relative to Existing Conditions, Alternative 5A would result in substantially increased chloride concentrations in the Delta on a long-term average that would result in adverse effects on the municipal and industrial water supply beneficial use. Additional exceedance of the 150 mg/L and 250 mg/L objectives is not expected, and substantial long-term degradation is not expected that would result in adverse effects on the municipal and industrial water supply beneficial use.

Chloride concentrations would be reduced under Alternative 5A in water exported from the Delta to the SWP/CVP Export Service Areas thus reflecting a potential improvement to chloride loading in the lower San Joaquin River.

Chloride is not a bioaccumulative constituent, thus any increased concentrations under the Alternative 5A would not result in substantial chloride bioaccumulation impacts on aquatic life or humans. Alternative 5A maintenance would not result in any substantial changes in chloride concentration upstream of the Delta or in the SWP/CVP Export Service Areas.

Based on these findings, this impact is determined to be less than significant. No mitigation is required.

Impact WQ-8: Effects on Chloride Concentrations Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** The implementation of Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 5A would present no new direct sources of chloride to the affected environment, including areas Upstream of the Delta, within the Plan Area, and the SWP/CVP Export Service Areas. Consequently, as they pertain to chloride, implementation of these environmental commitments would not be expected to adversely affect any of the beneficial uses of the affected environment. Moreover, some habitat restoration activities would occur on lands within the Delta currently used for irrigated agriculture. The potential reduction in irrigated lands within the Delta may result in reduced discharges of agricultural field drainage with elevated chloride concentrations, which would be considered an improvement relative to the No Action Alternative (ELT and LLT). Therefore, the effects on chloride from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are considered to be not adverse.

***CEQA Conclusion*:** Implementation of the Environmental Commitments 3, 4, 6–12, 15, and 16 under Alternative 5A would not present new or substantially changed sources of chloride to the affected environment upstream of the Delta, within Delta, or in the SWP/CVP Export Service Areas. Replacement of irrigated agricultural land uses in the Delta with habitat restoration may result in some reduction in discharge of agricultural field drainage with elevated chloride concentrations, thus resulting in improved water quality conditions. Based on these findings, this impact is considered to be less than significant. No mitigation is required.

Impact WQ-9: Effects on Dissolved Oxygen Resulting from Facilities Operations and Maintenance

As described in detail for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS), DO levels are primarily affected by water temperature, flow velocity, turbulence, amounts of oxygen demanding substances present (e.g., ammonia, organics), and rates of photosynthesis (which is influenced by nutrient levels), respiration, and decomposition. Water temperature and salinity affect the maximum DO saturation level (i.e., the highest amount of oxygen the water can dissolve). Flow velocity affects the turbulence and re-aeration of the water (i.e., the rate at which oxygen from the atmosphere can be dissolved in water). High nutrient content can support aquatic plant and algae growth, which in turn generates oxygen through photosynthesis and consumes oxygen through respiration and decomposition.

As described for Alternative 4, amounts of oxygen demanding substances present (e.g., ammonia, organics) in the reservoirs and rivers upstream of the Delta, rates of photosynthesis (which is influenced by nutrient levels/loading), and respiration and decomposition of aquatic life is not expected to change sufficiently under Alternative 5A to substantially alter DO levels relative to Existing Conditions or the No Action Alternative (ELT and LLT). Further, the rivers upstream of the Delta are well oxygenated and experience periods of supersaturation (i.e., when DO level exceeds the saturation concentration). Because these are large, turbulent rivers, any reduced DO saturation level that would be caused by an increase in temperature under Alternative 5A would not be expected to cause DO levels to be outside of the range seen historically. Flow changes that would occur under Alternative 5A would not be expected to have substantial effects on river DO levels; likely, the changes would be immeasurable. This is because sufficient turbulence and interaction of river water with the atmosphere would continue to occur to maintain water saturation levels (due to these factors) at levels similar to that of Existing Conditions and the No Action Alternative (ELT and LLT).

Also as described for Alternative 4, salinity changes would generally have relatively minor effects on Delta DO levels. Further, the relative degree of tidal exchange of flows and turbulence, which contributes to exposure of Delta waters to the atmosphere for reaeration, would not be expected to substantially change relative to Existing Conditions or the No Action Alternative (ELT and LLT), such that these factors would reduce Delta DO levels below objectives or levels that protect beneficial uses. Similarly, increased temperature under Alternative 5A would generally have relatively minor effects on Delta DO levels, relative to Existing Conditions.

Similar to Alternative 4, flows in the San Joaquin River at Stockton were evaluated, and are shown in Figure DO-1 in Appendix B of this RDEIR/SDEIS. The Figure shows that while flows do would change somewhat, they are would generally be within the range of flows seen under Existing Conditions and the No Action Alternative. Reports indicate that the aeration facility performs adequately under the range of flows from 250–1,000 cfs (ICF International 2010). Based on the above, the expected changes in flows in the San Joaquin River at Stockton are not expected to substantially move the point of minimum DO, and therefore the aeration facility will would likely still be located appropriately to keep DO levels above Basin Plan objectives.

Overall, assuming continued operation of the aerators, the alternative is not expected to have a substantial impact adverse effect on DO in the Deep Water Ship Channel. It is expected that DO levels in the Deep Water Ship Channel, which is CWA Section 303(d) listed as impaired due to low DO, would remain similar to those under Existing Conditions and the No Action Alternative (ELT and LLT) or improve as TMDL-required studies are completed and actions are implemented to improve DO levels. DO levels in other Clean Water Act Section 303(d)-listed waterways would not be expected to change relative to Existing Conditions or the No Action Alternative (ELT and LLT), as the circulation of flows, tidal flow exchange, and re-aeration would continue to occur.

In the SWP/CVP Export Service Areas, the primary factor that would affect DO in the conveyance channels and ultimately the receiving reservoirs would be changes in the levels of nutrients and oxygen-demanding substances and DO levels in the exported water. As described above and for Alternative 4, exported water could potentially be warmer and have higher salinity relative to Existing Conditions and the No Action Alternative (ELT and LLT). Nevertheless, because the biochemical oxygen demand of the exported water would not be expected to substantially differ from that under Existing Conditions or the No Action Alternative (ELT and LLT) due to water quality regulations, canal turbulence, exposure of the water to the atmosphere, and the algal communities that exist within the canals that would establish an equilibrium for DO levels within the canals. The same would occur in downstream reservoirs.

NEPA Effects: Because DO levels are not expected to change substantially relative to the No Action Alternative (ELT and LLT), the effects on DO from implementing Alternative 5A are determined to not be adverse.

CEQA Conclusion: The effects of Alternative 5A on DO levels in surface waters upstream of the Delta, in the Delta, and in the SWP/CVP Export Service Areas relative to Existing Conditions would be similar to those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). Reservoir storage reductions that would occur under Alternative 5A, relative to Existing Conditions, would not be expected to result in a substantial adverse change in DO levels in the reservoirs, because oxygen sources (surface water aeration, aerated inflows, vertical mixing) would remain. Similarly, river flow rate reductions would not be expected to result in a substantial adverse change in DO levels in the rivers upstream of the Delta, given that mean monthly flows would remain within the ranges historically seen under Existing Conditions and the affected river are large and turbulent. Any reduced DO saturation level that may be caused by increased water temperature would not be expected to cause DO levels to be outside of the range seen historically. Finally, amounts of oxygen demanding substances and salinity would not be expected to change sufficiently to affect DO levels.

It is expected there would be no substantial change in Delta DO levels in response to a shift in the Delta source water percentages under this alternative or substantial degradation of these water bodies, with regard to DO. DO levels would be affected by nutrient loading, which the state regulates the discharges of, and this loading would not be expected to lower DO levels relative to Existing Conditions based on historical DO levels. Further, the anticipated changes in salinity would have relatively minor effects on DO levels, and tidal exchange, which contribute to the reaeration of Delta waters would not be expected to change substantially.

There is not expected to be substantial, if even measurable, changes in DO levels in the SWP/CVP Export Service Areas waters, relative to Existing Conditions, because the biochemical oxygen demand of the exported water would not be expected to substantially differ from that under Existing Conditions (due to water quality regulations), canal turbulence and exposure of the water to the atmosphere and the algal communities that exist within the canals that would establish an equilibrium for DO levels within the canals. The same would occur in downstream reservoirs.

Therefore, this alternative is not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would result in significant impacts on any beneficial uses within affected water bodies. Because no substantial changes in DO levels are expected, long-term water quality degradation would not be expected to occur, and, thus, beneficial uses would not be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels would be expected, greater degradation and DO-related impairment of these areas would not be expected. Based on these findings, this impact would be less than significant. No mitigation is required.

Impact WQ-10: Effects on Dissolved Oxygen Resulting from Implementation of Environmental Commitments 3, 4, 6–12, 15, and 16

***NEPA Effects*:** Environmental Commitments 3, 4, 6–11 would involve habitat restoration actions. The increased habitat provided by these environmental commitments could contribute to an increased biochemical or sediment demand, through contribution of organic carbon and plants decaying. However, the areal extent of new habitat would be small relative to the existing and No Action Alternative habitat areas, and similar habitat existing in the Delta is not identified as contributing to adverse DO conditions. The remaining environmental commitments would not be expected to affect DO levels because they are actions that do not affect the presence of oxygen-demanding substances. Therefore, the effects on DO from implementing Environmental Commitments 3, 4, 6–12, 15, and 16 are determined to not be adverse.

***CEQA Conclusion*:** It is expected that DO levels in the Upstream of the Delta Region, in the Plan Area, or in the SWP/CVP Export Service Areas following implementation of Environmental Commitments 3–12, 15, and 16 under Alternative 5A would not be substantially different from existing DO conditions, because these would contribute to a minimal, localized change in oxygen-demanding substances associated with habitat restoration, if at all. Therefore, these environmental commitments are not expected to cause additional exceedance of applicable water quality objectives by frequency, magnitude, and geographic extent that would result in significant impacts on any beneficial uses within affected water bodies. Because no substantial changes in DO levels would be expected, long-term water quality degradation would not be expected, and, thus, beneficial uses would not be adversely affected. Various Delta waterways are CWA Section 303(d)-listed for low DO, but because no substantial decreases in DO levels would be expected, greater degradation and impairment of these areas would not be expected. Based on these findings, this impact would be less than significant. No mitigation is required.

Impact WQ-11: Effects on Electrical Conductivity Concentrations Resulting from Facilities Operations and Maintenance

Upstream of the Delta

The effects of Alternative 5A on EC levels in reservoirs and rivers upstream of the Delta would be similar to those effects described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). The extent of new urban growth would be less in the ELT, thus discharges of EC-elevating parameters in runoff and wastewater discharges to water bodies upstream of the Delta would be expected to be less than in the LLT. However, the state is regulating point source discharges of EC-related parameters and implementing a program to further decrease loading of EC-related parameters to tributaries. Based on these considerations, and those described in Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS, EC levels (highs, lows, typical conditions) in the Sacramento River and its tributaries, the eastside tributaries, or their associated reservoirs upstream of the Delta would not be expected to be outside the ranges occurring under Existing Conditions.

For the San Joaquin River, increases in EC levels under Alternative 5A could occur, but would be slightly less than those described for Alternative 4 (see Chapter 8, Section 8.3.3.9 in Appendix A of the RDEIR/SDEIS). This is because the effects of climate change and increase water demands on flows, which could effect dilution of high EC discharges, would be less in the ELT. The implementation of the adopted TMDL for the San Joaquin River at Vernalis and the ongoing development of the TMDL for the San Joaquin River upstream of Vernalis are expected to contribute to improved EC levels. Based on these considerations, substantial changes in EC levels in the San Joaquin River relative to Existing Conditions would not be expected to be of sufficient magnitude and geographic extent that would result in adverse effects on any beneficial uses, or substantially degrade the quality of these water bodies, with regard to EC.

Delta

As mentioned at the beginning of Section 4.5.4, the analysis of EC under Alternative 5A is based on modeling conducted for Alternative 5 in the ELT, which assumes implementation of Yolo Bypass Improvements and 25,000 acres of tidal natural communities restoration. Also, the modeling was originally performed assuming the Emmaton compliance point shifted to Threemile Slough. However, Yolo Bypass Improvements are not a component of Alternative 5A and the amount of tidal habitat restoration (i.e., Environmental Commitment 4) would be significantly less than that represented in the modeling Alternative 5A. Also, Alternative 5A does not include a change in compliance point from Emmaton to Threemile Slough. Furthermore, there are several factors related to the modeling approach that may result in modeling artifacts that show objective exceedance, when in reality no such exceedance would occur. The result of all of these factors is that the quantitative modeling results presented in this assessment is not entirely predictive of actual effects under Alternative 5A, and the results should be interpreted with caution. In order to understand the significance of all of these factors on the results, sensitivity analyses and further other analyses were performed to evaluate the impact of maintaining the compliance point at Emmaton, the impact of having substantially less restoration than included in the modeling that was analyzed, and whether exceedances were indeed modeling artifacts or were potential alternative-related effects that may actually occur. For more information on these sensitivity analyses, refer to Chapter 8, Section 8.3.1.7, Electrical Conductivity, and Appendix 8H Attachment 1, both in Appendix A of the RDEIR/SDEIS.

In this assessment, the modeling results are described and then in most cases are qualified in light of findings from the sensitivity analyses. Conclusions thus represent assessment of the combination of the modeling results and sensitivity analysis findings.

The modeling of EC under Alternative 5A included assumptions regarding how certain habitat restoration activities would affect Delta hydrodynamics. The amount of habitat restoration completed under Alternative 5A would be substantially less than under Alternative 4. To the extent that restoration actions would alter hydrodynamics within the Delta region, which affects mixing of source waters, these effects are included in this assessment of operations-related water quality changes (i.e., water conveyance facilities). Other effects of environmental commitments not attributable to hydrodynamics are discussed within Impact WQ-12. See Chapter 8, Section 8.3.1.3, *Plan Area*, in Appendix A of the RDEIR/SDEIS for more information regarding the hydrodynamic modeling methodology.

Relative to Existing Conditions and the No Action Alternative (ELT), initial review of modeling results indicated that Alternative 5A would potentially result in an increase in the number of days the Bay-Delta WQCP EC objectives would be exceeded in the Sacramento River at Emmaton, and San Joaquin River at Jersey Point, San Andreas Landing, and Prisoners Point (Table EC-9 in Appendix B of this RDEIR/SDEIS). Additionally, the modeling results indicated potentially large increases in EC in Suisun Marsh. However, to understand and interpret these results, considerations must be made regarding uncertainty in the modeling, differing assumptions between the modeling and the alternative, and sensitivity analyses. These objectives and locations are addressed in the context of these considerations in detail below. At all other locations, the level of exceedance and EC in the modeling results was approximately equivalent or lower than under Existing Conditions and the No Action Alternative (ELT).

Sacramento River at Emmaton

Modeling results indicated that the Emmaton EC objective would be exceeded more often under Alternative 5A than under Existing Conditions and the No Action Alternative (ELT), and that increases in EC could cause substantial water quality degradation in summer months of dry and critical water years. However, sensitivity analyses have shown that the level of effect would be less than presented in the modeling. Remaining increases in exceedance of the objective and degradation are expected to be addressed via real-time operations, including real time management of the north Delta and south Delta intakes, as well as Delta Cross Channel operation. Further discussion is provided below.

Modeling results indicated that the percent of days the Emmaton EC objective would be exceeded for the entire period modeled (1976–1991) would increase from 6% under Existing Conditions, or 13% under the No Action Alternative (ELT), to 17% and the percent of days out of compliance would increase from 11% under Existing Conditions, or 21% under the No Action Alternative (ELT), to 28%. Although these results are for modeling that was originally performed for Alternative 5 at the ELT assuming the Emmaton compliance point shifted to Threemile Slough, Alternative 5A does not include a change in compliance point from Emmaton to Threemile Slough. Sensitivity analyses were performed that modeled Alternative 4 scenario H3 at the LLT with Emmaton as the compliance point. These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT, because the factors affecting salinity findings in the sensitivity analysis (e.g., modeling assumptions, physical hydrodynamic mechanisms) are similar between the ELT and LLT (see Appendix 8H, Attachment 1 in Appendix A of the RDEIR/SDEIS). Assuming the compliance location at Emmaton instead of Threemile Slough in the CALSIM II modeling decreased exceedances at Emmaton from 28% to 15% under Alternative 4, operations scenario H3 at the LLT (see Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS for more discussion of these sensitivity analyses), which would still be greater than Existing Conditions, but is very close to the No Action Alternative (ELT). Table 2 of Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS indicates that most of these exceedances are a result of modeling artifacts, but some exceedances are due to deadpool conditions that occurred in 1977, 1981, and 1990 under Alternative 4 scenario H3 at the LLT and not under Existing Conditions. As discussed in Chapter 5, *Water Supply*, Section 5.3.1, *Methods for Analysis*, in the Draft EIR/EIS, under extreme hydrologic and operational conditions where there is not enough water supply to meet all requirements, CALSIM II uses a series of operating rules to reach a solution that is a simplified version of the very complex decision processes that SWP and CVP operators would use in actual extreme conditions. Thus, it is unlikely that the Emmaton objective would actually be violated due to dead pool conditions. However, these results indicate that water supply could be either under greater stress or under stress earlier in the year, and EC levels at Emmaton and in the western Delta may increase as a result, leading to EC degradation and increased possibility of adverse effects to agricultural beneficial uses.

This is evidenced in the modeling results, which indicated that long-term monthly average EC levels at Emmaton would increase 3–12% for the entire period modeled (1976–1991) and 3–29% during the drought period modeled (1987–1991), relative to the No Action Alternative (ELT) (Table EC-17 in Appendix B of this RDEIR/SDEIS). The largest increases in EC would occur during the summer months of the drought period, and more generally in dry and critical water year types. During these periods, additional flow in the Sacramento River at Emmaton would reduce or eliminate increases in EC. It is expected that for May–September of dry and critical water years, less pumping from the north Delta intakes and greater reliance on south Delta intakes would allow for enough flow in the Sacramento River at Emmaton to reduce water quality degradation to levels closer to the No Action Alternative that would be considered not adverse.

San Joaquin River at San Andreas Landing

Alternative 5A is not expected to have adverse effects on EC in the San Joaquin River at San Andreas Landing, relative to Existing Conditions and the No Action Alternative (ELT). Modeling results estimated that the percent of days the San Andreas Landing EC objective would be exceeded would increase by <1% relative to Existing Conditions, and the percent of days out of compliance would increase from 1% under Existing Conditions to 2% (Table EC-9 in Appendix B of this RDEIR/SDEIS). San Andreas Landing average EC would increase by <1% for the entire period modeled and 7% during the drought period modeled, relative to Existing Conditions (Table EC-17 in Appendix B of this RDEIR/SDEIS). Results relative to the No Action Alternative (ELT) were similar (Table EC-17 in Appendix B of this RDEIR/SDEIS). However, sensitivity analyses performed for Alternative 4 scenario H3 at the LLT indicate that many of these exceedances are likely modeling artifacts, and the small number of remaining exceedances would be small in magnitude, lasting only a few days, and could be addressed with real time operations of the SWP and CVP (see Chapter 8, Section 8.3.1.1, *Models Used and Their Linkages*, of this RDEIR/SDEIS for a description of real time operations of the SWP and CVP). These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT, because the factors affecting salinity findings in the sensitivity analysis (e.g., modeling assumptions, physical hydrodynamic mechanisms) are similar between the ELT and LLT (see Appendix 8H Attachment 1, in Appendix A of the RDEIR/SDEIS).

San Joaquin River at Prisoners Point

Modeling results indicated that the EC objective that applies between the San Joaquin River at Jersey Point and Prisoners Point would be exceeded at Prisoners Point more often under Alternative 5A than under Existing Conditions and the No Action Alternative (ELT). However, modeling results without restoration areas would be expected to show a lesser effect, and remaining exceedances are expected to be able to be addressed via real-time operations, including real time management of the north Delta and south Delta intakes, as well as Head of Old River Barrier management. Further discussion is provided below.

Modeling results estimated that the percent of days the Prisoners Point EC objective would be exceeded would increase from 6% under Existing Conditions, or 1% under the No Action Alternative (ELT), to 7% and the percent of days out of compliance with the EC objective would increase from 10% under Existing Conditions, or 1% under the No Action Alternative (ELT), to 10% (Table EC-9 in Appendix B of this RDEIR/SDEIS). The magnitude of the exceedances is estimated to be very small—the objective is 440 μmhos/cm, and the EC during times of exceedance was generally between 440 and 550 μmhos/cm. The exceedances generally occurred in drier water years, when flows are lower. During these times, the EC in the San Joaquin River at Vernalis is greater than in the Sacramento River entering the Delta, and is high enough on its own to cause an exceedance.

There are two main drivers of the increase in exceedances under the alternative: an increase in San Joaquin River flow at Prisoners Point during April and May under the alternative, relative to Existing Conditions and the No Action Alternative (ELT), and a reduction in the amount of Sacramento River water moving past Prisoners Point under the alternative. The result is increased San Joaquin River water at Prisoners Point, and a reduction in the dilution that the Sacramento River provides the higher EC San Joaquin River. The increase in San Joaquin River flow at Prisoners Point is due to a reduction in pumping from the south Delta under the alternative, as well as due to the presence of the Head of Old River Barrier, which increases flow in the San Joaquin River downstream of Old River by preventing flow from entering Old River. The reduction in Sacramento River water influence is due to less pumping at the south Delta pumping plants (i.e., greater pumping draws more Sacramento River water through the Delta).

Sensitivity analyses conducted for Alternative 4 scenario H3 at the LLT indicated that removing all tidal restoration areas (such as is largely the case in Alternative 5A at the ELT) would reduce the number of exceedances by about 9 percentage points, but there would still be more exceedances than under Existing Conditions or the No Action Alternative. Sensitivity analyses also indicated that if the Head of Old River Barrier was open in April and May, exceedances would be reduced by about 5 percentage points. Both of these analyses also showed lower EC during April and May, including during times when modeling showed the objective to be exceeded. These sensitivity analyses were only run at the LLT, but it is expected that the findings can generally be extended to the ELT. Results of the sensitivity analyses indicate that the exceedances are partially a function of the restoration that was assumed in the Alternative 2D modeling, but partly due also to operations of the alternative itself, perhaps due to Head of Old River Barrier assumptions and south Delta export differences (see Appendix 8H, Attachment 1, in Appendix A of the RDEIR/SDEIS for more discussion of these sensitivity analyses). Appendix 8H, Attachment 2, in Appendix A of the RDEIR/SDEIS contains a more detailed assessment of the likelihood of these exceedances estimated via modeling for Alternatives 1–9 impacting aquatic life beneficial uses. Specifically, Appendix 8H, Attachment 2, in Appendix A of the RDEIR/SDEIS discusses whether these exceedances might have indirect effects on striped bass spawning in the Delta, and concludes that the high level of uncertainty precludes making a definitive determination for those alternatives. However, based on the sensitivity analyses conducted, modeling of Alternative 5A that did not contain restoration areas would likely show a lesser level of effects than presented herein (using the Alternative 5 ELT modeling), both in terms of frequency and magnitude of exceedance. Additionally, by adaptively managing the Head of Old River Barrier and the fraction of south Delta versus north Delta diversions, EC levels at Prisoners Point would likely be decreased to a level that would not adversely affect aquatic life beneficial uses.

San Joaquin River at Jersey Point

Modeling results indicated that the EC objective that applies between the San Joaquin River at Jersey Point and Prisoners Point also would be exceeded at Jersey Point more often under Alternative 5A than under Existing Conditions and the No Action Alternative (ELT). At Jersey Point, modeling results estimated that the percent of days the EC objective would be exceeded would increase from 0% under Existing Conditions, or 3% under the No Action Alternative (ELT), to 4% and the percent of days out of compliance with the EC objective would increase from 0% under Existing Conditions, or 3% under the No Action Alternative (ELT), to 5% (Table EC-9 in Appendix B of this RDEIR/SDEIS). The incremental increase in the frequency of objective exceedance relative to the No Action Alternative (ELT), which reflects only the effects due to the alternative, and not effects of climate change, sea level rise and water demands, would be 1%. This small incremental increase is within the model uncertainty and, thus, the alternative is not expected to contribute to exceedances during real-time operation of the alternative. Therefore, the incremental increase in objective exceedance shown in the modeling results is not expected to adversely affect aquatic life beneficial uses.

Suisun Marsh

For Suisun Marsh October–May is the period when Bay-Delta WQCP EC objectives for protection of fish and wildlife apply. Modeling results indicate that average EC for the entire period modeled would increase in the Sacramento River at Collinsville during the months of March through May relative to Existing Conditions, by 0.2 mS/cm (Table EC-11 in Appendix B of this RDEIR/SDEIS). In Montezuma Slough at National Steel, average EC levels would increase in December through March by 0.1–0.5 mS/cm (Table EC-12 in Appendix B of this RDEIR/SDEIS). The most substantial EC increase would occur in Montezuma Slough near Beldon Landing, with long-term average EC levels increasing by 1.4–5.8 mS/cm, depending on the month, at least doubling during some months the long-term average EC relative to Existing Conditions (Table EC-13 in Appendix B of this RDEIR/SDEIS). Sunrise Duck Club and Volanti Slough also would have long-term average EC increases during October–May ranging 1.4–3.7 mS/cm (Tables EC-14 and EC-15 in Appendix B of this RDEIR/SDEIS). Modeled long-term average EC increases in Suisun Marsh under Alternative 4A relative to the No Action Alternative (ELT) are similar to the increases relative to Existing Conditions.
